Field	Function
31-28 DATRDREQINFO	DATRDREQINFO AHB-prot/AXI-cache/OCP-ReqInfo for Data Read (DatRdReqInfo) Input to BUS-GM.
27-24 DESRDREQINFO	DESRDREQINFO AHB-prot/AXI-cache/OCP-ReqInfo for Descriptor Read (DesRdReqInfo). Input to BUS-GM.
23-20	DATWRREQINFO AHB-prot/AXI-cache/OCP-ReqInfo for Data Write (DatWrReqInfo). Input to BUS-GM.

Table continues on the next page...

Field	Function
DATWRREQINFO	
19-16 DESWRREQINFO	DESWRREQINFO AHB-prot/AXI-cache/OCP-ReqInfo for Descriptor Write (DesWrReqInfo) Input to BUS-GM.
15-12 —	Reserved for future use
11 DATBIGEND	Data Access is Big Endian This bit controls the endian mode for data accesses. - Little-endian (default); - Big-endian; In big-endian mode, DMA access (both read and write) for packet data a Byte Invariant Big-Endian mode (see "Little-Endian and Big-Endian" section in the DWC SuperSpeed USB 3.0 Controller User Guide). Note: Since AXI requires byte invariant endianness, setting DescBigend and DatBigEnd to one causes an address invariant transform to be applied, which is not appropriate. See section 9.3 and 9.4 of the AMBA AXI Specification. Hence for an AXI master (DWC_USB3_MBUS_TYPE=1), this bit must be set to zero.
10 DESBIGEND	Descriptor Access is Big Endian This bit controls the endian mode for descriptor accesses. - Little-endian (default) - Big-endian In big-endian mode, DMA access (both read and write) for descriptors uses a Byte Invariant Big-Endian mode (see "Little-Endian and Big-Endian" section in the DWC SuperSpeed USB 3.0 Controller User Guide. Data is considered as 'embedded data' in the descriptors in the following cases: - Device mode: The buffer pointer of a Setup TRB points to the Setup TRB itself. - Host mode: The Immediate Data (IDT) bit in a Transfer TRB is set to 1. In device mode, if the system uses different endian modes for descriptor and data, software must not use 'embedded' data. In host mode, if the system uses different endian modes for data and descriptors, the controller treats 'embedded data' as descriptor (not as data) in terms of endian mode handling. If this is not the expectation of the system, the software must manipulate the 'embedded data' accordingly. Note: Since AXI requires byte invariant endianness, setting DescBigend and DatBigEnd to one causes an address invariant transform to be applied, which is not appropriate. See section 9.3 and 9.4 of the AMBA AXI Specification. Hence for an AXI master (DWC_USB3_MBUS_TYPE=1), this bit must be set to zero.
9-8 —	Reserved
7 INCR256BRSTENA	INCR256 Burst Type Enable Input to BUS-GM For the AHB/AXI configuration, if software set this bit to 1, the AHB/AXI master uses INCR to do the 256-beat burst.
6 INCR128BRSTENA	INCR128 Burst Type Enable Input to BUS-GM For the AHB/AXI configuration, if software set this bit to 1, the AHB/AXI master uses INCR to do the 128-beat burst.
5 INCR64BRSTENA	INCR64 Burst Type Enable Input to BUS-GM For the AHB/AXI configuration, if software set this bit to 1, the AHB/AXI master uses INCR to do the 64-beat burst.
4 INCR32BRSTENA	INCR32 Burst Type Enable Input to BUS-GM For the AHB/AXI configuration, if software set this bit to 1, the AHB/AXI master uses INCR to do the 32-beat burst.
3 INCR16BRSTENA	INCR16 Burst Type Enable Input to BUS-GM For the AHB/AXI configuration, if software set this bit to '1', the AHB/AXI master uses INCR to do the 16-beat burst.
2	INCR8 Burst Type Enable Input to BUS-GM

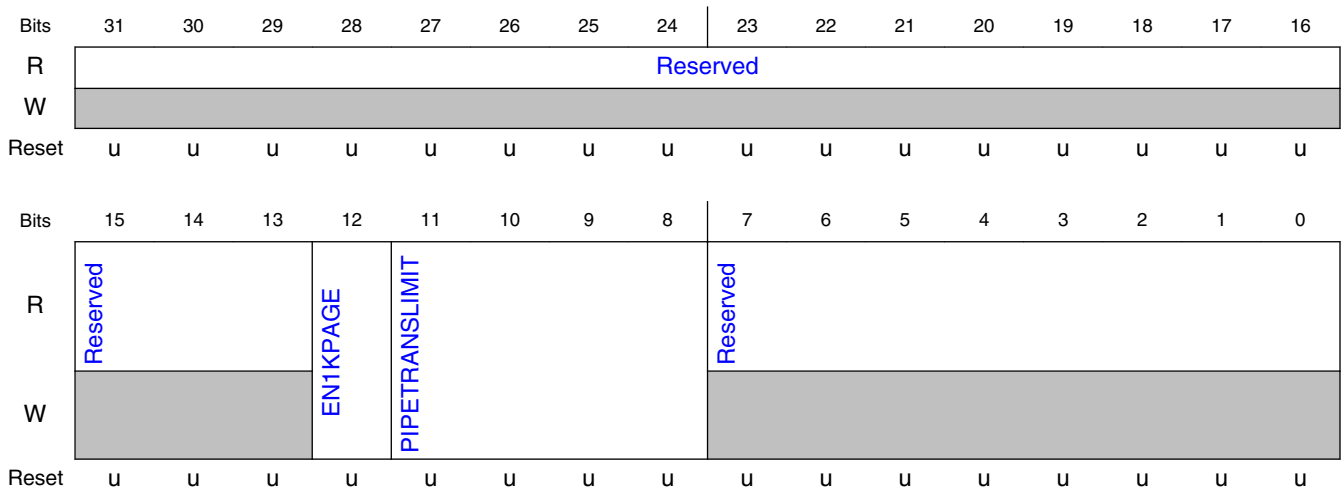
Table continues on the next page...

Field	Function
INCR8BRSTENA	For the AHB/AXI configuration, if software set this bit to "1", the AHB/AXI master uses INCR to do the 8-beat burst.
1 INCR4BRSTENA	INCR4 Burst Type Enable Input to BUS-GM For the AXI configuration, when this bit is enabled the controller is allowed to do bursts of beat length 1, 2, 3, and 4. It is highly recommended that this bit is enabled to prevent descriptor reads and writes from being broken up into separate transfers.
0 INCRBRSTENA	Undefined Length INCR Burst Type Enable Input to BUS-GM This bit determines the set of burst lengths the master interface uses. It works in conjunction with the GSBUSCFG0[7:1] enables (INCR256/128/64/32/16/8/4). 0: INCRX burst mode HBURST (for AHB configurations) and ARLEN/AWLEN (for AXI configurations) do not use INCR except in case of non-aligned burst transfers. In the case of address-aligned transfers, they use only the following burst lengths: - 1 - 4 (if GSBUSCFG0.INCR4BrstEna = 1) - 8 (if GSBUSCFG0.INCR8BrstEna = 1) - 16 (if GSBUSCFG0.INCR16BrstEna = 1) - 32 (if GSBUSCFG0.INCR32BrstEna = 1) - 64 (if GSBUSCFG0.INCR64BrstEna = 1) - 128 (if GSBUSCFG0.INCR128BrstEna = 1) - 256 (if GSBUSCFG0.INCR256BrstEna = 1) Note: - In case of non-address-aligned transfers, INCR may get generated at the beginning and end of the transfers to align the address boundaries, even though INCR is disabled. - In AHB mode, if INCRX burst mode is enabled, but none of the supported INCRx bursts bits are enabled, then the controller will perform (undefined length) INCR bursts. 1: INCR (undefined length) burst mode - AHB configurations: HBURST uses SINGLE or INCR of any length with handling 1KB boundary breakup. - AXI configurations: ARLEN/AWLEN uses any length less than or equal to the largest-enabled burst length of INCR32/64/128/256. For cache line-aligned applications, this bit is typically set to 0 to ensure that the master interface uses only power-of-2 burst lengths (as enabled via GSBUSCFG0[7:0]).

11.2.5.1.51 Global SoC Bus Configuration Register 1 (GSBUSCFG1)

11.2.5.1.51.1 Offset

Register	Offset
GSBUSCFG1	C104h



11.2.5.1.51.2 Function

xHCI Register Power-On Value: If you are using a standard xHCI host driver, make sure to set the register's power-on value during coreConsultant configuration (DWC_USB3_GSBUSCFG1_INIT parameter) because the standard xHCI driver does not access this register.

30 —	Reserved
29 USBTXPKTCNTSEL	USB Transmit Packet Count Enable This field enables/disables the USB transmission multi-packet thresholding: - 0: USB transmission multi-packet thresholding is disabled; the core can start transmission on the USB after the entire (one full) packet has been fetched into the corresponding TXFIFO. - 1: USB transmission multi-packet thresholding is enabled. The core can only start transmission on the USB after USB Transmit Packet Count amount of packets for the USB transaction (burst) are already in the corresponding TXFIFO. This mode is valid in both host and device modes. It is only used for SuperSpeed operation.
28	Reserved

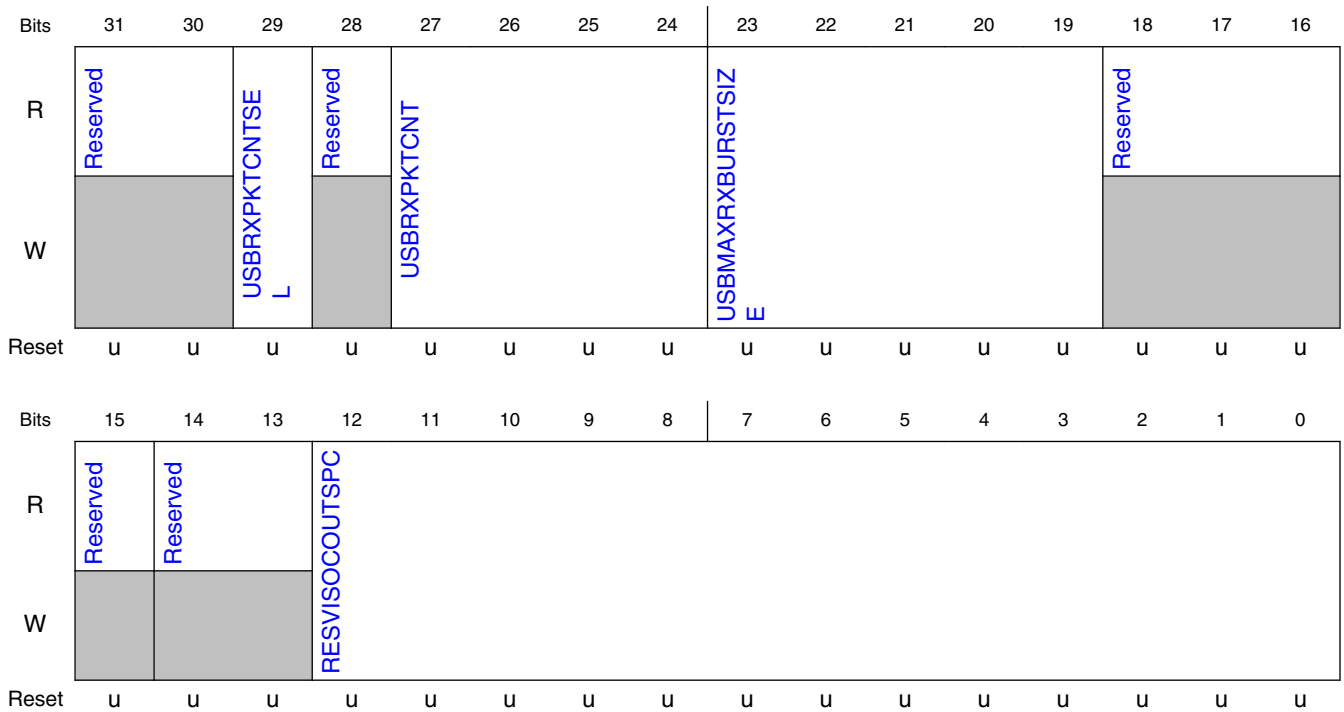
Table continues on the next page...

Field	Function
—	
27-24 USBTXPKTCNT	USB Transmit Packet Count This field specifies the number of packets that must be in the TXFIFO before the core can start transmission for the corresponding USB transaction (burst). This field is only valid when the USB Transmit Packet Count Enable field is set to one. Valid values are from 1 to 15. Note: - In device mode, if device controller does not have the TRBs for the number of packets or if it cannot fetch the TRBs because of high latency or switching between other endpoints, then it does not wait for the threshold number of packets. The threshold number of packets will be honored only when the TRBs are available in the controller for the number of packets before it starts the data fetch. - This field must be less than or equal to the USB Maximum TX Burst Size field.
23-16 USBMAXTXBURSTSIZE	USB Maximum TX Burst Size When UsbTxPktCntSel is one, this field specifies the Maximum Bulk OUT burst the core can do. When the system bus is slower than the USB, TX FIFO can underrun during a long burst. User can program a smaller value to this field to limit the TX burst size that the core can do. Host mode: It only applies to SS Bulk, Isochronous, and Interrupt OUT endpoints. Device mode: This value is not used in device mode, but users need to program a value when using the TX threshold feature to make sure that the value programmed in UsbTxPktCnt is less than this value. Valid values are from 1 to 16.
15 —	Reserved
14 —	Reserved1 Register field must write only 0 by the application. The read value must be treated as X (unknown).
13-11 —	Reserved The register field must write only 0 by the application. The read value must be treated as X (unknown).
10-0 —	Reserved for future use

11.2.5.1.53 Global Rx Threshold Control Register (GRXTHRCFG)

11.2.5.1.53.1 Offset

Register	Offset
GRXTHRCFG	C10Ch



11.2.5.1.53.2 Function

This register is not applicable for debug target and USB 2.0-only mode. In a normal case, a Tx burst starts as soon as one packet is prefetched; an Rx burst starts as soon as 1-packet space is available.

Reset Mask:0xD007E000

Reset Default Value:0x0

11.2.5.1.53.3 Diagram

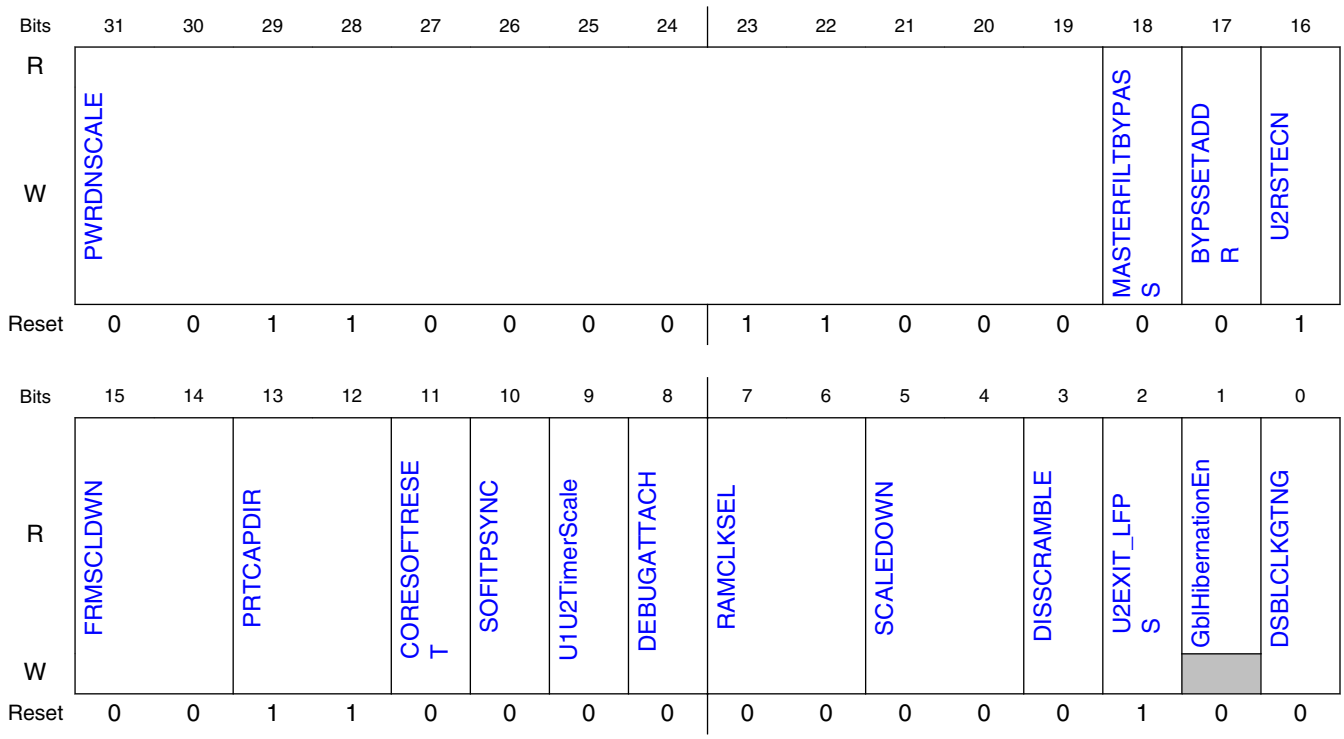
11.2.5.1.53.4 Fields

Field	Function
31-30 —	Reserved
29 USBRXPKTCNTSEL	USB Receive Packet Count Enable This field enables/disables the USB reception multi-packet thresholding: - 0: The core can only start reception on the USB when the RX FIFO has space for at least one packet. - 1: The core can only start reception on the USB when the RX FIFO has space for at least UsbRxPktCnt amount of packets. This mode is valid in both host and device mode. It is only used for SuperSpeed. In device mode, - Setting this bit to 1 also enables the functionality of reporting NUMP in the ACK TP based on the RX FIFO space instead of reporting a fixed NUMP derived from DCFG.NUMP for non-control endpoints. - If you are using external buffer control (EBC) feature, disable this mode by setting UsbRxPktCntSel to 0.
28 —	Reserved
27-24 USBRXPKTCNT	USB Receive Packet Count In host mode, this field specifies the space (in terms of the number of packets) that must be available in the RX FIFO before the core can start the corresponding USB RX transaction (burst). In device mode, this field specifies the space (in terms of the number of packets) that must be available in the RX FIFO before the core can send ERDY for a flow-controlled endpoint. This field is valid only when the USB Receive Packet Count Enable field is set to 1. The valid values for this field are from 1 to 15. Note: This field must be less than or equal to the USB Maximum Receive Burst Size field.

Table continues on the next page...

Field	Function
23-19 USBMAXRXBURSTSIZE	USB Maximum Receive Burst Size In host mode, this field specifies the Maximum Bulk IN burst the DWC_usb3 core can perform. When the system bus is slower than the USB, RX FIFO can overrun during a long burst. You can program a smaller value to this field to limit the RX burst size that the core can perform. It only applies to SS Bulk, Isochronous, and Interrupt IN endpoints in the host mode. In device mode, this field specifies the NUMP value that is sent in ERDY for an OUT endpoint. The programmed value should not exceed the RXFIFO size. This field is valid only when UsbRxPktCntSel is one. The valid values for this field are from 1 to 16.
18-16 —	Reserved
15 —	Reserved
14-13 —	Reserved
12-0 RESVISOCOUTSPC	Space Reserved in Rx FIFO for ISOC OUT In host mode, this field is not applicable and must be programmed to 0. In device mode, this value represents the amount of space to be reserved for ISOC OUT packets. The value to be programmed should be chosen so as to ensure that non ISOC packets are not completely dropped. If no space needs to be reserved for ISOC OUT packets, program this field to 0. This field is valid only in device mode. The maximum configurable depth of RX FIFO is 8192. Therefore, this field is 13 bits wide. The value of space reserved is in terms of DWC_USB3_MDWIDTH. For SS, the space reservation is always rounded off to the nearest packet boundary. Therefore, it is always recommended to program a value corresponding to MPS or its multiples. For HS/FS, the space reservation is the actual value. Note: For SS, reserve space for ISOC when the Rx FIFO space can accommodate two MPS or more. Otherwise, this may result in degraded performance for non-ISOC packets. If the space is entirely allocated for ISOC, the non-ISOC packets will be completely dropped. To help you decide during the time of configuring the core, refer to the section "Device-Mode Receive Path" in Chapter 3.

11.2.5.1.54 Global Core Control Register (GCTL)



11.2.5.1.54.1 Offset

Register	Offset
GCTL	C110h

11.2.5.1.54.2 Function

Note: When Hibernation is not enabled, you can write any value to GblHibernationEn. It always returns 0 when read.

11.2.5.1.54.3 Diagram

11.2.5.1.54.4 Fields

Field	Function
31-19 PWRDNSCALE	Power Down Scale The USB3 suspend_clk input replaces pipe3_rx_pclk as a clock source to a small part of the USB3 core that operates when the SS PHY is in its lowest power (P3) state, and therefore does not provide a clock. The Power Down Scale field specifies how many suspend_clk periods fit into a 16 kHz clock period. When performing the division, round up the remainder. For example, when using an 8-bit/16-bit/32-bit PHY and 25-MHz Suspend clock, Power Down Scale = 25000 kHz/16 kHz = 13'd1563 (rounder up) Note: - Minimum Suspend clock frequency is 32 kHz - Maximum Suspend clock frequency is 125 MHz The LTSSM uses Suspend clock for 12-ms and 100-ms timers during suspend mode. According to the USB 3.0 specification, the accuracy on these timers is 0% to +50%. - 12 ms + 0~+50% accuracy = 18 ms (Range is 12 ms - 18 ms) - 100 ms + 0~+50% accuracy = 150 ms (Range is 100 ms - 150 ms). The suspend clock accuracy requirement is: - (12,000/62.5) * (GCTL[31:19]) * actual suspend_clk_period must be between 12,000 and 18,000 - (100,0000/62.5) * (GCTL[31:19]) * actual suspend_clk_period must be between 100,000 and 150,000 For example, if your suspend_clk frequency varies from 7.5 MHz to 10.5MHz, then the value needs to programmed is: Power Down Scale = 10500/16 = 657 (rounded up; and fastest frequency used).
18 MASTERFILTBYPASS	Master Filter Bypass When this bit is set to 1'b1, irrespective of the parameter `DWC_USB3_EN_BUS_FILTERS chosen, all the filters in the DWC_usb3_filter module are bypassed. The double synchronizers to mac_clk preceding the filters are also bypassed. For enabling the filters, this bit must be 1'b0.
17 BYPSSETADDR	Bypass SetAddress in Device Mode When BYPSSETADDR bit is set, the device core uses the value in the DCFG[DevAddr] bits directly for comparing the device address in the tokens. For simulation, you can use this feature to avoid sending an

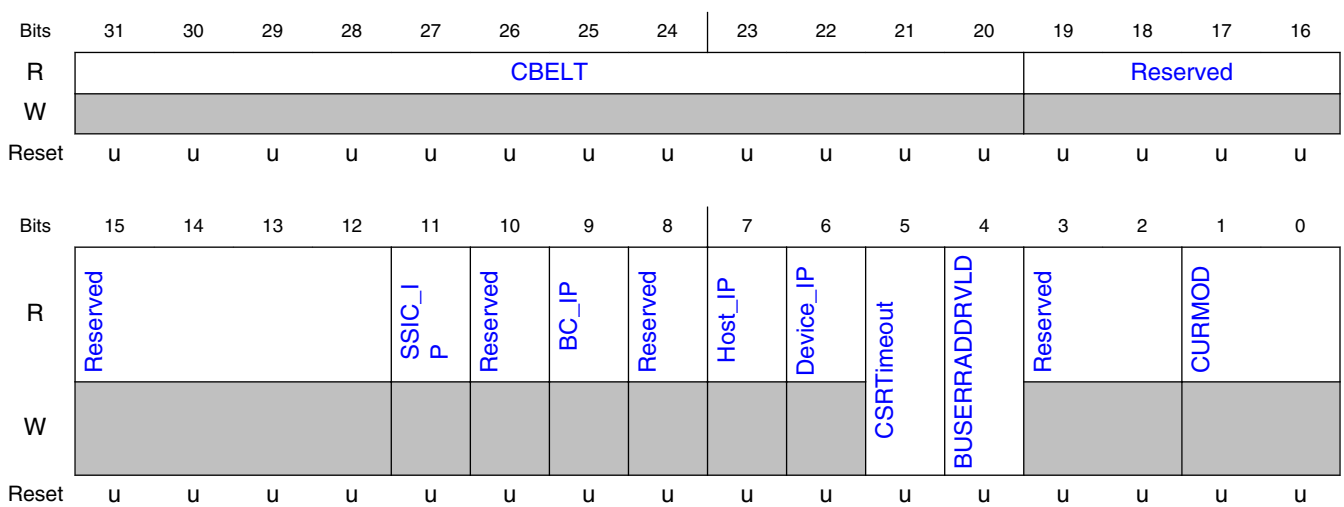
Table continues on the next page...

Field	Function
	actual SET ADDRESS control transfer on the USB, and make the device core respond to a new address. When the xHCI Debug capability is enabled and this bit is set, the Debug Target immediately enters the configured state without requiring the Debug Host to send a SetAddress or SetConfig request. Note: You can set this bit for simulation purposes only. In the actual hardware, this bit must be set to 1'b0.
16 U2RSTECN	If the SuperSpeed connection fails during POLL or LMP exchange, the device connects at non-SS mode. If this bit is set, then device attempts three more times to connect at SS, even if it previously failed to operate in SS mode. For each attempt, the device checks receiver termination eight times. From 2.60a release, this bit controls whether to check for Rx.Detect eight times or one time for every attempt. Device controller on USB 2.0 reset checks for receiver termination eight times per attempt if this bit is set to zero, or only once per attempt if the bit is set to one. Note: This bit is applicable only in device mode.
15-14 FRMSCLDWN	This field scales down device view of a SOF/USOF/ITP duration. For SS/HS mode: - Value of 2'h3 implements interval to be 15.625 us - Value of 2'h2 implements interval to be 31.25 us - Value of 2'h1 implements interval to be 62.5 us - Value of 2'h0 implements interval to be 125us For FS mode, the scale-down value is multiplied by 8. When xHCI Debug Capability is enabled, this field also scales down the MaxPacketSize of the IN and OUT bulk endpoint to allow more traffic during simulation. It can only be changed from a non-zero value during simulation. - 2'h0: 1024 bytes - 2'h1: 512 bytes - 2'h2: 256 bytes - 2'h3: 128 bytes
13-12 PRTCAPDIR	Port Capability Direction 2'b01: for Host configurations - 2'b10: for Device configurations . The sequence for switching modes in DRD configuration is as follows: Switching from Device to Host: 1. Reset the controller using GCTL[11] (CoreSoftReset). 2. Set GCTL[13:12] (PrtCapDir) to 2'b01 (Host mode). 3. Reset the host using USBCMD.HCRESET. 4. Follow the steps in "Initializing Host Registers" section of the databook. Switching from Host to Device: 1. Reset the controller using GCTL[11] (CoreSoftReset). 2. Set GCTL[13:12] (PrtCapDir) to 2'b10 (Device mode). 3. Reset the device by setting DCTL[30] (CSftRst). 4. Follow the steps in "Register Initialization" section of the databook. Programming this field with random data causes the core to keep toggling between the host mode and the device mode . Bit Bash register testing is not recommended.
11 CORESOFTRESET	Core Soft Reset 1'b0 - No soft reset - 1'b1 - Soft reset to core Clears the interrupts and all the CSRs except the following registers: - GCTL - GUCTL - GSTS - GSNPSID - GGPIO - GUID - GUSB2PHYCFGn registers - GUSB3PIPECTLn registers - DCFG - DCTL - DEVTEN - DSTS When you reset PHYs (using GUBS3PHYCFG or GUSB3PIPECTL registers), you must keep the core in reset state until PHY clocks are stable. This controls the bus, ram, and mac domain resets. Refer to the "Reset Generation" section in the Architecture Details chapter in the DesignWare Cores SuperSpeed USB 3.0 Controller Databook. Note: This bit is for debug purposes only. Use USBCMD.HCRESET in xHCI Mode and DCTL.SoftReset in device mode for soft reset. Programming this field with random data will reset the internal logic of the host controller. Due to this side effect Bit Bash register testing is not recommended.
10 SOFITPSYNC	If this bit is set to '0' operating in host mode, the core keeps the UTMI/ULPI PHY on the first port in a non-suspended state whenever there is a SuperSpeed port that is not in Rx.Detect, SS.Disable and U3. If this bit is set to '1' operating in host mode, the core keeps the UTMI/ULPI PHY on the first port in a non-suspended state whenever the other non-SuperSpeed ports are not in a suspended state. This feature is useful because it saves power by suspending UTMI/ULPI when SuperSpeed only is active, and it helps resolve when the PHY does not transmit a host resume unless it is placed in suspend state. This bit must be programmed as a part of initialization at power-on reset, and must not be dynamically changed afterwards. Note: - USB2PHYCFGn[6].PhySusp eventually decides to put the UTMI/ULPI PHY in to suspend state. In addition, when this bit is set to '1', the core generates ITP from the ref_clk based counter. Otherwise, ITP and SOF are generated from utmi/ulpi_clk[0] based counter. To program the reference clock period inside the core, refer to GUCTL[31:22].REFCLKPER. - This feature is valid in Host and DRD configurations and used only in Host mode operation. - If you never use this feature or the GFLADJ.GFLADJ_REFCLK_LPM_SEL, the minimum frequency for the ref_clk can be as low as 32KHz. You can connect the suspend_clk (as low as 32 KHz) to the ref_clk. - If you plan to enable hardware-based LPM or software-based LPM (PORTPMSC. HLE=1), then you cannot use this feature. Turn off this feature by setting this bit to '0' and use the GFLADJ.GFLADJ_REFCLK_LPM_SEL feature. - If you set this bit to '1', the GUSB2PHYCFG.U2_FREECLK_EXISTS bit and the

Table continues on the next page...

Field	Function
	DWC_USB3_FREECLK_USB2_EXIST parameter must be set to '0'. Program this bit to 0 if the core is intended to be operated in USB 3.0 mode.
9 U1U2TimerScale	Disable U1/U2 timer Scaledown If set to '1' along with GCTL[5:4] (ScaleDown) = 2'bX1, disables the scale down of U1/U2 inactive timer values. This is for simulation mode only.
8 DEBUGATTACH	Debug Attach When this bit is set, - SS Link proceeds directly to the Polling link state (after RUN/STOP in the DCTL register is asserted) without checking remote termination; - Link LFPS polling timeout is infinite; - Polling timeout during TS1 is infinite (in case link is waiting for TXEQ to finish).
7-6 RAMCLKSEL	RAM Clock Select 2'b00: bus clock - 2'b01: pipe clock (Only used in device mode) - 2'b10: In device mode , pipe/2 clock.In Host mode, controller switches ram_clk between pipe/2 clock, mac2_clk and bus_clk based on the status of the U2/U3 ports - 2'b11: In device mode, selects mac2_clk as ram_clk (when 8-bit UTMI or ULPI used. Not supported in 16-bit UTMI mode) In Host mode, controller switches ram_clk between pipe_clk, mac2_clk and bus_clk based on the status of the U2/U3 ports. In device mode, upon a USB reset and USB disconnect, the hardware clears these bits to 2'b00. For more information on how to select the RAM clock, see "Clock Generation and Clock Tree Synthesis (CTS) Requirements" in the Architectural Details chapter in the DesignWare Cores SuperSpeed USB 3.0 Controller Databook. Note: - In device mode, if you set RAMClkSel to 2'b11 (mac2_clk), the controller internally switches the ram_clk to bus_clk when the link state changes to Suspend (L2 or L3), and switches the ram_clk back to mac2_clk when the link state changes to resume or U2. - In host mode, if a value of 2/3 is chosen, then controller switches ram_clk between bus_clk, mac2_clk and pipe_clk, pipe_clk/2, based on the state of the U2/U3 ports. For example if only the U2 port is active and the U3 ports are suspended, then the ram_clk is swicthed to mac2_clk. When only the U3 ports are active and the U2 ports are suspended, then the core internally swicth the ram_clk to pipe3 clock and when all U2 and U3 ports are suspended, it switch the ram_clk to bus_clk. This allows de coupling the ram_clk from the bus_clk and depending on the bandwidth requiredmnet allows the bus_clk to be run at a lower frequency than the ram_clk requirements. bus_clk frequency still cannot go below 60Mhz in host mode, and this is not verified. A value of 2 can be chosen only if the pipe data width is 8 or 16 bits. In this case the when the ram_clk is switched to pipe_clk, it uses pipe_clk/2 instead of pipe_clk. If a value of 3 is chosen for RAMClkSel, then when ram_clk is switched to pipe_clk, then pipe_clk is used without any divider. - In device mode, when RAMClkSel != 2'b00, the bus_clk_early frequency can be a minimum of 1 MHz. This is tested in simulation and also in hardware with Linux, Microsoft Windows 8, and MCCI Windows7 host drivers. Only control and non periodic transfers are supported when bus_clk is 1 MHz. For periodic applications, the bus_clk_early minimum frequency is higher depending on your application and SoC bus. Even though 1 MHz has been tested with standard host drivers, Synopsys recommends 5 MHz minimum for ASIC designs to provide a margin or at least have a backup option to increase the bus_clk frequency to 5 MHz if needed. Programming this field with random data will cause side effect. Bit Bash register testing is not recommended.
5-4 SCALEDOWN	Scale-Down Mode When Scale-Down mode is enabled for simulation, the core uses scaled-down timing values, resulting in faster simulations. When Scale-Down mode is disabled, actual timing values are used. This is required for hardware operation. HS/FS/LS Modes - 2'b00: Disables all scale-downs. Actual timing values are used. - 2'b01: Enables scale-down of all timing values except Device mode suspend and resume. These include Speed enumeration, and Host mode suspend and resume - 2'b10: Enables scale-down of Device mode suspend and resume timing values only. - 2'b11: Enables bit 0 and bit 1 scale-down timing values. SS Mode - 2'b00: Disables all scale-downs. Actual timing values are used. - 2'b01: Enables scaled down SS timing and repeat values including: (1) Number of TxEq training sequences reduce to 8; (2) LFPS polling burst time reduce to 256 nS; (3) LFPS warm reset receive reduce to 30 uS. Refer to the rtl_vip_scaledown_mapping.xls file under <workspace>/sim/SoC_sim directory for the complete list. - 2'b10: No TxEq training sequences are sent. Overrides Bit 4. - 2'b11: Enables bit 0 and bit 1 scale-down timing values.
3 DISSCRAMBLE	Disable Scrambling Transmit request to Link Partner on next transition to Recovery or Polling.

Table continues on the next page...



Field	Function
2 U2EXIT_LFPS	If this bit is, - 0: the link treats 248ns LFPS as a valid U2 exit. - 1: the link waits for 8us of LFPS before it detects a valid U2 exit. This bit is added to improve interoperability with a third-party host/device controller. This host/device controller in U2 state while performing receiver detection generates an LFPS glitch of about 4ms duration. This causes the host/device to exit from U2 state because the LFPS filter value is 248ns. With the new functionality enabled, the host/device can stay in U2 while ignoring this glitch from the host/device controller. This bit is applicable for both host and device controller. This bit is added to improve interoperability with a third party host controller. This host controller in U2 state while performing receiver detection generates an LFPS glitch of about 4ms duration. This causes the device to exit from U2 state because the LFPS filter value is 248ns. With the new functionality enabled, the device can stay in U2 while ignoring this glitch from the host controller.
1 GblHibernationEn	Global Hibernation Enable This bit enables hibernation at the global level. If hibernation is not enabled through this bit, the PMU immediately accepts the D0->D3 and D3->D0 power state change requests, but does not save or restore any core state. In addition, the PMUs never drive the PHY interfaces and let the core continue to drive the PHY interfaces.
0 DSBLCLKGTNG	Disable Clock Gating This bit is set to 1 and the core is in Low Power mode, internal clock gating is disabled. You can set this bit to 1'b1 after Power On Reset.

Field	Function
31 DEV_DECOUPLE_L1L2_EVT	DEV_DECOUPLE_L1L2_EVT - 0: Default behavior, no change in device events L1/L2U3 events are not decoupled (old behavior of v2.90a and before) - 1: Feature enabled, L1 and L2 events are separated when operating in 2.0 mode. Separate event enable bits for L1 suspend and wake events. This bit is applicable for device mode only. If this feature is enabled, L1 suspend and wake events have individual controls to enable/mask them. Enable this feature if you want to get L1 (LPM) events separtely and not combined with L2 events when operating in 2.0 speeds.
30 DS_RXDET_MAX_TOUT_CTRL	DS_RXDET_MAX_TOUT_CTRL This bit is used to control the tRxDetectTimeoutDFP timer for the SuperSpeed link. - 0: Default behavior; 12ms is used as tRxDetectTimeoutDFP. - 1: 120ms is used as the tRxDetectTimeoutDFP. This bit is used only in host mode. For more details, refer to ECN020 for USB 3.0 Specification.

Table continues on the next page...

Field	Function
29 FILTER_SE0_FSLS_EOP	FILTER_SE0_FSLS_EOP - 0: Default behavior, no change in Linestate check for SE0 detection in FS/LS - 1: Feature enabled, FS/LS SE0 is filtered for 2 clocks for detecting EOP This bit is applicable for FS/LS operation. If this feature is enabled, then SE0 on the linestate is validated for 2 consecutive utmi/ulpi clock edges for EOP detection. This feature is applicable only in FS in device mode and FS/LS mode of operation in host mode. Device mode: FS - If GUCTL1.FILTER_SE0_FSLS_EOP is set, then for device LPM handshake, the core will ignore single SE0 glitch on the linestate during transmit. Only 2 or more SE0 is considered as a valid EOP on FS. Host mode: FS/LS - If GUCTL1.FILTER_SE0_FSLS_EOP is set, then the core will ignore single SE0 glitch on the linestate during transmit. Only 2 or more SE0 is considered as a valid EOP on FS/LS port. Enable this feature if the LineState has SE0 glitches during transmission. This bit is quasi-static, that is, it must not be changed during device operation.
28 TX_IPGAP_LINECHECK_DIS	TX_IPGAP_LINECHECK_DIS - 0: Default behavior, no change in Linestate check - 1: Feature enabled, 2.0 MAC disables Linestate check during HS transmit This bit is applicable for HS operation of u2mac. If this feature is enabled, then the 2.0 mac operating in HS ignores the UTMI/ULPI Linestate during the transmit of a token (during token-to-token and token-to-data IPGAP). When enabled, the controller implements a fixed 40-bit TxEndDelay after the packet is given on UTMI and ignores the Linestate during this time. This feature is applicable only in HS mode of operation. Device mode: If GUCTL1.TX_IPGAP_LINECHECK_DIS is set, then for device LPM handshake, the core will ignore the linestate after TX and wait for fixed clocks (40 bit times equivalent) after transmitting ACK on utmi. Host mode: If GUCTL1.TX_IPGAP_LINECHECK_DIS is set, then the ipgap between (tkn to tkn/data) is added by 40 bit times of TXENDDELAY, and linestate is ignored during this 40 bit times delay. Enable this bit if the LineState will not reflect the expected line state (J) during transmission. This bit is quasi-static, that is, it must not be changed during device operation.
27 DEV_TRB_OUT_SPR_IND	DEV_TRB_OUT_SPR_IND - 0: Default behavior, no change in TRB status dword - 1: Feature enabled, OUT TRB status indicates Short Packet This bit is applicable for device mode only (and ignored in host mode). If the device application (software/hardware) wants to know if a short packet was received for an OUT in the TRB status itself, then this feature can be enabled, so that a bit is set in the TRB writeback in the buf_size dword. Bit[26] - SPR of the {trbstatus, RSVD, SPR, PCM1, bufsize} dword will be set during an OUT transfer TRB write back if this is the last TRB used for that transfer descriptor. This bit is quasi-static, that is, it must not be changed during device operation.
26 DEV_FORCE_20_CLK_FOR_30_CLK	DEV_FORCE_20_CLK_FOR_30_CLK - 0: Default behavior, Uses 3.0 clock when operating in 2.0 mode - 1: Feature enabled This bit is applicable (and to be set) for device mode (DCFG.Speed != SS) only. In the 3.0 device core, if the core is programmed to operate in 2.0 only (that is, Device Speed is programmed to 2.0 speeds in DCFG[Speed]), then setting this bit makes the internal 2.0 (utmi/ulpi) clock to be routed as the 3.0 (pipe) clock. Enabling this feature allows the pipe3 clock to be not-running when forcibly operating in 2.0 device mode. Note: - When using this feature, all pipe3 inputs must be in inactive mode. In particular, the pipe3 clocks must not be running and the pipe3_phystatus_async must be tied to 0. This bit should not be set if the core is programmed to operate in SuperSpeed mode (even when it falls back to 2.0). - This bit is quasi-static, that is, it must not be changed during operation. - If the parameter "DWC_USB3_REMOVE_PIPE_CLK_MUX_FOR_20_MODE" is enabled, then muxing 2.0 clock/signals to pipe_clk/signals have to be done outside the controller for this feature to work.
25 P3_IN_U2	P3_IN_U2 - 0: Default behavior, When SuperSpeed link is in U2, PowerState P2 is attempted on the PIPE Interface. - 1: When SuperSpeed link is in U2, PowerState P3 is attempted if GUSB3PIPECTL[17] is set. Setting this bit enables P3 Power State when the SuperSpeed link is in U2. Another Power Saving option. Check with your PHY vendor before enabling this option.When setting this bit to 1 to enable P3 in P2, GUSB3PIPECTL[27] should be set to 0 to make sure that the U2 exit is attempted in P0. This bit should be set only when GCTL.SOFITPSYNC=1 or GFLADJ.GFLADJ_REFCLK_LPM_SEL=1.
24 DEV_L1_EXIT_BY_HW	DEV_L1_EXIT_BY_HW - 0: Default behavior, disables device L1 hardware exit logic - 1: feature enabled This bit is applicable for device mode (2.0) only. This field enables device controller sending remote wakeup for L1 if the device becomes ready for sending/accepting data when in L1 state. If the host expects the device to send remote wakeup signaling to resume after going into L1 in flow controlled state, then this bit can be set to send the remote wake signal automatically when the device controller becomes ready. This hardware remote wake feature is applicable only to bulk and interrupt transfers, and not for Isoch/Control - When control transfers are in progress, the LPM will be rejected (NYET response). Only after control transfers are completed (either with ACK/STALL), LPM will be accepted - For Isoch transfers, the host needs to do the wake-up and start the transfer. Device controller will not do remote-

Table continues on the next page...

Field	Function
	wakeup when Isoch endpoints get ready. The device SW needs to keep the GUSB2PHYCFG[EnblSlpM] reset in order to keep the PHY clock to be running for keeping track of SOF intervals. - When L1 hibernation is enabled, the controller will not do automatic exit for hibernation requests thru L1. This bit is quasi-static, that is, it must not be changed during device operation.
23-21 IP_GAP_ADD_ON	This register field is used to add on to the default inter packet gap setting in the USB 2.0 MAC. This should be programmed to a non zero value only in case where you need to increase the default inter packet delay calculations in the USB 2.0 MAC module DWC_usb3_u2mac.v
20 DEV_LSP_TAIL_LOCK_DIS	DEV_LSP_TAIL_LOCK_DIS - 0: Default behavior, enables device lsp lock logic for tail TRB update - 1: Fix disabled This is a bug fix for STAR 9000716195 that affects the CSP mode for OUT endpoints in device mode. The issue is that tail TRB index is not synchronized with the cache Scratchpad bytecount update. If the fast-forward request comes in-between the bytecount update on a newly fetched TRB and the tail-index write update in TPF, the RDP works on an incorrect tail index and misses the byte count decrement for the newly fetched TRB in the fast-forwarding process. This fix needs to be present all the times.
19 NAK_PER_ENH_FS	NAK_PER_ENH_FS - 1: Enables performance enhancement for FS async endpoints in the presence of NAKs - 0: Enhancement not applied If a periodic endpoint is present , and if a bulk endpoint which is also active is being NAKed by the device, then this could result in a decrease in performance of other Full Speed bulk endpoint which is ACked by the device. Setting this bit to 1, will enable the host controller to schedule more transactions to the async endpoints (bulk/ control) and hence will improve the performance of the bulk endpoint. This control bit should be enabled only if the existing performance with the default setting is not sufficient for your FullSpeed application. Setting this bit will only control, and is only required for Full Speed transfers.
18 NAK_PER_ENH_HS	NAK_PER_ENH_HS - 1: Enables performance enhancement for HS async endpoints in the presence of NAKs - 0: Enhancement not applied If a periodic endpoint is present, and if a bulk endpoint which is also active is being NAKed by the device, then this could result in decrease in performance of other High Speed bulk endpoint which is ACked by the device. Setting this bit to 1, will enable the host controller to schedule more transactions to the async endpoints (bulk/ control) and hence will improve the performance of the bulk endpoint. This control bit should be enabled only if the existing performance with the default setting is not sufficient for your HighSpeed application. Setting this bit will only control, and is only required for High Speed transfers.
17 PARKMODE_DISABLE_SS	PARKMODE_DISABLE_SS This bit is used only in host mode, and is for debug purpose only. When this bit is set to '1' all SS bus instances in park mode are disabled.
16 PARKMODE_DISABLE_HS	PARKMODE_DISABLE_HS This bit is used only in host mode. When this bit is set to '1' all HS bus instances park mode are disabled. To improve performance in park mode, the xHCI scheduler queues in three requests of 4 packets each for High Speed asynchronous endpoints in a micro-frame. But if a device is slow and if it NAKs more than 3 times, then it is rescheduled only in the next micro-frame. This could decrease the performance of a slow device even further. In a few high speed devices (such as Sandisk Cruzer Blade 4GB VID:1921, PID:21863 and Flex Drive VID:3744, PID:8552) when an IN request is sent within 900ns of the ACK of the previous packet, these devices send a NAK. When connected to these devices, if required, the software can disable the park mode if you see performance drop in your system. When park mode is disabled, pipelining of multiple packet is disabled and instead one packet at a time is requested by the scheduler. This allows up to 12 NAKs in a micro-frame and improves performance of these slow devices.
15 PARKMODE_DISABLE_FSLS	PARKMODE_DISABLE_FSLS This bit is used only in host mode, and is for debug purpose only. When this bit is set to '1' all FS/LS bus instances in park mode disabled.
14-11 —	Reserved
10	RESUME_OPMODE_HS_HOST This bit is used only in host mode, and is for USB 2.0 opmode behavior in HS Resume. - When this bit is set to '1', the UTMI/ULPI opmode will be changed to "normal" along with HS terminations after EOR. This option is to support certain legacy UTMI/ULPI PHYs. - When this bit is

Table continues on the next page...

Field	Function
RESUME_OPMODE_HS_HOST	set to '0', the UTMI/ULPI opmode will be changed to "normal" 2us after HS terminations change after EOR. This is the default behavior.
9 DEV_HS_NYET_BULK_SPR	DEV_HS_NYET_BULK_SPR - 0: Default behavior, no change in device response - 1: Feature enabled, HS bulk OUT short packet gets NYET response This bit is applicable for device mode only (and ignored in host mode) to be used in 2.0 operation. If this bit is set, the device core sends NYET response instead of ACK response for a successfully received bulk OUT short packet. If NYET is sent after receiving short packet, then the host would PING before sending the next OUT; this improves the performance as well as clears up the buffer/cache on the host side. Internal to the device core, short packet (SPR=1) processing takes some time, and during this time, the USB is flow controlled. With NYET response instead of ACK on short packet, the host does not send another OUT-DATA without pinging in HS mode. This bit is quasi-static, that is, it must not be changed during device operation.
8 L1_SUSP_THRLD_EN_FOR_HOST	L1_SUSP_THRLD_EN_FOR_HOST This bit is used only in host mode. The host controller asserts the utmi_l1_suspend_n and utmi_sleep_n output signals (see "LPM Interface Signals" table in the Databook) as follows: The controller asserts the utmi_l1_suspend_n signal to put the PHY into deep low-power mode in L1 when both of the following are true: - The HIRD/BESL value used is greater than or equal to the value in L1_SUSP_THRLD_FOR_HOST field. - The L1_SUSP_THRLD_EN_FOR_HOST bit is set to 1'b1. The controller asserts utmi_sleep_n on L1 when one of the following is true: - The HIRD/BESL value used is less than the value in L1_SUSP_THRLD_FOR_HOST field. - The L1_SUSP_THRLD_EN_FOR_HOST bit is set to 1'b0.
7-4 L1_SUSP_THRLD_FOR_HOST	L1_SUSP_THRLD_FOR_HOST This field is effective only when the L1_SUSP_THRLD_EN_FOR_HOST bit is set to 1. For more details, refer to the description of the L1_SUSP_THRLD_EN_FOR_HOST bit.
3 HC_ERRATA_ENABLE	Host ELD Enable When this bit is set to 1, it enables the Exit Latency Delta (ELD) support defined in the xHCI 1.0 Errata. This bit is used only in the host mode. This bit has to be set to 1 in Host mode.
2 HC_PARCHK_DISABLE	Host Parameter Check Disable When this bit is set to '0' (by default), the xHC checks that the input slot/EP context fields comply to the xHCI Specification. Upon detection of a parameter error during command execution, the xHC generates an event TRB with completion code indicating 'PARAMETER ERROR'. When the bit is set to '1', the xHC does not perform parameter checks and does not generate 'PARAMETER ERROR' completion code.
1 OVRLD_L1_SUSP_COM	OVRLD_L1_SUSP_COM If this bit is set, the utmi_l1_suspend_com_n is overloaded with the utmi_sleep_n signal. This bit is usually set if the PHY stops the port clock during L1 sleep condition. Note: The recommended connection for the SUSPENDM/SLEEPM signals to the PHY with respect to this bit is as follows. For non-zero ports: Connect: - utmi_sleep_n[n] to SLEEPM[n] - (utmi_suspend_n[n] & utmi_l1_suspend_n[n]) to SUSPENDM[n] - USB2 PHYCLK[n] to utmi_clk[n] GUCTL1.OVRLD_L1_SUSP_COM impacts only Port0. For Port0: For Synopsys PHY, GUSB2PHYCFGn.U2_FREECLK_EXISTS=1; With this connection, the PHY keeps PLL active so that FREECLK is always available irrespective of suspend/sleep. - Connect USB2 PHY COMMONONN to 0. - Connect utmi_sleep_n[0] to SLEEPM[0]. - Connect (utmi_suspend_n[0] & utmi_l1_suspend_n[0]) to SUSPENDM[0]. - Connect USB2 PHY FREECLK to utmi_clk[0]. - Leave utmi_suspend_com_n, utmi_l1_suspend_com_n unconnected. - GUCTL1.OVRLD_L1_SUSP_COM can be set to any value. For Third Party PHY, GUSB2PHYCFGn.U2_FREECLK_EXISTS=0; With this connection the PHY can shut off all the clocks when the required conditions are met (like, GUSB2PHYCFGn[8,6], GUCTL1[1], GFLADJ[23], GCTL[10], Suspend condition, HW LPM enable etc). - Connect -utmi_suspend_com_n to SUSPENDM[0] (or equivalent). - Connect -utmi_l1_suspend_com_n to SLEEPM[0] (or equivalent). - Connect PHYCLK0 (first port clock) to utmi_clk[0]. - Leave utmi_suspend_n[0], utmi_l1_suspend_ n[0], utmi_sleep_n[0] unconnected. - Set GUCTL1.OVRLD_L1_SUSP_COM to 1'b1.
0 LOA_FILTER_EN	LOA_FILTER_EN If this bit is set, the USB 2.0 port babble is checked at least three consecutive times before the port is disabled. This prevents false triggering of the babble condition when using low quality cables. Note: This bit is valid only in host mode.

11.2.5.1.58.3 Diagram

11.2.5.1.58.4 Fields

Field	Function
31-22 REFCLKPER	This field indicates in terms of nano seconds the period of ref_clk. The default value of this register is set to 'h8 (8ns/125 MHz). This field needs to be updated during power-on initialization, if GCTL.SOFITPSYNC or GFLADJ.GFLADJ_REFCLK_LPM_SEL is set to '1'. The programmable maximum value is 62ns, and the minimum value is 8ns. You must use a reference clock with a period that is an integer multiple, so that ITP can meet the jitter margin of 32ns. The allowable ref_clk frequencies whose period is not integer multiples are 16/17/19.2/24/39.7MHz. This field must not be set to '0' at any time. If you never plan to use this feature, then set this field to 'h8, the default value.
21 NoExtrDI	No Extra Delay Between SOF and the First Packet Some HS devices misbehave when the host sends a packet immediately after a SOF. However, adding an extra delay between a SOF and the first packet can reduce the USB data rate and performance. This bit is used to control whether the host must wait for 2 microseconds before it sends the first packet after a SOF, or not. User can set this bit to one to improve the performance if those problematic devices are not a concern in the user's host environment. - 1'b0: Host waits for 2 microseconds after a SOF before it sends the first USB packet. - 1'b1: Host doesn't wait after a SOF before it sends the first USB packet.
20-18	Reserved

Table continues on the next page...

Field	Function
—	
17 SprsCtrlTransEn	Sparse Control Transaction Enable Some devices are slow in responding to Control transfers. Scheduling multiple transactions in one microframe/frame can cause these devices to misbehave. If this bit is set to 1'b1, the host controller schedules transactions for a Control transfer in different microframes/frames.
16 ResBwHSEPS	Reserving 85% Bandwidth for HS Periodic EPs By default, HC reserves 80% of the bandwidth for periodic EPs. If this bit is set, the bandwidth is relaxed to 85% to accommodate two high speed, high bandwidth ISOC EPs. USB 2.0 required 80% bandwidth allocated for ISOC traffic. If two High-bandwidth ISOC devices (HD Webcams) are connected, and if each requires 1024-bytes X 3 packets per Micro-Frame, then the bandwidth required is around 82%. If this bit is set, then it is possible to connect two Webcams of 1024bytes X 3 paylod per Micro-Frame each. Otherwise, you may have to reduce the resolution of the Webcams. This bit is valid in Host and DRD configuration and is used in host mode operation only. Ignore this bit in device mode.
15 —	Reserved
14 USBHstInAutoRetryEn	Host IN Auto Retry When set, this field enables the Auto Retry feature. For IN transfers (non-isochronous) that encounter data packets with CRC errors or internal overrun scenarios, the auto retry feature causes the Host core to reply to the device with a non-terminating retry ACK (that is, an ACK transaction packet with Retry = 1 and NumP != 0). If the Auto Retry feature is disabled (default), the core will respond with a terminating retry ACK (that is, an ACK transaction packet with Retry = 1 and NumP = 0). - 1'b0: Auto Retry Disabled - 1'b1: Auto Retry Enabled Note: When enabling Auto Retry feature, if the system latency is large enough to cause the internal PSQ full (PSQ can be full as the result of messages not being processed because of pending fetches before flushing the TxQ due to NRDY/ERDY conditions), then the host controller can generate a transaction error.
13 EnOverlapChk	Enable Check for LFPS Overlap During Remote Ux Exit: If this bit is set to, - 1'b1: The SuperSpeed link when exiting U1/U2/U3 waits for either the remote link LFPS or TS1/TS2 training symbols before it confirms that the LFPS handshake is complete. This is done to handle the case where the LFPS glitch causes the link to start exiting from the low power state. Looking for the LFPS overlap makes sure that the link partner also sees the LFPS. - 1'b0: When the link exists U1/U2/U3 because of a remote exit, it does not look for an LFPS overlap.
12 ExtCapSupptEN	External Extended Capability Support Enable When set, this field enables extended capabilities to be implemented outside the core. When the ExtCapSupEN is set and the Debug Capability is enabled, the Next Capability pointer in "Debug Capability" returns 16. A read to the first DWORD of the last internal extended capability (the "xHCI Supported Protocol Capability for USB 3.0" when the Debug Capability is not enabled) returns a value of 4 in the Next Capability Pointer field. This indicates to software that there is another capability four DWORDs after this capability (for example, at address N+16 where N is the address of this DWORD). If enabled, an external address decoder that snoops the xHC slave interface must be implemented. If it sees an access to N+16 or greater, the slave access is re-routed to a piece of hardware which returns the external capability pointer register of the new capability and also handles reads/writes to this new capability and the side effects. If disabled, a read to the first DWORD of the last internal extended capability returns 0 in the 'Next Capability Pointer field. This indicates there are no more capabilities.
11 InsrtExtrFSBODI	Insert Extra Delay Between FS Bulk OUT Transactions Some FS devices are slow to receive Bulk OUT data and can get stuck when there are consecutive Bulk OUT transactions with short inter-transaction delays. This bit is used to control whether the host inserts extra delay between consecutive Bulk OUT transactions to a FS Endpoint. - 1'b0: Host doesn't insert extra delay between consecutive Bulk OUT transactions to a FS Endpoint. - 1'b1: Host inserts about 12us extra delay between consecutive Bulk OUT transactions to a FS Endpoint to work around the device issue. Note: Setting this bit to one will reduce the Bulk OUT transfer performance for most of the FS devices.

Table continues on the next page...

Field	Function
10-9 DTCT	Device Timeout Coarse Tuning This field is a Host mode parameter which determines how long the host waits for a response from device before considering a timeout. The core first checks the DTCT value. If it is 0, then the timeout value is defined by the DTFT. If it is non-zero, then it uses the following timeout values: - 2'b00: 0 usec -> use DTFT value instead - 2'b01: 500 usec - 2'b10: 1.5 msec - 2'b11: 6.5 msec Note: When the system latency is larger than the programmed DTCT/DTFT value, if the host controller is not able to accept certain transactions on the bus (because of system bus delays), the controller may not release header credits which in turn can cause the host to report a transaction error. Therefore, program this value to be larger than your system delay.
8-0 DTFT	Device Timeout Fine Tuning This field is a Host mode parameter which determines how long the host waits for a response from device before considering a timeout. For the DTFT field to take effect, DTCT must be set to 2'b00. The DTFT value is the number of 125 MHz clocks * 256 to count before considering a device timeout. The minimum value of DTFT is 2. For example, if the mac3_clk is 125 MHz clk (8 ns period), this is calculated as follows: (DTFT value) * 256 * (8 ns) Quick Reference: - if DTFT = 0x2, 2*256*8 = 4usec timeout - if DTFT = 0x5, 5*256*8 = 10usec timeout - if DTFT = 0xA, 10*256*8 = 20usec timeout - if DTFT = 0x10, 16*256*8 = 32usec timeout - if DTFT = 0x19, 25*256*8 = 51usec timeout - if DTFT = 0x31, 49*256*8 = 100usec timeout - if DTFT = 0x62, 98*256*8 = 200usec timeout Note: - When SSIC is enabled, in HS_G1_G2_G3 mode when ssic_soc_pa_clk_freq = 2'b01, then DTFT value must be calculated for 156.25 MHz clock, for example, for equivalent delay of 32usec DTFT value must be 9'h14. - When the system latency is larger than the programmed DTCT/DTFT value, if the host controller is not able to accept certain transactions on the bus (because of system bus delays), the controller may not release header credits which in turn can cause the host to report a transaction error. Therefore, program this value to be larger than your system delay.

11.2.5.1.59 Gobal SoC Bus Error Address Register - Low (GBUSERRADDRLO)

11.2.5.1.59.1 Offset

Register	Offset
GBUSERRADDRLO	C130h

11.2.5.1.59.2 Function

When the AHB or AXI Master Bus returns an "Error" response, the "SoC Bus Error" is generated. In the Host mode, the host_system_err port indicates this condition. In addition, it is also indicated in the USBSTS.HSE field. In the Device mode, the GSTS.BusErrAddrVld field is the only indication of the SoC Bus Error

11.2.5.1.60.4 Fields

Field	Function
31-0 BUSERRADDR	Bus Address - High This register contains the higher 32 bits of the first bus address that encountered a SoC bus error. It is valid when the GSTS.BusErrAddrVld field is 1. It can only be cleared by resetting the core. Note: Only supported in AHB and AXI configurations.

11.2.5.1.61 Global SS Port to Bus Instance Mapping Register - Low (GPRTBIMAPLO)

11.2.5.1.61.1 Offset

Register	Offset
GPRTBIMAPLO	C138h

11.2.5.1.61.2 Function

This register specifies the SuperSpeed USB instance number to which each USB 3.0 port is connected. By default, USB 3.0 ports are evenly distributed among all SS USB instances. The software can program this register to specify how USB 3.0 ports are connected to SS USB instances. Register fields are read-write with respect to number of port instantiated. writeAsRead constraint is added to limit side effects for unused fields.

GPRTBIMAP_FSLO	C188h

11.2.5.1.73.2 Function

This register specifies the Full Speed USB instance number to which each USB 3.0 port is connected. By default, USB 3.0 ports are evenly distributed among all FS USB instances. Software can program this register to specify how USB 3.0 ports are connected to FS USB instances. - Register fields are read-write with respect to number of port instantiated. writeAsRead constraint is added to limit side effects for unused fields.

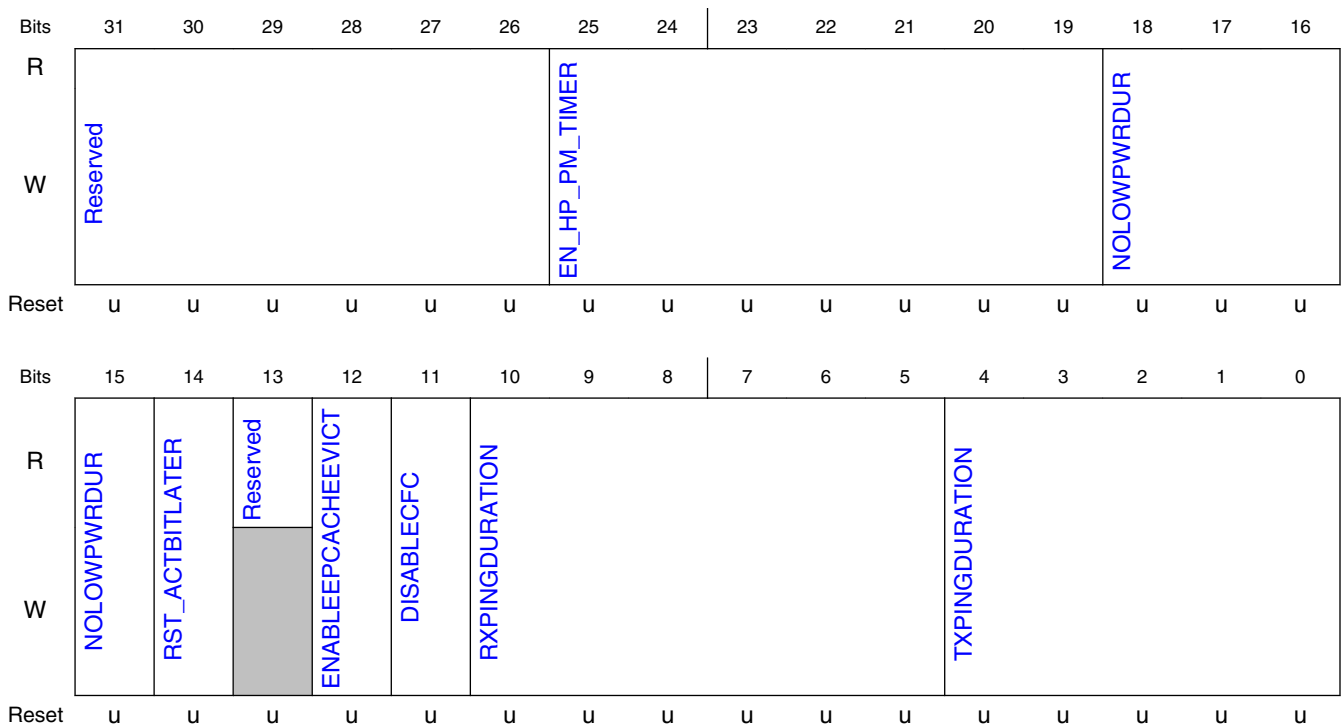
11.2.5.1.77.1 Offset



Register	Offset
GUCTL2	C19Ch

11.2.5.1.77.2 Function

This register provides a few options for the software to control the core behavior in the Host and device mode.

Reset Mask: 0x3FC008000

11.2.5.1.77.3 Diagram

11.2.5.1.77.4 Fields

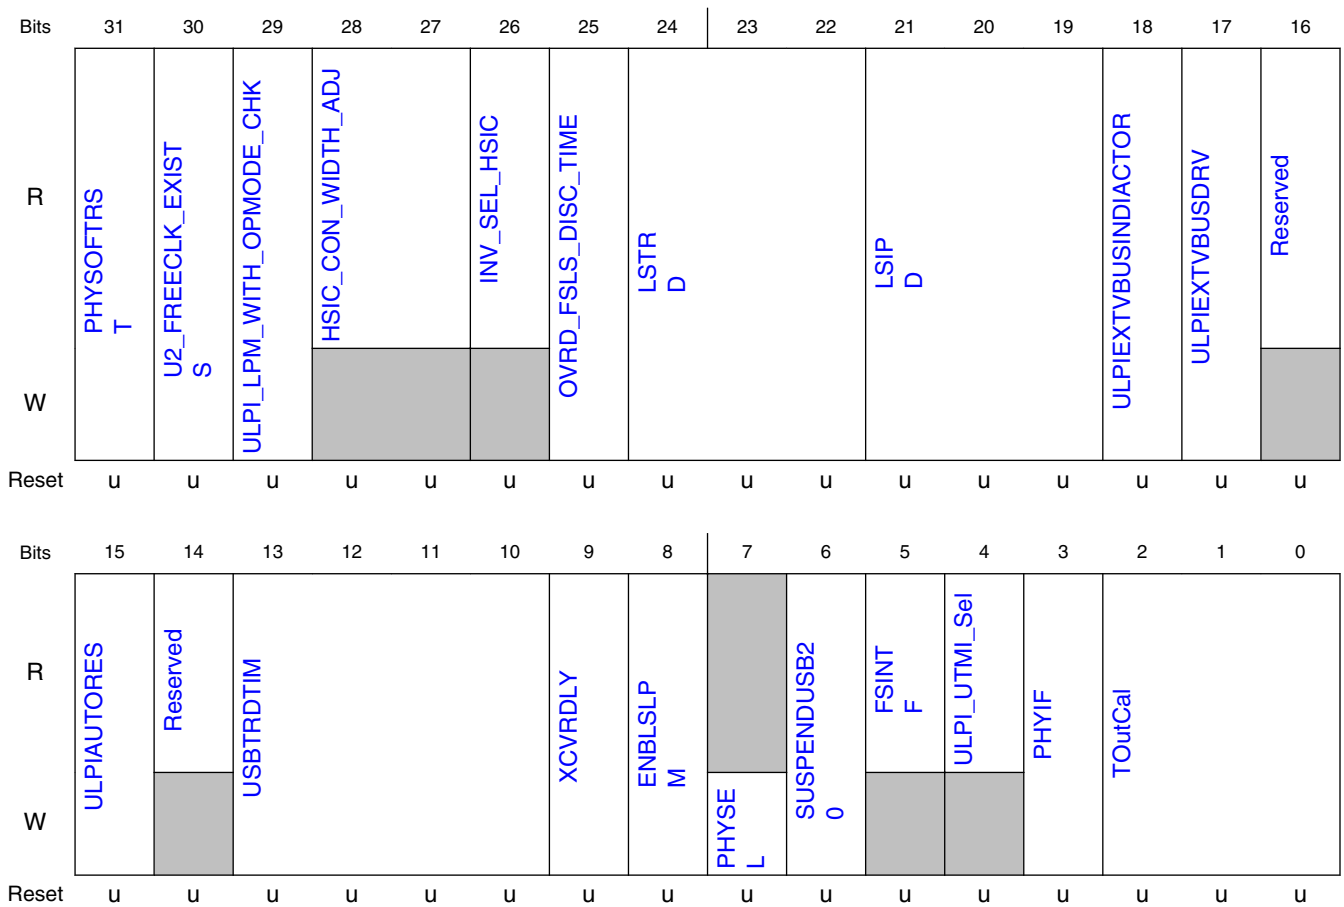
Field	Function
31-26 —	Reserved
25-19	This register field is used to set new HP and PM timers. - To enable PM timer, set GUCTL2[19] bit as 1. - To enable HP timer, set GUCTL2[20] bit as 1. Default value is 4us, when new HP timer is enabled default value is 11us. Use GUCTL2[25:21] to specify HP timer value in microseconds.

Table continues on the next page...

Field	Function
EN_HP_PM_TIMER	
18-15 NOLOWPWRDUR	No Low Power Duration This bit is applicable for device mode only and is ignored in host mode. After starting a transfer on an ESS ISOC endpoint, the application must program these bits. Each count represents the duration in terms of milli seconds. For example, a value of 3 represents 3 ms. **NOTE:** • To disable this feature, set this field to 4'b0. • These bits are applicable only in device mode and ignored in host mode. • Some xHCI hosts do not send ITPs when performing ISOC transfers when the link enters U1/U2 low power states. This causes the device to lose frame synchronization over a period of time resulting in ISOC packets being dropped.
14 RST_ACTBITLATER	Enable clearing of the command active bit for the ENDXFER command after the command execution is completed. This bit is valid in device mode only.
13 —	Reserved for future use
12 ENABLEEPCACHEEVICT	Enable Evicting Endpoint Cache after Flow Control for bulk endpoints In 3.00a release, a performance enhancement was done to keep the non-stream capable bulk IN endpoint in cache after flow control. Setting this bit will disable this enhancement. This should be set only for debug purpose.
11 DISABLECFC	Disable xHCI Errata Feature Contiguous Frame ID Capability This field controls the xHCI Errata feature Contiguous FrameID capability. When set, the xHCI HCCPARAMS1 bit 11 will be set to 0 indicating that CFC is not supported. Disable this feature only if your application cannot tolerate Misssed Service Error events for Isoc transfers, and your system latencies are large to cause Missed Service errors even if the software is following the Isochronous Thresholding rules.
10-5 RXPINGDURATION	Recieve Ping Maximum Duration This field is relevant to Host mode and controls the maximum duration of received LFPS to be treated as a Ping LFPS. The Max duration of the Ping LFPS is controlled by programming this value and is in terms of 8 ns granularity. Eg: A value of 32 indicates 256 ns.
4-0 TXPINGDURATION	Transmit Ping Maximum Duration This field is relevant to Device mode and controls the maximum duration for which the controller should instruct the PHY to transmit a Ping LFPS. The duration of the Ping LFPS is controlled by programming this value and is in terms of 8 ns granularity. Eg: A value of 13 indicates 104 ns.

11.2.5.1.78 Global USB2 PHY Configuration Register (GUSB2PHYCFG)

11.2.5.1.78.1 Offset



Register	Offset
GUSB2PHYCFG	C200h

11.2.5.1.78.2 Function

The application must program this register before starting any transactions on either the SoC bus or the USB.

Reset Mask:0x2014000

11.2.5.1.78.3 Diagram

11.2.5.1.78.4 Fields

Field	Function
31 PHYSOFTRST	UTMI PHY Soft Reset Causes the usb2phy_reset signal to be asserted to reset a UTMI PHY.
30 U2_FREECLK_EXISTS	U2_FREECLK_EXISTS Specifies whether your USB 2.0 PHY provides a free-running PHY clock, which is active when the clock control input is active. Specifies whether your USB 2.

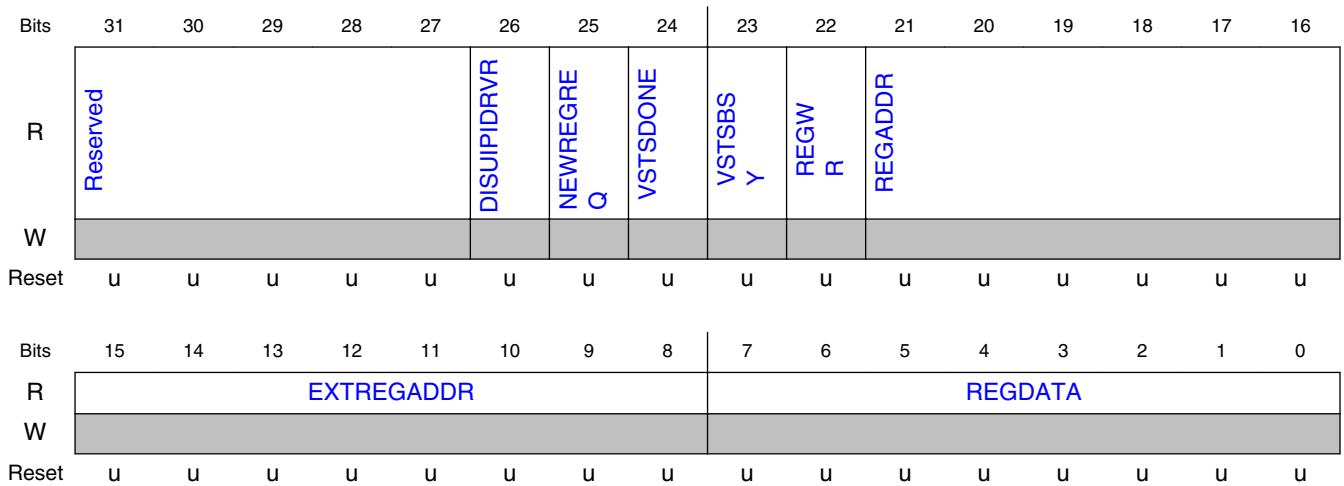
Table continues on the next page...

Field	Function
	free-running PHY clock, which is active when the clock control input is active. If your USB 2.0 PHY provides a free-running PHY clock, it must be connected to the utmi_clk[0] input. The remaining utmi_clk[n] must be connected to the respective port clocks. The core uses the Port-0 clock for generating the internal mac2 clock. - 1'b0: USB 2.0 free clock does not exist - 1'b1: USB 2.0 free clock exists Note: When the core is configured as device-only (DWC_USB3_MODE = 0), do not set this bit to 1.
29 ULPI_LPM_WITH_OPMODE_CHK	Support the LPM over ULPI without NOPID token to the ULPI PHY. If this bit is set, the ULPI PHY is expected to qualify the EXT PID with OPMODE=2'b00 for LPM and not treat it as a NOPID. Check with your PHY vendor about your PHY behavior. This bit is valid only when the DWC_USB3_HSPHY_INTERFACE parameter is 2 or 3. - 1'b0: A NOPID is sent before sending an EXTPID for LPM; - 1'b1: An EXTPID is sent without previously sending a NOPID; Note: This bit is valid only in host mode. This bit should be '0' for Synopsys PHY.
28-27 HSIC_CON_WIDTH_ADJ	This bit is used in the HSIC device mode of operation.
26 INV_SEL_HSIC	The application driver uses this bit to control the HSIC enable/disable function.
25 OVRD_FSLS_DISC_TIME	Overriding the FS/LS Disconnect Time • If this value is 0, the FS/LS disconnect time is set to 2.5us as per the USB specification. • If this value is non-0, the disconnect detection time is set to 32us. Normally, this value is set to 0. However, if the USB 2.0 PHYs introduce noise on the UTMI linestate and cause SE0 glitches longer than 2.5us, then a false disconnect condition may get triggered. To avoid interoperability issues with these PHYs, this bit can be set to 1.
24-22 LSTRD	LS Turnaround Time This field indicates the value of the Rx-to-Tx packet gap for LS devices.
21-19 LSIPD	LS Inter-Packet Time This field indicates the value of Tx-to-Tx packet gap for LS devices.
18 ULPIEXTVBUSINDIACTOR	ULPI External VBUS Indicator Indicates the ULPI PHY VBUS over-current indicator.
17 ULPIEXTVBUSDRV	ULPI External VBUS Drive Selects supply source to drive 5V on VBUS, in the ULPI PHY.
16 —	Reserved
15 ULPIAUTORES	ULPI Auto Resume Sets the AutoResume bit in Interface Control register on the ULPI PHY.
14 —	Reserved
13-10 USBTRDTIM	USB 2.0 Turnaround Time
9 XCVRDLY	Transceiver Delay Enables a delay between the assertion of the UTMI/ULPI Transceiver Select signal (for HS) and the assertion of the TxValid signal during a HS Chirp.
8	Enable utmi_sleep_n and utmi_l1_suspend_

Table continues on the next page...

Field	Function
ENBLSLPM	The application uses this bit to control utmi_sleep_n and utmi_l1_suspend_n assertion to the PHY in the L1 state..
7 PHYSEL	USB 2.0 High-Speed PHY or USB 1.1 Full-Speed Serial Transceiver Select
6 SUSPENDUSB20	Suspend USB2.0 HS/FS/LS PHY
5 FSINTF	Full-Speed Serial Interface Select The application uses this bit to select a unidirectional or bidirectional USB 1.1 full-speed serial transceiver interface.
4 ULPI_UTMI_Sel	ULPI or UTMI+ Select The application uses this bit to select a UTMI+ or ULPI Interface.
3 PHYIF	PHY Interface If UTMI+ is selected, the application uses this bit to configure the core to support a UTMI+ PHY with an 8- or 16-bit interface.
2-0 TOutCal	HS/FS Timeout Calibration The number of PHY clocks, as indicated by the application in this field, is multiplied by a bit-time factor; this factor is added to the high-speed/full-speed interpacket timeout duration in the core to account for additional delays introduced by the PHY.

11.2.5.1.79 Global USB 2.0 ULPI PHY Vendor Control Register (GUSB2PHYACC_ULPI)



11.2.5.1.79.1 Offset

Register	Offset

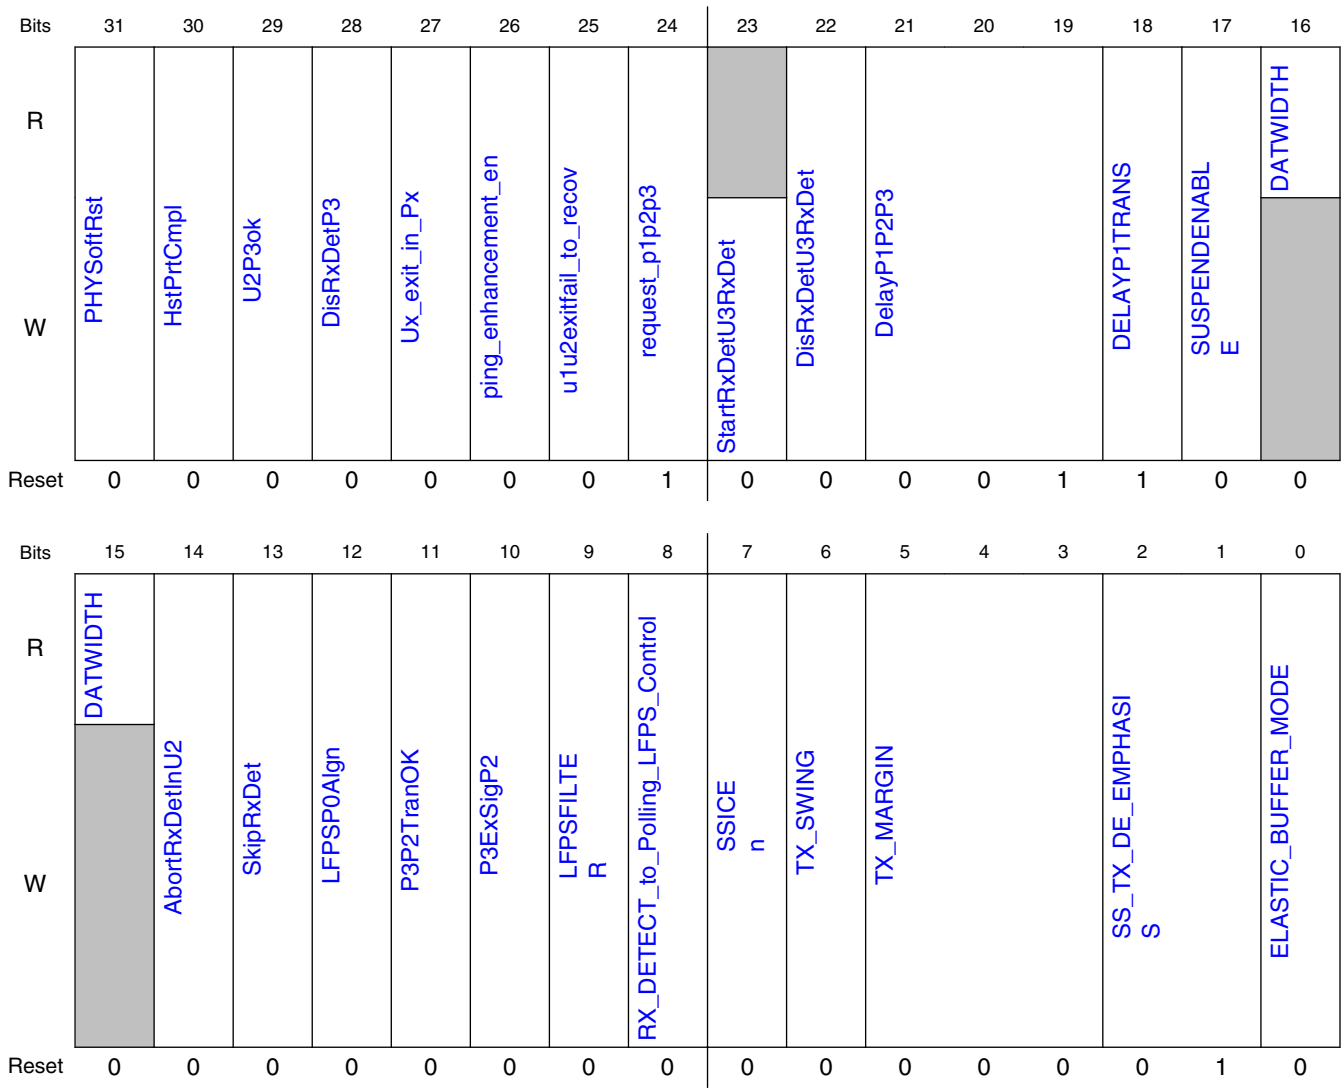
Field	Function
31-27 —	Reserved
26 DISUIPIDRVR	DISUIPIDRVR
25 NEWREGREQ	New Register Request New Register Request The application sets this bit for a new vendor control access..
24 VSTSDONE	VSTSDONE
23 VSTSBSY	VSTSBSY
22 REGWR	Register Write The application sets this bit for register writes and clears it for register reads. **NOTE:** This bit is applicable for ULPI register read/write access only.
21-16 REGADDR	Register Address The 6-bit PHY register address for immediate PHY Register Set access. Set to 6'h2F for Extended PHY Register Set access. **NOTE:** These bits are applicable for ULPI only.
15-8 EXTREGADDR	EXTREGADDR
7-0 REGDATA	REGDATA

11.2.5.1.80 Global USB 3.0 PIPE Control Register (GUSB3PIPECTL)



11.2.5.1.80.1 Offset

Register	Offset
GUSB3PIPECTL	C2C0h

11.2.5.1.80.2 Function

The application uses this register to configure the USB3 PHY and PIPE interface. Device-only configuration requires only one register. In Host mode, registers are implemented for each port. Note: - GUSB3PIPECTLn registers are not applicable for USB 2.0-only mode.

11.2.5.1.80.3 Diagram

11.2.5.1.80.4 Fields

Field	Function
31 PHYSoftRst	USB3 PHY Soft Reset After setting this bit to '1', the software needs to clear this bit.
30 HstPrtCmpl	This feature tests the PIPE PHY compliance patterns without having to have a test fixture on the USB 3.
29 U2P3ok	P3 OK for U2 0: During link state U2/SS.Inactive, put PHY in P2 (Default) 1: During link state U2/SS.Inactive, put PHY in P3.
28	Disabled Receiver Detection in P3

Table continues on the next page...

Field	Function
DisRxDetP3	0:If PHY is in P3 and controller needs to perform receiver detection, The controller performs receiver detection in P3. (Default) 1: If PHY is in P3 and controller needs to perform receiver detection, The controller changes the PHY power state to P2 and then performs receiver detection. After receiver detection, the cores changes PHY power state to P3.
27 Ux_exit_in_Px	Ux Exit in Px 0: The core does U1/U2/U3 exit in PHY power state P0 (default behavior). 1: The controller does U1/U2/U3 exit in PHY power state P1/P2/P3 respectively.
26 ping_enhancement_en	Ping Enhancement Enable When set, the Downstream port U1 ping receive timeout becomes 500 ms instead of 300 ms. Minimum Ping.LFPS receive duration is 8 ns (one mac3_clk). This field is valid for the downstream port only.
25 u1u2exitfail_to_recov	U1U2exitfail to Recovery When set, and U1/U2 LFPS handshake fails, the LTSSM transitions from U1/U2 to Recovery instead of SS Inactive. If Recovery fails, then the LTSSM can enter SS.Inactive. This is an enhancement only. It prevents interoperability issue if the remote link does not do proper handshake.
24 request_p1p2p3	Always Request P1/P2/P3 for U1/U2/U3 When set, the core always requests PHY power change from P0 to P1/P2/P3 during U0 to U1/U2/U3 transition. If this bit is 0, and immediate Ux exit (remotely initiated, or locally initiated) happens, the controller does not request P1/P2/P3 power state change.
23 StartRxDetU3RxDet	Start Receiver Detection in U3/Rx.Detect If DWC_USB3_GUSB3PIPECTL_INIT[22] is set, and the link is in either U3 or Rx.Detect state, the core starts receiver detection on the rising edge of this bit. This can only be used for Downstream ports. This bit must be set to '0' for Upstream ports. This feature must not be enabled for normal operation.
22 DisRxDetU3RxDet	Disable Receiver Detection in U3/Rx.Detect Disable Receiver Detection in U3/Rx.Det When set, the core does not handle receiver detection in either U3 or Rx.Detect states. DWC_USB3_GUSB3PIPECTL_INIT[23] must be used to start receiver detection manually. This bit can only be used for the downstream port. This bit must be set to "0" for Upstream ports. This feature must not be enabled for normal operation.
21-19 DelayP1P2P3	Delay P1P2P3 Delay P0 to P1/P2/P3 request when entering U1/U2/U3 until (DWC_USB3_GUSB3PIPECTL_INIT[21:19]*8) 8B10B error occurs, or Pipe3_RxValid drops to 0.
18 DELAYP1TRANS	Delay PHY Power It change from P0 to P1/P2/P3 when link state changing from U0 to U1/U2/U3 respectively. 1'b1: When entering U1/U2/U3, delay the transition to P1/P2/P3 until the pipe3 signals, Pipe3_RxElecIdle is 1 and pipe3_RxValid is 0. 1'b0: When entering U1/U2/U3, transition to P1/P2/P3 without checking for Pipe3_RxElecIdle and pipe3_RxValid.
17 SUSPENDENABLE	Suspend USB3 SS PHY When set, and if Suspend conditions are valid, the USB 3.0 PHY enters Suspend mode. For DRD configurations, it is recommended that this bit is set to '0' during coreConsultant configuration. If it is set to '1', then the application must clear this bit after power-on reset. Application needs to set it to '1' after the controller initialization is completed. For all other configurations, this bit can be set to '1' during controller configuration.
16-15 DATWIDTH	PIPE Data Width 2'b00: 32 bits 2'b01: 16 bits -

Table continues on the next page...

Field	Function
	One clock after reset, these bits receive the value seen on the pipe3_DataBusWidth. The simulation testbench uses the coreConsultant parameter to configure the VIP. These bits in the coreConsultant parameter must match your PHY data width and the pipe3_DataBusWidth port.
14 AbortRxDetInU2	Abort Rx Detect in U2 When set, and the link state is U2, then the core will abort receiver detection if it receives U2 exit LFPS from the remote link partner. This bit is for the downstream port only.
13 SkipRxDet	Skip Rx Detect When set, the core skips Rx Detection if pipe3_RxElecIdle is low.
12 LFPSP0Algn	LFPS P0 Align When set, the core deasserts LFPS transmission on the clock edge that it requests Phy power state 0 when exiting U1, U2, or U3 low power states. Otherwise, LFPS transmission is asserted one clock earlier. The controller requests symbol transmission two pipe3_rx_pclks periods after the PHY asserts PhyStatus as a result of the PHY switching from P1 or P2 state to P0 state.
11 P3P2TranOK	P3 P2 Transitions OK When set, the core transitions directly from Phy power state P2 to P3 or from state P3 to P2. When not set, P0 is always entered as an intermediate state during transitions between P2 and P3, as defined in the PIPE3 Specification. According to the PIPE3 Specification, any direct transition between P3 and P2 is illegal
10 P3ExSigP2	P3 Exit Signal in P2 When this bit is set, the core always changes the PHY power state to P2, before attempting a U3 exit handshake.
9 LFPSFILTER	LFPS Filter When set, filter LFPS reception with pipe3_RxValid in PHY power state P0, that is, ignore LFPS reception from the PHY unless both pipe3_Rxelecidle and pipe3_RxValid are deasserted.
8 RX_DETECT_to_Polling_LFPS_Control	RX_DETECT to Polling LFPS Control 1'b0 (Default): Enables a 400us delay to start Polling LFPS after RX_DETECT. This allows VCM offset to settle to a proper level. 1'b1: Disables the 400us delay to start Polling LFPS after RX_DETECT. During controller certification with third party PHY it is observed that the PHY is not able to meet the Tx AC common mode voltage active (VTX-CM-ACPP_ACTIVE <100mv) if the link starts polling within 80us from the time rx.detect is performed. To meet this VTX-CM-ACPP_ACTIVE specification, the polling must be delayed further. If the PHY does not have issue then they can set this bit to 1 which allows polling to start within 80us.
7 SSICEn	USB3 SSIC Enable This bit is valid only when coreConsultant parameter DWC_USB3_EN_SSIC=1 else this bit needs to be set to 1'b0.
6 TX_SWING	Tx Swing
5-3 TX_MARGIN	Tx Margin [2:0]
2-1 SS_TX_DE_EMPHASIS	Tx Deemphasis The value driven to the PHY is controlled by the LTSSM during USB3 Compliance mode.
0	Elastic Buffer Mode

Field	Function
ELASTIC_BUFFER_MODE	

11.2.5.1.81 Global Transmit FIFO Size Register (GTXFIFOSIZ0 - GTXFIFOSIZ7)

11.2.5.1.81.1 Offset

For a = 0 to 7:

Register	Offset
GTXFIFOSIZa	C300h + (a × 4h)

11.2.5.1.81.2 Function

This register specifies the RAM start address and depth (both in MDWIDTH-bit words) for each implemented TxFIFO.

11.2.5.1.81.3 Diagram

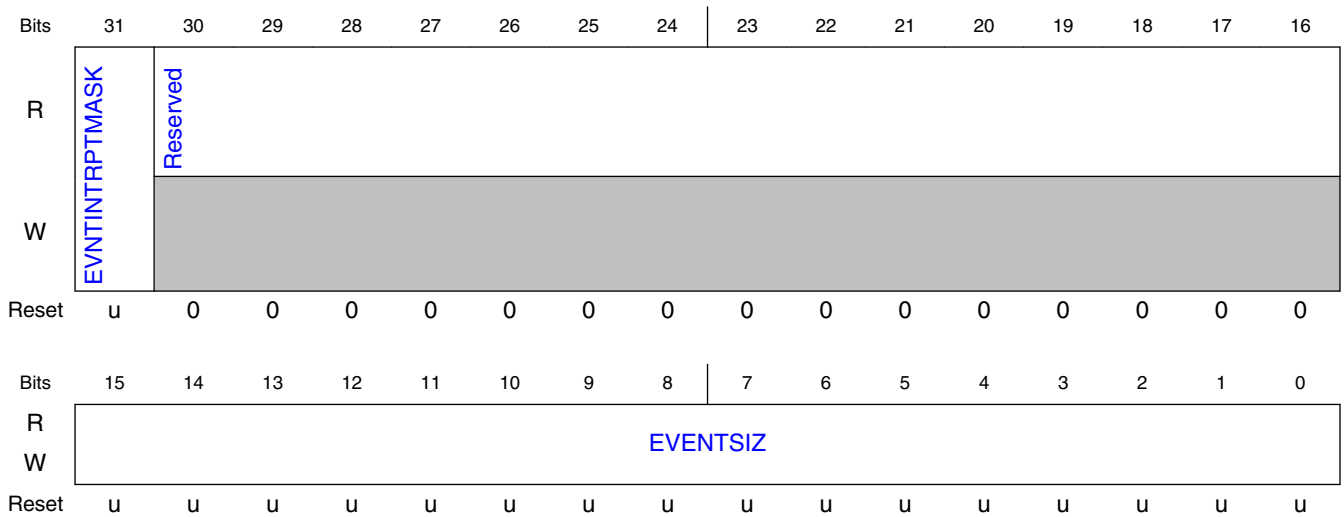
31-0 EVNTADRHI	Event Buffer Address Holds the higher 32 bits of start address of the external memory for the Event Buffer.

11.2.5.1.85 Global Event Buffer Size Register (GEVNTSIZ)

11.2.5.1.85.1 Offset



Register	Offset
GEVNTSIZ	C408h

11.2.5.1.85.2 Function

This register holds the Event Buffer Size and the Event Interrupt Mask bit. During power-on initialization, software must initialize the size with the number of bytes allocated for the Event Buffer. The Event Interrupt Mask will mask the interrupt, but events are still queued. After configuration, software must preserve the Event Buffer Size value when changing the Event Interrupt Mask.

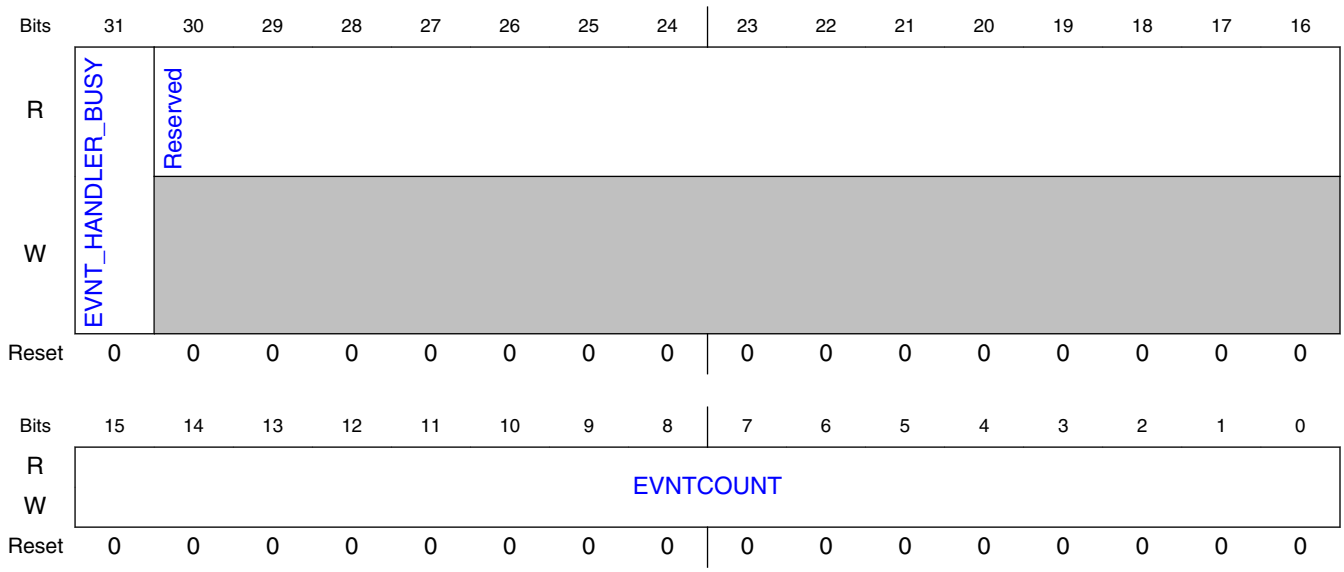
Reset Mask:0x7FFF0000

11.2.5.1.85.3 Diagram

11.2.5.1.85.4 Fields

Field	Function
31 EVNTINTRPTMASK	Event Interrupt Mask.
30-16 —	Reserved
15-0 EVENTSIZ	Event Buffer Size in Bytes Holds the size of the Event Buffer in bytes; must be a multiple of four.

11.2.5.1.86 Global Event Buffer Count Register (GEVNTCOUNT)



11.2.5.1.86.1 Offset

Register	Offset
GEVNTCOUNT	C40Ch

11.2.5.1.86.2 Function

This register holds the number of valid bytes in the Event Buffer.

11.2.5.1.86.3 Diagram

11.2.5.1.86.4 Fields

Field	Function
31 EVNT_HANDLER_BUSY	Event Handler Busy Device software event handler busy indication.
30-16 —	Reserved
15-0 EVNTCOUNT	Event Count When read, returns the number of valid events in the Event Buffer (in bytes).

11.2.5.1.87 Global Hardware Parameters Register 8 (GHWPARAMS8)

11.2.5.1.87.1 Offset

Register	Offset
GHWPARAMS8	C600h

11.2.5.1.87.2 Function

This register contains the hardware configuration options that you can select in the coreConsultant GUI.

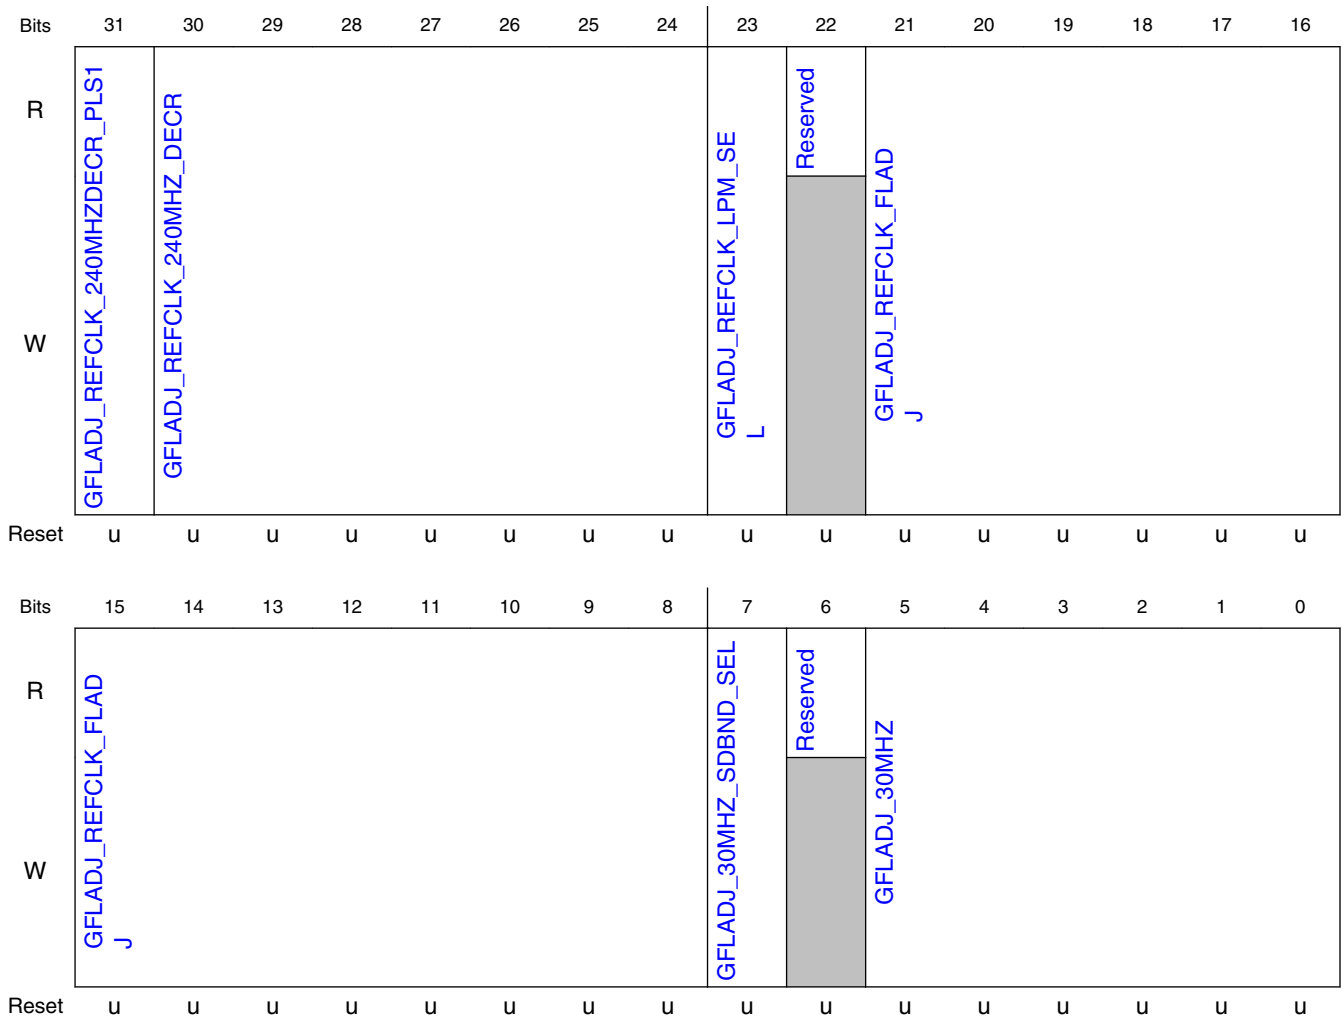
11.2.5.1.94.1 Offset



Register	Offset
GFLADJ	C630h

11.2.5.1.94.2 Function

This register provides options for the software to control the core behavior with respect to SOF (Start of Frame) and ITP (Isochronous Timestamp Packet) timers and frame timer functionality.

Reset Mask:0x400040

11.2.5.1.94.3 Diagram

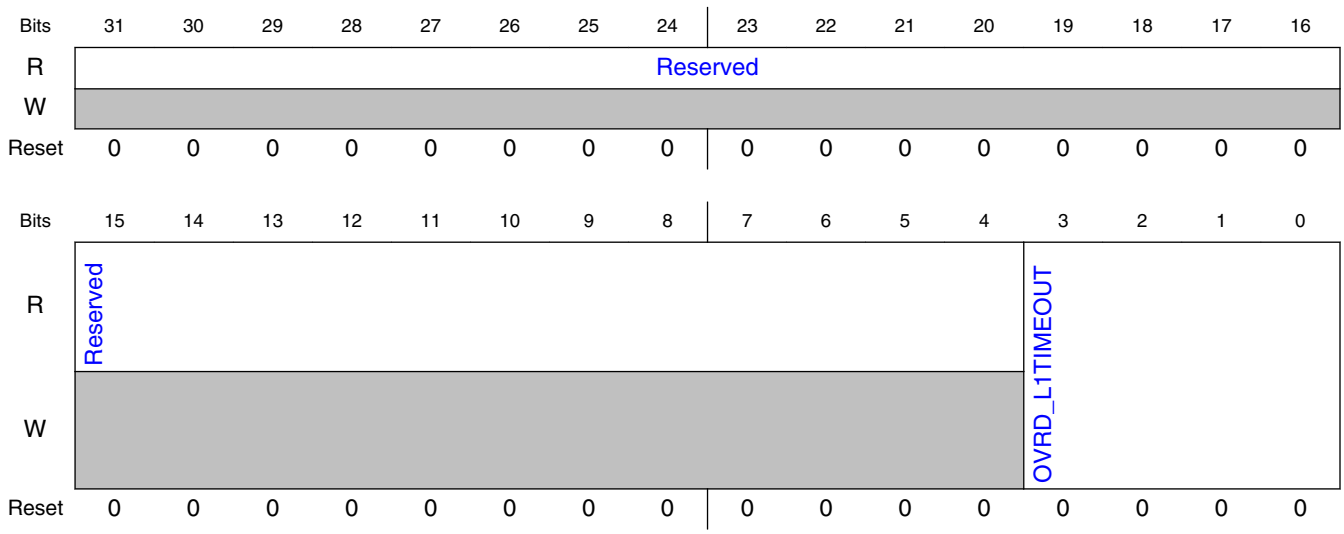
11.2.5.1.94.4 Fields

Field	Function
31 GFLADJ_REFCLK_240MHZDECR_PLS1	This field indicates that the decrement value that the controller applies for each ref_clk must be GFLADJ_REFCLK_240MHZ_DECR and GFLADJ_REFCLK_240MHZ_DECR +1 alternatively on each ref_clk. Set this bit to a '1' only if GFLADJ_REFCLK_LPM_SEL is set to '1' and the fractional component of 240/ref_frequency is greater than or equal to 0.5. Examples: If the ref_clk is 19.2 MHz then - GUCTL.REF_CLK_PERIOD = 52 - GFLADJ.GFLADJ_REFCLK_240MHZ_DECR = (240/19.2) = 12.5 - GFLADJ.GFLADJ_REFCLK_240MHZDECR_PLS1 = 1 If the ref_clk is 24 MHz then - GUCTL.REF_CLK_PERIOD = 41 - GFLADJ.GFLADJ_REFCLK_240MHZ_DECR = (240/24) = 10 - GFLADJ.GFLADJ_REFCLK_240MHZDECR_PLS1 = 0
30-24 GFLADJ_REFCLK_240MHZ_DECR	This field indicates the decrement value that the controller applies for each ref_clk in order to derive a frame timer in terms of a 240-MHz clock. This field must be programmed to a non-zero value only if GFLADJ_REFCLK_LPM_SEL is set to '1'. The value is derived as follows: GFLADJ_REFCLK_240MHZ_DECR = 240/ref_clk_frequency Examples: If the ref_clk is 24 MHz then -

Table continues on the next page...

Field	Function
	GUCTL.REF_CLK_PERIOD = 41 - GFLADJ.GFLADJ_REFCLK_240MHZ_DECR = 240/24 = 10 If the ref_clk is 48 MHz then - GUCTL.REF_CLK_PERIOD = 20 - GFLADJ.GFLADJ_REFCLK_240MHZ_DECR = 240/48 = 5 If the ref_clk is 17 MHz then - GUCTL.REF_CLK_PERIOD = 58 - GFLADJ.GFLADJ_REFCLK_240MHZ_DECR = 240/17 = 14
23 GFLADJ_REFCLK_LPM_SEL	This bit enables the functionality of running SOF/ITP counters on the ref_clk. This bit must not be set to '1' if GCTL.SOFITPSYNC bit is set to '1'. Similarly, if GFLADJ_REFCLK_LPM_SEL set to '1', GCTL.SOFITPSYNC must not be set to '1'. When GFLADJ_REFCLK_LPM_SEL is set to '1' the overloading of the suspend control of the USB 2.0 first port PHY (UTMI/ULPI) with USB 3.0 port states is removed. For example, for Synopsys PHY, the COMMONONN signal can be tied to '1'. Note that the ref_clk frequencies supported in this mode are 16/17/19.2/20/24/39.7/40 MHz. The utmi_clk[0] signal of the core must be connected to the FREECLK of the PHY. Note: If you set this bit to '1', the GUSB2PHYCFG.U2_FREECLK_EXISTS bit must be set to '0'.
22 —	Reserved for future use
21-8 GFLADJ_REFCLK_FLADJ	This field indicates the frame length adjustment to be applied when SOF/ITP counter is running on the ref_clk. This register value is used to adjust the ITP interval when GCTL[SOFITPSYNC] is set to '1'; SOF and ITP interval when GLADJ.GFLADJ_REFCLK_LPM_SEL is set to '1'. This field must be programmed to a non-zero value only if GFLADJ_REFCLK_LPM_SEL is set to '1' or GCTL.SOFITPSYNC is set to '1'. The value is derived as follows: FLADJ_REF_CLK_FLADJ=((125000/ref_clk_period_integer)-(125000/ref_clk_period)) * ref_clk_period where - the ref_clk_period_integer is the integer value of the ref_clk period got by truncating the decimal (fractional) value that is programmed in the GUCTL.REF_CLK_PERIOD field. - the ref_clk_period is the ref_clk period including the fractional value. Examples: If the ref_clk is 24 MHz then - GUCTL.REF_CLK_PERIOD = 41 - GFLADJ.GLADJ_REFCLK_FLADJ = ((125000/41)-(125000/41.6666))*41.6666 = 2032 (ignoring the fractional value) If the ref_clk is 48 MHz then - GUCTL.REF_CLK_PERIOD = 20 - GFLADJ.GLADJ_REFCLK_FLADJ = ((125000/20)-(125000/20.8333))*20.8333 = 5208 (ignoring the fractional value)
7 GFLADJ_30MHZ_SDBND_SEL	This field selects whether to use the input signal fladj_30mhz_reg or the GFLADJ.GFLADJ_30MHZ to adjust the frame length for the SOF/ITP. When this bit is set to, - 1, the controller uses the register field GFLADJ.GFLADJ_30MHZ value - 0, the controller uses the input signal fladj_30mhz_reg value
6 —	Reserved for future use
5-0 GFLADJ_30MHZ	This field indicates the value that is used for frame length adjustment instead of considering from the sideband input signal fladj_30mhz_reg. This enables post-silicon frame length adjustment in case the input signal fladj_30mhz_reg is connected to a wrong value or is not valid. For details on how to set this value, refer to section 5.2.4, "Frame Length Adjustment Register (FLADJ)," of the xHCI Specification.

11.2.5.1.95 Global USB 2.0 Root Hub Control Register (GUSB2RHBCTL)



11.2.5.1.95.1 Offset

Register	Offset
GUSB2RHBCTL	C640h

11.2.5.1.95.2 Function

The application must program this register before starting any transactions on the USB if a non-default value is desired. In Device-only configurations, only one register is needed. In Host mode, per-port registers are implemented.

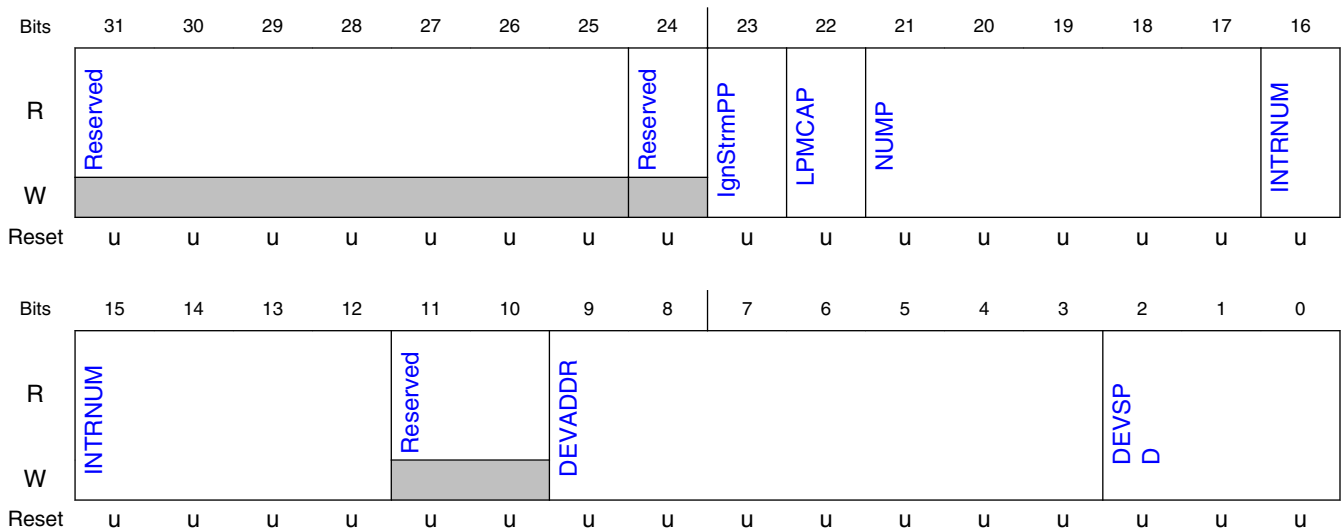
11.2.5.1.95.3 Diagram

11.2.5.1.95.4 Fields

Field	Function
31-4 —	Reserved
3-0 OVRD_L1TIMEOUT	Overriding Driver Programmed L1Timeout Value If this value is 0, the L1 Timeout value is taken from the xHCI PORTHLPMC register. If this value is non-0, then this will override the L1 Timeout value programmed in the xHCI PORTHLPMC register.

11.2.5.1.96 Device Configuration Register (DCFG)

11.2.5.1.96.1 Offset



Register	Offset
DCFG	C700h

11.2.5.1.96.2 Function

This register configures the core in device mode after power-on or after certain control commands or enumeration. Do not make changes to this register after initial programming.

Reset Mask:0x7F000C00

11.2.5.1.96.3 Diagram

11.2.5.1.96.4 Fields

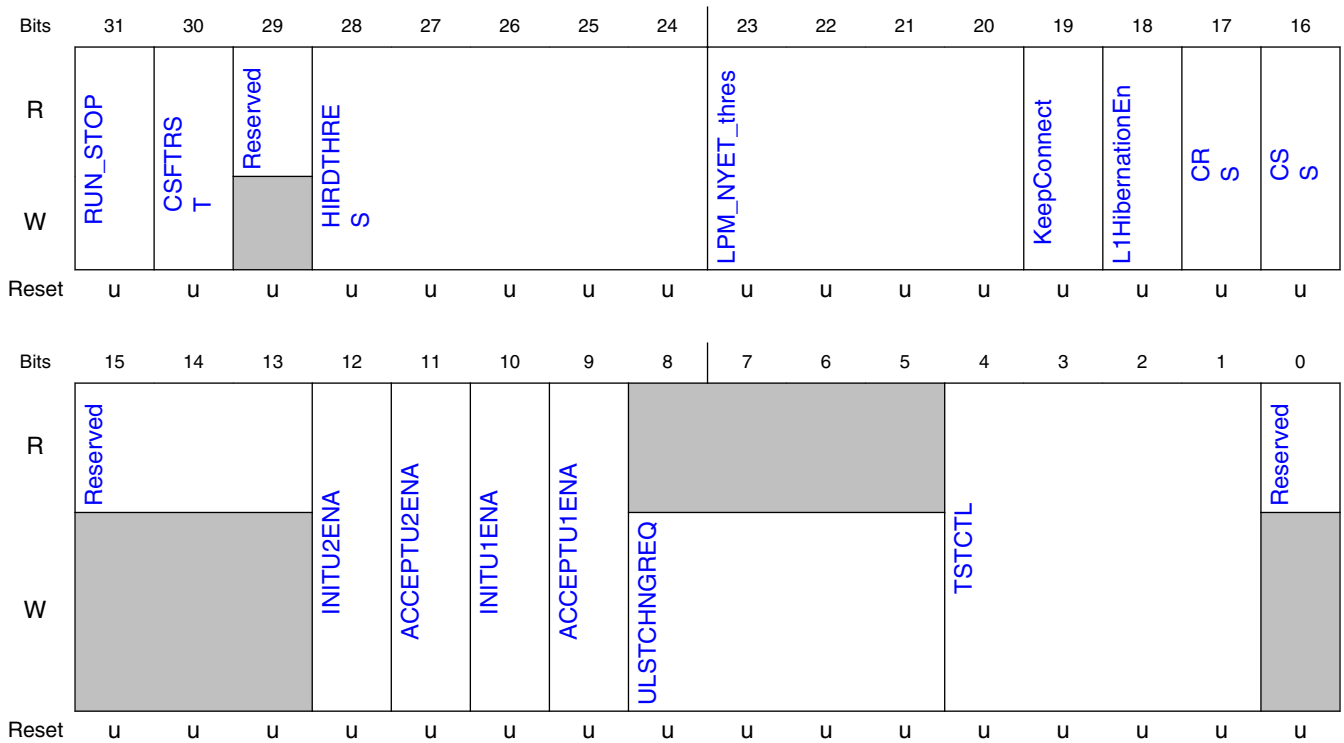
Field	Function
31-25 —	Reserved
24 —	Reserved
23 IgnStrmPP	Ignore Stream PP This bit only affects stream-capable bulk endpoints. When this bit is set to '0' and the controller receives a Data Packet with the Packet Pending (PP) bit set to 0 for OUT endpoints, or it receives an ACK with the NumP field set to 0 and PP set to 0 for IN endpoints, the core attempts to search for another stream (CStream) to initiate to the host. However, there are two situations where this behavior is not optimal: - When the host is setting PP=0 even though it has not finished the stream, or - When the endpoint on the device is configured with one transfer resource and therefore does not have any other streams to initiate to the host. When this bit is set to '1', the core ignores the Packet Pending bit for the purposes of stream selection and does not search for another stream when it receives DP(PP=0) or ACK(NumP=0, PP=0). This can enhance the performance when the device system bus bandwidth is low or the host responds to the core's ERDY transmission very quickly.
22 LPMCAP	LPM Capable

Table continues on the next page...

Field	Function
	The application uses this bit to control the DWC_usb3 core LPM capabilities. If the core operates as a non-LPM-capable device, it cannot respond to LPM transactions. - 1'b0: LPM capability is not enabled. - 1'b1: LPM capability is enabled.
21-17 NUMP	Number of Receive Buffers This bit indicates the number of receive buffers to be reported in the ACK TP. The DWC_usb3 controller uses this field for non-control endpoints if GRXTHRCFG.UsbRxPktCntSel is set to '0'. The application can program this value based on RxFIFO size, buffer sizes programmed in descriptors, and system latency. For an OUT endpoint, this field controls the number of receive buffers reported in the NumP field of the ACK TP transmitted by the core. Note: This bit is used in host mode when Debug Capability is enabled.
16-12 INTRNUM	Interrupt Number Indicates interrupt/EventQ number on which non-endpoint-specific device-related interrupts (see DEVT) are generated.
11-10 —	Reserved
9-3 DEVADDR	Device Address The application must perform the following: - Program this field after every SetAddress request. - Reset this field to zero after USB reset.
2-0 DEVSPD	Device Speed Indicates the speed at which the application requires the core to connect, or the maximum speed the application can support. However, the actual bus speed is determined only after the chirp sequence is completed, and is based on the speed of the USB host to which the core is connected. - 3'b100: SuperSpeed (USB 3.0 PHY clock is 125 MHz or 250 MHz) - 3'b000: High-speed (USB 2.0 PHY clock is 30 MHz or 60 MHz) - 3'b001: Full-speed (USB 2.0 PHY clock is 30 MHz or 60 MHz) 000b - 001b - 100b -

11.2.5.1.97 Device Control Register (DCTL)

11.2.5.1.97.1 Offset



Register	Offset
DCTL	C704h

11.2.5.1.97.2 Function

When hibernation is not enabled using GCTL[GBLHIBERNATIONEN] bit

- Any value can be written to CSS, CRS, L1HIBERNATIONEN, and KEEPCONNECT bits
- L1HIBERNATIONEN and KEEPCONNET bits always return 0 when read in this hibernation-disabled state

11.2.5.1.97.3 Diagram

11.2.5.1.97.4 Fields

Field	Function
31 RUN_STOP	Run/Stop The software writes 1 to this bit to start the device controller operation. To stop the device controller operation, the software must remove any active transfers and write 0 to this bit. When the controller is stopped, it sets the DSTS.DevCtrlHlt bit when the core is idle and the lower layer finishes the disconnect process. The Run/Stop bit must be used in following cases as specified: - After power-on reset and CSR initialization, the software must write 1 to this bit to start the device controller. The controller does not signal connect to the host until this bit is set. - The software uses this bit to control the device controller to perform a soft disconnect. When the software writes 0 to this bit, the host does not see that the device is connected. The device controller stays in the disconnected state until the software writes 1 to this bit. The minimum duration of keeping this bit cleared is specified in the Note below. If the software attempts a connect after the soft disconnect or detects a disconnect event, it must set DCTL[8:5] to 5 before reasserting the Run/Stop bit. - When the USB or Link is in a lower power state and the Two Power Rails configuration is selected, software writes 0 to this bit to indicate that it is going to turn off the Core Power Rail. After the software turns on the Core Power Rail again and re-initializes the device controller, it must set this bit to start the device controller. For more details, see "Low Power Operation" section of the Databook. Note: The following is the minimum duration under various conditions for which the soft disconnect (SftDiscon) bit must be set for the USB host to detect a device disconnect: 30ms: - For SuperSpeed, when the device state is Suspended, Idle, Transmit, or Receive. 10ms: - For high-speed, when the device state is Suspended, Idle, or not Idle/Suspended (performing transactions) - For full-speed/low-speed, when the device state is Suspended, Idle, or not Idle/Supended (performing transactions) To accommodate clock jitter, it is recommended that the application add extra delay to the specified minimum duration.
30	Core Soft Reset

Table continues on the next page...

Field	Function
CSFTRST	Resets the all clock domains as follows: - This bit clears the interrupts and all the CSRs except GSTS, GSNPSID, GGPIO, GUID, GUSB2PHYCFGn registers, GUSB3PIPECTLn registers, DCFG, DCTL, DEVTEN, and DSTS registers. - All module state machines (except the SoC Bus Slave Unit) are reset to the IDLE state, and all the TxFIFOs and the RxFIFO are flushed. - Any transactions on the SoC bus Master are terminated as soon as possible, after gracefully completing the last data phase of a SoC bus transfer. Any transactions on the USB are terminated immediately. The application can write this bit at any time to reset the core. This is a self-clearing bit; the core clears this bit after all necessary logic is reset in the core, which may take several clocks depending on the core's current state. Once this bit is cleared, the software must wait at least 3 PHY clocks before accessing the PHY domain (synchronization delay). Typically, software reset is used during software development and also when you dynamically change the PHY selection bits in the USB configuration registers listed above. When you change the PHY, the corresponding clock for the PHY is selected and used in the PHY domain. Once a new clock is selected, the PHY domain must be reset for proper operation. Note: Programming this field with random data causes side effect . Bit Bash register testing is not recommended.
29 —	Reserved
28-24 HIRDTHRES	HIRD Threshold The core asserts output signals utmi_l1_suspend_n and utmi_sleep_n (see "LPM Interface Signals" table in the Databook) on the basis of this signal: The core asserts utmi_l1_suspend_n to put the PHY into Deep Low-Power mode in L1 when both of the following are true: - HIRD value is greater than or equal to the value in DCTL.HIRD_Thres[3:0] - HIRD_Thres[4] is set to 1'b1. The core asserts utmi_sleep_n on L1 when one of the following is true: - If the HIRD value is less than HIRD_Thres[3:0] or - HIRD_Thres[4] is set to 1'b0. Note: This field must be set to '0' during SuperSpeed mode of operation.
23-20 LPM_NYET_thres	LPM NYET Threshold When LPM Errata is enabled: Bits [23:20]: LPM NYET Response Threshold (LPM_NYET_thres) Handshake response to LPM token specified by device application. Response depends on DCFG.LPMCap. - DCFG.LPMCap is 1'b0 - The core always responds with Timeout (that is, no response). - DCFG.LPMCap is 1'b1 - The core responds with an ACK on successful LPM transaction, which requires that all of the following are satisfied: - There are no PID or CRC5 errors in both the EXT token and the LPM token (if not true, inactivity results in a timeout ERROR). - No data is pending in the TxFIFO and RxFIFO is empty (else NYET). - The BESL value in the LPM token is less than or equal to LPM_NYET_thres[3:0]
19 KeepConnect	Keep Connect When '1', this bit enables the save and restore programming model by preventing the core from disconnecting from the host when DCTL.RunStop is set to '0'. It also enables the Hibernation Request Event to be generated when the link goes to U3 or L2. The device core disconnects from the host when DCTL.RunStop is set to '0'. This bit indicates whether to preserve this behavior ('0'), or if the core must not disconnect when RunStop is set to 0 ('1'). This bit also prevents the LTSSM from automatically going to U0/L0 when the host requests resume from U3/L2. Note: If Hibernation is disabled, that is, GCTL[1].GblHibernationEn = 0, this bit is tied to zero.
18 L1HibernationEn	L1 Hibernation Enable When this bit is set along with KeepConnect, the device core generates a Hibernation Request Event if L1 is enabled and the HIRD value in the LPM token is larger than the threshold programmed in DCTL.HIRD_Thres. The core does not exit the LPM L1 state until software writes Recovery into the DCTL.ULStChngReq field. This prevents corner cases where the device is entering hibernation at the same time the host is attempting to exit L1. Note: If Hibernation is disabled, that is, GCTL[1].GblHibernationEn = 0, this bit is tied to zero.
17 CRS	Controller Restore State This command is similar to the USBCMD.CRS bit in host mode and initiates the restore process. When software sets this bit to '1', the controller immediately sets DSTS.RSS to '1'. When the controller has finished the restore process, it sets DSTS.RSS to '0'. Note: When read, this field always returns '0'.

Table continues on the next page...

Field	Function
16 CSS	Controller Save State This command is similar to the USBCMD.CSS bit in host mode and initiates the save process. When software sets this bit to '1', the controller immediately sets DSTS.SSS to '1'. When the controller has finished the save process, it sets DSTS.SSS to '0'. Note: When read, this field always returns '0'.
15-13 —	Reserved
12 INITU2ENA	Initiate U2 Enable 1'b0: May not initiate U2 (default) - 1'b1: May initiate U2 On USB reset, hardware clears this bit to 0. Software sets this bit after receiving SetFeature(U2_ENABLE), and clears this bit when ClearFeature(U2_ENABLE) is received. If DCTL[11] (AcceptU2Ena) is 0, the link immediately exits U2 state.
11 ACCEPTU2ENA	Accept U2 Enable 1'b0: Reject U2 except when Force_LinkPM_Accept bit is set (default) - 1'b1: Core accepts transition to U2 state if nothing is pending on the application side. On USB reset, hardware clears this bit to 0. Software sets this bit after receiving a SetConfiguration command.
10 INITU1ENA	Initiate U1 Enable 1'b0: May not initiate U1 (default); - 1'b1: May initiate U1. On USB reset, hardware clears this bit to 0. Software sets this bit after receiving SetFeature(U1_ENABLE), and clears this bit when ClearFeature(U1_ENABLE) is received. If DCTL[9] (AcceptU1Ena) is 0, the link immediately exits U1 state.
9 ACCEPTU1ENA	Accept U1 Enable 1'b0: Core rejects U1 except when Force_LinkPM_Accept bit is set (default) - 1'b1: Core accepts transition to U1 state if nothing is pending on the application side. On USB reset, hardware clears this bit to 0. Software sets this bit after receiving a SetConfiguration command.
8-5 ULSTCHNGREQ	Software writes this field to issue a USB/Link state change request. A change in this field indicates a new request to the core. If software wants to issue the same request back-to-back, it must write a 0 to this field between the two requests. The result of the state change request is reflected in the USB/Link State in DSTS. These bits are self-cleared on the MAC Layer exiting suspended state. If software is updating other fields of the DCTL register and not intending to force any link state change, then it must write a 0 to this field. SS Compliance mode is normally entered and controlled by the remote link partner. Refer to the USB 3.0 specification. Alternatively, you can force the local link directly into compliance mode, by resetting the SS link with the RUN/STOP bit set to zero. If you then write '10' to the USB/Link State Change field and '1' to RUN/STOP, the link goes to compliance mode. Once you are in compliance, you may alternately write zero and '10' to this field to advance the compliance pattern. In SS mode: - Value Requested Link State Transition/Action - 0 No Action - 4 SS.Disabled - 5 Rx.Detect - 6 SS.Inactive - 8 Recovery - 10 Compliance - Others: Reserved In HS/FS/LS mode: - ValueRequested USB state transition - 8 Remote wakeup request - Others: Reserved The Remote wakeup request must be issued 2us after the device goes into suspend state (DSTS[21:18] is 3 - refer to Table "Fields for Register: DSTS" in the Databook). Note: After coming out of hibernation, software must write 8 (Recovery) into this field to confirm exit from the suspended state.
4-1 TSTCTL	Test Control 4'b000: Test mode disabled - 4'b001: Test_J mode - 4'b010: Test_K mode - 4'b011: Test_SE0_NAK mode - 4'b100: Test_Packet mode - 4'b101: Test_Force_Enable - Others: Reserved
0 —	Reserved

10 —	Reserved
9 ERRTICERREVTEN	Erratic Error Event Enable
8 L1SUSPEN	L1 Suspend Event Enable Note: Only if GUCTL1[DEV_DECOUPLE_L1L2_EVT] is enabled, this bit is for L1 Suspend Event Enable.
7 SOFTEVTEN	Start of (u)frame
6 U3L2L1SuspEn	U3/L2 or U3/L2L1 Suspend Event Enable Note: - If GUCTL1[DEV_DECOUPLE_L1L2_EVT] is enabled, then this bit is for U3/L2 Suspend Event Enable. - If GUCTL1[DEV_DECOUPLE_L1L2_EVT] is not enabled, then this bit is for U3/L2L1 Suspend Event Enable.
5 HibernationReqEvtEn	Hibernation Request Event This bit enables/disables the generation of the Hibernation Request Event.
4 WKUPEVTEN	U3/L2 or U3/L2L1 Resume Detected Event Enable Note: - If GUCTL1[DEV_DECOUPLE_L1L2_EVT] is enabled, then this bit is for U3/L2 Resume Detected Event Enable. - If GUCTL1[DEV_DECOUPLE_L1L2_EVT] is not enabled, then this bit is for U3/L2L1 Resume Detected Event Enable.
3 ULSTCNGEN	USB/Link State Change Event Enable
2 CONNECTDONEEVTEN	Connection Done Enable
1 USBRSTEVTEN	USB Reset Enable
0	Disconnect Detected Event Enable

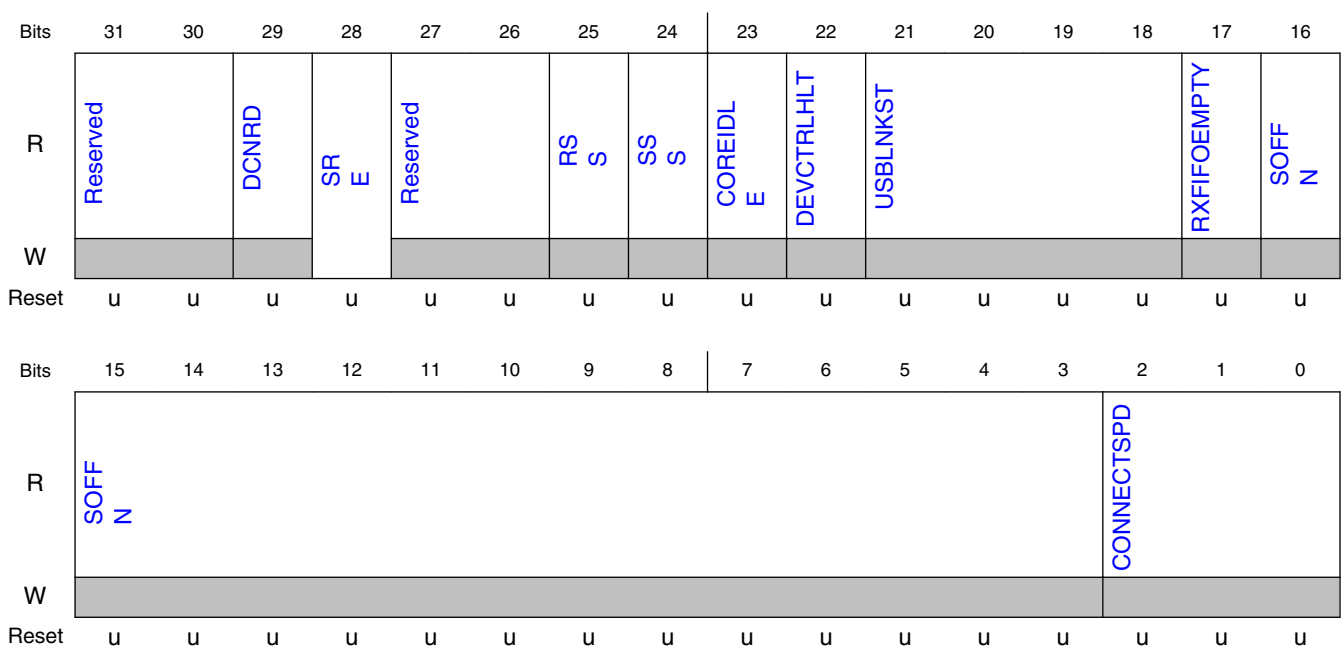
Field	Function
DISSCONNEVTEN	

11.2.5.1.99 Device Status Register (DSTS)

11.2.5.1.99.1 Offset

Register	Offset
DSTS	C70Ch

11.2.5.1.99.2 Function



This register indicates the status of the device controller with respect to USB-related events.

Reset Mask:0xDC000000

NOTE

When hibernation is not enabled, RSS and SSS bits always return 0 when read.

11.2.5.1.99.3 Diagram

11.2.5.1.99.4 Fields

Field	Function
31-30 —	Reserved
29 DCNRD	Device Controller Not Ready The bit indicates that the core is in the process of completing the state transitions after exiting from hibernation. To complete the state transitions, it takes 256 bus clock cycles from the time DCTL[31].Run/Stop is set. During hibernation, if the UTMI/ULPI PHY is in suspended state, then the 256-bus clock cycle delay starts after the PHY exited suspended state. Software must set DCTL[31].Run/Stop to '1' and wait for this bit to be de-asserted to zero before processing DSTS.USBLnkSt. This bit is valid only when DWC_USB3_EN_PWROPT is set to 2 and GCTL[1].GblHibernationEn =1.
28 SRE	Save Restore Error Currently not supported.
27-26 —	Reserved
25 RSS	Restore State Status This bit is similar to the USBSTS.RSS in host mode. When the controller finishes the restore process, it completes the command by setting DSTS.RSS to '0'.
24 SSS	Save State Status This bit is similar to the USBSTS.SSS in host mode. When the controller has finished the save process, it completes the command by setting DSTS.SSS to '0'.
23 COREIDLE	Core Idle The bit indicates that the core finished transferring all RxFIFO data to system memory, writing out all completed descriptors, and all Event Counts are zero. Note: While testing for Reset values, mask out the read value. This bit represents the changing state of the core and does not hold a static value.
22 DEVCTRLHLT	Device Controller Halted This bit is set to 0 when the Run/Stop bit in the DCTL register is set to 1. The core sets this bit to 1 when, after SW sets Run/Stop to 0, the core is idle and the lower layer finishes the disconnect process. When Halted=1, the core does not generate Device events. Note: - The core does not set this bit to 1 if GEVNTCOUNTn has some valid value. Software needs to acknowledge the events that are generated (by writing to GEVNTCOUNTn) while it is waiting for this bit to be set to 1. - When Interrupt Moderation is enabled, there could be delay in raising the interrupt line when the event count is non-zero. Software should read the GEVNTCOUNT register directly and acknowledge them.
21-18 USBLNKST	USB/Link State In SS mode: LTSSM State - 4'h0: U0 - 4'h1: U1 - 4'h2: U2 - 4'h3: U3 - 4'h4: SS_DIS - 4'h5: RX_DET - 4'h6: SS_INACT - 4'h7: POLL - 4'h8: RECOV - 4'h9: HRESET - 4'ha: CMPLY - 4'hb: LPBK - 4'hf: Resume/Reset In HS/FS/LS mode: - 4'h0: On state - 4'h2: Sleep (L1) state - 4'h3: Suspend (L2) state - 4'h4: Disconnected state (Default state) - 4'h5: Early Suspend state (valid only when Hibernation is disabled, GCTL[1].GblHibernationEn = 0) - 4'he: Reset (valid only when Hibernation is enabled, GCTL[1].GblHibernationEn = 1) - 4'hf: Resume (valid only when Hibernation is enabled, GCTL[1].GblHibernationEn = 1) The link state Resume/Reset indicates that the core received a resume or USB reset request from the host while the link was in hibernation. Software must write '8' (Recovery) to the DCTL.ULStChngReq field to acknowledge the resume/reset request. When Hibernation is enabled, GCTL[1].GblHibernationEn = 1, this field USBLnkSt is valid only when DCTL[31].Run/Stop set to '1' and DSTS[29].DCNRD = 0. Note: If SSIC is enabled, while exiting a low power state, the USBLnkSt field indicates Resume/Reset even for a disconnect condition because a resume precedes the disconnect.
17	RxFIFO Empty.

Table continues on the next page...

Field	Function
RXFIFOEMPTY	
16-3 SOFFN	Frame/Microframe Number of the Received SOF When the core is operating at SuperSpeed, - [16:3] indicates the uframe/ITP number When the core is operating at high-speed, - [16:6] indicates the frame number - [5:3] indicates the microframe number When the core is operating at full-speed, - [16:14] is not used. Software can ignore these 3 bits - [13:3] indicates the frame number
2-0 CONNECTSPD	Connected Speed Indicates the speed at which the DWC_usb3 core has come up after speed detection through a chirp sequence. - 3'b100: SuperSpeed (PHY clock is running at 125 or 250 MHz) - 3'b000: High-speed (PHY clock is running at 30 or 60 MHz) - 3'b001: Full-speed (PHY clock is running at 30 or 60 MHz) Low-speed is not supported for devices using a UTMI+ PHY. 000b - 001b - 100b -

11.2.5.1.102.4 Fields

Field	Function
31-0 USBACTEP	USB active endpoints This bit indicates if a USB endpoint is active in the current configuration and interface. Bit[0]: USB EP0-OUT Bit[1]: USB EP0-IN Bit[2]: USB EP1-OUT Bit[3]: USB EP1-IN Bit[4]: USB EP2-OUT Bit[5]: USB EP2-IN Bit[6]: USB EP3-OUT Bit[7]: USB EP3-IN The entity programming this register must set bits 0 and 1 because they enable control endpoints that map to physical endpoints (resources) after USB reset. Hardware clears these bits for all endpoints (other than EP0-OUT and EP0-IN) after detecting a USB reset event. After receiving SetConfiguration and SetInterface requests, the application must program endpoint registers accordingly and set these bits.

11.2.5.1.103 Device Physical Endpoint-n Command Parameter 2 Register (DEPCMDPAR2)

11.2.5.1.103.1 Offset

Register	Offset
DEPCMDPAR2	C800h

11.2.5.1.103.2 Function

This register indicates the physical endpoint command Parameter 2.

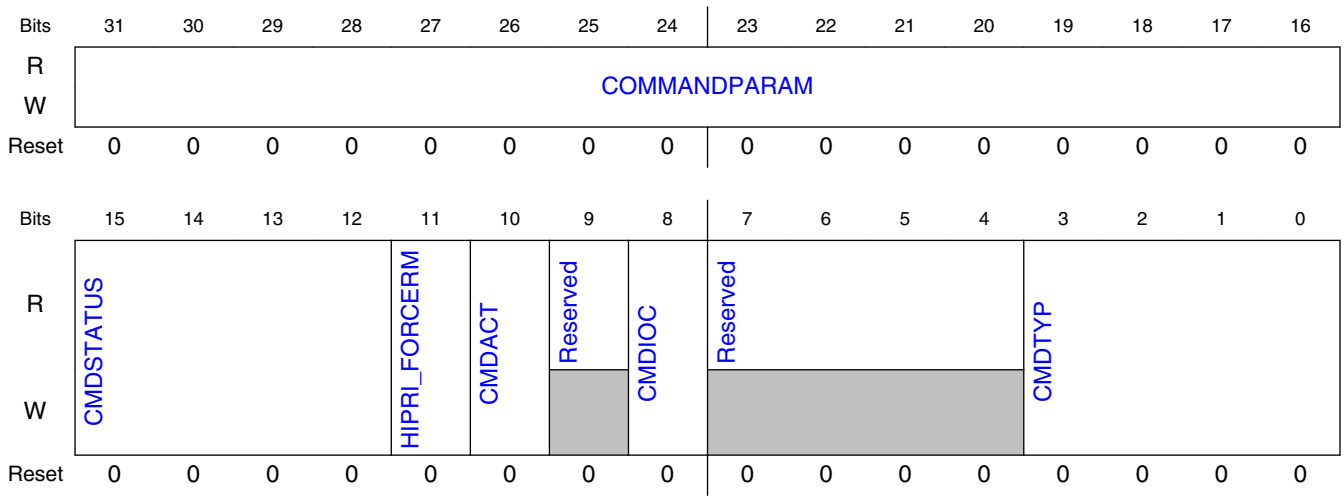
11.2.5.1.106 Device Physical Endpoint-n Command Register (DEPCMD)



11.2.5.1.106.1 Offset

Register	Offset
DEPCMD	C80Ch

11.2.5.1.106.2 Function

This register enables software to issue physical endpoint-specific commands.

11.2.5.1.106.3 Diagram

11.2.5.1.106.4 Fields

Field	Function
31-16 COMMANDPARAM	Command Parameters or Event Parameters Command Parameters When this register is written for Start Transfer command: - [31:16]: StreamID. The USB StreamID assigned to this transfer
15-12 CMDSTATUS	Command Completion Status Additional information about the completion of this command is available in this field.
11 HIPRI_FORCERM	High Priority/ForceRM HighPriority: Only valid for Start Transfer command ForceRM: Only valid for End Transfer command ClearPendIN:Only valid for Clear Stall command .
10 CMDACT	Command Active Software sets this bit to 1 to enable the device endpoint controller to execute the generic command. The device controller sets this bit to 0 when the CmdStatus field is valid and the endpoint is ready to accept another command. This does not imply that all the effects of the previously-issued command have taken place.
9 —	Reserved
8 CMDIOC	CMDIOC Command Interrupt on Complete When this bit is set, the device controller issues a generic Endpoint Command Complete event after executing the command. Note that this interrupt is mapped to DEPCFG.IntrNum. When the DEPCFG command is executed, the command interrupt on completion goes to the interrupt pointed by the DEPCFG.IntrNum in the current command. **NOTE:** This field must not set to 1 if the DCTL.RunStop field is 0.
7-4 —	Reserved

Table continues on the next page...

Field	Function
3-0 CMDTYP	Command Type Specifies the type of command the software driver is requesting the core to perform. 01h: Set Endpoint Configuration 64 or 96-bit Parameter

11.2.5.2 USB3_GLUE register descriptions

Between USB3.0 Core and USB PHY, there is a GLUE architecture to make the connection more configurable.

11.2.5.2.1 GLUE_usb3 memory map

USB GLUE architecture makes the connection between Core and PHY more configurable. USB GLUE contains some configurable registers and status signal monitoring to Core/PHY. There are two GLUE blocks and each has its own configurable registers.

USB1_GLUE base address: 381F_0000h

USB2_GLUE base address: 382F_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	USB3 Controller 0 (USB3_CTRL0)	32	RW	0020_F003h
4h	USB3 Controller 1 (USB3_CTRL1)	32	RW	0000_0000h
20h	USB3 Status 0 (USB3_STS0)	32	RO	0000_07E8h
40h	PHY Controller 0 (PHY_CTRL0)	32	RW	0000_CE10h
44h	PHY Controller 1 (PHY_CTRL1)	32	RW	0018_0006h
48h	PHY Controller 2 (PHY_CTRL2)	32	RW	0000_0300h
4Ch	PHY Controller 3 (PHY_CTRL3)	32	RW	88D4_66EBh

11.2.5.2.2.1 Offset

Register	Offset
USB3_CTRL0	0h

11.2.5.2.2.2 Function

USB Core Configurable bits Register

11.2.5.2.2.3 Diagram

11.2.5.2.2.4 Fields

Field	Function
31-27 —	Reserved
26 DISRXDETU3RXDET	DisRxDetU3RxDet of USB 3.0 SS Ports This input signal requests the controller to stop issuing more PHY commands and release the PIPE ownership. The controller acknowledges this request by asserting the DisRxDetU3RxDet_ack signal. This signal is for Type-C support.
25 STARTRXDETU3RXDET	StartRxdetU3RxDet of USB 3.0 SS Ports This signal is the Start Receiver Detection in U3/Rx.Detect (StartRxdetU3RxDet). If DisRxDetU3RxDet is set and the link is in either U3 or Rx.Detect state, the controller starts receiver detection on the rising

Table continues on the next page...

Field	Function
	edge of this bit. This signal can only be used for downstream ports. It must be set to '0' for upstream ports.
24 UTMI_IDDIG_SEL	Iddig Source Select Signal 0b - USB PHY ID0 1b - GPIO PAD
23-22 HUB_PORT_PERM_ATTACH	Indicates if the device attached to a downstream port is permanently attached or not. bit[22] for usb2 port, bit[23] for usb3_SS port. 00b - Not permanently attached 01b - Permanently attached
21-16 FLADJ_30MHZ_REG	HS Jitter Adjustment. Indicates the correction required to accommodate mac3 clock and utmi clock jitter to measure 125 's duration. Default 0x20, each count is equal to 16 high speed bit times.
15 —	Reserved
14 XHC_BME	Disable the bus mastering capability of the xHC This signal is used to disable the bus mastering capability of the xHC. In a PCI system, it comes from the Bus Master Enable (BME) bit of the Device Control Register in the PCI Configuration register space. **NOTE:** In Host mode, For a non-PCI system, the xhc_bme is always tied to 1'b1 for the controller master to work. For a PCI system, connect the BME register bit of the PCI to this xhc_bme input. In Device mode, the xhc_bme can be any value, but it is recommended to tie this signal to 1. 0b - Bus mastering capability is disabled. The host controller cannot use the bus master interface. 1b - Bus mastering capability is enabled.
13 —	Reserved
12 HOST_PORT_POWER_CONTROL_PRESENt	This port defines the bit [3] of Capability Parameters (HCCPARAMS). Change the PPC value through the pin Port Power Control (PPC). This indicates whether the host controller implementation includes port power control. 0b - Indicates that the port does not have port power switches. 1b - Indicates that the port has port power switches.
11-8 BUS_FILTER_BYPASS	Bus Filter Bypass. It is expected that this signal is set or reset at power-on reset and is not changed during the normal operation of the controller. The function of each bit is: bus_filter_bypass[3]: Reserved bus_filter_bypass[2]: Bypass the filter for utmisrp_bvalid bus_filter_bypass[1]: Bypass the filter for pipe3_PowerPresent all U3 ports bus_filter_bypass[0]: Bypass the filter for utmi_vbusvalid all U2 ports In Host-only mode, internal bus filters are not needed. Therefore, bus_filter_bypass[2:0] must be connected to logic high value (3'b111). The reserved bit can be tied to 0 or 1, but should not be floating.
7 HOST_U3_PORT_DISABLE	USB 3.0 SS Port Disable Control. This signal, when '1', stops reporting connect/disconnect events the port and keeps the port in disabled state. This could be used for security reasons where hardware can disable a port irrespective of whether xHCI driver enables a port or not. The 'Number of Ports' field of the HCSPARAMS1 register is not affected by this signal.

Table continues on the next page...

Field	Function
	This signal should be either static (should not change during operation), or change only once from 0 to 1 during operation and stay at 1 after that. **NOTE:** This signal is not present in USB 2.0-only mode. **NOTE:** The SuperSpeed Port0 (first SS port) must not be disabled if the other SuperSpeed ports are operational. 0b - Port Enabled 1b - Port Disabled
6 HOST_U2_PORT_DISABLE	USB 2.0 Port Disable Control. This could be used for security reasons where hardware can disable a port irrespective of whether xHCI driver enables a port or not. The 'Number of Ports' field of the HCSPARAMS1 register is not affected by this signal. This signal should be either static (should not change during operation), or change only once from 0 to 1 during operation and stay at 1 after that. Note: Port-0 (the first U2 port) must not be disabled if any other U2 port is operational. 0b - Port Enabled 1b - Port Disabled. When '1', this signal stops reporting connect/disconnect events the port and keeps the port in disabled state.
5-4 —	Reserved
3-0 —	Reserved

11.2.5.2.4.3 Diagram

11.2.5.2.4.4 Fields

Field	Function
31-17 —	Reserved
16 DISRXDETU3RXDET_ACK	DisRxDetU3RxDet_ack of USB 3.0 SS Ports This signal is an acknowledgment of DisRxDetU3RxDet. When this signal is 1'b1, the controller releases the ownership of the the PIPE interface and does not issue PHY commands to the PIPE interface.
15 IDDIG	This controller signal indicates whether the connected plug is a mini-A or mini-B plug. This signal must be valid within 20 ms after the IDPULLUP0 signal is set to 1’b1. 0b - Connected plug is a mini-A plug. 1b - Connected plug is a mini-B plug.
14 PME_GENERATION	PME# Generation. This signal is used to generate a PME# (Power Management Event). When the Run/Stop bit of the USB Command Register is cleared during USB suspend mode, the controller cannot generate an event and cannot assert a regular interrupt. In this case, the controller asserts a pme_generation signal to report any wakeup condition if pme_en is high.

Table continues on the next page...

Field	Function
	This is a level signal that gets cleared when the software clears CSC, OCC and PLC bits in all the PORTSC registers.
13 BC_CHIRP_ON	When asserted indicates an imminent chirp signal.
12 HOST_SYSTEM_ERR	Host System Error This signal indicates that a Host System Error has occurred as reflected in the USBSTS[HSE] field. This signal is asserted only if the USBCMD[HSEE] field is set to '1'. It can occur when the host controller encounters an 'Error' response in the AHB, the AXI, or the Native Master Bus. When the USBSTS[HSE] field is cleared by software, this signal is deasserted unless the master continues to assert its bus error output. The typical software response to an HSE is to reset the controller.
11-0 HOST_CURRENT_BELT	Current BELT Value This signal indicates the minimum value of all received BELT values and the BELT that is set by the Set LTV command. This signal is valid only in Host mode.

11.2.5.2.5 PHY Controller 0 (PHY_CTRL0)

11.2.5.2.5.3 Diagram

11.2.5.2.5.4 Fields

Field	Function
31-24 —	Reserved
23-21 SSC_RANGE	Spread Spectrum Clock Range Selects the range of spread spectrum modulation when ssc_en is asserted and the PHY is spreading the high-speed transmit clocks. Applies a fixed offset to the phase accumulator. ssc_range[2:0] Down Spread of Clock (ppm) 000b - 4980 001b - 4492 010b - 4003
20-12 SSC_REF_CLK_SEL	Spread Spectrum Reference Clock Shifting Enables non-standard oscillator frequencies to generate targeted MPLL output rates. Input corresponds to frequency-synthesis coefficient. ssc_ref_clk_sel[8:6] = modulous – 1 ssc_ref_clk_sel[5:0] = 2’s complement push amount
11 SSC_EN	Spread Spectrum Enable Enables spread spectrum clock production (0.5% down-spread at ~ 31.5 KHz) in the USB 3.0 femtoPHY. Set this signal to 1'b1.
10-5 FSEL	100111b - 100 MHz ref clock 101010b - 24 MHz ref clock
4-3 —	Reserved
2 REF_SSP_EN	Reference Clock Enable for SS function. Enables the reference clock to the prescaler. The ref_ssp_en signal must remain deasserted until the reference clock is running at the appropriate frequency, at which point ref_ssp_en can be asserted. For lower power states, ref_ssp_en can also be deasserted.
1-0 —	Reserved

Field	Function
31-22 —	Reserved
21 —	Reserved
20 VDATDETENB0	Battery Charging Attach/Connect Detection Enable Enables or disables attach/connect detection. 1: Data detect voltage (CHG_DET) is enabled. 0: Data detect voltage (CHG_DET) is disabled
19 VDATSRCENB0	Battery Charging Sourcing Select Enables or disables sourcing for battery charging. 1: Data source voltage (VDAT_SRC) is enabled. 0: Data source voltage (VDAT_SRC) is disabled.

Table continues on the next page...

Field	Function
18 CHRGSEL0	Battery Charging Source Select Determines whether current is sourced onto or sunk from DPn or DMn. 1: Data source voltage (VDAT_SRC) is sourced onto DMn and sunk from DPn. 0: Data source voltage (VDAT_SRC) is sourced onto DPn and sunk from DMn.
17 DCDENB0	Data Contact Detection Enable Enables current sourcing on the D+ line. For special applications, the IDP_SRC control and the RDM_DWN control are separated. For standard DCD operation in accordance with the Battery Charger v1.2 specification,simultaneously set DCDENBn = 1'b1 (to enable IDP_SRC) and set DMPULLDOWNn = 1'b1 (to enable RDM_DWN). Set both signals to 1'b0 when DCD is completed. 1: IDP_SRC current is sourced onto DPn, pull-down resistance on DMn is enabled. 0: IDP_SRC current is disabled, pull-down resistance on DMn is disabled. **NOTE:** During USB 3.0 femtoPHY normal operation, set this signal low
16 ACAENB0	Battery Charging Source Select Determines whether current is sourced onto or sunk from DPN or DMN. 1: Data source voltage (VDAT_SRC) is sourced onto DMN and sunk from DPN. 0: Data source voltage (VDAT_SRC) is sourced onto DPN and sunk from DMN.
15 RTUNE_REQ	Resistor Tune Request Assertion triggers a resistor tune request (if one is not already in progress). When this signal is asserted, rtune_ack goes high until calibration of the termination impedances is complete. Note that termination resistance tuning disrupts the normal flow of data; therefore, assert rtune_req only when the PHY is inactive. Because the PHY automatically performs a tune after coming out of a reset, rtune_req can be tied low unless you want to be able to manually force a tuning.
14-12 —	Reserved
11 PHY_TEST_POWERDOWN_HSP	USB3.0 PHY Signal Powers down all HS function circuitry in the PHY for IDDQ testing. Before asserting this signal, ensure that VDATSRCENBn, VDATDETENBn, DCDENBn, BYPASSSELn, and test_burnin are set to 1'b0 now it's 1 if ioring_ipp_ind_test_mode.
10 PHY_TEST_POWERDOWN_SSP	USB3.0 PHY Signal Powers down all SS function circuitry in the PHY for IDDQ testing ioring_test_mode 0.
9-2 —	Reserved
1 COMMONONN	Common Block Power-Down Control Controls the power-down signals in the PLL block when the USB 3.0 femtoPHY is in Suspend or Sleep mode. While the PHY is not in either Suspend mode nor Sleep state, COMMONONN can be dynamically controlled. 1: In Suspend or Sleep mode, the PLL block is powered down. 0: In Suspend or Sleep mode, the PLL block remains powered and continues to draw current.
0 PHY_RESET	USB3.0 PHY Signal

Field	Function
	Resets the core and all state machines with the exception of the reference clock buffer and the JTAG interface. Asserting phy_reset triggers the assertion of the tx<#>_reset and rx<#>_reset signals.

11.2.5.2.7 PHY Controller 2 (PHY_CTRL2)

Field	Function
—	
16 RX0LOSLFPSEN	RX LOS LFPS Filter Enable Enables the RX LOS LFPS filter. During USB 3.0 operation, set to 1'b1. Change this pin setting only during a reset. **NOTE:** In Scan mode, tie this pin to 0 1: Enables RX LOS LFPS filter. 0: Disables RX LOS LFPS filter.
15 —	Reserved
14 UTMI_IDPULLUP	Analog ID Input Sample Enable This controller signal controls IDN line sampling. 1: IDN pin sampling is enabled, and the IDDIG0 output is valid. 0: IDN pin sampling is disabled, and the IDDIG0 output is not valid.
13-12 —	Reserved
11 VBUSVLDEXTSEL0	Selects the VBUSVLDEXTn input or the internal Session Valid comparator to indicate when the VBUSn signal on the USB cable is valid. This signal is a strapping option that must be set prior to a power-on reset and remain static during normal operation. Strapping options are not critical for STA,and any other timings or loading limits for the pin are specified in the .lib timing model included in the product deliverables. 1: VBUSVLDEXTn input is used. 0: Internal Session Valid comparator is used.
10 VBUSVLDEXT0	External VBUS Valid Indicator Valid in Device mode and only when the VBUSVLDEXTSEL0 signal is set to 1’b1. VBUSVLDEXTn indicates whether the VBUSn signal on the USB cable is valid. In addition, VBUSVLDEXTn enables the pull- up resistor on the D+ line. In Host mode, this input is not used and can be tied to 1’b0. 1: VBUSn signal is valid, and the pull-up resistor on D+ is enabled. 0: VBUSn signal is not valid, and the pull-up resistor on D+ is disabled.
9 —	Reserved
8 TXENABLEN0	USB 1.1 Data Enable This controller signal enables the FSDATAEXTn and FSSE0EXTn inputs. TXENABLENn is valid only when the FSXCVROWNERn signal is set to 1’b1. 1: FSDATAEXTn and FSSE0EXTn are disabled. 0: FSDATAEXTn and FSSE0EXTn are enabled.
7 FSXCVROWNER0	UTMI+/Serial Interface Select This controller signal enables the UTMI+ or serial interface. 1: TXENABLENn, FSDATAEXTn, and FSSE0EXTn inputs drive USB 2.0 data output onto the D+ and D– lines. Data that the USB 3.0 femtoPHY receives from the D+ and D– lines appears on the FSVMINUSn and FSVPLUSn outputs.

Table continues on the next page...

Field	Function
	0: Data on the D+ and D– lines is transmitted and received through the UTMI+.
6 FSSE0EXT0	USB 1.1 Transmit Data This controller signal sets the USB (2.0) to either a J or K state. This signal is valid only if FSXCVROWNERn is set to 1'b1, TXENABLENn is set to 1'b0, and FSSE0EXTn is set to 1'b0. 1: D+ and D– lines are driven to a Differential 1. 0: D+ and D– lines are driven to a Differential 0.
5 FSDATAEXT0	USB 1.1 SE0 Generation This controller signal sets the USB (2.0) to an SE0 state. This signal is valid only if FSXCVROWNERn is set to 1'b1 and TXENABLENn is set to 1'b0.
4-0 —	Reserved

Valid settings: 011: Corresponds to a launch amplitude of 1.12 V. 010: Corresponds to a launch amplitude of 1.04 V. 000: Corresponds to a launch amplitude of 0.88 V.
28-26 IOS_BIAS	Loss-of-Signal Detector Threshold Level Control Sets the LOS detection threshold level. To enable tuning at the board level, connect this bus to a register. 111: 135 mV 110: 120 mV 101: 105 mV 100: 90 mV 011: 75 mV 010: 60 mV (default) 001: 45 mV 000: Invalid

Table continues on the next page...

Field	Function
25-22 TXREFTUNE0	HS DC Voltage Level Adjustment Adjusts the high-speed DC level voltage. To enable tuning at the board level, connect this bus to a register. 0000b - - 6% 0001b - - 4% 0010b - - 2% 0011b - 0 (default) 0100b - + 2% 0101b - + 4% 0110b - + 6% 0111b - + 8% 1000b - + 10 1001b - + 12% 1010b - + 14% 1011b - + 16% 1100b - + 18% 1101b - + 20% 1110b - + 22% 1111b - + 24%
21-20 TXRISETUNE0	HS Transmitter Rise/Fall Time Adjustment Adjusts the rise/fall times of the high-speed waveform. To enable tuning at the board level, connect this bit to a register. 00b - + 3% 01b - 0 (default) 10b - - 1% 11b - - 3%
19-18 TXRESTUNE0	USB Source Impedance Adjustment Some applications require additional devices to be added on the USB, such as a series switch, which can add significant series resistance. This bus adjusts the driver source impedance to compensate for added series resistance on the USB. **NOTE:** Any setting other than the default can result in source impedance variation across process, voltage, and temperature conditions that does not meet USB 2.0 specification limits. If this bus is not used, leave it at the default setting 00b - Source impedance is increased by approximately 2 Ω 01b - 0 (Design default) 10b - Source impedance is decreased by approximately 3 Ω 11b - Source impedance is decreased by approximately 4.5 Ω
17 TXPREEMPULSETUNE0	HS Transmitter Pre-Emphasis Duration Control This signal controls the duration for which the HS pre-emphasis current is sourced onto DP or DM. The HS Transmitter pre-emphasis duration is defined in terms of unit amounts. One unit of pre-emphasis duration is approximately 580 ps and is defined as 1X pre-emphasis duration. This signal is valid only if either TXPREEMPMPTUNE[1] or TXPREEMPMPTUNE[0] is set to 1'b1. 0b - long pre-emphasis current duration (design default). If TXPREEMPULSETUNE is not used, set it to 1'b0 1b - Short pre-emphasis current duration
16-15 TXPREEMPMPTUNE0	HS Transmitter Pre-Emphasis Current Control This signal controls the amount of current sourced to DPn and DMn after a J-to-K or K-to-J transition. The HS Transmitter pre-emphasis current is defined in terms of unit amounts. One unit amount is approximately 600 uA and is defined as 1X pre-emphasis current. 00b - Disabled (default) 01b - 1x pre-emphasis current

Table continues on the next page...

Field	Function
	10b - 2x pre-emphasis current 11b - 3x pre-emphasis current
14-13 TXSHXSTUNE0	Transmitter High-Speed Crossover Adjustment. This bus adjusts the voltage at which the DPn and DMn signals cross while transmitting in HS mode. 00b - Reserved 01b - - 16 mV 10b - + 14 mV 11b - 0 (default)
12-9 TXFSLSTUNE0	FS/LS Source Impedance Adjustment Adjusts the low- and full-speed single-ended source impedance while driving high. To enable tuning at the board level, connect this bus to a register. This parameter control is encoded in thermometer code. Any non-thermometer code setting (that is, 1001) is reserved and not supported. 0000b - + 3.5% 0001b - + 1.8% 0011b - 0 (default) 0111b - - 1.7% 1111b - - 3.5%
8-6 SQRXTUNE0	Squelch Threshold Adjustment Adjusts the voltage level for the threshold used to detect valid high-speed data. To enable tuning at the board level, connect this bus to a register. 000b - + 16.07% 001b - + 10.71% 010b - + 5.36% 011b - 0 (default) 100b - - 5.36% 101b - - 10.71% 110b - - 16.07% 111b - - 22.32%
5-3 TUNE0	VBUS Valid Threshold Adjustment This bus adjusts the voltage level for the VBUS valid threshold. To enable tuning at the board level, connect this bus to a register. 111: + 5.8% 110: + 2.9% 101: 0 (default) 100: – 2.9% 011: – 5.8% 010: – 8.7% 001: – 11.6% 000: – 14.5%
2-0 COMPDISTUNE	Disconnect Threshold Adjustment. Adjusts the voltage level for the threshold used to detect a disconnect event at the host. To enable tuning at the board level, connect this bus to a register. 000b - - 9.01% 001b - - 6.5% 010b - - 3.04%

Field	Function
	011b - 0 (default) 100b - + 4.08 101b - + 7.52% 110b - + 11.86% 111b - + 15.54%

26-21 PCS_TX_DEEMPH_6DB	TX De-Emphasis at 6 dB This static value sets the TX driver de-emphasis value when pipeP_tx_deemph[1:0] is set to 2'b10 (according to the PIPE3 specification). This bus is provided for completeness and as a second potential launch amplitude.
20-15 PCS_TX_DEEMPH_3B5DB	TX De-Emphasis at 3.5 dB This static value sets the TX driver de-emphasis value when pipeP_tx_deemph[1:0] is set to 2'b01 (according to the PIPE3 specification). To enable tuning at the board level for RX eye compliance, connect this signal to a register.
14-5 PCS_RX_LOS_MSK_VAL	Configurable Loss-of-Signal Mask Width Sets the number of reference clock cycles to mask the incoming LFPS in U3 and U2 states. Masks the incoming LFPS for the number of reference clock cycles equal to the value of pcs_rx_los_mask_val[9:0]. This control filters out short, non-compliant LFPS glitches sent by a non-compliant host. For normal operation, set to a targeted mask interval of 10 µs (value = 10 µs / Tref_clk). If the ref_clkdiv2 signal is used, the value = 10 µs / (2 * Tref_clk). Setting this bus to 10'b0 disables masking. This bus should be accessible to general configuration registers for system testing and debug. The value should be defined when in reset. Changing this value during operation might disrupt normal operation of the link.Sets the number of reference clock cycles to mask the incoming LFPS. For normal operation, set to a targeted mask interval of 10 µs (value = 10 µs / Tref_clk). If the ref_clkdiv2 signal is used, the value = 10 µs / (2 * Tref_clk).

11.3 Universal Serial Bus PHY (USB_PHY)

11.3.1 Overview

The USB 3.0 PHY is designed for USB 3.0 SuperSpeed applications connecting to a USB controller. The USB 3.0 PHY supports the USB 3.0 SuperSpeed (5 Gbps) protocol and data rate and is backward compatible with USB 2.0 high-speed (480 Mbps), full-speed (12 Mbps), and low-speed (1.5 Mbps) protocols and data rates. This block guide provides an introduction to the USB 3.0 PHY and its features.

NOTE

The information within this block guide is Synopsys Proprietary. Used with permission.

11.3.1.1 Block Diagram

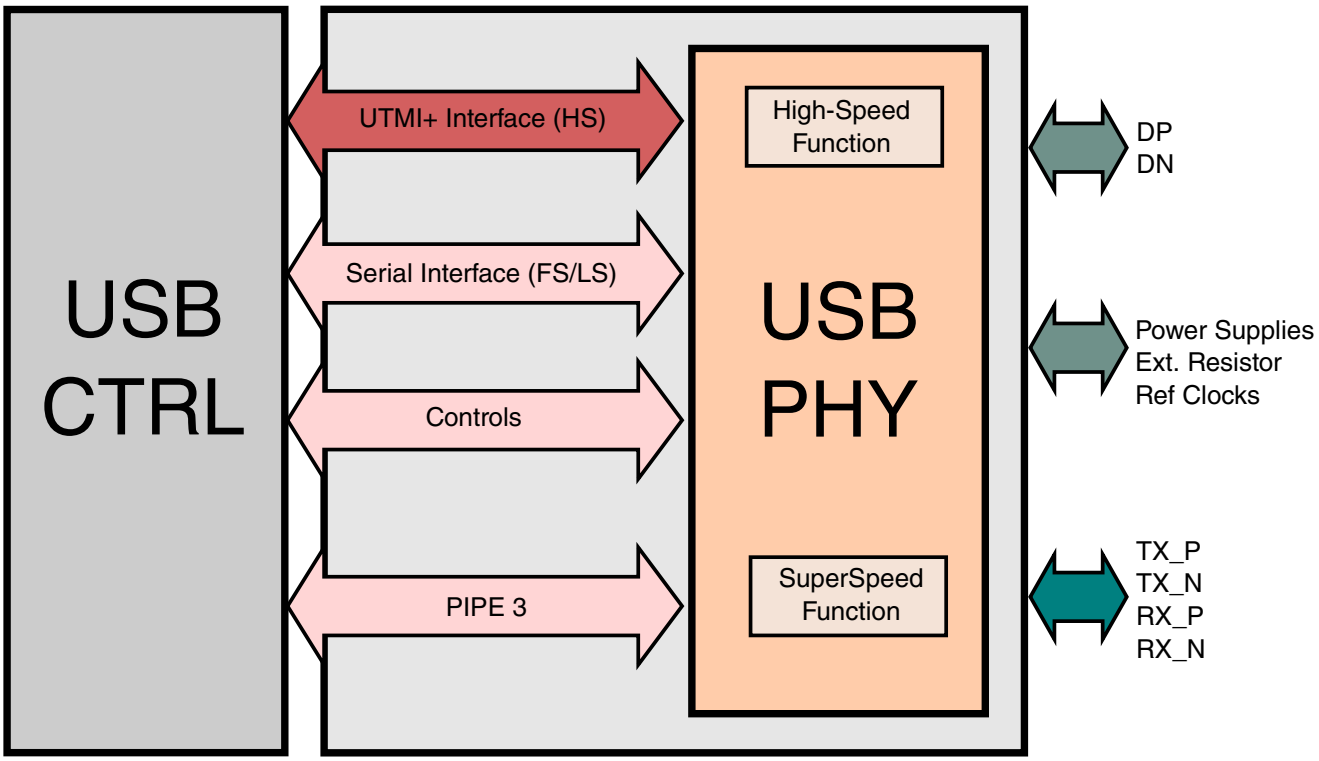

Figure 11-30. USB PHY Block Diagram

11.3.1.2 Features

The USB 3.0 PHY provides the following general features:

- Built-in VBUS threshold comparators;
- Single reference clock input for both USB 3.0 and USB 2.0 operating modes
- Integrated 3.3-V-to-1.8-V regulator in the PHY

The USB 3.0 PHY provides the following USB 3.0 features:

- 5-Gbps SuperSpeed data transmission rate through 3-m USB 3.0 cable
- PIPE 3-compliant SuperSpeed USB 3.0 Transceiver interface
- Integrated PHY includes transmitter, receiver, SSC generation, PLL, digital core, and ESD
- Adaptive Rx equalization
- Low-jitter PLL technology with excellent supply isolation

The USB 3.0 PHY provides the following USB 2.0 features:

- Built-in VBUS threshold comparators;
- 480-Mbps high-speed, 12-Mbps full-speed, and 1.5-Mbps low-speed serial (Host mode only) data transmission rates

- Supports high-speed power modes: suspend, resume, and remote wakeup
- 45-Ω termination, 1.5-kΩ pull-up and 15-kΩ pull-down resistors with support for independence control of the pull-down resistors
- 8/16-bit unidirectional parallel interfaces for HS, FS, and LS (Host mode only) modes of operation in accordance with the UTMI+ specification
- Dual (HS/FS) mode host/device support
- Data recovery from serial data on the USB connector
- SYNC/End-of-Packet (EOP) generation and checking
- Bit stuffing and unstuffing, and bit-stuffing error detection
- Non Return to Zero Invert (NRZI) encoding and decoding
- Bit serialization and deserialization
- VBUS threshold comparators

11.3.1.3 Standards Compliance

The USB 3.0 PHY is fully compliant with all the required features of the following standards:

- Universal Serial Bus 3.0 Specification, Revision 1.0
  - Supports 5.0-Gbps SuperSpeed (SS) through 3-m cable, 480-Mbps high-speed (HS), 12-Mbps fullspeed (FS), and 1.5-Mbps low-speed (LS) serial (Host mode only) data transmission rates, with a high-speed (HS) transmit-to-receive interpacket delay requirement of 38 bit-times as implied by the UTMI specification, version 1.05.
  - Supports beaconing, receiver detection, and electrical idle
  - Four-wire SuperSpeed connection (two Tx and two Rx unidirectional) with built-in Tx and Rx equalization
- PIPE 3-compliant USB 3.0 SuperSpeed interface
- UTMI+ Specification, Revision 1.0 (Level 3)
- Battery Charging Specification, Revision 1.2

11.3.2 Functional Description

11.3.2.1 PIPE Interface

The datapath of the USB 3.0 PHY is through the standard PIPE 3 interface. This interface can connect directly to any USB 3.0 controller. For more information about the PIPE 3 interface signals, refer to PHY Interface For the PCI Express and USB 3.0 Architectures.

11.3.2.2 Termination Tuning

The PHY uses an external resistor to calibrate the termination impedances of the PHY's high-speed inputs and outputs. The resistor is shared between the USB 2.0 high-speed outputs and the SuperSpeed I/O. Each time the PHY is taken out of a reset, a termination calibration is performed. The termination calibration is continuous for USB 2.0 operation except when the USB 2.0 port is suspended. The termination calibration is performed only when coming out of a reset in SuperSpeed operation.

A resistor calibration on the SuperSpeed link cannot be performed while the link is operational. At no point is a request for calibrating the SuperSpeed link using rtune_req required; this feature is provided only for completeness.

11.3.2.3 Battery Charging

The USB 3.0 PHY supports battery charger detection to enable devices to draw increased current from VBUS for charging and/or powering up from dedicated charging ports or charging downstream ports.

11.3.2.4 Dead Battery Provision

The dead battery provision enables a device to draw increased current (up to 100 mA) from VBUS in certain conditions. This function can be used only if all power supplies are stable and at their respective, normal, valid operating levels.

11.3.2.5 Data Contact Detect

Prior to a device performing battery charger detection, DCD is performed to determine if the D+ and D– pins in the device have made contact with those in the host or charger.

11.3.2.6 UART / Autoresume

The USB 3.0 PHY's single-ended receivers are used for UART and Autoresume data reception, while the full-speed drivers are used for data transmission. UART and Autoresume signaling levels are the same as signaling levels for USB 2.0 FS mode.

In this mode of operation, the driver source impedance is not calibrated; however, the driver retains the settings of the last calibration. In addition, the rise/fall time control is disabled, so changes in the state of DP and DN driven by this mode are not expected to meet the rise and fall times as defined in the USB 2.0 specification.

11.3.2.7 Serial Interface

The serial interface supports full-speed and low-speed data transmission rates to and from a USB 1.1 controller.

11.3.2.8 Clocks

The USB 3.0 PHY supports a wide range of input reference clocks from both external and on-chip clock sources. To support both SuperSpeed and high-speed operations, one of the following must be provided:

- A compatible, shared reference clock frequency
- Separate clock sources to support SuperSpeed operation and high-speed operation

11.3.3 External Signals

This section describes the USB 3.0 PHY signals that go to pins:

- External reference resistor: resref
- Receive pins: RX_N, RX_P
- Transmit pins: TX_N, TX_P
- USB 2.0 D+/D– lines: DN, DP
- USB mini-receptacle identifier: ID
- USB 5-V power supply pin: VBUS

11.4 PCI Express (PCIe)

11.4.1 Overview

The PCI Express interface is compatible with the PCI Express™ Base Specification, Revision 4.0, Version 0.7 (available from http://www.pcisig.com). It is beyond the scope of this manual to document the intricacies of the PCI Express protocol. This chapter describes the PCI Express controller of this device and provides a basic description of the

PCI Express protocol. The specific emphasis is directed at how the device implements the PCI Express specification. Designers of systems incorporating PCI Express devices should refer to the specification for a thorough description of PCI Express.

NOTE

The information within this block guide is Synopsys Proprietary. Used with permission.

11.4.1.1 Block Diagram

The following figure is the PCIe Application diagram.

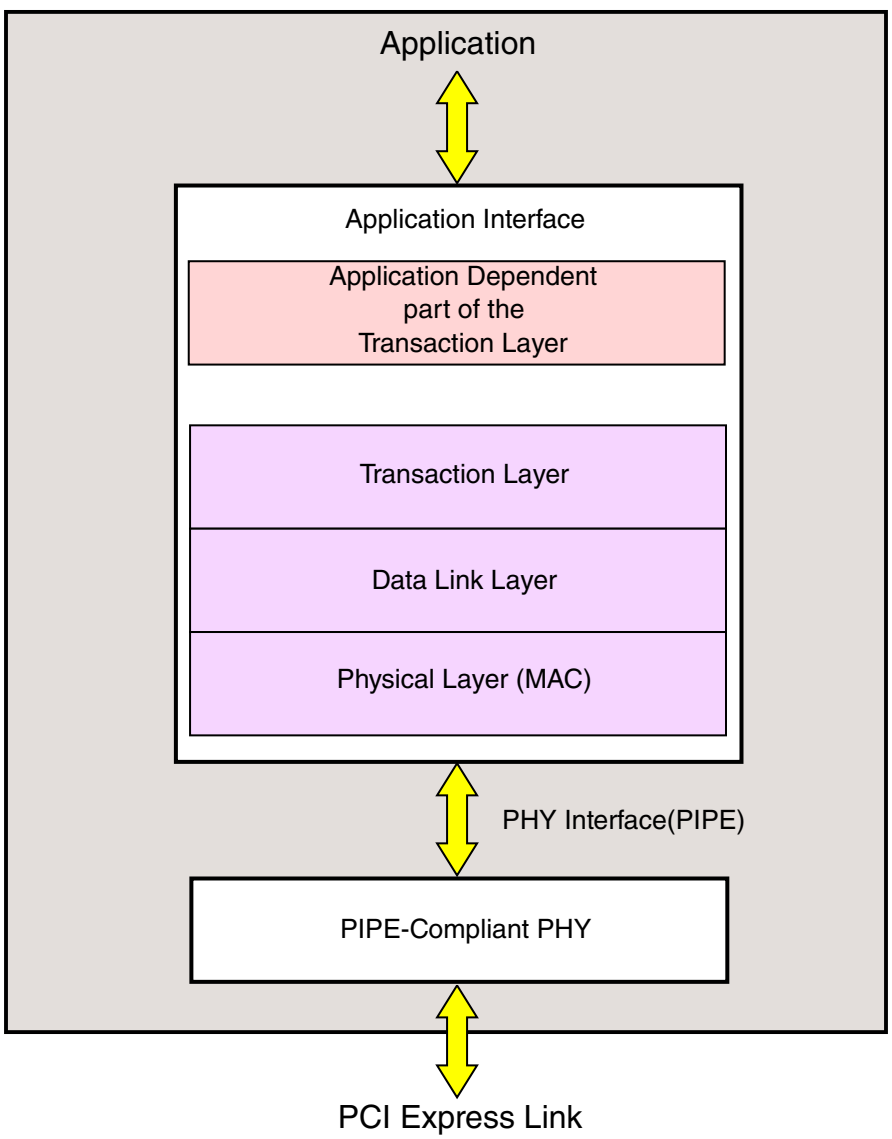

Figure 11-31. PCIe Application

11.4.1.2 Features

The following is a list of features supported by the PCI Express controller:

- Supports Root Complex (RC) and Endpoint (EP) configurations
- Maximum link speed up to Gen3 (8 GT/s)
- x1 link width
- 128-byte maximum payload size (MAX_PAYLOAD_SIZE)
- 32- and 64-bit PCI Express address support
- Supports accesses to all PCI Express memory and I/O address spaces (RC mode requestor only)
- Supports posting of processor-to-PCI Express and PCI Express-to-memory writes
- Embedded DMA
- AXI3 bridge
- Credit-based flow control management handled by PCI Express core
- One Virtual Channel (VC0)
- PCI Express configuration space registers with Type 0 Header in EP mode and Type 1 Header in RC mode
- Internal Address Translation Unit
- Resizable BAR (RBAR) with Expanded RBAR support
- Configurable BAR Filtering, I/O Filtering, Configuration Filtering and Completion Lookup/Timeout
- Supports Completion Timeout Ranges
- Extended Tag Support
- Supports strong and relaxed transaction ordering rules
- Configurable Filtering Rules for Posted, Non-posted, and Completion Traffic
- ECRC Generation and Checking
- Baseline and Advanced Error Reporting (AER) support
- PCI Express Advanced Error Reporting (AER) with Multiple Header Logging
- Supports PCI Express messages and interrupts
- Supports 64-bit MSI interrupts
- Internal MSI-X Generation Module
- MSI and MSI-X with Per-Vector Masking (PVM), Extended message data for MSI
- Latency Tolerance Reporting (LTR)
- ID-Based Ordering (IDO)
- PASID
- L1 Substates (L1SS)
- Separate Refclk with Independent Spread Spectrum Clocking (SRIS)
- Lightweight Notifications (LN)
- Readiness Notifications (RN)
- PCI Express Active State Power Management (ASPM)

- Vital Product Data (VPD)
- Power Gating (UPF) Support
- Advanced Power and Clock Management

The PCIe controller implementation is compatible with the following standards:

- *PCI Express Base Specification, Revision 4.0, Version 0.7*
- PCI Local Bus Specification, Revision 3.0
- PCI Bus Power Management Specification, Revision 1.2
- PCI Express Card Electromechanical Specification, Revision 1.1

11.4.2 Functional Description

The PCI Express controller connects the internal platform to a serial interface. As both an initiator and a target device, the PCI Express interface is capable of high-bandwidth data transfer and is designed to support next generation I/O devices. Upon coming out of reset, the PCI Express interface performs link speed and width negotiation and exchanges flow control credits with its link partner. Once link auto negotiation is successful, the controller is in operation.

Internally, the design contains queues to keep track of inbound and outbound transactions. There is control logic that handles buffer management, bus protocol, transaction spawning and tag generation. In addition, there are memory blocks used to store inbound and outbound data.

The PCI Express controller can be configured to operate as either a PCI Express Root Complex (RC) or Endpoint (EP) device. An RC device connects the host CPU/memory subsystem to I/O devices while an EP device typically denotes a peripheral or I/O device. In RC mode, a PCI Express Type 1 configuration header is used; in EP mode, a PCI Express Type 0 configuration header is used.

A complete PCI Express port solution includes the controller, an analog PHY macro, and internal platform as the application logic to source and sink data.

See the high-level block diagram of the PCI Express controller and analog PHY macro.

As an initiator, the PCI Express controller supports memory read and write operations. In addition, configuration and I/O transactions are supported if the PCI Express controller is in RC mode. As a target interface, the PCI Express controller accepts read and write operations to local memory space. As an EP device, the PCI Express controller accepts configuration transactions to the internal PCI Express configuration registers. Message generation and acceptance are supported in both RC and EP modes. Locked transactions and inbound I/O transactions are not supported.

11.4.2.1 Outbound Transactions

Outbound internal platform transactions to PCI Express are first mapped to a translation window to determine what PCI Express transactions are to be issued. A transaction from the internal platform can become a PCI Express Memory, I/O, Message, or Configuration transaction depending on the window attributes.

A transaction may be broken up into smaller sized transactions depending on the original request size, transaction type, and either the PCI Express Device Control register [PCIE_CAP_MAX_PAYLOAD_SIZE_CS] field for write requests or the PCI Express Device Control register [PCIE_CAP_MAX_READ_REQ_SIZE] field for read requests. The controller performs PCI Express ordering rule checking to determine which transaction is to be sent on the PCI Express link.

In general, transactions are serviced in the order that they are received from the internal platform . Only when there is a stalled condition does the controller apply PCI Express ordering rules to outstanding transactions. For posted write transactions, once all data has been received from the internal platform , the data is forwarded to the PCI Express link and the transaction is considered as done. For non-posted write transactions, the controller waits for the completion packets to return before considering the transaction finished. For non-posted read transactions, the controller waits for all completion packets to return and then forwards all data back to the internal platform before terminating the transaction

NOTE

After reset or when recovering from a link down condition, external transactions should not be attempted until the link has successfully trained. Software can poll the LTSSM state status to check the status of link training before issuing external requests.

In EP mode, after reset or when recovering from a link down condition, the SoC must not generate any outbound memory or I/O transactions until the remote host has configured the Bus Master Enable bit in the PCI Command register.

11.4.2.2 Inbound Transactions

Inbound PCI Express transactions to internal platform are first mapped to a translation window to determine what internal platform transactions are to be issued.

A transaction may be broken up into smaller sized transactions when sending to the internal platform depending on the original request size, byte enables and starting/ending addresses. The controller performs PCI Express ordering rule checking to determine what transaction is to be sent next to the internal platform.

In general, transactions are serviced in the order that they are received from the PCI Express link. Only when there is a stalled condition does the controller apply PCI Express ordering to outstanding transactions. For posted write transactions, once all data has been received from the PCI Express link, the data is forwarded to the internal platform and the transaction is considered as done. For non-posted read transactions, the controller forwards internal platform data back to the PCI Express link.

NOTE

The controller splits transactions at the crossing of every 128-byte-aligned boundary when sending completion data back to the PCI Express link.

11.4.2.3 Link Establishment

The controller implements the LTSSM function according to the *PCI Express Base Specification, Revision 4.0, Version 0.7. .*

11.4.2.3.1 Transmit TLP Processing

The following section describe the flow of transmit TLPs through the controller.

NOTE

The controller does not check the TLP for errors.

The PCIe controller ensures transmitted TLP Payload sizes are less than or equal to the maximum payload size limit.

11.4.2.3.1.1 Transmit TLP Arbitration

TLPs and DLLPs have equal priorities during transmit arbitration as shown in the figure below. The priority of TLP types and DLLP types are shown in tables below.

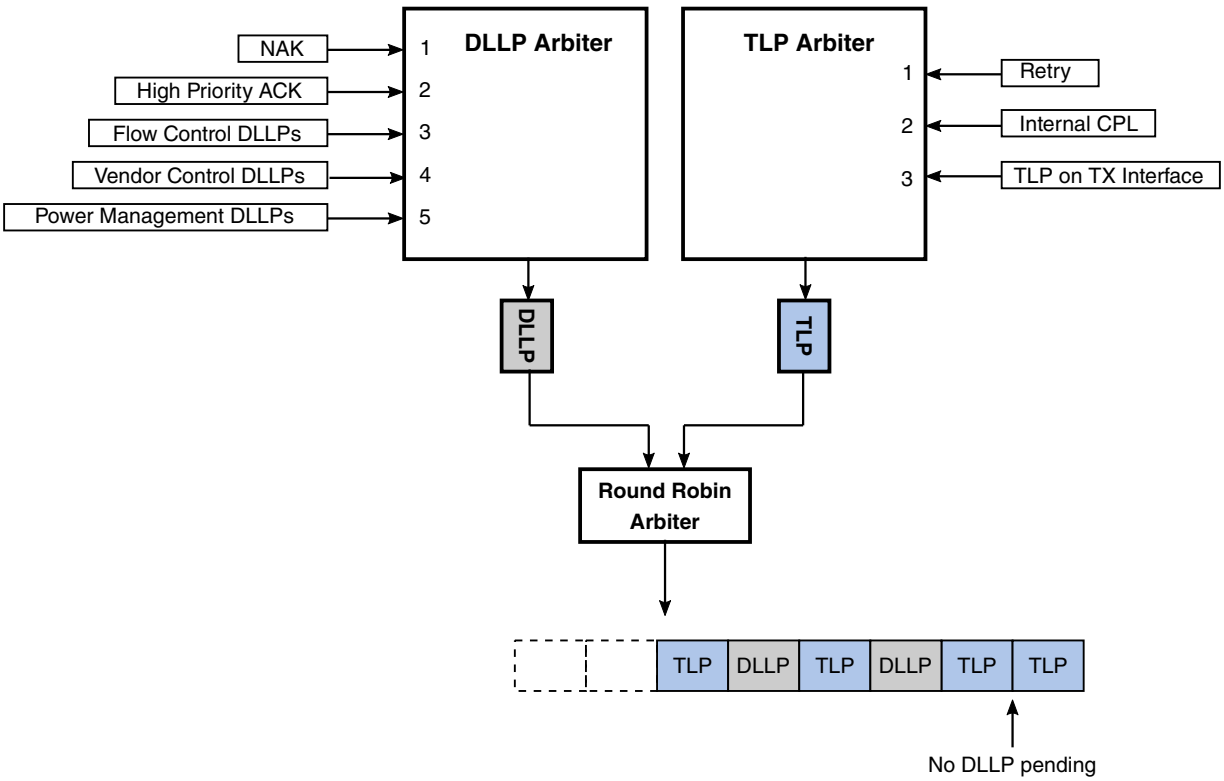

Figure 11-32. Transmit TLP/DLLP Arbitration

Table 11-30. TLP Arbitration Priority (1= Highest, 4= Lowest)

Priority	TLP Type
1	Completion of any TLP currently in progress
2	Retry buffer retransmissions
3	TLPs from the transaction layer (in the following order of priority): • Messages generated by the controller (including by your application through the MSI interface) • Upstream ports: Completions generated by the controller (including memory or I/O mapped application register space) for Type 0 configuration read and write requests, or responses to error conditions (unsupported requests) • Downstream ports: Completions generated by the controller for unsupported requests or completer aborts
4	TLPs on the AXI Master/Slave interface

Table 11-31. DLLP Arbitration Priority (1= Highest, 6 = Lowest)

Priority	DLLP Type

Table continues on the next page...

Table 11-31. DLLP Arbitration Priority (1= Highest, 6 = Lowest) (continued)

1	Completion of any DLLP currently in progress
2	NAK DLLP
3	High Priority ACK DLLP
4	Flow Control DLLP
5	Vendor Specific Message DLLP
6	Power management or any other Low Priority DLLP

11.4.2.3.1.1.1 Effects of Flow Control Credits On Transmit Client Arbitration

The controller checks that enough flow control (FC) credits are available in the remote device for the specific type of transaction (posted, non-posted, completion) before allowing a transmission of a TLP. TLPs that passed the credit check are arbitrated according to the supported arbitration method. Internally generated completions and messages are also gated by the arbitration logic, though at highest priority, and must also pass the FC credit test before they are accepted for transmission.

11.4.2.3.1.2 Transmit Replay

You can modify the time-out value of the replay buffer as shown in the figure below. For a typical system, you do not have to modify the default settings, unless the remote device is executing unexpected replays.

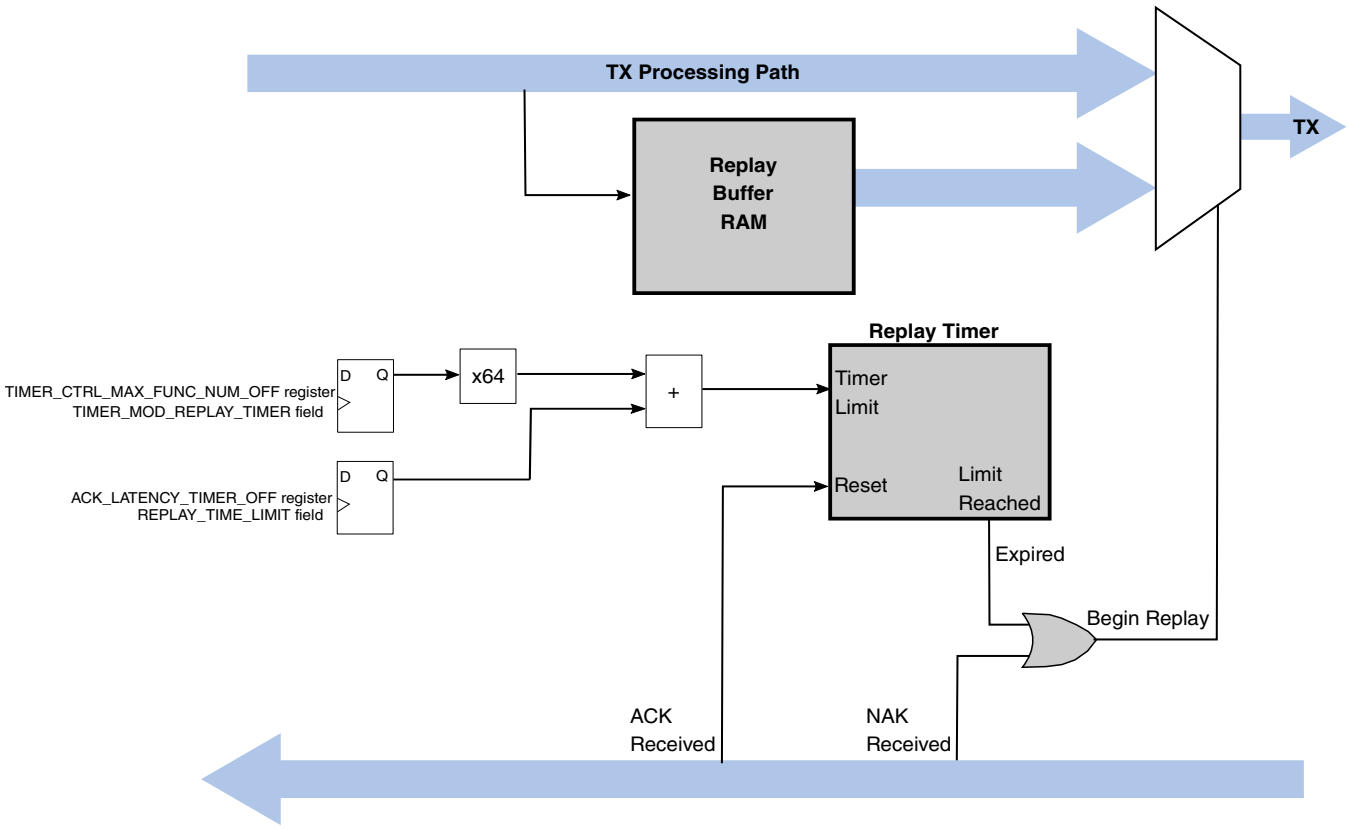

Figure 11-33. Replay Buffer And Time (Representative)

11.4.2.3.2 Receive TLP Processing

This section describes the flow of received TLPs through the controller.

11.4.2.3.2.1 Receive Filtering

The controller contains a filter module that is responsible for the following tasks:

- Determine the status of a received TLP using filtering rules.
- Determine the destination of a received TLP based on the filtering status.
- Indicate the status of the received TLP using outputs.
- Report Errors to AER registers based on filter results. When more than one type of error is detected, Error Pollution, of the *PCI Express Base Specification, Revision 4.0, Version 0.7* is followed.
- The controller filters and routes received TLPs according to a set of rules determined by the TLP type based on the *PCI Express Base Specification, Revision 4.0, Version 0.7* and user-configurable filtering options.

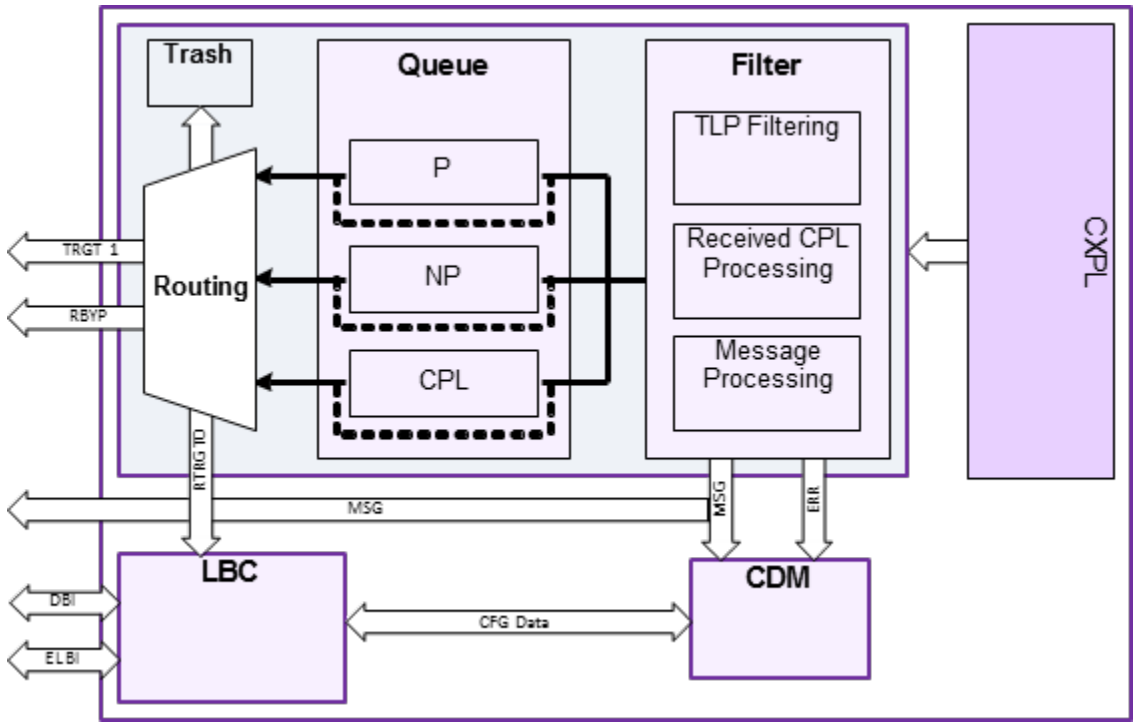

Figure 11-34. RADM Block Diagram

The following general rules apply to all incoming TLPs that are not malformed. For details on what happens to malformed TLPs, see "Error Detection for Received TLPs" By default:

- For a function in device power states D1, D2, and D3hot, the controller only accepts CFG and MSG requests TLPs for that function. All other incoming request types for that function are treated as unsupported requests (UR).
- When the controller detects an error in a received TLP, it normally performs the following:
  - Discards the TLP
  - Generates a completion (for non-posted requests) with the completion status set to CA or UR
  - Sets the status in the PCI-compatible Status register
  - Sets the status in the AER registers
  - Generates an error message (upstream port only)

All error-free MSG requests are decoded internally, signaled on the SII interface and then dropped. When you want to have the decoded message also sent to the application interface, then see “Routing of Received Messages”.

11.4.2.3.2.2 Receive Routing

This section discusses how the RADM routes different TLP types to different receive interfaces depending on TLP type and filter result. TRGT1 refers to the AXI interface. TRGT0 refers to the internal interface used to access the CDM registers or the ELBI in an upstream port.

11.4.2.3.2.2.1 EP Mode Routing Overview

The possible destinations of a posted or non-posted request TLP are TRGT1 interface, TRGT0 interface and Discard. By default:

- CFG requests are routed to TRGT0 and then to CDM through the LBC.
- BAR-matched MEM and I/O requests are routed to TRGT1.
- MSG requests are decoded internally, signaled on the SII interface, and then terminated.

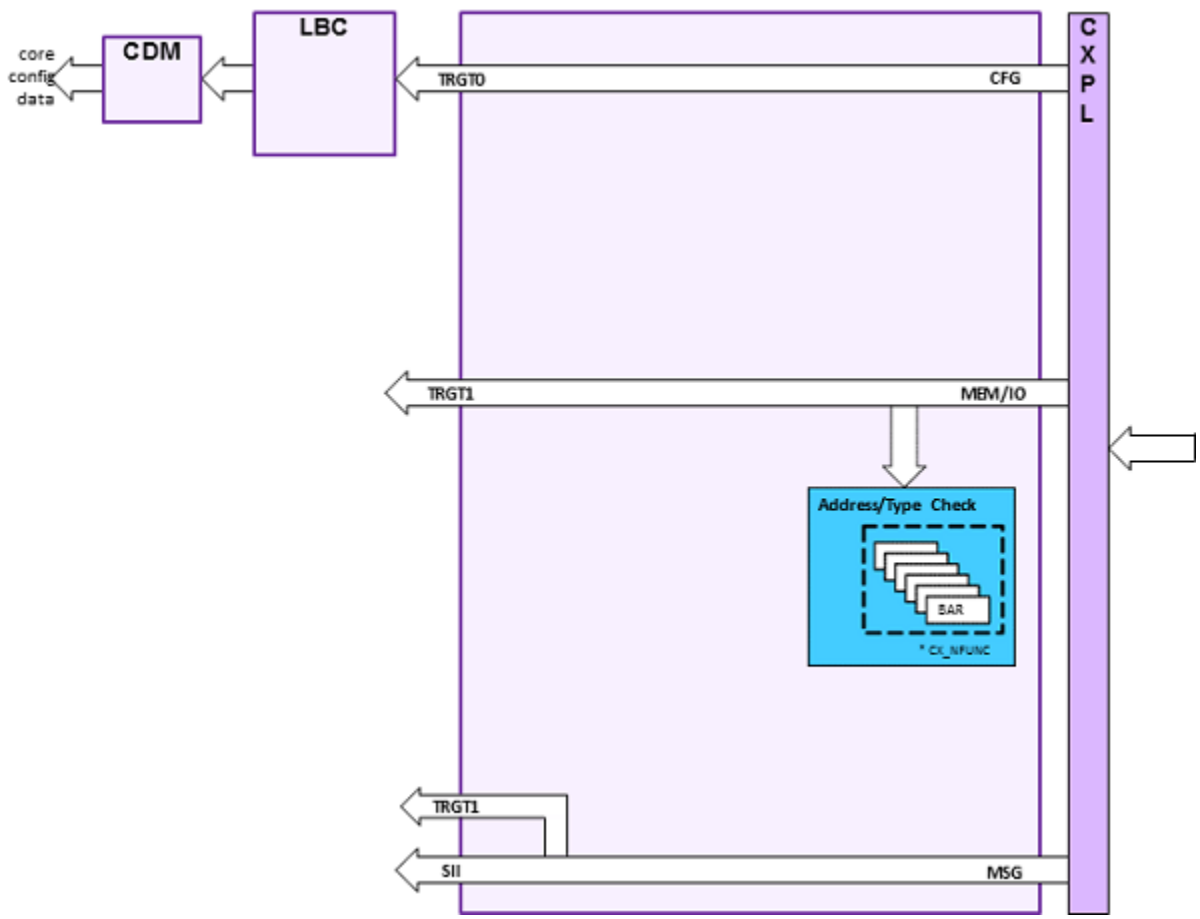

Figure 11-35. EP Mode Routing

11.4.2.3.2.2.2 RC Mode Routing Overview

The possible destinations of a posted or non-posted request are TRGT1 and Discard. By default:

- MEM requests outside of the memory range and prefetchable memory range as determined by the corresponding Base and Limit fields in the Type-1 header are routed to TRGT1.
- MSG requests are decoded internally, signaled on the SII interface, and then terminated.
- An RC does not expect to receive CFG or I/O requests.
- BARs should be disabled and not used.

The possible destinations of a completion TLP are TRGT1 and Discard.

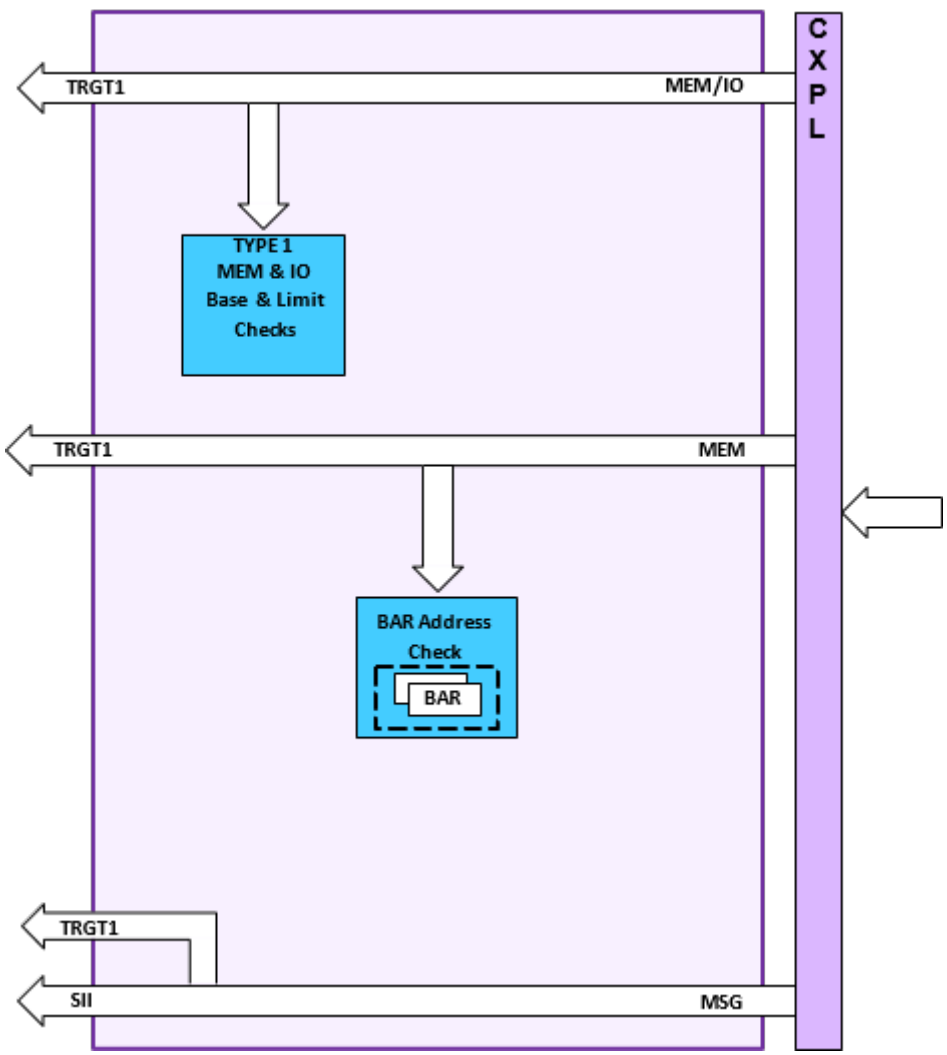

Figure 11-36. Default Request TLP Routing (Assuming no TLPs with CA/CRS/UR Error Status)

11.4.2.3.2.3 Error Handling

The controller supports the Baseline Capabilities, AER capabilities, and Advisory Non-Fatal Error Messaging as specified in section "Error Signaling and Logging" of the *PCI Express Base Specification, Revision 4.0, Version 0.7*. These include Correctable and Uncorrectable (Fatal and Non-Fatal) errors. For an RC port, the reporting of most errors is internal to the root port. No external error notifications are generated. One exception to this (for example) is unsupported request (UR) completion status.

11.4.2.3.2.3.1 Error Detection for Received TLPs

The controller performs all mandatory error detections, the error reporting mechanism based on the PCI Express Base Specification, Revision 4.0, Version 0.7. When the controller detects an error in a received TLP, it normally performs the following:

- Discards the TLP
- Generates a completion (for non-posted requests) with the completion status set to CA or UR
- Sets the status in the PCI-compatible status register
- Sets the status in the AER registers
- Generates an error MSG (upstream port only)

11.4.2.3.2.3.2 AER Multiple Header Logging

The controller supports the AER multiple header logging as specified in Section, "Multiple Error Handling (Advanced Error Reporting Capability)" of the *PCI Express Base Specification, Revision 4.0, Version 0.7*.

11.4.2.3.2.3.3 Physical Functions

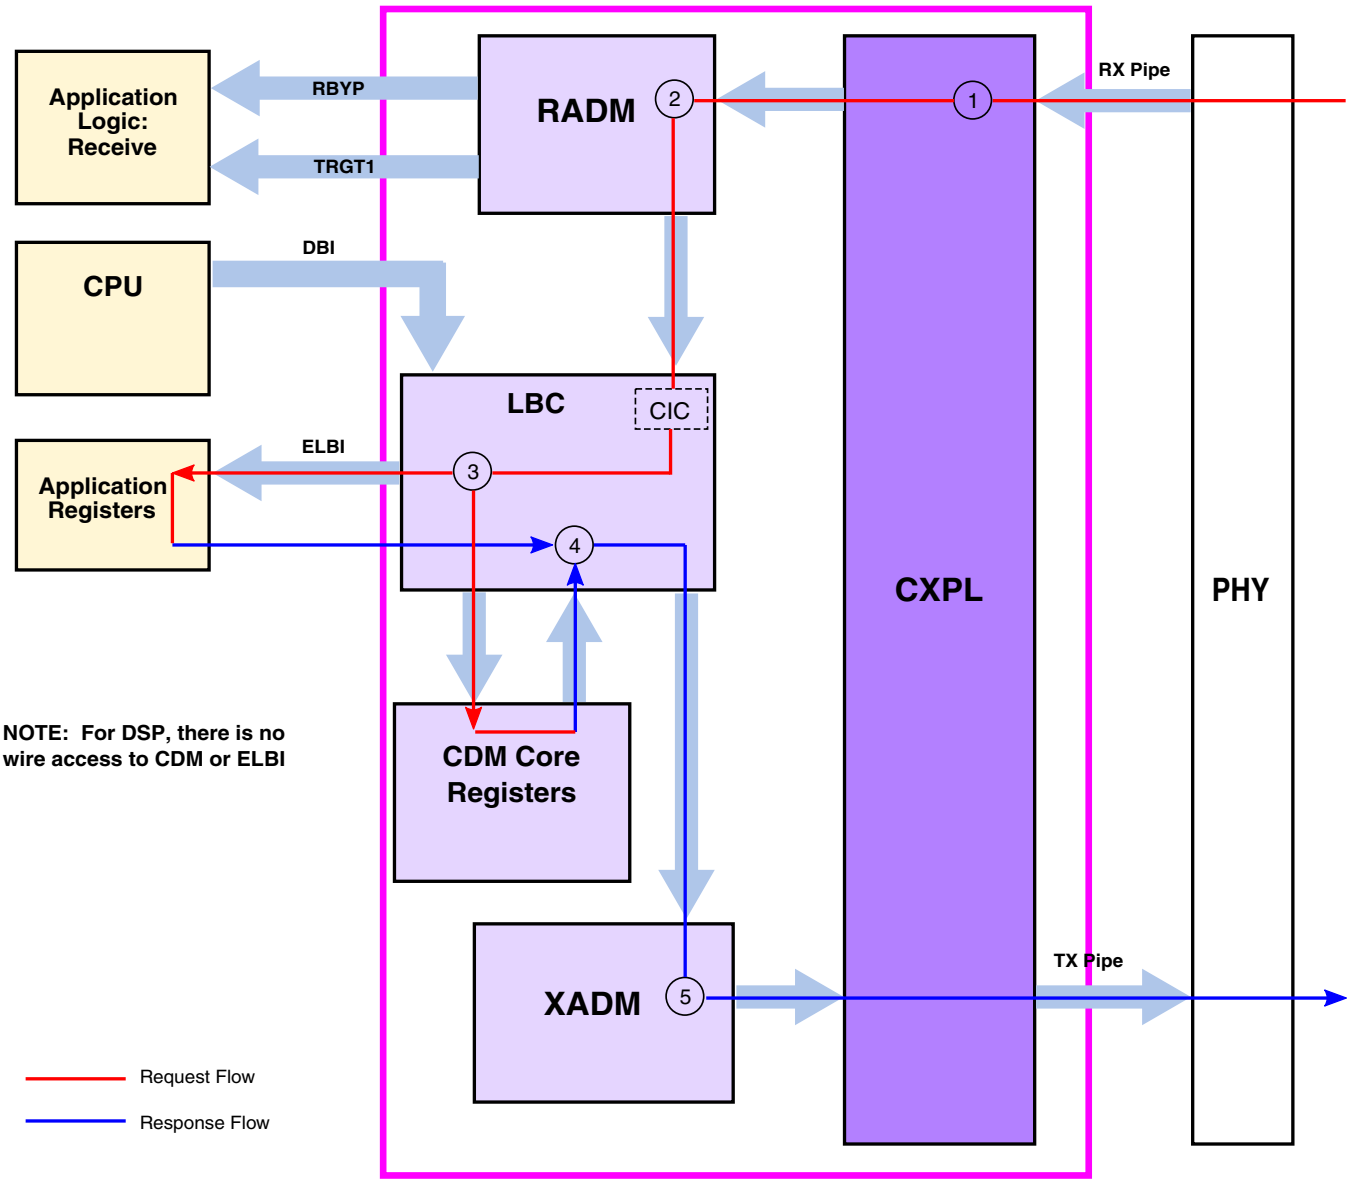
By default, each physical function only logs the first header that caused an error. Per physical function, the controller implements a FIFO queue that interfaces with the AER Header Log registers (HDR_LOG_i_OFF). A valid queue entry is never overwritten. When the queue is full and your software does not read the header log registers fast enough, new header log information will be missed.

11.4.2.3.3 Register Module and Data Bus Interface (DBI)

11.4.2.3.3.1 Overview

The Local Bus Controller (LBC) module provides a mechanism for a link partner (in upstream mode) or a local CPU (through the DBI) to access:

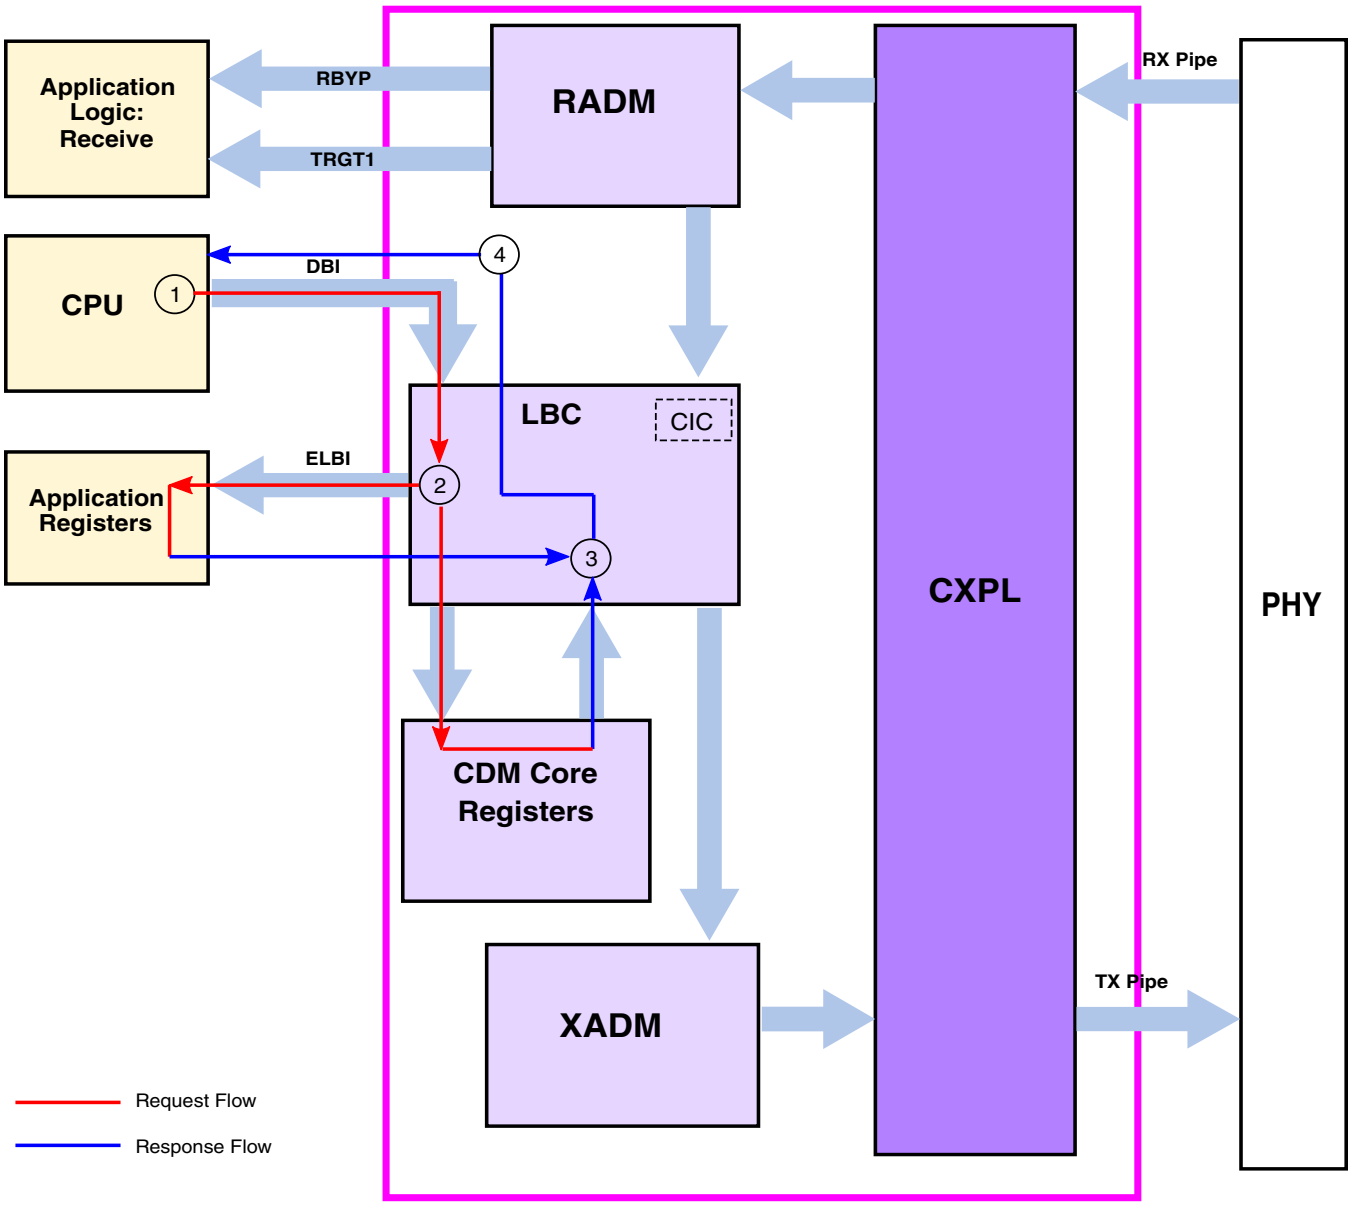
- Internal registers (in the CDM)
- External application registers connected externally to the ELBI
- In RC mode:
- There is no PCIe wire access to the CDM registers and ELBI.
- There is full DBI access to the CDM registers and ELBI.
- The controller has 4096 bytes of register PCIe configuration and port logic space per function. The controller also has a common iATU and DMA configuration register space for all functions. The controller register space is fully accessible from the DBI without any restrictions.



NOTE

Please refer to the Memory Map for the assigned space for the PCIe controller.

Table 11-32. EP Mode Port Region Access



Register Location		CDM					ELBI
Register Type		PCI-SIG		Port Logic			User
		Normal	Shadow	Misc	IATU	DMA	User
Access Details	CDM/ELBI Selector Bit[1] Value	0	0	0	1	1	1
	CS2 Selector Bit Value	0	1	0	1	1	0
DBI/Wire Access Allowed							
DBI		Y	Y	Y	Y	Y	Y
Wire	**CFG Request**	Y	-	Y	-	-	Y
	BAR Matched MEM Request	-	-	Y[2]	Y	Y	Y[-1]

1. Selector bit locations are configuration-dependent.
2. IO request also supported.

1. Incoming request from PCIe remote link partner
2. Request is filtered and routed by RADM and through TRGT0 to LBC
3. LBC forwards the request to external registers (through ELBI) or internal registers in CDM
4. LBC forms completion TLPs with response received from ELBI or internal registers in CDM
5. PCIe controller transmits response completion to remote link partner

Figure 11-37. PCIe Wire Access to CDM Registers or ELBI

1. Request from Local CPU through DBI
2. LBC forwards the request to external registers (through ELBI) or internal registers in CDM
3. LBC forms completion TLPs with response received from ELBI or internal registers in CDM
4. PCIe controller presents response to Local CPU through DBI

Figure 11-38. DBI Access to CDM Registers or ELBI

11.4.2.3.3.2 CDM Register Space Layout

11.4.2.3.3.2.1 Overview

The controller has 4096(0x1000) bytes of register PCIe configuration and port logic space per function. The controller also has a common iATU and DMA configuration register space for all functions. The controller register space is fully accessible from the DBI without any restrictions. Please see the Memory Map for the register base address assignment.

Table 11-33. Port Region Access

Register Location		CDM					ELBI
Register Type		PCI-SIG		Port Logic			User
		Normal	Shadow	Misc	IATU	DMA	User
Access Details	CDM/ELBI Selector Bit[1] Value	0	0	0	1	1	1
	CS2 Selector Bit Value	0	1	0	1	1	0
DBI/Wire Access Allowed							
DBI		Y	Y	Y	Y	Y	Y
Wire	**CFG Request**	Y	-	Y	-	-	Y
	BAR Matched MEM Request	-	-	Y[2]	Y	Y	Y[-1]

1. Selector bit locations are configuration-dependent.
2. IO request also supported.

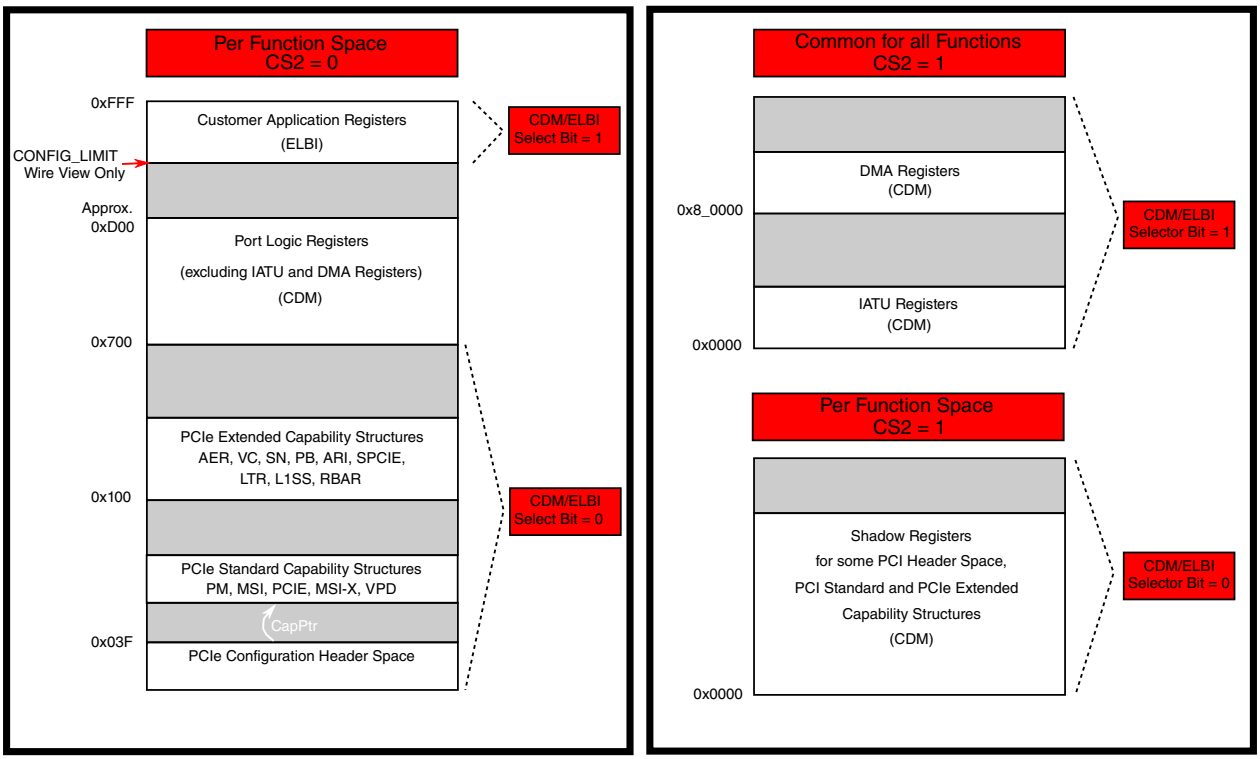


Figure 11-39. Controller Configuration Space Layout (EP Mode)

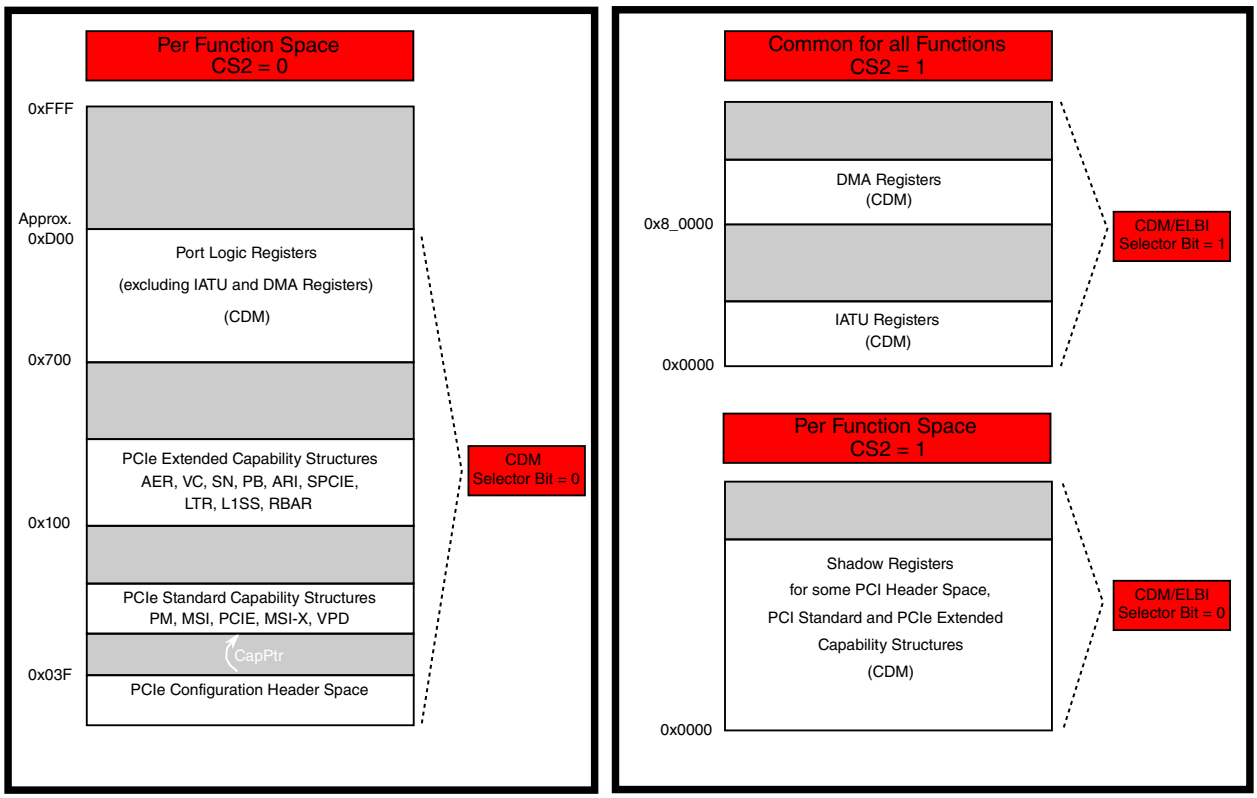

Figure 11-40. Controller Configuration Space Layout: (RC Mode)

Wire Access (Upstream Ports Only):

- Any CFG > CONFIG_LIMIT goes to TRGT1 or ELBI
- Any MEM/IO captured by a BAR whose interface target is TRGT0 goes to ELBI
- Any MEM captured by BAR*n* (*n* =UNROLL_BAR_NUM) when
- ENABLE_MEM_MAP_UNROLL_{DMA|ATU}_REG=1, whose interface target is TRGT0, and whose address falls into the range defined in "Memory Mapping iATU and DMA Port Logic Registers" goes to the IATU/DMA registers.

DBI Access (Upstream and Downstream Ports):

- No concept of MEM/IO/CFG
- Uses the specified address bit to route the access to ELBI or CDM
- No restrictions regarding what spaces can be accessed or not

11.4.2.3.3.2.2 Core Configuration Space Registers

- CDM Registers
  - PCI Configuration Header and Capability Registers:
    - The *PCI configuration header and capability registers* in the previous diagrams are PCIe controller configuration registers specified by the *PCI Express Base Specification, Revision 4.0, Version 0.7*. Access from the PCIe

wire is possible with CFG requests (upstream ports). These registers are fully accessible from the DBI without any restrictions.

- Port Logic Registers:
  - The port logic (PL) registers are configuration registers which are not specified by the *PCI Express Base Specification, Revision 4.0, Version 0.7*. Access from the PCIe wire is normally with CFG requests. These registers are fully accessible from the DBI without any restrictions.
- iATU and DMA Port Logic Registers:
  - This memory space is dedicated for iATU and DMA configuration registers. Access from the PCIe wire is with specific BAR matched MEM requests. These registers are fully accessible from the DBI without any restrictions.

11.4.2.3.3.2.3 PCIe Wire Access (EP Mode)

By default all requests to the standard PCI configuration space or to the port logic registers (except iATU and DMA registers) are routed to TRGT0 and then to the CDM through the LBC. To access the iATU/DMA registers, you must use MEM requests that target the BAR you have setup to capture these addresses. For more details, "Memory Mapping iATU and DMA Port Logic Registers."

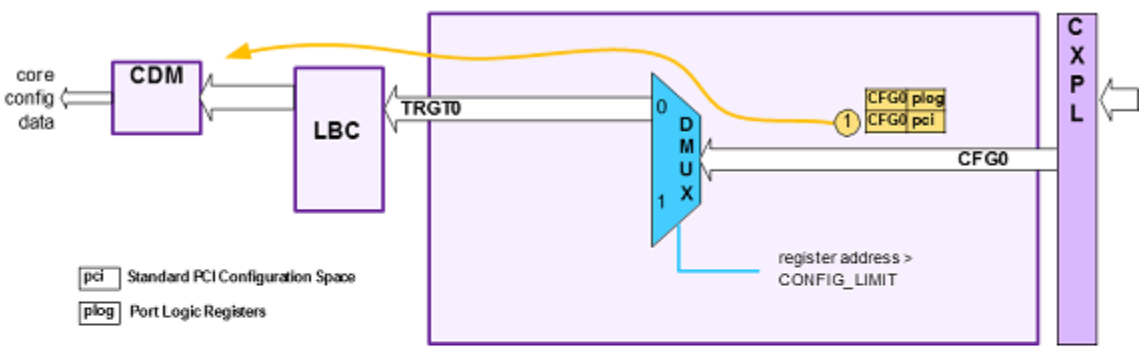

Figure 11-41. Request TLP Routing: Typical Use Model

11.4.2.3.3.3 Data Bus Interface (DBI)

11.4.2.3.3.3.1 Overview

The DBI can access all 4096 bytes (1024 DWORDs) of the PCI Express configuration space per function. DBI can also access iATU and DMA configuration space. This address space is fully accessible from the DBI without any restrictions.

11.4.2.3.3.4 Features and Limitations

The following limitations exist for the LBC.

- CDM Access Restrictions:
  - Maximum payload Length =1 DWORD.
  - PCIe MEM requests with Length > 1 are processed as completer abort.
  - PCIe MEM requests with Length =0 are processed as completer abort.
  - PCIe IO or CFG requests with Length !=1 are processed as malformed TLPs.
- ELBI Access Restrictions:
  - CS2 bit must be 1'b0.
  - PCIe MEM requests with Length =0 are processed as completer abort.
  - PCIe IO or CFG requests with Length !=1 are processed as malformed TLPs.
  - Does not support "Atomic Operations (AtomicOps)"
  - Does not support TPH. Core does not forward the TPH bits to the ELBI.
  - Data (Read)
- DBI Data/Address Port Widths (with no AXI bridge):
  - Data: 32 bit
  - Address: 32 bit

11.4.2.3.3.4.1 Additional AXI DBI Limitations

The following limitations exist when you configure the controller to use the AXI bridge module.

- The DBI address must be a DWORD address.
- AXI transfer widths of 8, 16, and 32 bits are supported. The AXI dedicated/shared DBI interface returns an error response to requests with width greater than 32 bits. The type of error response is programmable through AMBA_ERROR_RESPONSE_DEFAULT_OFF register1.
- The CDM only supports 32-bit data access. The AXI dedicated/shared DBI interface returns an error response to multi beat requests. The type of error response is programmable through AMBA_ERROR_RESPONSE_DEFAULT_OFF register.

A zero-byte write over DBI is processed as a read and should never be issued. The AXI dedicated/shared DBI slave drops a zero-byte write before it reaches the internal (native controller) DBI and returns an error response. The type of error response is programmable through AMBA_ERROR_RESPONSE_DEFAULT_OFF register.

The type of error response returned by the AXI dedicated/shared DBI slave is the same as that programmed for UR completions in the AMBA_ERROR_RESPONSE_DEFAULT_OFF register.

11.4.2.3.4 Flow Control

The flow control mechanism is divided into two phases: initialization and update. The controller automatically performs both of these phases with minimal support required from your application. By default the RADM is responsible for returning flow control credits when it reads data out of the receive queues.

11.4.2.3.4.1 Initial Credit Advertisement by the Controller

To prevent overflow of the link partner's receiver buffers and for order-compliance purposes, the transmitter cannot send transactions unless it has enough flow control (FC) credits to send. Each device maintains an FC credit pool. The FC information is conveyed between the two link partners by DLLPs during link training (initial credit advertisement). The transaction layer performs the FC accounting functions. One FC unit is four DWs (16-bytes) of data.

Table 11-34. Initial Credit Advertisement By The Controller

Credit Type	Initial Credit Advertisement
PH (Memory Write, Message Write)	12
PD (Memory Write, Message Write)	25 (or 400 bytes)[1]
NPH (Memory Read, IO Read, Cfg Read, Cfg Write)	12
NPD (IO Write, Cfg Write)	3 (or 48 bytes)
CPLH (Memory Read Completion, IO R/W Completion, Cfg R/W Completion)	Infinite
CPLD (Memory Read Completion, IO Read Completion, Cfg Read Completion)	Infinite

1. When the outstanding inbound posted write data transfer size exceeds 400 Bytes, the number of inbound posted write transactions that the i.MX 8M Plus PCI Express Controller can support is up to 12 headers or 400 bytes of data payload, whichever is consumed first. Refer to application note, AN13164, iMX8MP PCIe Bandwidth Analysis for more detailed information.

NOTE

When the outstanding inbound write data transfer size exceeds 400Bytes, all inbound MWr (Memory Write) transactions to the

i.MX 8M Plus PCIe Controller support up to a maximum of 12 PCIe write packet headers and up to 25 (400 Byte) write packet data payload.

11.4.2.3.4.2 Calculation of Initial Credits and Receive Buffer Sizes For The Link Partner

The default buffer sizes and credits for each TLP type are automatically calculated from the number of lanes, the controller datapath width, the maximum PCIe payload , flow control update latencies, internal delays, and the PHY latency.

You can determine the transmit posted, non-posted, and completion credits that are advertised by the receiver at the other end of the link by reading the following port logic registers:

- Transmit Posted FC Credit Status (TX_P_FC_CREDIT_STATUS)
- Transmit Non-Posted FC Credit Status (TX_NP_FC_CREDIT_STATUS)
- Transmit Completion FC Credit Status (TX_CPL_FC_CREDIT_STATUS)

NOTE

You can override the default flow control update latency timer value using the FC Latency Timer Override Value field (TIMER_MOD_FLOW_CONTROL) in the Queue Status register (Q_STATUS).

11.4.2.3.5 Completion Timeout Ranges

Timeout ranges are supported as defined in the *PCI Express Base Specification, Revision 4.0, Version 0.7*. The controller supports all ranges. The Device Control 2 Register has a default equal to the default in the specification: 0000b Default range: 50 us to 50 ms. When the default is used, then the timeout is in Range B: 0101b: 16 ms to 55 ms. This range was chosen for the default because the *PCI Express Base Specification, Revision 4.0, Version 0.7* states, "It is strongly recommended that the completion Timeout mechanism not expire in less than 10 ms". The table below illustrates the specification values versus the PCI Express controller values for the ranges.

NOTE

As the PCIe specification states, This mechanism is intended to be activated only when there is no reasonable expectation that the completion is returned, and should never occur under normal operating conditions.

Table 11-35. Comparison of PCIe Specification and PCIe Core Completion Timeout Ranges

Range	Encoding	Spec Minimum	Spec Maximum	PCIe controller Minimum	PCIe controller Maximum
Default	0000b	50 us	50 ms	28 ms	45 ms
A	0001b	50 us	100 us	65 us	99 ms
A	0010b	1 ms	10 ms	4.1 ms	6.2 ms
B	0101b	16 ms	55 ms	28 ms	44 ms
B	0110b	65 ms	210 ms	86 ms	131 ms
C	1001b	260 ms	900 ms	260 ms	390 ms
C	1010b	1s	3.5 s	1.8 s	2.8 s
D	1101b	4s	13 s	5.4 s	8.2 s
D	1110b	17s	64 s	38 s	58 s

11.4.2.4 DMA Controller

This section describes the embedded multichannel DMA controller.

11.4.2.4.1 DMA Overview

The RC system CPU, or the EP application CPU, can offload the transferring of large blocks of data to the embedded DMA controller, leaving the CPU free to perform other tasks. It can simultaneously perform the following types of memory transactions (as shown in the figure 'System Level View of DMA'):

DMA write: Transfer (copy) of a block of data from local (application) memory to remote (link partner) memory.

DMA read: Transfer (copy) of a block of data from remote (link partner) memory to local (application) memory.

Therefore the DMA supports full duplex operation, processing read and write transfers at the same time, and in parallel with normal (non-DMA) traffic. Upon completion of a DMA transfer or an error, the DMA optionally interrupts the local CPU or sends an interrupt MWr (IMWr) to the remote CPU.

In linked list mode, the DMA fetches the transfer control information (called channel context) for each transfer (block), from a list of DMA elements that you have constructed in local memory.

11.4.2.4.2 DMA Architecture

This section describes the architecture of the DMA.

11.4.2.4.2.1 Architecture Overview

A DMA write and read channel operate independently to maximize the performance of the DMA read and write data transfers over the PCIe link. DMA with multiple read channels uses a weighted round robin (WRR) arbitration scheme to select the next read channel to be serviced. The same applies for multiple write channels.

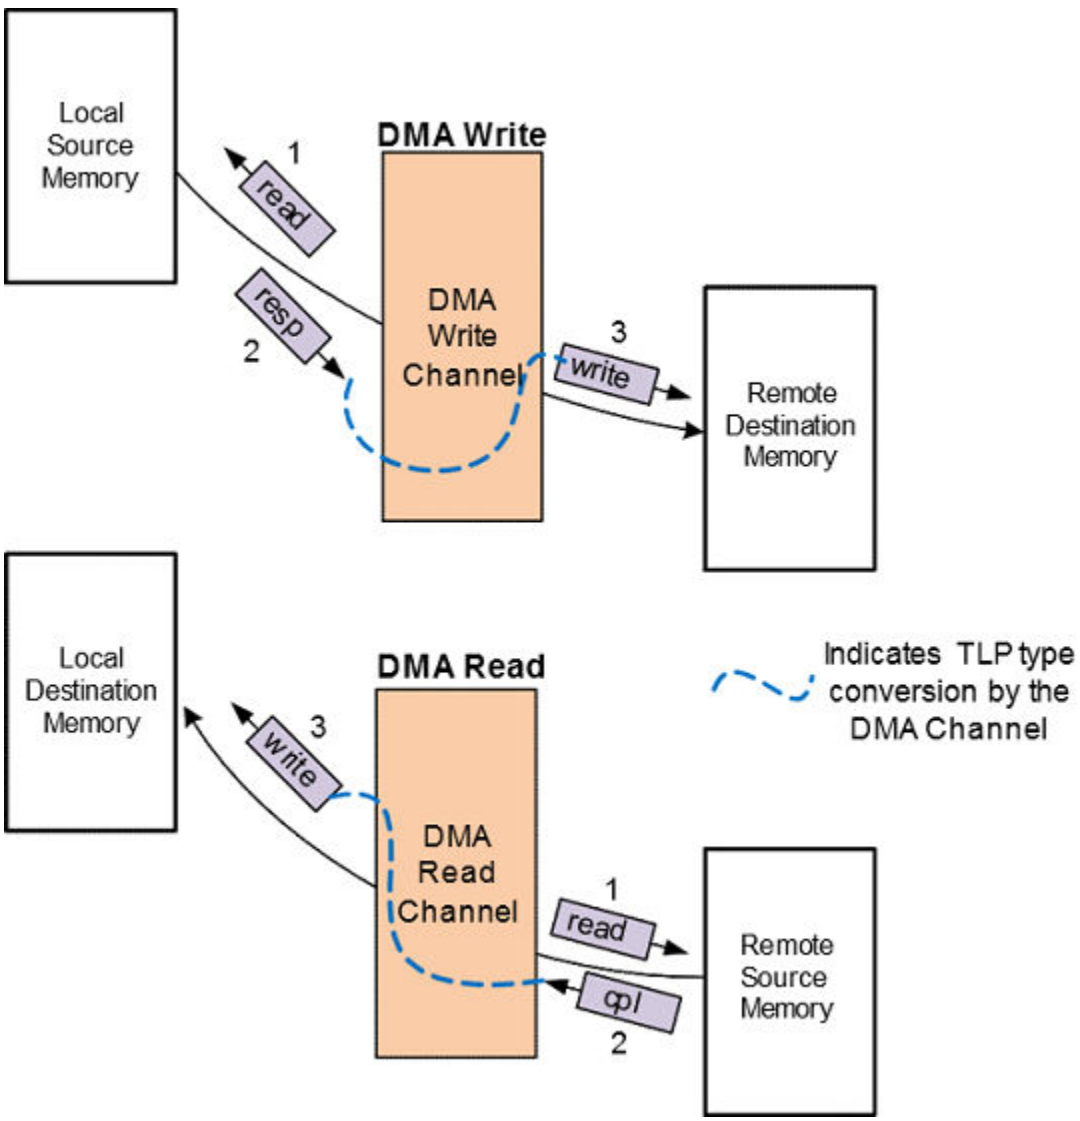

Figure 11-42. System Level View of DMA

11.4.2.4.2.1.1 DMA Read Transfer

The DMA injects multiple MRd requests of size less than or equal to the minimum of {Max Read Request Size, Max Payload Size} into the outbound request path, directed toward the remote link partner. The DMA converts the read responses into write requests, that it then transmits to the local application. When the DMA data transfer is complete, the CPU is notified. For a read transfer, the SAR is the address of the remote memory, and the DAR is the address of the local memory.

11.4.2.4.2.1.2 DMA Write Transfer

The DMA injects multiple MRd requests of size less than or equal to Max_Payload_Size into the inbound request path, directed toward the local application. The DMA converts the read responses into MWr TLPs, that it then transmits to the remote link partner. When the DMA data transfer is complete, the CPU is notified. For a write transfer, the SAR is the address of the local memory, and the DAR is the address of the remote memory.

11.4.2.4.2.2 Interrupts and Error Handling

11.4.2.4.2.2.1 Interrupt Handling

The DMA generates two interrupts per channel:

Done: The DMA successfully completes the transfer.

Abort: The DMA fails to complete the transfer, or an error occurs during the transfer.

The interrupt handling mechanism is different for linked list (LL) mode (than non LL mode), and there are also some differences between the read and write channels.

11.4.2.4.2.2.2 Non Linked List Mode

You enable the local and remote interrupts through the local and remote interrupt enable (LIE and RIE) bits:

DMA_CH_CONTROL1_OFF_WRCH_0.lie and
DMA_CH_CONTROL1_OFF_WRCH_0.rie.

In the write channel, there is only one error condition that results in an abort interrupt. For more details, see "Linked List Mode". You mask, clear, and read the status of each of the two interrupts (done and abort) through the DMA interrupt registers as indicated in figure 'Write Interrupt Generation - Non Linked List Mode - Shown For Write Channel #0'.

In the read channel, there are five error conditions that results in an abort interrupt. For more details, see "Linked List Mode". You mask and clear each of the two interrupts (done and abort) through the DMA interrupt registers as indicated in figure 'Read Interrupt Generation - Non Linked List Mode - Shown For Read Channel #0'. However, you can read the status of each of the five abort errors (that contribute to the abort interrupt) through DMA_READ_ERR_STATUS_LOW_OFF and DMA_READ_ERR_STATUS_HIGH_OFF.

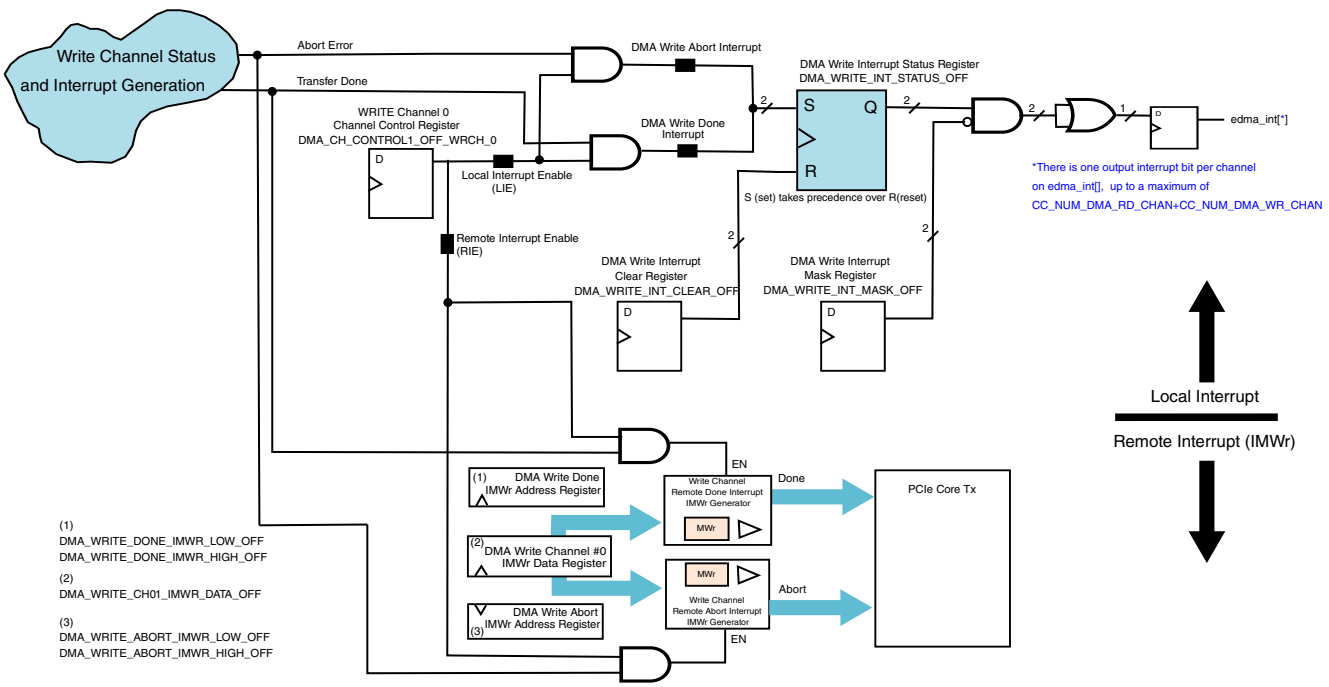

Figure 11-43. Write Interrupt Generation - Non Linked List Mode - Shown For Write Channel #0

If you want a remote interrupt and not a local interrupt then:

- Set LIE and RIE
- Mask the local interrupt using the mask register

This will allow you to poll the status register to distinguish a DONE from an ABORT

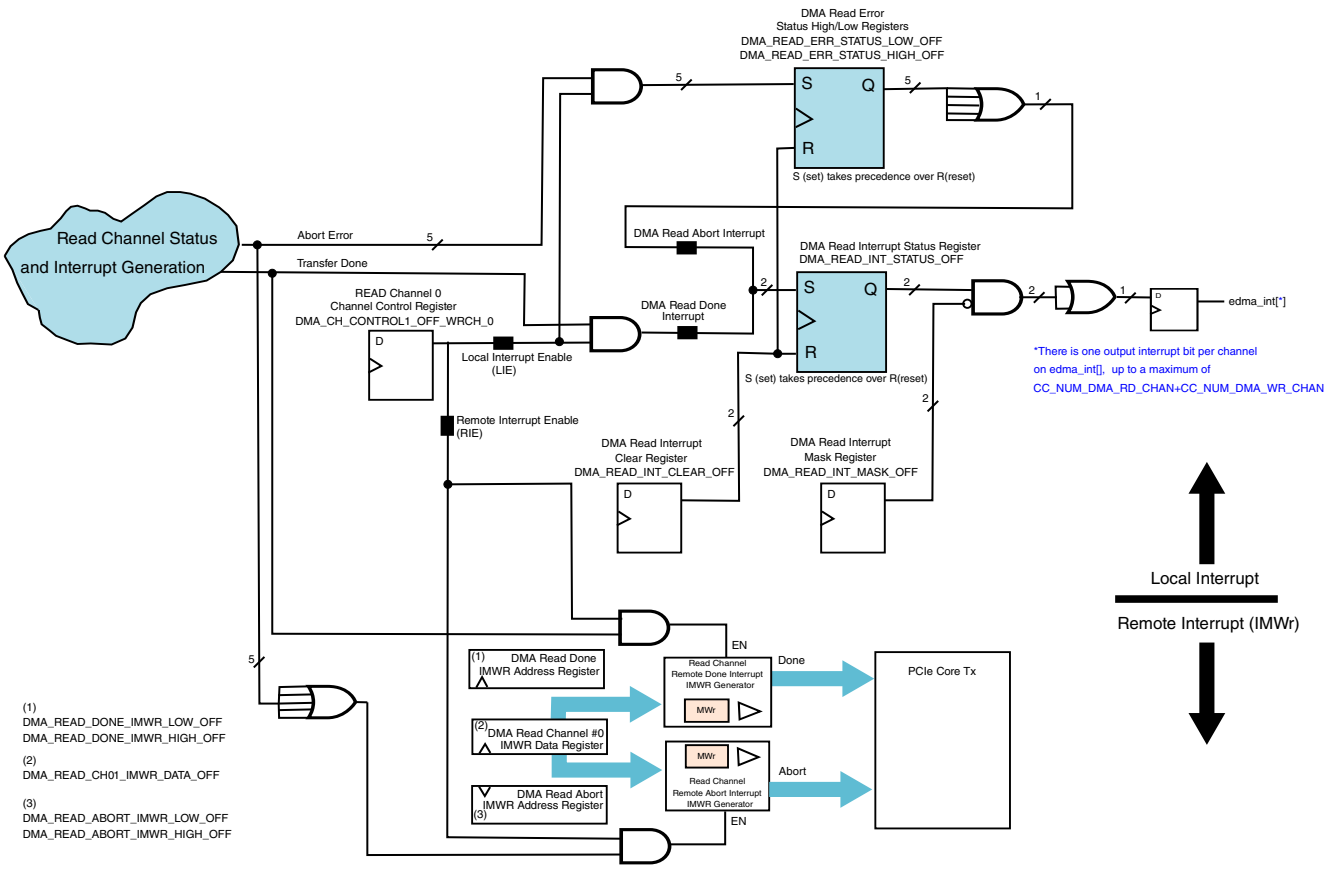

Figure 11-44. Read Interrupt Generation - Non Linked List Mode - Shown For Read Channel #0

11.4.2.4.2.2.3 Linked List Mode

The LIE and RIE bits in the LL element enable the channel done interrupts (local and remote). The LLLAIE and LLRAIE bits of the DMA_WRITE_LINKED_LIST_ERR_EN_OFF/ DMA_READ_LINKED_LIST_ERR_EN_OFF registers enable the channel abort interrupts (local and remote). In the write channel, there are two error conditions that results in an abort interrupt. For more details, see "Linked List Mode". You mask and clear each of the two interrupts (done and abort) through the DMA interrupt registers as indicated in the figure below. You can read the status of each of the two abort errors (that contribute to the abort interrupt) through the DMA_WRITE_ERR_STATUS_OFF register.

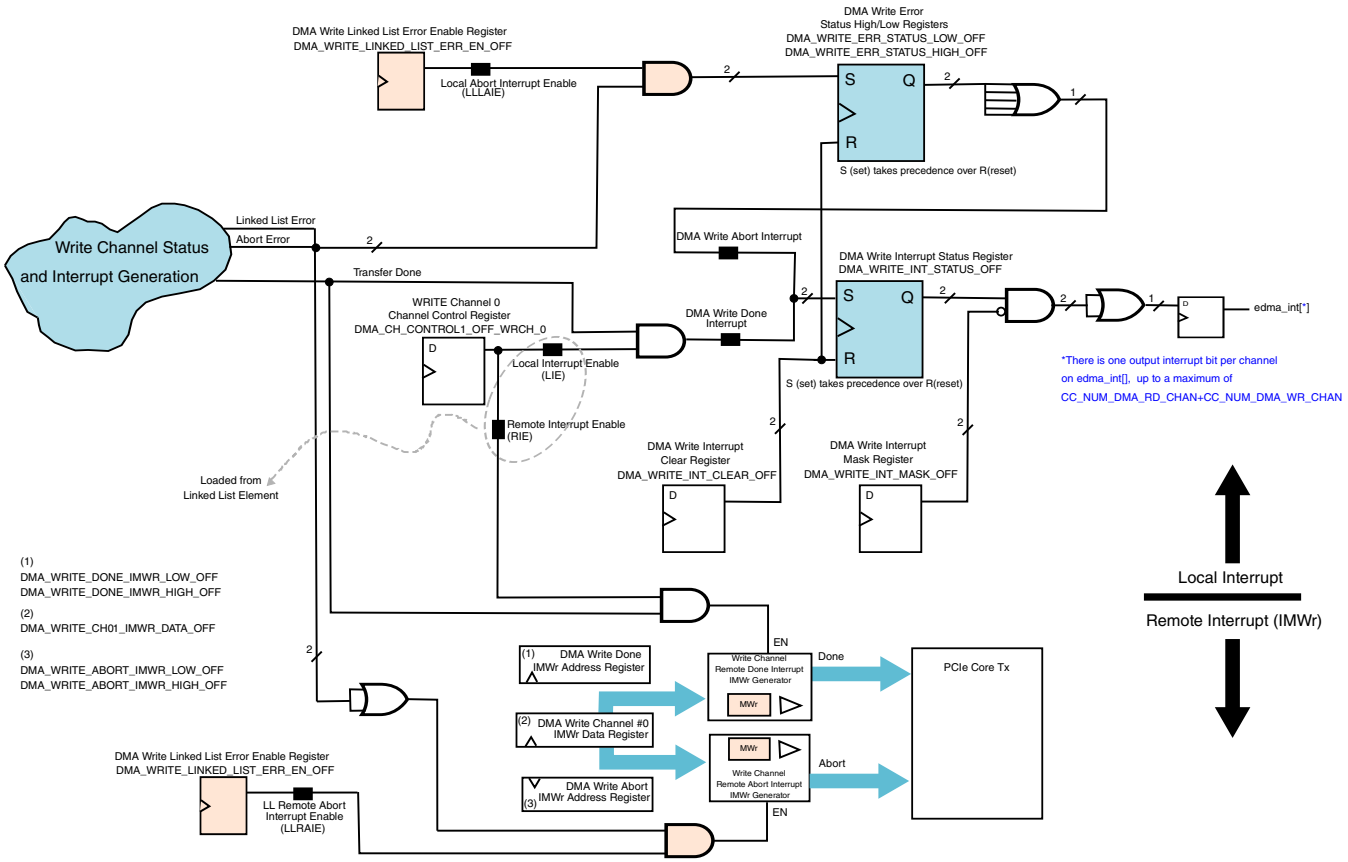

Figure 11-45. Write Interrupt Generation - Linked List Mode - Shown For Write Channel #0

In the read channel, there are six error conditions that results in an abort interrupt. For more details, see "Linked List Mode". You mask and clear each of the two interrupts (done and abort) through the DMA interrupt registers as indicated in the figure below. You can read the status of each of the six abort errors (that contribute to the abort interrupt) through the DMA_READ_ERR_STATUS_LOW_OFF and DMA_READ_ERR_STATUS_HIGH_OFF registers.

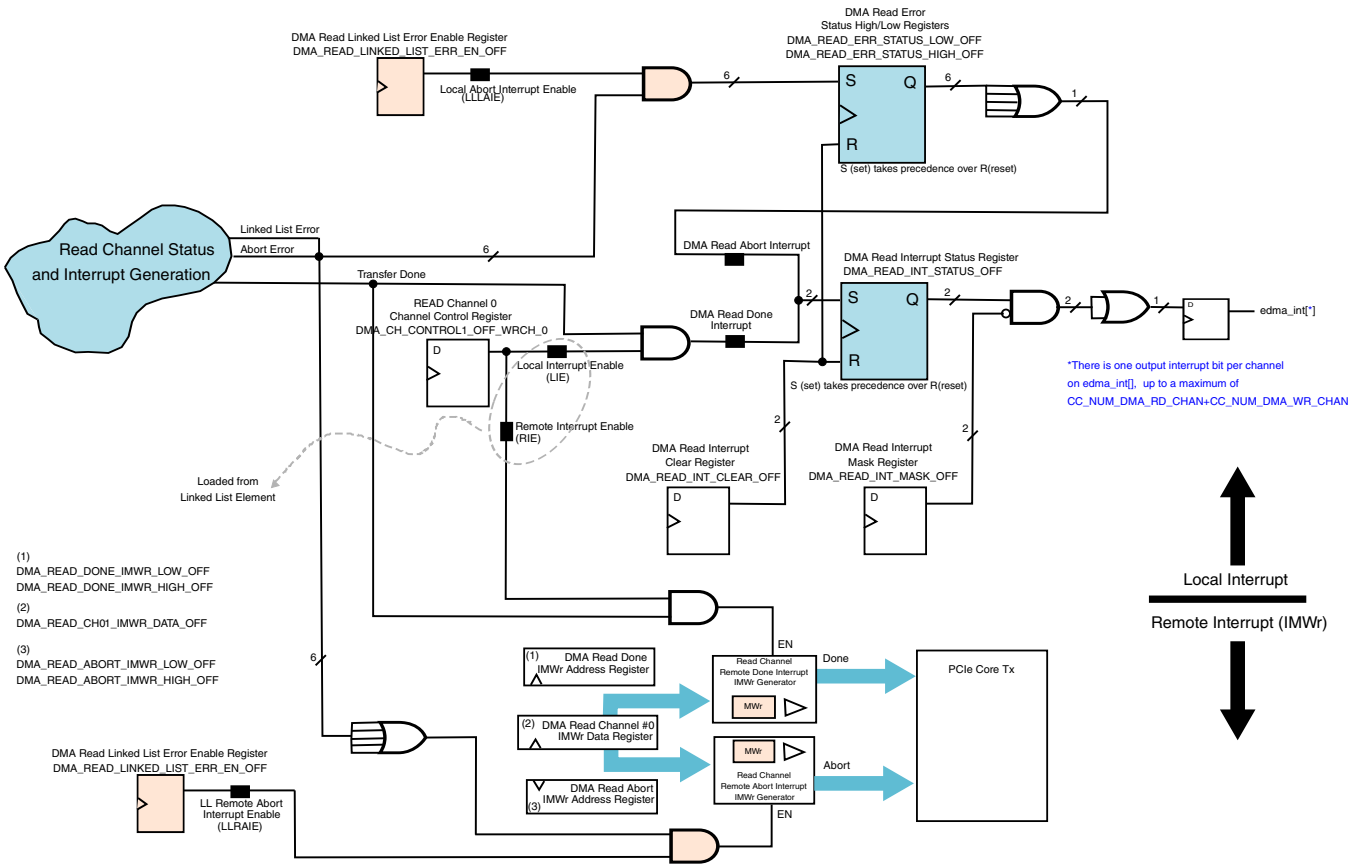

Figure 11-46. Read Interrupt Generation - Linked List Mode - Shown For Read Channel #0

NOTE

In non-linked list mode, LIE acts as a global switch. However when in linked list mode, LIE is just local to the current linked list element and the global switch is LLLAIE.

NOTE

If the DMA driver is running on the host and the interrupt service routine is reading local interrupts to determine if the transfer is successful, then you must set LIE and RIE in the same element and you should mask or ignore the local interrupt pin. Setting RIE and LIE in element A followed by RIE (only) in element B is not a verified usage scenario.

11.4.2.4.2.3 Linked List Mode

The DMA provides a linked list (LL) mode to efficiently move data from source to destination with minimal intervention from the local CPU. This mode provides an alternative to programming the DMA multiple times to transfer multiple blocks of data.

The programming information (address, size, and so on) for each block of memory is pre-programmed by your software into a LL element (also known as a descriptor) in local memory. Each element (called a data element) in the LL structure (called a transfer list) can transfer up to 4 GB of data. You enable LL operation for a channel, by setting the LLE field of the DMA_CH_CONTROL1_OFF_WRCH_0 (Replace WRCH with RDCH for a read channel) register to 1. You can enable LL mode independently for each channel. When you enable LL for more than one channel, then you must have a separate LL structure in local memory for each channel. Your application must produce the LL element structure in local memory as shown in the figure below. Normally, all of the elements are contiguous (one after the other) in memory, and each element has six DWORDs containing the information about the block of data to be transferred. You program the channel context registers (DMA_LLP_LOW_REG_WRCH_0 and DMA_LLP_HIGH_OFF_WRCH_0) with the location of where you have placed the LL element structure in local memory.

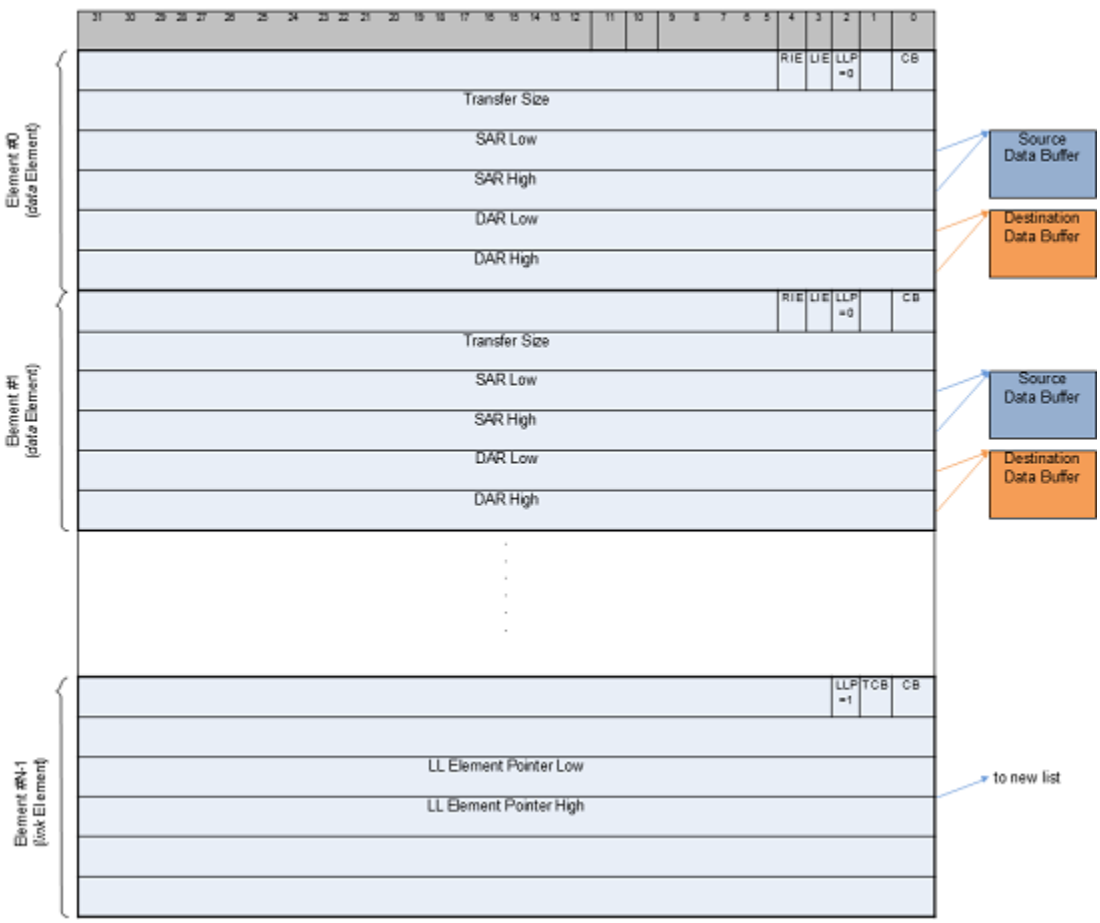

Figure 11-47. Linked List Element/Descriptor Structure in Local Memory with N Elements

When you start the DMA transfer (by writing to the DMA Write Doorbell Register DMA_WRITE_DOORBELL_OFF or DMA Read Doorbell Register DMA_READ_DOORBELL_OFF), the DMA reads (consumes) each element from local memory, and loads the information (SAR, DAR, size, and so on) from that element into the channel context registers in the DMA. These channel context registers determine the operation of the channel that the DMA controller is currently servicing. The DMA then proceeds to transfer the block of data (as defined by the element), and when it is finished, reads the next element from local memory. Normally, all of the elements are contiguous (one after the other) in memory, with the starting address defined in the channel context DMA Linked List Pointer Low Register DMA_LLP_LOW_OFF_WRCH_0. When you want to jump in local memory to another element list (or recycle the consumed elements), then you set the LLP bit in the element (for example, link element #N-1 in figure shown)), specify the location of the next element structure using the LL Element Pointer DWORDs (as indicated in the figure), and, set TCB to 1 (for recycling) or to 0 (to jump to another list).

11.4.2.4.2.3.1 Relationship Between Element DWORDs and Channel Context Registers

Notice the similarity between a data element and the DMA Channel Context registers for each channel. Each element has six DWORDs as in figure 'Linked List Element/ Descriptor Structure in Local Memory with N Elements'. There are eight channel context registers (DWORDs) for a channel. The DMA loads the six element DWORDs into the following channel context:

- CB, LLP, LIE, and RIE fields of the DMA Channel Control 1 register.
- DMA Transfer Size
- DMA SAR Low and DMA SAR High
- DMA DAR Low and DMA DAR High

The definitions of the element DWORD bit fields are the same as the DMA Channel Context registers described in the "DMA Software Register Map", with the exception of the LIE and RIE bits. The LIE and RIE bits in a LL element, only enable the done interrupt. In non-LL mode, the RIE and LIE bits (in the channel context registers) enable the done and abort interrupts.

When the LLP field of the first DWORD in the element is set to 1, the element is a link element. The DMA only loads the following information into the channel context registers:

- CB, TCB, and LLP bits of the first DWORD. The LIE and RIE bits are not defined in a link element.
- LL Element Pointer (3rd and 4th DWORDs) into the DMA Linked List Pointer registers (DMA_LL- P_LOW_REG_WRCH_0 and DMA_LLP_HIGH_OFF_WRCH_0).

Linked List Operation

- When you enable linked list operation (DMA_CH_CONTROL1_OFF_WRCH_0.lle =1b1), then the DMA overwrites the following DMA channel context registers with the following information from linked list data elements:
  - The CB, LLP, LIE, and RIE fields of the DMA Channel Control 1 register.
  - DMA Transfer Size
  - DMA SAR Low & High
  - DMA DAR Low & High
- The structure of a link element is different to that of the data element. A data element has no TCB field. A link element has no LIE or RIE fields. It has no SAR, DAR, or Transfer Size DWORDs, but has LL Element Pointer DWORDs instead of the SAR DWORDs.
- The LIE and RIE bits in a LL element, only enable the done interrupt. In non-LL mode, the RIE and LIE bits enable the done and abort interrupts. For more information, see "Interrupts and Error Handling".

11.4.2.4.3 Using the DMA

This section describes how to use the DMA. It can simultaneously perform the following types of memory transactions:

- DMA write : Transfer (copy) of a block of data from local memory to remote memory
- DMA read :Transfer (copy) of a block of data from remote memory to local memory

Therefore the DMA supports full duplex operation, processing read and write transfers at the same time, and in parallel with normal (non-DMA) traffic. Upon completion of a DMA transfer or an error, the DMA sends an interrupt MWr (IMWr).

The channels are named read channel 7..0 and write channel 7..0. Each channel is programmed using a number of registers.

11.4.2.4.3.1 Source and Destination Address Registers (SAR, DAR)

The DMA channel context SAR and DAR registers (DMA_SAR_LOW_OFF_WRCH_01 / DMA_SAR_HIGH_OFF_WRCH_0 / DMA_DAR_LOW_OFF_WRCH_0 / DMA_DAR_HIGH_OFF_WRCH_0) provide support for remote-to-local, and local-to-remote PCIe address mapping. You program the start of the local and remote data buffers using these registers, and the DMA increments the SAR and DAR as the DMA transfer progresses. For a write transfer, the SAR is the address of the local memory, and the DAR is the address of the remote memory, as shown in Figure 'Write Transfer: SAR and DAR for Write Channel 0'.

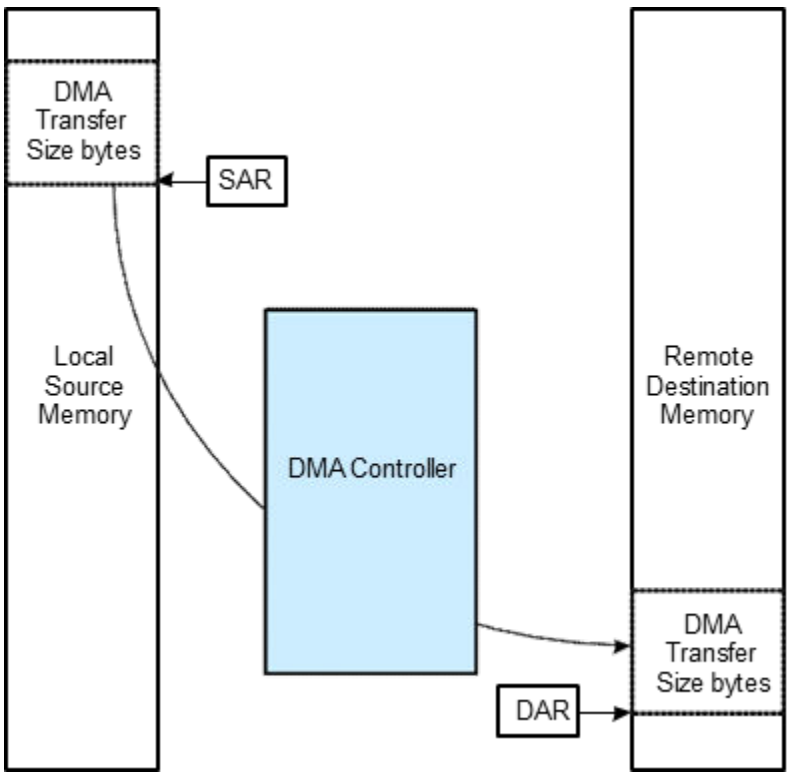

Figure 11-48. Write Transfer: SAR and DAR for Write Channel 0

For a read transfer, the SAR is the address of the remote memory, and the DAR is the address of the local memory, as shown in the figure below.

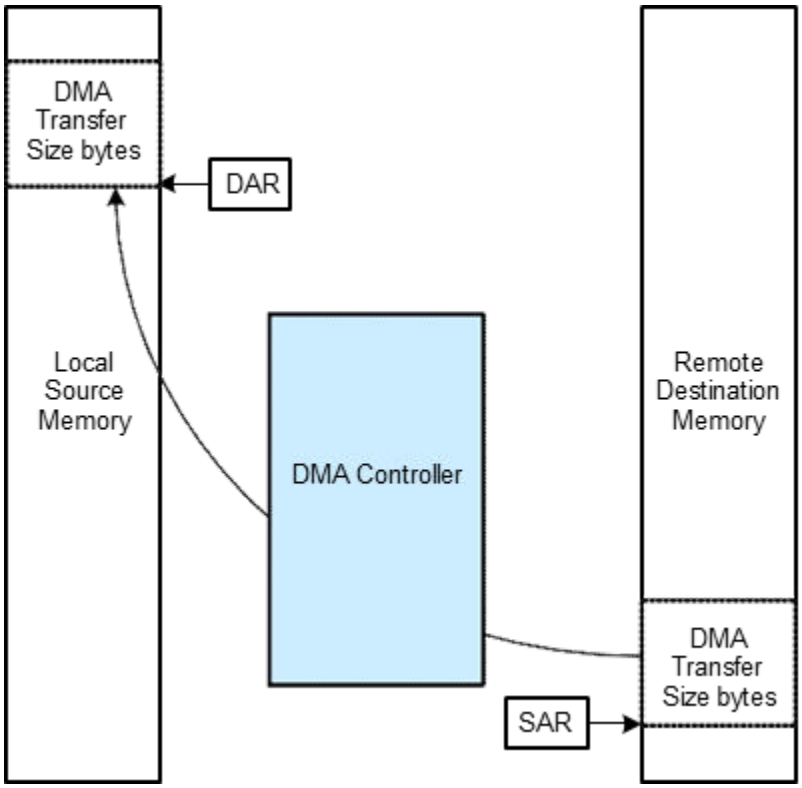

Figure 11-49. Read Transfer: SAR and DAR for Read Channel 0

The presence of the DMA controller does not affect:

- Normal filtering rules for inbound TLPs (for example, BAR checking in an Endpoint, as described in as described in “Receive Filtering”
- The operation of any internal or external address translation as described in “Internal Address Translation Unit (iATU)”).

NOTE

When you do not want the iATU to translate outbound requests that are generated by the internal DMA module, then you must implement one of the following approaches:

- Ensure that the combination of DMA channel programming and iATU control register programming, causes no translation of DMA traffic to be done in the iATU.
- Activate the DMA bypass mode to allow request TLPs which are initiated by the DMA controller to pass through the iATU untranslated. You can activate DMA bypass mode by setting the DMA Bypass field of the iATU Control 2 Register (IATU_REGION_C-TRL_OFF_2_OUTBOUND_0).

11.4.2.4.3.2 DMA Transfer Size Register

You program the DMA transfer size using the DMA Transfer Size Register (DMA_TRANSFER_SIZE_OFF_WRCH_0). The DMA decrements the value in this register as the DMA transfer progresses. You can read this register at any time to determine the number of bytes remaining to be transferred. When all bytes are successfully transferred, the result is zero. The DMA transfer size can be of any value from one byte, up to a maximum of 4 GB.

11.4.2.4.3.3 Starting The DMA Transfer

After you program the DMA controller registers (including writing to the DMA Read Engine Enable or DMA Write Engine Enable register), you start a DMA transfer by writing the channel number to the Doorbell Number field of the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF) or DMA Read Doorbell Register (DMA_READ_DOORBELL_OFF). You can program and start both a read and a write transfer at the same time. The DMA supports full duplex operation, processing read and write transfers at the same time and in parallel with normal (non-DMA) traffic. You can program and start any number of channels in the DMA controller sequentially or simultaneously.

Sequentially: configure and start a channel, and then configure and start another channel

Simultaneously: configure multiple channels, and then start multiple channels

NOTE

You must not write to any of the context registers for a particular channel after you start the channel by writing the channel number to the Doorbell Number field of the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF) or DMA Read Doorbell Register (DMA_READ_DOORBELL_OFF).

11.4.2.4.3.4 Detecting the End of The DMA Transfer

If a DMA transfer proceeds without any errors, it stops automatically when finished.

11.4.2.4.3.4.1 Detecting End of Transfer without Errors

The normal end of a DMA transfer is detected by any of the following methods:

- Done local interrupt (pin) asserted.
- Done remote interrupt (IMWr) received.

- Channel status field of the Channel Control 1 register is Stopped, and the DMA Transfer Size register is 0x0.
- Polling of the DMA Write Interrupt Status Register (DMA_WRITE_INT_STATUS_OFF) or DMA Read Interrupt Status Register (DMA_READ_INT_STATUS_OFF).

11.4.2.4.3.4.2 Detecting End of Transfer with Errors

The abnormal end of a DMA transfer is detected by any of the following methods:

- Abort local interrupt (pin) asserted.
- Abort remote interrupt (IMWr) received.
- Polling of the DMA Write Interrupt Status Register (DMA_WRITE_INT_STATUS_OFF) or DMA Read Interrupt Status Register (DMA_READ_INT_STATUS_OFF).
- Channel Status field of the Channel Control 1 register is halted. When the DMA controller detects an error, it forces the DMA to stop issuing requests for the channel. It also sets the channel status field of the Channel Control 1 register to halted, generates an abort interrupt (if enabled), and sends an abort IMWr (if enabled). The DMA Transfer Size register indicates the remaining number bytes to be transferred, except when there is an AXI write error during a DMA read transfer. For more details, see table 'Possible Sources of an Error during a DMA Read Transfer'.
- Channel Status field of the Channel Control 1 register is Stopped, and the DMA Transfer Size register is not 0x0. You have prematurely stopped this channel as described in “Stopping the DMA Transfer (Software Stop)”.

11.4.2.4.3.5 Stopping the DMA Transfer (Software Stop)

You can manually abort (stop) the DMA transfer by writing the channel number to the Doorbell Number field and writing 1 to the Stop field in DMA_WRITE_DOORBELL_OFF. This causes the DMA to:

- Place the channel in a Stopped state.
- The channel Status field in DMA_CH_CONTROL1_OFF_WRCH_0 is Stopped and the value in DMA_TRANS- FER_SIZE_OFF_WRCH_0 will not be 0x0.
- Wait for all outstanding pending transactions.
- Assert the abort interrupt (if it is enabled) in DMA_WRITE_INT_STATUS_OFF.

You might do this as part of error handling which is described in “Error Handling Assistance by Remote Software”, which is only necessary during software development if you incorrectly program the DMA write channel DAR. You might also do this as part of a function level reset (FLR). FLR does not directly affect the DMA transfer so you must manually stop the DMA transfer before initiating an FLR.

Use This Feature With Caution in Linked List Mode

You should not use the STOP feature in operational mode. It is only a debug feature and has associated hazards.

- Before setting the Stop bit, you must read the channel status field (CS) of the DMA Channel Control 1 register to ensure that the corresponding channel is Running (transferring data). To eliminate the possibility of a race condition between these two actions (read and write), you should confirm the presence of the abort bit in the DMA Write Interrupt Status Register (DMA_WRITE_INT_STATUS_OFF) or DMA Read Interrupt Status Register (DMA_READ_INT_STATUS_OFF) and check the status of any fatal error if some other event has occurred.
- After a Stop event, you cannot seamlessly resume the transfer again because the DMA will not carry on exactly from the point that it was stopped at. Therefore you must setup and start the complete channel context again, including the
  - linked list pointer
  - linked list structure in memory
  - related PCS and CCS values

11.4.2.4.3.6 TLP Generator Header Control

You must program bits [31:12] of the DMA Channel Control 1 Register (DMA_CH_CONTROL1_REG_ WRCH_0/DMA_CH_CONTROL1_OFF_RDCH_0), so that the DMA TLP generator correctly sets the TC, RO, NS, AT, and FN TLP header fields for any TLPs that it generates. When SRIOV is enabled, then you must also program DMA_CH_CONTROL2_OFF_WRCH_0/ DMA_CH_CONTROL2_OFF_RDCH_0.

11.4.2.4.3.7 DMA Software Register Map

This section discusses the grouping and access methods of the DMA registers. The following registers are present when the DMA is enabled.

The DMA Global Registers control the global settings

Table 11-36. DMA Global Registers

Name	Description
0x8_0000 +0x000	DMA Arbitration Scheme for TRGT1 Interface
+0x008	Number of DMA Channels
+0x00C	DMA Write Engine Enable
+0x010	DMA Write Doorbell
+0x018	DMA Write Engine Channel Arbitration Weight Low
+0x01C	DMA Write Engine Channel Arbitration Weight High
+0x02C	DMA Read Engine Enable
+0x030	DMA Read Doorbell
+0x034	DMA Global Read Control
+0x038	DMA Read Engine Channel Arbitration Weight Low
+0x03C	DMA Read Engine Channel Arbitration Weight High

The DMA Interrupt Registers control the generation of local interrupts and remote IMWr. The IMWr addresses and data are stored in RAM.

Table 11-37. DMA Interrupt Registers

Byte Offset	Description
0x8_0000 +0x4C	DMA Write Interrupt Status
+0x50	Not used (RsvdP).
+0x54	DMA Write Interrupt Mask
+0x58	DMA Write Interrupt Clear
+0x5C	DMA Write Error Status
+0x60	DMA Write Done IMWr Address Low
+0x64	DMA Write Done IMWr Address High
+0x68	DMA Write Abort IMWr Address Low
+0x6C	DMA Write Abort IMWr Address High
+0x70	DMA Write Channels 1 and 0 IMWr Data
+0x84	DMA Write Channels 3 and 2 IMWr Data
+0x88	DMA Write Channels 5 and 4 IMWr Data
+0x8C	DMA Write Channels 7 and 6 IMWr Data
+0x90	DMA Write Linked List Error Enable
up to +0x9C	Not used (RsvdP).
+0xA0	DMA Read Interrupt Status
+0xA4	Not used (RsvdP).
+0xA8	DMA Read Interrupt Mask
+0xAC	DMA Read Interrupt Clear
+0xB0	Not used (RsvdP).
+0xB4	DMA Read Error Status Low
+0xB8	DMA Read Error Status High

Table continues on the next page...

Table 11-37. DMA Interrupt Registers (continued)

up to +0xC0	Not used (RsvdP).
+0xC4	DMA Read Linked List Error Enable
+0xC8	Not used (RsvdP).
+0xCC	DMA Read Done IMWr Address Low
+0xD0	DMA Read Done IMWr Address High
+0xD4	DMA Read Abort IMWr Address Low
+0xD8	DMA Read Abort IMWr Address High
+0xDC	DMA Read Channels 1 and 0 IMWr Data
+0xE0	DMA Read Channels 3 and 2 IMWr Data
+0xE4	DMA Read Channels 5 and 4 IMWr Data
+0xE8	DMA Read Channels 7 and 6 IMWr Data

DMA Channel Context Registers: these registers (which are stored in RAM) are for the control and status information that is specific to each channel. There is a set of registers for each channel.

Table 11-38. DMA Channel Context Registers for Each Channel

Byte Offset	Description
DMA Channel Context	
0x8_0000 + 0x200*ia + 0x100*(WR|RD)b	DMA Channel Control 1 Register
+0x004*i + 0x200*i + 0x100 *(WR|RD)	DMA Channel Control 2 Register
+0x008*i + 0x200*i + 0x100 *(WR|RD)	DMA Transfer Size
+0x00C*i +0x200*i + 0x100 *(WR|RD)	DMA SAR Low
+0x010*i + 0x200*i + 0x100 *(WR|RD)	DMA SAR High
+0x014*i + 0x200*i + 0x100 *(WR|RD)	DMA DAR Low
+0x018*i + 0x200*i + 0x100 *(WR|RD)	DMA DAR High
+0x01C*i + 0x200*i + 0x100 *(WR|RD)	DMA Linked List Pointer Low
+0x020*i + 0x200*i + 0x100 *(WR|RD)	DMA Linked List Pointer High

a. i is the number of channels

b. WR=0 | RD=1

11.4.2.4.3.7.1 Implementation of Channel Context Registers

- The channel context registers are stored in RAM whose contents are automatically initialized after power-on.
  - Therefore, you must program every “register” value as the default is undefined

  - You must program all fields marked Reserved to 1’b0
  - These registers are not affected by any of the reset signals
- You must not write to any of the context registers for a particular channel after you start the channel by writing the channel number to the Doorbell Number field of the DMA Write Door- bell Register (DMA_WRITE_DOORBELL_OFF) or DMA Read Doorbell Register (DMA_READ_DOORBELL_OFF).

Linked List Operation

When you enable linked list operation (Linked List Enable field of DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) t o 1b1), the DMA overwrites the following DMA channel context registers with the following information from linked list data elements:

- The CB, LLP, LIE, and RIE fields of the DMA Channel Control 1 register.
- DMA Transfer Size
- DMA SAR Low
- DMA SAR High
- DMA DAR Low
- DMA DAR High

NOTE

- The structure of a link element is different to that of the data element. A data element has no TCB field. A link element has no LIE or RIE fields. It has no SAR, DAR, or Transfer Size DWORDs, but has LL Element Pointer DWORDs instead of the SAR DWORDs. For more details, see Relationship Between Element DWORDs and Channel Context Registers.
- The LIE and RIE bits in a LL element, only enable the Done interrupt. In non-LL mode, the RIE and LIE bits enable the Done and Abort interrupts. For more information, see Interrupts and Error Handling.

11.4.2.4.3.8 Programming Examples

This section provides a programming and operation flow for each of the following scenarios:

- 1 MB Write Transfer On Write Channel #0 Initiated by Local CPU (Non LL mode)
- 1 MB Read Transfer On Read Channel #0 Initiated by Local CPU (Non LL mode)
- 1 MB Write Transfer On Write Channel #5 Initiated by Remote CPU (Non LL mode)

- 1 MB Read Transfer On Read Channel #5 Initiated by Remote CPU (Non LL mode)
- Linked List Mode Programming Example (Write Channel #0)

NOTE

The order in which the registers in the following examples are programmed is not important, except for the Doorbell register, which initiates the DMA transfer. Therefore, to start both a "1 MB Write Transfer On Write Channel #0 Initiated by Local CPU (Non LL mode)" and a "1 MB Read Transfer On Read Channel #0 Initiated by Local CPU (Non LL mode)" by executing the commands on the table. If, as mentioned in "Starting The DMA Transfer" , you want both channels to start at (approximately) the same time, then do not execute the last command (at 0x280) in the table 'DMA Register Setup' until after you have executed all the commands in table.

NOTE

You must enable the DMA before you start a DMA channel. Therefore you must write ‘1’ to DMA Read Engine Enable or DMA Write Engine Enable register before you write ‘1’ to the DMA Read Doorbell or DMA Write Doorbell register.

11.4.2.4.3.8.1 1 MB Write Transfer On Write Channel #0 Initiated by Local CPU (Non LL mode)

In this example, the IMWr generation is disabled, as the local CPU initiates the DMA transfer. The local CPU is interrupted using the edma_int bus. The SAR is the address of the local memory, and the DAR is the address of the remote memory, as shown in the figure below. The table below provides the programming details for this example transfer.

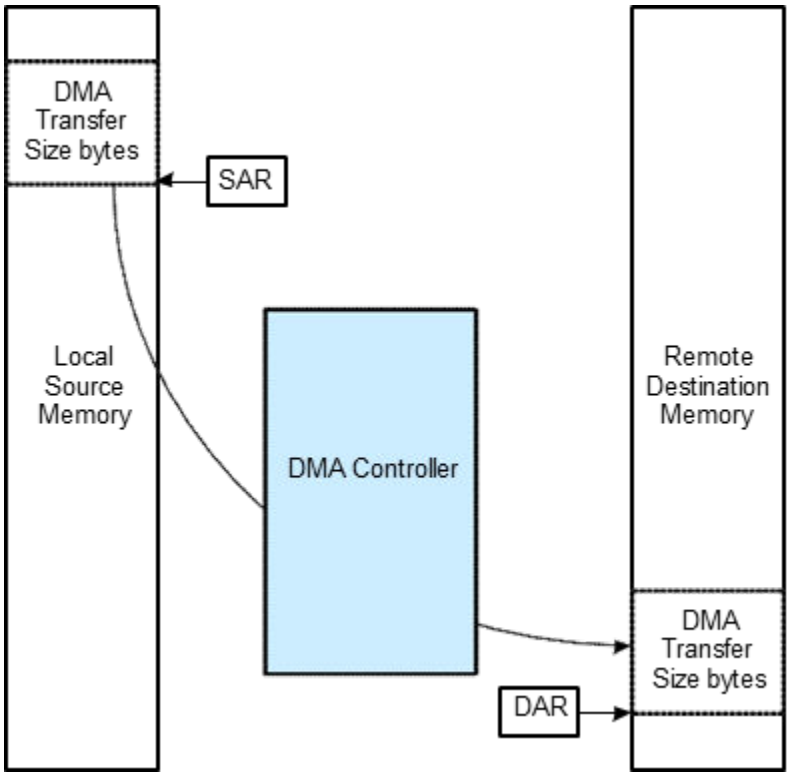

Figure 11-50. 1 MB Write DMA Transfer from 0xBEEF_BEE0 to 0xCAFE_CAF0

Table 11-39. 1 MB Write DMA Transfer from 0xBEEF_BEE0 to 0xCAFE_CAF0

Address (0x8_0000+)	Name	Value
0x00C	DMA Write Engine Enable You must not write 0 to this register. Even temporarily writing 0 to this register resets the DMA logic. For more details, see DMA Write Engine Enable Register (DMA_WRITE_ENGINE_EN_OFF).	0x1
0x054	DMA Write Interrupt Mask	0x0
0x200	DMA Channel Control 1 register • Local Interrupt Enable (LIE) =1 • Remote Interrupt Enable (RIE) =0 • AT, • RO, NS, TC, Function Number =0	0x04000008

0x210	DMA SAR High	0x0000_0000
0x214	DMA DAR Low	0xCAFE_CAF0
0x218	DMA DAR High	0x0000_0000
0x010	DMA Write Doorbell	0x0

11.4.2.4.3.8.2 1 MB Read Transfer On Read Channel #0 Initiated by Local CPU (Non LL mode)

In this example, the IMWr generation is disabled, as the local CPU initiates the DMA transfer. The local CPU is interrupted using the edma_int bus. The SAR is the address of the remote memory, and the DAR is the address of the local memory, as shown in the figure below. The table below provides the programming details for this example transfer.

0x310	DMA SAR High	0x0000_0000
0x314	DMA DAR Low	0xCAFE_CAF0
0x318	DMA DAR High	0x0000_0000
0x030	DMA Read Doorbell	0x0

11.4.2.4.3.8.3 1 MB Write Transfer On Write Channel #5 Initiated by Remote CPU (Non LL mode)

In this example, the local interrupt generation is disabled, as the remote CPU initiates the DMA transfer. The remote CPU is interrupted using an IMWr. The SAR is the address of the local memory, and the DAR is the address of the remote memory, as shown in the figure below. The table below provides the programming details for this example transfer.

11.4.2.4.3.8.5 Linked List Mode Programming Example (Write Channel #0)

This write channel example corresponds to figure 'Example Producer (Software) - Consumer (DMA) Synchronization Flow', with the following features:

- Recycled linked list (LL) of nine data elements1and one link element.
- Transfer is initiated by local CPU.
- Each data element corresponds to a 1 MB (0x0010_0000) write transfer.
- The SARs for each element are separated by 2 MB (0x0020_0000). The DAR for each element are sepa- rated by 16 MB (0x0100_0000). The SAR is the address of the local memory, and the DAR is the address of the remote memory, as shown in the figure below.
- The LL transfer list is located at address 0x0000_0200 in local memory.
- No remote interrupt is generated so the IMWr generation is disabled, as the local CPU initiates the DMA transfer. The local CPU is interrupted using the edma_int bus.
- There is a Watermark interrupt at element #5, and an Empty interrupt at element #8. Both of these interrupts are done interrupts (as opposed to abort interrupts).

You should familiarize yourself with the Linked List Flow for Producer and Consumer as shown in Figure 'Linked List Flow for Producer and Consumer'. These are the main steps for this process in this example:

Step 1: Create TL in local memory:

- Create the 10 elements as per Table 'Linked List Element Initial Setup'.
  - For elements 0, 1, 2, 3, 4, 6, 7: RIE, LIE, LLP, CB =0,0,0,1
  - For element 5: RIE, LIE, LLP, CB =0,1,0,1 ❑For element 8: RIE, LIE, LLP, CB =0,1,0,1 ❑For element 9: LLP, TCB, CB =1,1,0
- For more details, see “PCS-CCS-CB-TCB Producer-Consumer Synchronization” and “Linked List Mode”

Step 2: Program and Start DMA:

- Configure and start the DMA registers as per Table 'DMA Register Setup'.

Step 4: Wait for done interrupt and recycle TL

- For more details, see “Using Interrupts for Linked List Producer-Consumer Synchronization”
- When recycling elements, consider “Element Recycling”

NOTE

If the DMA driver is running on the host and the interrupt service routine is reading local interrupts to determine if the transfer is successful, then you must set LIE and RIE in the same element and you should mask or ignore the local interrupt pin. Setting RIE and LIE in element A followed by RIE (only) in element B is not a verified usage scenario.

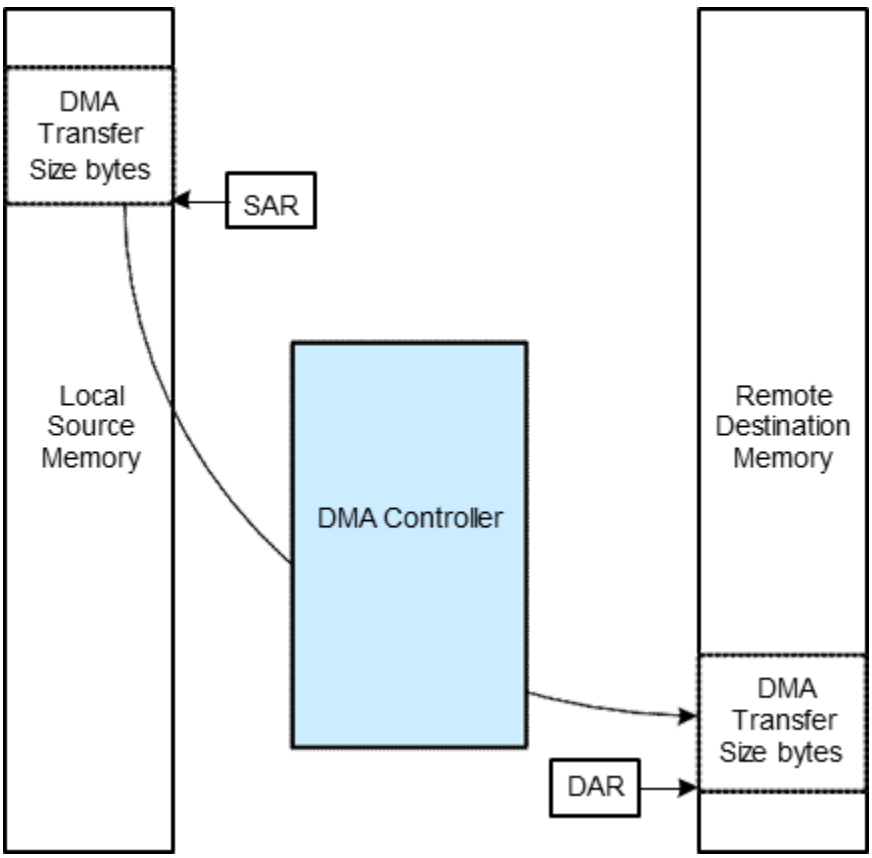

Figure 11-54. 1 MB Write DMA Transfer from SAR to DAR

11.4.2.4.4 Advanced DMA Information and Operation

This section discusses advanced features and operation of the DMA.

11.4.2.4.4.1 Overview

The DMA write and read channels operate independently to maximize the performance of the DMA read and write data transfers over the PCIe link.

The DMA can simultaneously perform the following types of memory transactions:

- DMA write: transfer (copy) of a block of data from local memory to remote memory
- DMA read: transfer (copy) of a block of data from remote memory to local memory

After you have programmed and started a DMA transfer (see "Using the DMA"), the DMA transfers the data as described in "**DMA Write Transfer"** and "**DMA Read Transfer"**

11.4.2.4.4.2 DMA Ordering

The DMA assumes that all DMA read channel data must be written to the local application memory in strict address order. For a DMA read transfer, each original outgoing request has a unique PCIe tag. The remote link partner or intermediate switch does not have to preserve the order of CPLs corresponding to such individual requests. When the DMA receives the CPLs out of order, it reorders that data in the "Read Buffer" as described in "**DMA Read Transfer"** . DMA write transfer data is sourced from the local application memory and sent to the remote memory in address order.

11.4.2.4.4.3 Error Handling

The DMA supports full AXI and PCIe error handling in conjunction with the PCIe controller. The tables below list the possible sources of an error for DMA read and write transfers.

Table 11-45. Possible Sources of an Error during a DMA Read Transfer

Source	Type	Description
Application Write Error Detected	Fatal	The DMA read channel has received an error response from the AXI bus at the bridge master interface (or TRGT1 interface when the AXI bridge is not used) while writing posted data to it. This error is fatal. • You must restart the transfer from the beginning because the channel context is corrupted.

Table continues on the next page...

Table 11-45. Possible Sources of an Error during a DMA Read Transfer (continued)

		• The MWr is not rolled back. • The AXI bridge master does not report this error to software through error logging or MSG. **NOTE:** During linked list mode, the Application Write Error only corrupts the current element in the linked list. This is because the DMA does not fetch the next element from local memory until it has completely finished transferring the current block of data (as defined by the current linked list element). Finished implies that your application has successfully acknowledged (without ERROR) all of the MWr requests.
Unsupported Request (UR)	Non-fatal	The DMA read channel has received a PCIe UR CPL status from the remote device in response to the MRd request.
Completer Abort (CA)	Non-fatal	The DMA read channel has received a PCIe CA CPL status from the remote device in response to the MRd request.
CPL Time Out	Non-fatal	The DMA read channel has timed-out while waiting for the remote device to respond to the MRd request, or a malformed CplD has been received.
Data Poisoning	Fatal	The DMA read channel has detected data poisoning in the CPL from the remote device in response to the MRd request. The DMA read channel will drop the completion and then be halted.
Linked List Element Fetch Error Detected	Fatal	The DMA read channel has received an error response from the AXI bus (or TRGT1 interface when the AXI bridge is not used) while reading a linked list element from local memory.

Table 11-46. Possible Sources of an Error during a DMA Write Transfer

Source	Type	Description
Application Read Error Detected	Fatal	The DMA write channel has received an error response from the AXI bus at the bridge master interface (or TRGT1 interface when the AXI bridge is not used) while reading data from it. • The response TLP is discarded by the DMA and is not converted to an outbound MWr TLP.

Table continues on the next page...

Table 11-46. Possible Sources of an Error during a DMA Write Transfer (continued)

		• The UR or CA CPL status TLP generated by the bridge is discarded by the DMA. • The AXI bridge master does not report this error to software through error logging or MSG.
Linked List Element Fetch Error Detected	Fatal	The DMA write channel has received an error response from the AXI bus at the bridge master interface (or TRGT1 interface when the AXI bridge is not used) while reading a linked list element from local memory. • The UR or CA CPL status TLP generated by the bridge is discarded by the DMA. • The AXI bridge master1 does not report this (or for non-DMA traffic) error to software through error logging or MSG.

When the DMA detects an error, it performs the following actions (for the channel with the error):

- Stops issuing new requests to the remote link partner.
- Stops issuing new requests.
  - All data in the “Read Buffer”, that was received before the error was detected, is valid. In the case of a non-fatal error, this is reflected in the DMA Transfer Size Register DMA_TRANSFER_SIZE_OFF_WRCH_0.
  - All data in the read buffer (for that channel), that was received after the error was detected, is discarded.
- Places the DMA channel in a halted state (channel status field of the DMA Channel Control 1 Register is halted).
- Waits for all outstanding requests and CPLs to complete.
- Generates the abort interrupt or IMWr, if enabled, as outlined in “Interrupt Handling”.

For a DMA read transfer, you can read the DMA Read Error Status High Register (DMA_READ_ERR_ STATUS_HIGH_OFF) and DMA Read Error Status Low Register (DMA_READ_ERR_STATUS_LOW_OFF) to identify the source of the error. For a DMA write transfer (in linked list mode only), you can read the DMA Write Error Status Register (DMA_WRITE_ERR_STATUS_OFF) to identify the source of the error. After your software has finished error and interrupt routine handling for Non-Fatal errors, you can request the DMA to continue processing (for the channel with the error) by:

1. Reprogramming the SAR based on the number of bytes remaining in the DMA Transfer Size register
2. Writing the channel number to the Doorbell Number field of the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF) or DMA Read Doorbell Register (DMA_READ_DOORBELL_REG).

NOTE

You cannot continue after a Fatal Error is detected, as the channel context is corrupted. Any actions that were in progress are not rolled back. To exit from this condition, you need to Soft Reset the complete DMA controller, as described in DMA Write Engine Enable Register (DMA_WRITE_ENGINE_EN_OFF) and DMA Read Engine Enable Register (DMA_READ_ENGINE_EN_OFF).

When an error occurs in linked list mode, the next LL element is not fetched from local memory. DMA Linked List Pointer Low Register (DMA_LLP_LOW_OFF_WRCH_0) is not incremented by the DMA, but remains pointing to the element that caused the error.

11.4.2.4.4.3.1 Error Handling Assistance by Remote Software

During a DMA write transfer, the DMA is not aware of MWr errors that are detected in the remote device, because an MWr is a posted request and has no corresponding completion TLP. In these cases, your remote CPU must manually abort the DMA transfer by writing the channel number to the Doorbell Number field, and 1 to the Stop field of the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF). This causes the DMA to:

- Place the channel in a stopped state. The channel Status field of the DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) is stopped and the DMA Transfer Size register is not 0x0.
- Wait for all outstanding pending transactions.
- Assert the abort interrupt if it is enabled

11.4.2.4.4.4 Linked List Operation

This section describes the detailed operation of the DMA in linked list (LL) mode. It also discusses how the software should produce LL elements1, and how the DMA and software maintain synchronization.

11.4.2.4.4.4.1 LL Operation Overview

You should first read "Linked List Mode" for an overview of LL mode. In this section, a normal LL operation called recycling2 is described in detail. The process is described for a write channel, but it is possible to have duplicate processes running in parallel for other write or read channels. In this process interrupts are used to trigger the producer (software) to recycle elements. Typically a Watermark interrupt (positioned near the middle of the transfer list (TL)) and an Empty interrupt (in the last data element) are used by setting LIE in these two elements to '1'.

The steps in this process are:

1. Software creates a LL element structure called a TL in local memory consisting of N-1 data elements and one link element.

   The link elements "LL Element Pointer Low/High DWORDs"(as shown in Linked List Element figure in Linked List Mode topic) are programmed to point back to the beginning of the first data element.

   One of the data elements (near the middle of the TL) is programmed to generate a "Watermark" interrupt.

   The last data element is programmed to generate an "Empty" interrupt.

2. Software programs the DMA with the location of the TL. This is done by writing to the DMA Linked List Pointer Low Register (DMA_LLP_LOW_OFF_WRCH_0) and DMA Linked List Pointer High Register (DMA_LLP_HIGH_OFF_WRCH_0).
3. Software starts the DMA process by ringing the write channel Doorbell. This is done by writing to the DMA Write Doorbell Register (DMA_WRITE_DOORBELL_OFF).

   The solid purple loop L1 in Figure 11-55 corresponds to steps 1-3.

4. The DMA reads (**consumes**) each data element from local memory, and if the CB and CCS bits match, loads the information (SAR, DAR, size, and so on) from that data element into the channel context registers. These context registers determine the operation of the channel that the DMA is currently servicing. The DMA executes the check for the CB/CCS match after it has evaluated TCB and toggled CCS. The DMA always loads link elements into the channel context.

NOTE

If the DMA stops on a link element, then your software must set the DMA Linked List Pointer registers, and restart the DMA process by ringing the doorbell.

With recycling, the same LL structure is used over and over again. Another mode of operation would be to jump to a new LL element structure when the current one is consumed.

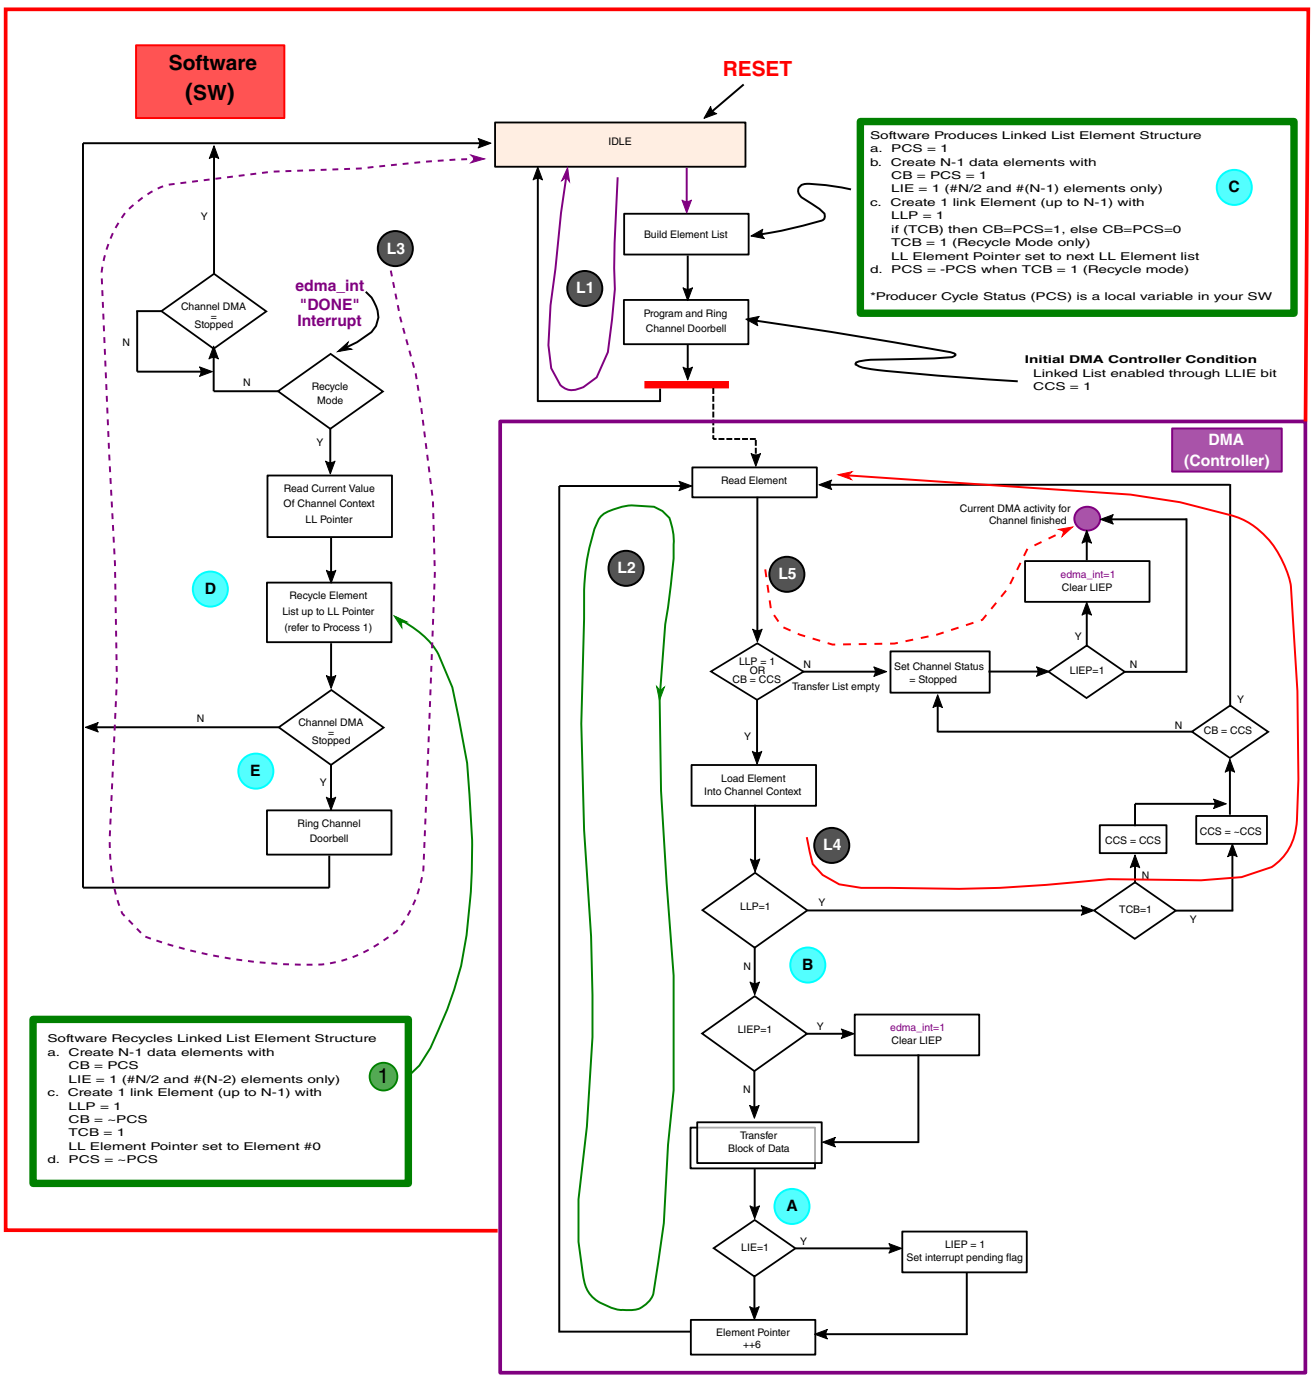

Figure 11-55. Linked List Flow for Producer and Consumer

5. The DMA then proceeds to transfer the block of data (as defined by the element), and when it is finished, reads the next element from local memory.

The solid green loop L2 in Figure 11-55 corresponds to steps 4-5.

6. The last element in the list (called a link element, and indicated by having its LLP field set to 1) is not used to transfer a block of data.

   It causes the DMA to effectively repeat the task in step 4.

   Its TCB is typically set to 1. This causes the DMA to toggle its CCS bit, and the software to toggle its PCS bit. The software and DMA use the "PCS-CCS-CB-TCB" producer-consumer synchronization mechanism to ensure that:

   Software does not recycle elements that have not yet being consumed by the DMA

   DMA correctly recognizes and consumes recycled elements. The solid red loop L4 in Figure 11-55 corresponds to step 6.

7. Upon reception of the interrupt (mentioned in step 1), the software starts to recycle the TL.

   Software reprograms each data element with new DMA transfer information.

   The software and DMA use the "PCS-CCS-CB-TCB" producer-consumer synchronization mecha- nism described later in this section.

   The dashed purple loop L3 in Figure 11-55 corresponds to step 7.

8. As some point, the software wants to terminate the complete DMA process, by not recycling any more elements. The DMA recognizes this condition when CB !=CCS, and sets the channel status to stopped

   The dashed red loop L5 in Figure 11-55 corresponds to step 8.

11.4.2.4.4.4.2 Using Interrupts for Linked List Producer-Consumer Synchronization

When the DMA is finished with an element, the DMA checks the LIE bit, before reading the next LL element. For more details, see circled step A in Figure 11-55. When the LIE is set, then the DMA does not assert the "done" interrupt immediately, but sets an internal interrupt pending flag (LIEP). It asserts the actual done interrupt after the next data element has been read from system memory. For more details, see circled step B in Figure 11-55. This automatic internal process of delaying the interrupt avoids a race condition between the DMA and software when the LIE bit is set in an element.

Your software should set the "Watermark" interrupt early to schedule the recycling of the consumed elements. Placing the Watermark interrupt too far down in the list, combined with a slow element recycling process in your application; ensures that the DMA returns to the start of the LL before your software has recycled it. The DMA channel STOPs, and you have to restart it by writing to its Doorbell. Typically a "Watermark interrupt"

(positioned near the middle of the TL) and an Empty interrupt (in the last data element) are used by setting LIE in these two elements to 1b1. Upon reception of the interrupt, the software starts to recycle the TL.

Operational interrupts are always "done" interrupts. For more details, see "Interrupts and Error Handling"

NOTE

The DMA processes the remote interrupt enable (RIE) bit in the LL element in the same way as the LIE. Therefore, everywhere that LIE and edma_int are mentioned in this section can be interpreted to mean LIE and edma_int, or RIE and IMWr.

11.4.2.4.4.4.3 PCS-CCS-CB-TCB Producer-Consumer Synchronization

The software and DMA use the "PCS-CCS-CB-TCB" producer-consumer synchronization mechanism to ensure that software does not recycle elements that have not yet being consumed by the DMA, and that the DMA correctly recognizes and consumes recycled elements. This process, which is shared between the DMA and the software, is illustrated through an example producer-consumer flow in the figure below.

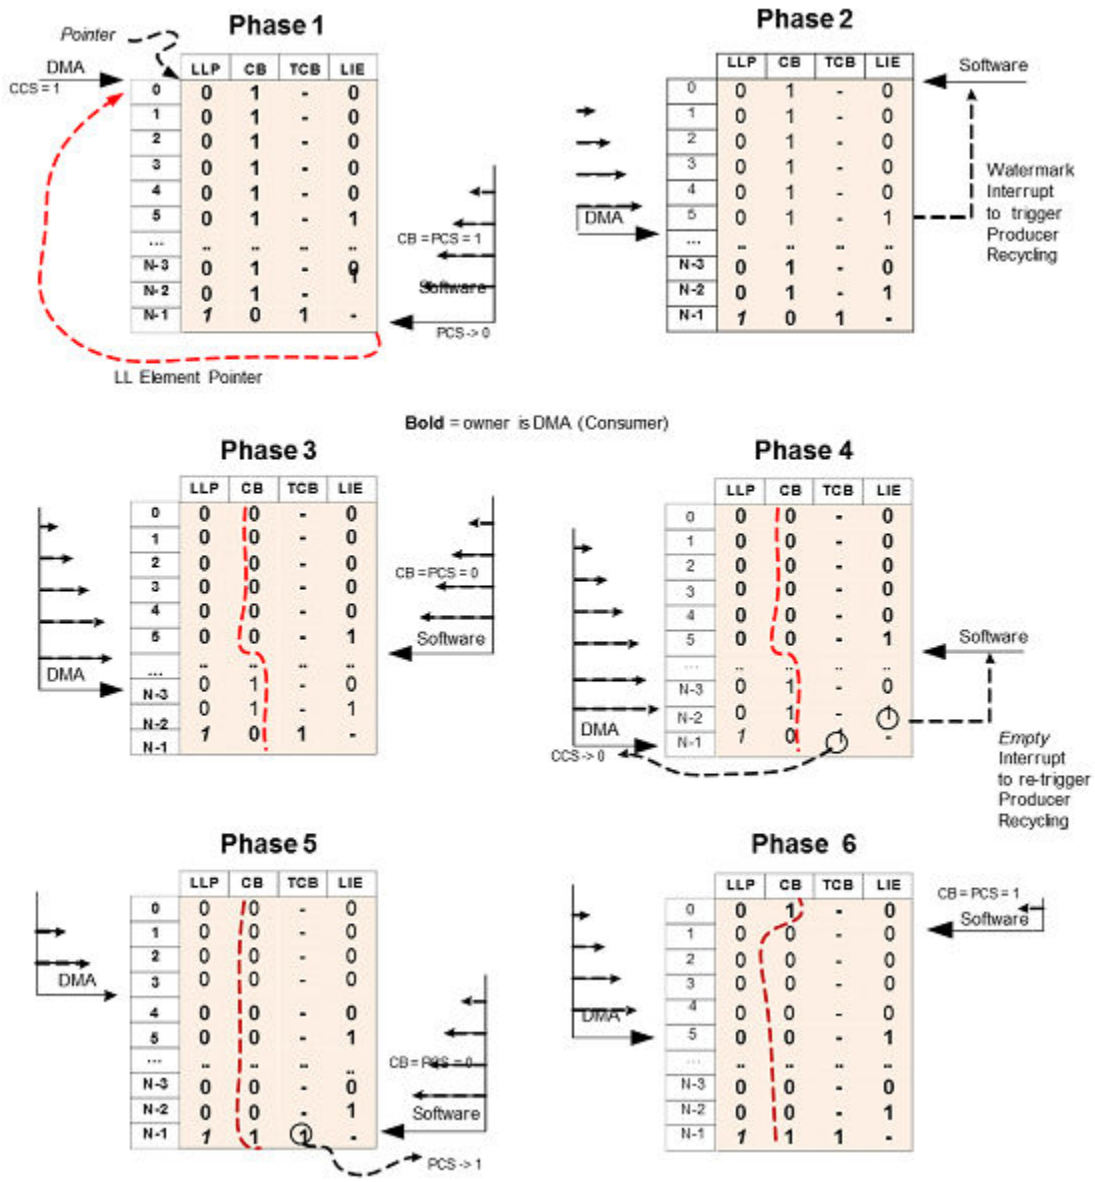

Figure 11-56. Example Producer (Software) - Consumer (DMA) Synchronization Flow

Before looking at the example in detail, it is useful to note that the DMA performs the following two tests as part of this process:

- Consumer-Owned Element, or Transfer List (TL) Empty Test

  The solid red loop L4 in the Figure 11-55 corresponds to this test. The Cycle Bit (CB) of DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) (which was loaded from the LL element) is tested against the DMA Consumer Cycle State (CCS) bit of the same register. When CB =CCS, the element is owned by the consumer (DMA) and the data transfer

is executed. When CB !=CCS, the TL is empty and the DMA sets channel Status (CS) in DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) to "Stopped".

- Toggle Cycle Bit (TCB) Test

  The Dashed Red Loop Marked L5 in Figure 11-55 corresponds to this test. When the Toggle Cycle Bit (TCB) of the DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) (which was loaded from the LL element) is set to 1, the DMA toggles the CCS bit of the DMA Channel Control 1 Register (DMA_CH_CONTROL1_OFF_WRCH_0) to be ~CB. The producer (software) also performs a similar action on its local variable "Producer Cycle Status" (PCS), as it sets PCS =~PCS. The TCB field is only valid in the last LL element (the link element). Toggling the PCS and CCS flags in this manner synchronizes the consumer to the producer.

The example in Figure 11-56 has the following six phases:

1. The software builds the transfer list for the write (or read) channel, according to the steps outlined in the circled step C in Figure 11-55. For each element, CB =PCS =CCS =1. The exception to this is the link element where CB is set to the next iteration value because the link element is always loaded into the channel context.
   - The link element points to the start of the TL and its TCB bit is 1. Software toggles its PCS variable.
   - Software writes the location of the TL into the channel context LL Pointer register.
   - Software rings the write channel Doorbell.
2. The DMA starts processing elements. After processing element 5 (and fetching the next element), the DMA asserts a Watermark “done” interrupt to signal the software to start recycling elements.
3. The software is recycling elements. It reads the channel context DMA Linked List Pointer Low Register (DMA_LLP_LOW_OFF_WRCH_0) and DMA Linked List Pointer High Register (DMA_LL- P_HIGH_OFF_WRCH_0), and recycles elements up to this location1in the TL. It sets CB for each element to be PCS. The Dashed Purple Loop Marked L3 in Figure 11-55 corresponds to this activity. The DMA continues processing (consuming) elements as before.
4. The DMA then asserts an Empty “done” interrupt (from the LIE bit in the last data element at the end of TL that was set in the previous phase) to indicate to the software, to start recycling elements again. The DMA reaches the end of the TL, and as the TCB is set to 1, it toggles its CCS bit to 0 (~CB). For more details, see circled step D in Figure 11-55.
5. The software reads the channel context DMA Linked List Pointer Low Register (DMA_LLP_LOW_REG_WRCH_0) and DMA Linked List Pointer High Register

(DMA_LLP_HIGH_OFF_WRCH_0), and recycles elements up to this location in the TL. It sets CB for each element to be PCS. As it recycles the link element, it detects that TCB is set to 1. It toggles its internal variable PCS to 0, and the initial TL has been fully recycled. The DMA starts processing the recycled elements.

6. The DMA continues processing (consuming) elements as before. Software did not have to ring the Doorbell, as the first element was already recycled before the DMA started processing it. The software might continue recycling from the top of the list, if the DMA had already returned to the top of the list when the software read the channel context DMA Linked List Pointer Low Register (DMA_LLP_LOW_OFF_WRCH_0) and DMA Linked List Pointer High Register (DMA_LL-P_HIGH_OFF_WRCH_0), in step 5. If not, it starts recycling again when the DMA processes element 4 and the DMA asserts a Watermark “done” interrupt.

11.4.2.4.4.4.4 Element Recycling

When your software is recycling elements, it should program the first DWORD (control bits) in the Figure 11-47 only after the other DWORDs have been programmed. In addition, it should set the CB bit (to ~PCS) within this DWORD only after the other bits in this DWORD have been set. This programming sequence avoids the DMA incorrectly fetching an element that software is currently recycling.

When the software is finished recycling it must check the channel context status (CS). When CS is "Stopped", the software must ring the channel Doorbell again. For more details, see circled step E in Figure 11-43. If your element recycling process was fast enough, then the DMA will seamlessly move from processing the last old element to the first new element, without the need for the software to ring the channel Doorbell again. To eliminate the possibility of a race condition between these two actions (read and write), you should first confirm the presence of the "done" interrupt bit in the DMA Write Interrupt Status Register (DMA_WRITE_INT_STATUS_OFF) or DMA Read Interrupt Status Register (DMA_READ_INT_ STATUS_OFF) and also check the DMA Linked List Pointer Low Register (DMA_LLP_LOW_REG_WRCH_0) to confirm that it is pointing to the correct location.

11.4.2.4.4.4.5 Link Down Recovery

During normal operation when the link goes down, the controller generates a "link reset" request. A

high-to-low transition on link_req_rst_not indicates that the PCIe controller is requesting external logic to reset the PCIe controller because the PHY link is down. For more details, see "Hot Reset". To determine the progress of the linked list operation when the

link went down, you can read the contents of the channel context DMA Linked List Pointer Low Register (DMA_LLP_LOW_OFF_WRCH_0) and DMA Linked List Pointer High Register (DMA_LLP_HIGH_OFF_WRCH_0).

11.4.2.4.4.5 Multichannel Arbitration

A DMA write and read channel operate independently in full duplex mode. This maximizes the performance of the DMA read and write data transfers over the PCIe link. When DMA is configured with multiple read channels, it uses a weighted round robin (WRR) arbitration scheme to select the next read channel to be serviced. The same applies when you have multiple write channels. The DMA handles the multiple channels in a time-multiplexed way. From a software point of view every channel operates independently, so each one has its own instance of linked list and context. The bandwidth for all channels is shared in time and is controlled by a weighted round-robin arbiter.

The arbitration weight for each channel can be set using the DMA_WRITE_CHANNEL_ARB_WEIGHT_LOW_OFF, DMA_WRITE_CHANNEL_ARB_WEIGHT_HIGH_OFF), DMA_READ_CHANNEL_ARB_WEIGHT_LOW_REG, and DMA_READ_CHANNEL_ARB_WEIGHT_HIGH_OFF registers. Each register has a 5-bit field (representing a weight from 1 to 32) for up to four channels. The weights must be set before "ringing" the doorbell.

The channel weight specifies the number of TLP requests that the DMA can issue for that channel before it must return to the arbitration routine. When the channel weight count is reached, the WWR arbiter selects the next channel to be processed. For example, consider two DMA write channels (write channel #0 and write channel #1) where you want to assign the bandwidth for write channel #1 to be two times that of write channel #3. Therefore set:

- Write channel #0 weight to 32
- Write channel #1 weight to 16

Depending on the transfer size and the Maximum Payload Size, the DMA will issue 32 MRd requests for write channel #0, followed by 16 MRd requests for write channel #1, followed by 32 MRd requests for write channel #0 and so on, until the current transfer (or element when using LL mode) is finished. Therefore in this example, the weights reserve 33% bandwidth for write channel #1 and 67% bandwidth for write channel #0.

NOTE

- Max tag constraints the maximum number of outstanding DMA write engine MRd requests to the application, so the

sum of weights should not exceed this value. The Max tag for this chip is 8.
- If these limits are exceeded, then the respective DMA engine requester thread is back back pressured, defeating purpose of the round-robin bandwidth sharing mechanism.
- When the ratio (transfer-size / TLP-size) is smaller than the round-robin arbiter setting (say, DMA_WRITE_CHANNEL_ARB_WEIGHT_LOW_OFF), the DMA issues less requests than the value in DMA_WRITE_CHANNEL_ARB_WEIGHT_LOW_OFF. The TLP size is determined by the DMA using each function's Maximum Payload Size and Maximum Read Request Size rules. This means that the arbitration value in DMA_WRITE_CHANNEL_ARB_WEIGHT_LOW_OFF determines the number of TLPs send and not the absolute data bandwidth.

11.4.2.4.4.5.1 Request, Response, and Descriptor-Fetch Threading In LL Mode For A Read Channel

For each read channel there are two threads (1) the request thread and (2) the response thread which are running in opposite directions. The DMA processes these threads independently. The request thread does not wait for the individual responses to arrive before issuing the next request. The request thread for the current channel i continues to issue requests until one of the following is true:

- The DMA exhausts its pool of available tags and the logic in the “Read Buffer” back-pres-sures the DMA read engine controller.
- The DMA completes its current DMA transfer block for the current channel. It has requested all of the data specified by the currently-loaded LL element.
- The current channel has issued Wi MRd requests, where Wi is the round robin weight associated with that channel.

A channel arbitration event now occurs and the DMA loads the context for the winning channel j. When the DMA is loading the new context, the response path for the previous channel i will be still utilizing the wire because the response thread lags the request thread. As soon as the DMA has loaded the context (and LL element if in LL mode) for the current channel j, it starts to issue requests. Therefore, in multichannel operation, when the block for channel i completes and a new LL element is been fetched, the DMA can be issuing requests belonging to other DMA channels. The currently inactive requester thread for channel i needs to synchronize with the response thread (that is, wait for all completions) before fetching its next LL element from local memory.

11.4.3 Memory Map and Register Definition

This section includes the PCIe module memory map and detailed descriptions of all registers.

NOTE

Synopsys Proprietary. Used with permission.

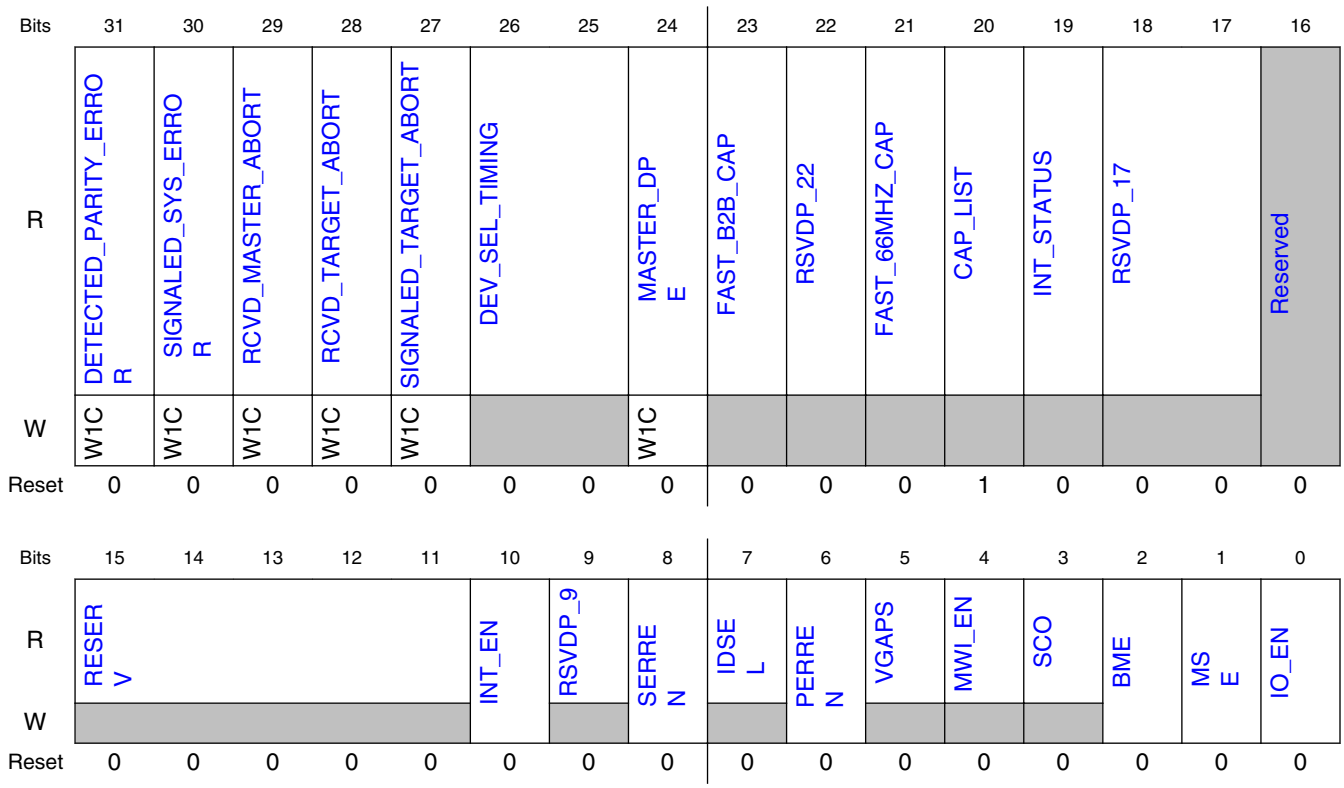
11.4.3.1.2.3 Fields



Field	Function
31-16 DEVICE_ID	Device ID. The Device ID register identifies the particular Function. This identifier is allocated by the vendor. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
15-0 VENDOR_ID	Vendor ID. The Vendor ID register identifies the manufacturer of the Function. Valid vendor identifiers are allocated by the PCI-SIG to ensure uniqueness. It is not permitted to populate this register with a value of FFFFh, which is an invalid value for Vendor ID. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

Register	Offset
TYPE1_STATUS_COMMAND_REG	4h

11.4.3.1.3.2 Diagram

11.4.3.1.3.3 Fields

Field	Function
31 DETECTED_PARITY_ERROR	Detected Parity Error. This bit is set by a Function whenever it receives a Poisoned TLP, regardless of the state the Parity Error Response bit in the Command register. The bit is set when the Poisoned TLP is received by a Function's primary side.
30 SIGNALED_SYS_ERROR	Signaled System Error. This bit is set when a Function sends an ERR_FATAL or ERR_NONFATAL Message, and the SERR# Enable bit in the Command register is 1b.
29 RCVD_MASTER_ABORT	Received Master Abort. This bit is set when a Requester receives a Completion with Unsupported Request Completion status. The bit is set when the Unsupported Request is received by a Function's primary side.
28 RCVD_TARGET_ABORT	Received Target Abort. This bit is set when a Requester receives a Completion with Completer Abort Completion status. The bit is set when the Completer Abort is received by a Function's primary side.
27 SIGNALED_TARGET_ABORT	Signaled Target Abort. This bit is set when a Function completes a Posted or Non-Posted Request as a Completer Abort error. This applies to a Function when the Completer Abort was generated by its primary side.
26-25	DEVSEL Timing. This field was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires it to 00b.

Table continues on the next page...

Field	Function
DEV_SEL_TIMING	
24 MASTER_DPE	Master Data Parity Error. This bit is set by a Function if the Parity Error Response bit in the Command register is 1b and either of the following two conditions occurs: - Port receives a Poisoned Completion going downstream - Port transmits a Poisoned Request upstream If the Parity Error Response bit is 0b, this bit is never set.
23 FAST_B2B_CAP	Fast Back-to-Back Transactions Capable. This bit was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
22 RSVDP_22	Reserved for future use.
21 FAST_66MHZ_CAP	66 MHz Capable. This bit was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
20 CAP_LIST	Capabilities List. Indicates the presence of an Extended Capability list item. Since all PCI Express device Functions are required to implement the PCI Express Capability structure, the controller hardwires this bit to 1b.
19 INT_STATUS	Interrupt Status. When set, indicates that an INTx emulation interrupt is pending internally in the Function. INTx emulation interrupts forwarded by Functions from the secondary side are not reflected in this bit. Setting the Interrupt Disable bit has no effect on the state of this bit. For Functions that do not generate INTx interrupts, the controller hardwires this bit to 0b.
18-17 RSVDP_17	Reserved for future use.
16 —	Reserved
15-11 RESERV	Reserved
10 INT_EN	Interrupt Disable. Controls the ability of a Function to generate INTx emulation interrupts. When set, Functions are prevented from asserting INTx interrupts. Note: - Any INTx emulation interrupts already asserted by the Function must be deasserted when this bit is set. INTx interrupts use virtual wires that must, if asserted, be deasserted using the appropriate Deassert_INTx message(s) when this bit is set. - Only the INTx virtual wire interrupt(s) associated with the Function(s) for which this bit is set are affected. - For Functions that generate INTx interrupts on their own behalf, this bit is required. This bit has no effect on interrupts forwarded from the secondary side. For Functions that do not generate INTx interrupts on their own behalf this bit is optional. If this bit is not implemented, the controller hardwires it to 0b.
9 RSVDP_9	Reserved for future use.
8 SERREN	SERR# Enable. When set, this bit enables reporting upstream of Non-fatal and Fatal errors detected by the Function. Note: The errors are reported if enabled either through this bit or through the PCI Express specific bits in the Device Control register. For more details see the "Error Registers" section of the PCI Express Specification. In addition, this bit controls transmission by the primary interface of ERR_NONFATAL and ERR_FATAL error Messages forwarded from the secondary interface. This bit does not affect the transmission of forwarded ERR_COR messages.
7 IDSEL	IDSEL Stepping/Wait Cycle Control. This bit was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
6 PERREN	Parity Error Response. This bit controls the logging of poisoned TLPs in the Master Data Parity Error bit in the Status register. For more details see the "Error Registers" section of the PCI Express Specification.

Table continues on the next page...

Field	Function
5 VGAPS	VGA Palette Snoop. This bit was originally described in the PCI Local Bus Specification and the PCI-to-PCI Bridge Architecture Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
4 MWI_EN	Memory Write and Invalidate. This bit was originally described in the PCI Local Bus Specification and the PCI-to-PCI Bridge Architecture Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b. For PCI Express to PCI/PCI-X Bridges, refer to the PCI Express to PCI/PCI-X Bridge Specification for requirements for this register.
3 SCO	Special Cycle Enable. This bit was originally described in the PCI Local Bus Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b.
2 BME	Bus Master Enable. This bit controls forwarding of Memory or I/O requests by a port in the Upstream direction. When this bit is 0b, Memory and I/O Requests received at a Root Port must be handled as Unsupported Requests (UR) For Non-Posted Requests a Completion with UR completion status must be returned. This bit does not affect forwarding of Completions in either the Upstream or Downstream direction. The forwarding of Requests other than Memory or I/O Requests is not controlled by this bit.
1 MSE	Memory Space Enable. This bit controls a Function's response to Memory Space accesses received on its primary side. - When set, the Function is enabled to decode the address and further process Memory Space accesses. - When clear, all received Memory Space accesses are caused to be handled as Unsupported Requests. You cannot write to this register if your configuration has no MEM bars; that is, the internal signal has_mem_bar =0. Note: The access attributes of this field are as follows: - Dbi: ! has_mem_bar ? RO : RW
0 IO_EN	IO Space Enable. This bit controls a Function's response to I/O Space accesses received on its primary side. - When set, the Function is enabled to decode the address and further process I/O Space accesses. - When clear, all received I/O accesses are caused to be handled as Unsupported Requests. You cannot write to this register if your configuration has no IO bars; that is, the internal signal has_io_bar =0. Note: The access attributes of this field are as follows: - Dbi: !has_io_bar ? RO : RW

11.4.3.1.4 Class Code and Revision ID Register. (TYPE1_CLASS_CODE_REV_ID_REG)

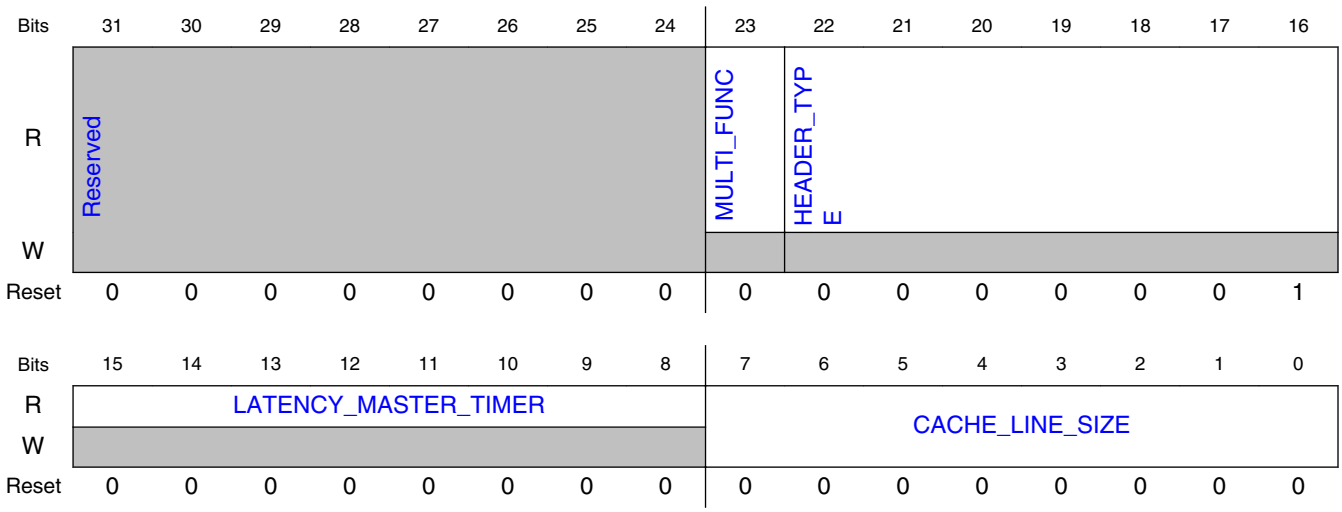
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

11.4.3.1.4.3 Fields



Field	Function
31-24 BASE_CLASS_CODE	Base Class Code. A code that broadly classifies the type of operation the Function performs. Encodings for base class, are provided in the PCI Code and ID Assignment Specification. All unspecified encodings are reserved. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
23-16 SUBCLASS_CODE	Sub-Class Code. Specifies a base class sub-class, which identifies more specifically the operation of the Function. Encodings for sub-class are provided in the PCI Code and ID Assignment Specification. All unspecified encodings are reserved. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
15-8 PROGRAM_INTERFACE	Programming Interface. This field identifies a specific register level programming interface (if any) so that device independent software can interact with the Function. Encodings for interface are provided in the PCI Code and ID Assignment Specification. All unspecified encodings are reserved. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
7-0 REVISION_ID	Revision ID. The value of this field specifies a Function specific revision identifier. The value is chosen by the vendor. Zero is an acceptable value. The Revision ID should be viewed as a vendor defined extension to the Device ID. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

11.4.3.1.5 Header Type, Latency Timer, and Cache Line Size Register. (TYPE1_HDR_TYPE_LAT_CACHE_LINE_SIZE_REG)

Register	Offset
TYPE1_HDR_TYPE_LAT_CACHE_LINE_SIZE_REG	Ch

11.4.3.1.5.2 Diagram

11.4.3.1.5.3 Fields

Field	Function
31-24 —	Reserved
23 MULTI_FUNC	Multi-Function Device. - When set, indicates that the device may contain multiple Functions, but not necessarily. Software is permitted to probe for Functions other than Function 0. - When clear, software must not probe for Functions other than Function 0 unless explicitly indicated by another mechanism, such as an ARI or SR-IOV Capability structure. Except where stated otherwise, it is recommended that this bit be set if there are multiple Functions, and clear if there is only one Function. Note: This register field is sticky.
22-16 HEADER_TYPE	Header Layout. This field identifies the layout of the second part of the predefined header. The controller uses 000 0001b encoding. The encoding 000 0010b is reserved. This encoding was originally described in the PC Card Standard Electrical Specification and is used in previous versions of the programming model. Careful consideration should be given to any attempt to repurpose it.
15-8 LATENCY_MASTER_TIMER	Latency Timer. This register is also referred to as Primary Latency Timer. The Latency Timer was originally described in the PCI Local Bus Specification and the PCI-to-PCI Bridge Architecture Specification. Its functionality does not apply to PCI Express. The controller hardwires this register to 00h.
7-0 CACHE_LINE_SIZE	Cache Line Size. The Cache Line Size register is programmed by the system firmware or the operating system to system cache line size. However, legacy conventional PCI software may not always be able to program this register correctly especially in the case of Hot-Plug devices. This read-write register is implemented for legacy compatibility purposes but has no effect on any PCI Express device behavior.

11.4.3.1.6 Secondary Latency Timer, Subordinate Bus Number, Secondary Bus Number, and Primary Bus Number Register. (SEC_LAT_TIMER_SUB_BUS_SEC_BUS_PRI_BUS_REG)

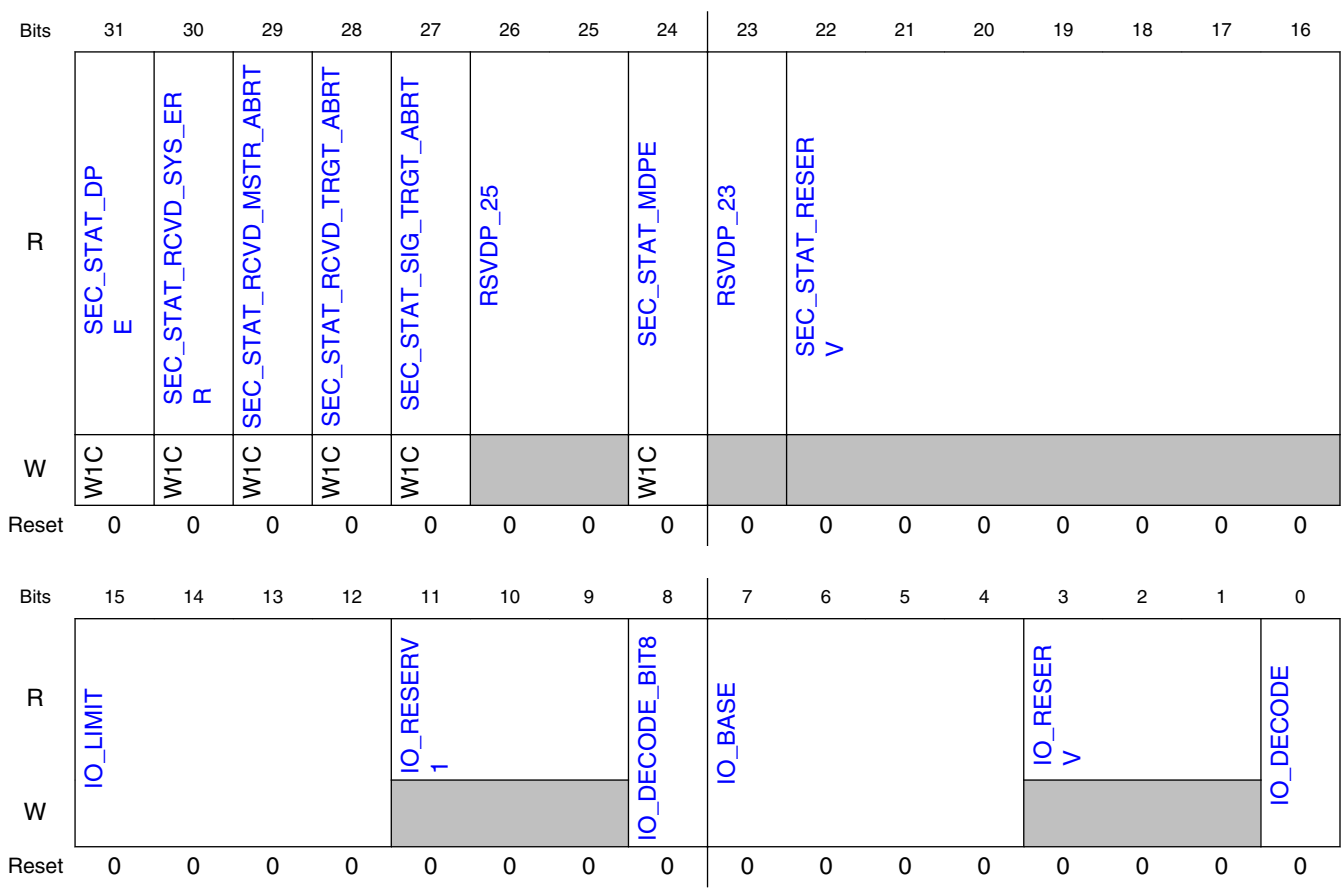
11.4.3.1.6.3 Fields

Field	Function
31-24 SEC_LAT_TIMER	Secondary Latency Timer. This register does not apply to PCI Express. The controller hardwires it to 00h.
23-16 SUB_BUS	Subordinate Bus Number. The Subordinate Bus Number register is used to record the bus number of the highest numbered PCI bus segment which is behind (or subordinate to) the bridge. Configuration software programs the value in this register. The bridge uses this register in conjunction with the Secondary Bus Number register to determine when to respond to and pass on a Type 1 configuration transaction on the primary interface to the secondary interface.
15-8 SEC_BUS	Secondary Bus Number. The Secondary Bus Number register is used to record the bus number of the PCI bus segment to which the secondary interface of the bridge is connected. Configuration software programs the value in this register. The bridge uses this register to determine when to respond to and convert a Type 1 configuration transaction on the primary interface into a Type 0 transaction on the secondary interface.
7-0 PRIM_BUS	Primary Bus Number. This register is not used by PCI Express Functions. It is implemented for compatibility with legacy software.

11.4.3.1.7 Secondary Status, and I/O Limit and Base Register. (SEC_STAT_IO_LIMIT_IO_BASE_REG)



11.4.3.1.7.1 Offset

Register	Offset
SEC_STAT_IO_LIMIT_IO_BASE_REG	1Ch

11.4.3.1.7.2 Function

Secondary Status, and I/O Limit and Base Register. The I/O Limit and I/O Base registers are optional and define an address range that is used by the bridge to determine when to forward I/O transactions from one interface to the other. If a bridge does not implement an I/O address range, then both the I/O Limit and I/O Base registers must be implemented as read-only registers that return zero when read. If a bridge supports an I/O address range, then these registers must be initialized by configuration software so default states are not specified.

11.4.3.1.7.3 Diagram

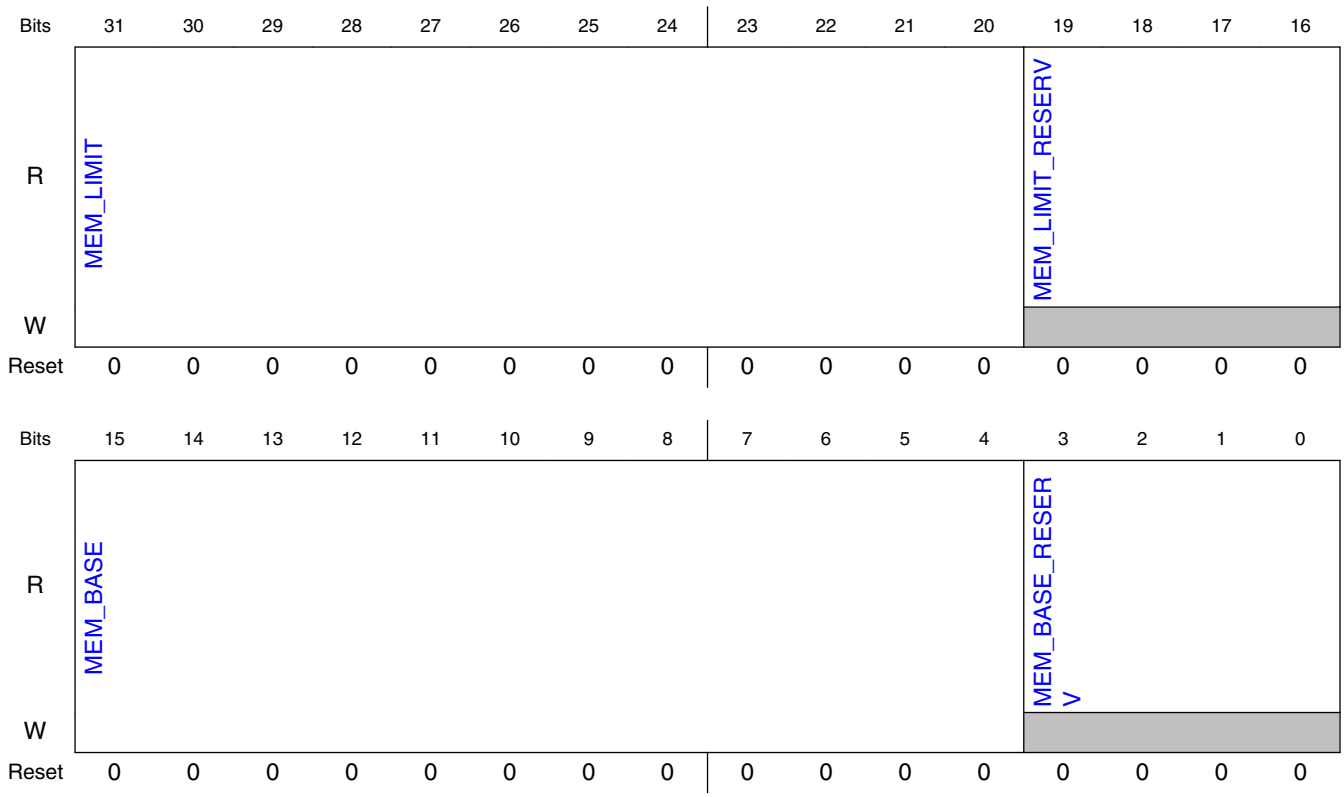
11.4.3.1.7.4 Fields

Field	Function
31 SEC_STAT_DPE	Detected Parity Error. This bit is set by a Function when a Poisoned TLP is received by its secondary side, regardless of the state the Parity Error Response Enable bit in the Bridge Control register.
30 SEC_STAT_RCVD_SYS_ERR	Received System Error. This bit is set when the secondary side of a Function receives an ERR_FATAL or ERR_NONFATAL message.
29 SEC_STAT_RCVD_MSTR_ABRT	Received Master Abort. This bit is set when the secondary side of a Function (for requests initiated by the Type 1 header Function itself) receives a Completion with Unsupported Request Completion status.
28 SEC_STAT_RCVD_TRGT_ABRT	Received Target Abort. This bit is set when the secondary side of a Function (for requests initiated by the Type 1 header Function itself) receives a Completion with Completer Abort Completion status.
27 SEC_STAT_SIG_TRGT_ABRT	Signaled Target Abort. This bit is set when the secondary side of the Function (for Requests completed by the Type 1 header Function itself) completes a Posted or Non-Posted request as a Completer Abort error.
26-25 RSVDP_25	Reserved for future use.
24 SEC_STAT_MDPE	Master Data Parity Error. This bit is set by a Function if the Parity Error Response Enable bit in the Bridge Control register is set, and either of the following two conditions occurs: - Port receives a Poisoned Completion coming Upstream - Port transmits a Poisoned Request Downstream If the Parity Error Response Enable bit is clear, this bit is never set.
23 RSVDP_23	Reserved for future use.
22-16 SEC_STAT_RESERV	Reserved
15-12 IO_LIMIT	I/O Limit Address. These bits correspond to the address[15:12] of IO address range. For the purpose of address decoding, the bridge assumes that the lower 12 address bits, address[11:0], of the I/O limit address (not implemented in the I/O Limit register) are FFFh. The I/O Limit register can be programmed to a smaller value than the I/O Base register, if there are no I/O addresses on the secondary side of the bridge. In this case, the bridge will not forward any I/O transactions from the primary bus to the secondary and will forward all I/O transactions from the secondary bus to the primary bus.
11-9 IO_RESERV1	Reserved
8 IO_DECODE_BIT8	I/O Addressing Encode (IO Limit Address). This bit encodes the IO addressing capability of the bridge. IO_DECODE_BIT8 indicates the following: - 0h: The bridge supports only 16-bit I/O addressing (for ISA compatibility). For the purpose of address decoding, the bridge assumes that the upper 16 address bits, Address[31:16], of the I/O limit address (not implemented in I/O Limit register) are zero. Note: The bridge must still perform a full 32-bit decode of the I/O address (that is, check that Address[31:16] are 0000h). In this case, the I/O address range supported by the bridge will be restricted to the first 64 KB of I/O Space (0000 0000h to 0000 FFFFh). - 01h: The bridge supports 32-bit I/O address decoding, and the I/O Limit Upper 16 Bits hold the upper 16 bits, corresponding to Address[31:16], of the 32-bit Limit address. In this case, system configuration software is permitted to locate the I/O address range supported by the bridge

Table continues on the next page...

Field	Function
	anywhere in the 4-GB I/O Space. Note: The 4-KB alignment and granularity restrictions still apply when the bridge supports 32-bit I/O addressing. Note: The access attributes of this field are as follows: - Dbi: R
7-4 IO_BASE	I/O Base Address. These bits correspond to the address[15:12] of IO address range. For the purpose of address decoding, the bridge assumes that the lower 12 address bits, address[11:0], of the I/O base address (not implemented in the I/O Base register) are zero.
3-1 IO_RESERV	Reserved
0 IO_DECODE	I/O Addressing Encode (IO Base Address) This bit encodes the IO addressing capability of the bridge. IO_DECODE indicates the following: - 0h: The bridge supports only 16-bit I/O addressing (for ISA compatibility). For the purpose of address decoding, the bridge assumes that the upper 16 address bits, Address[31:16], of the I/O base address (not implemented in I/O base register) are zero. Note: The bridge must still perform a full 32-bit decode of the I/O address (that is, check that Address[31:16] are 0000h). In this case, the I/O address range supported by the bridge will be restricted to the first 64 KB of I/O Space (0000 0000h to 0000 FFFFh). - 01h: The bridge supports 32-bit I/O address decoding, and the I/O Base Upper 16 Bits hold the upper 16 bits, corresponding to Address[31:16], of the 32-bit Base address. In this case, system configuration software is permitted to locate the I/O address range supported by the bridge anywhere in the 4-GB I/O Space. Note: The 4-KB alignment and granularity restrictions still apply when the bridge supports 32-bit I/O addressing. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R

11.4.3.1.8 Memory Limit and Base Register. (MEM_LIMIT_MEM_BASE_REG)



11.4.3.1.8.1 Offset

Register	Offset
MEM_LIMIT_MEM_BASE_REG	20h

11.4.3.1.8.2 Function

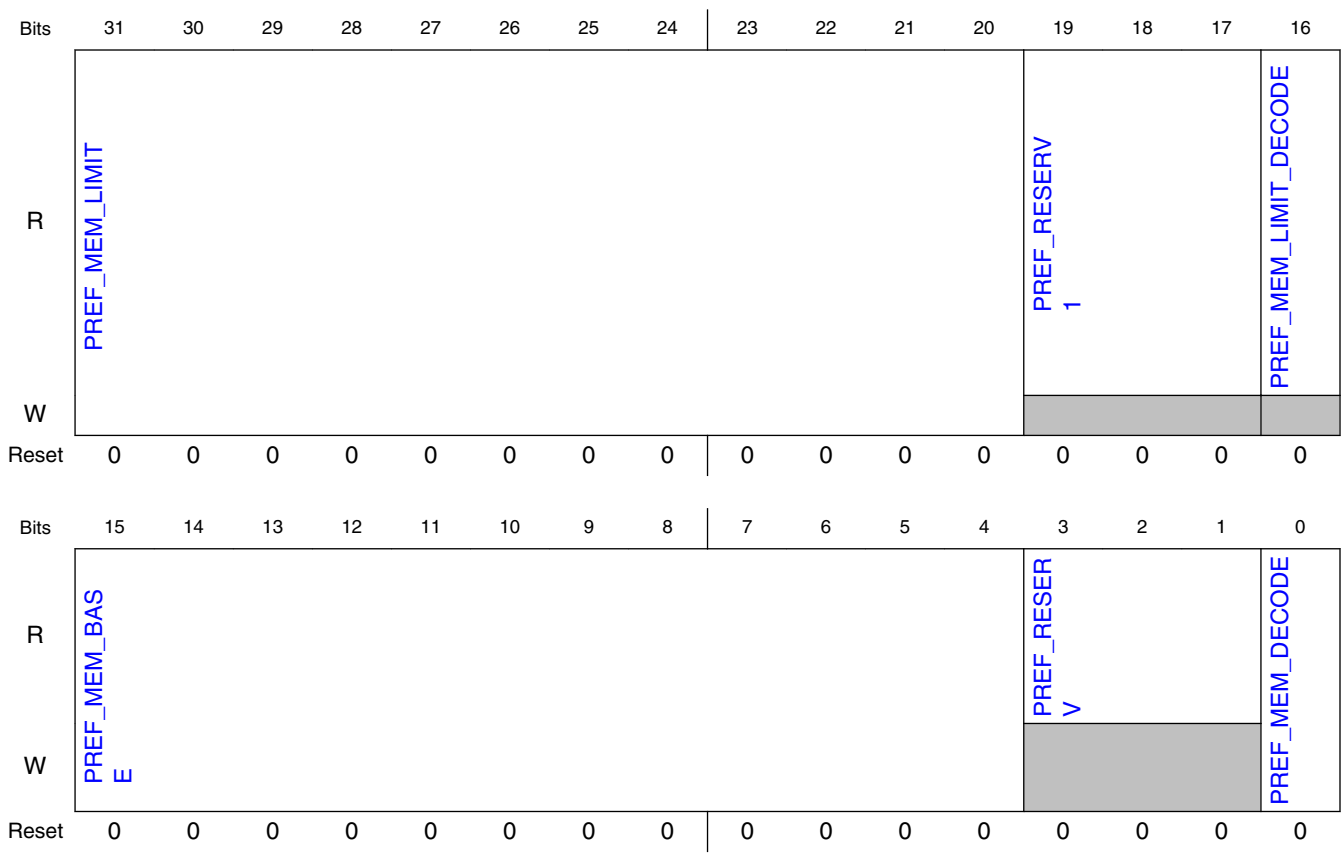
Memory Limit and Base Register. The Memory Limit and Memory Base registers define a memory mapped address range which is used by the bridge to determine when to forward memory transactions from one interface to the other. If there is no prefetchable memory space, and there is no memory-mapped space on the secondary side of the bridge, then the bridge will not forward any memory transactions from the primary bus to the secondary bus and will forward all memory transactions from the secondary bus to the primary bus.

11.4.3.1.8.3 Diagram

11.4.3.1.8.4 Fields

Field	Function
31-20 MEM_LIMIT	Memory Limit Address. These bits correspond to the upper 12 address bits, Address[31:20], of 32-bit addresses. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, Address[19:0], of the memory limit address (not implemented in the Memory Limit register) are F FFFFh. The Memory Limit register must be programmed to a smaller value than the Memory Base register if there is no memory-mapped address space on the secondary side of the bridge.
19-16 MEM_LIMIT_RESERV	Reserved
15-4 MEM_BASE	Memory Base Address. These bits correspond to the upper 12 address bits, Address[31:20], of 32-bit addresses. For the purpose of address decoding, the bridge assumes that the lower 20 address bits, Address[19:0], of the memory base address (not implemented in the Memory Base register) are zero.
3-0 MEM_BASE_RESERV	Reserved

11.4.3.1.9 Prefetchable Memory Limit and Base Register. (PREF_MEM_LIMIT_PREF_MEM_BASE_REG)



11.4.3.1.9.1 Offset

Register	Offset
PREF_MEM_LIMIT_PREF_MEM_BASE_REG	24h

11.4.3.1.9.2 Function

Prefetchable Memory Limit and Base Register. The Prefetchable Memory Limit and Prefetchable Memory Base registers must indicate that 64-bit addresses are supported, as defined in PCI-to-PCI Bridge Architecture Specification. The Prefetchable Memory Limit and Prefetchable Memory Base registers are optional. They define a prefetchable memory address range which is used by the bridge to determine when to forward memory transactions from one interface to the other (see the PCI-to-PCI Bridge Architecture Specification for additional details).

11.4.3.1.9.3 Diagram

11.4.3.1.9.4 Fields

Field	Function
31-20 PREF_MEM_LIMIT	Prefetchable Memory Limit Address. If the Prefetchable Memory Limit register indicates support for 32-bit addressing, then the Prefetchable Limit Upper 32 Bits register is implemented as a read-only register that returns zero when read. If the Prefetchable Memory Limit registers indicate support for 64-bit addressing, then the Prefetchable Limit Upper 32 Bits register is implemented as a read/write register which must be initialized by configuration software. If a 64-bit prefetchable memory address range is supported, the Prefetchable Limit Upper 32 Bits register specifies the upper 32 bits, corresponding to Address[63:32], of the 64-bit limit addresses which specify the prefetchable memory address range.
19-17 PREF_RESERV1	Reserved
16 PREF_MEM_LIMIT_DECODE	Prefetchable Memory Limit Decode. This bit encodes whether or not the bridge supports 64-bit addresses. The value of PREF_MEM_LIMIT_DECODE indicates the following: - 0b: Indicates that the bridge supports only 32 bit addresses - 1b: Indicates that the bridge supports 64 bit addresses. Prefetchable Limit Upper 32 Bits registers holds the rest of the 64-bit prefetchable limit address.
15-4 PREF_MEM_BASE	Prefetchable Memory Base Address. If the Prefetchable Memory Base register indicates support for 32-bit addressing, then the Prefetchable Base Upper 32 Bits register is implemented as a read-only register that returns zero when read. If the Prefetchable Memory Base register indicates support for 64-bit addressing, then the Prefetchable Limit Upper 32 Bits register is implemented as a read/write register which must be initialized by configuration software. If a 64-bit prefetchable memory address range is supported, the Prefetchable Base Upper 32 Bits register specifies the upper 32 bits, corresponding to Address[63:32], of the 64-bit base addresses which specify the prefetchable memory address range.
3-1 PREF_RESERV	Reserved
0 PREF_MEM_DECODE	Prefetchable Memory Base Decode. This bit encodes whether or not the bridge supports 64-bit addresses. The value of PREF_MEM_DECODE indicates the following: - 0b: Indicates that the bridge supports only 32 bit addresses. - 1b: Indicates that the bridge supports 64 bit addresses. Prefetchable Base Upper 32 Bits registers holds the rest of the 64-bit prefetchable base address. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.

11.4.3.1.12.4 Fields

Field	Function
31-16 IO_LIMIT_UPPER	I/O Limit Upper 16 Bits. If the I/O Limit register indicates support for 16-bit I/O address decoding, then this register is implemented as a read-only register which return zero when read. If the I/O Limit register indicates support for 32-bit I/O addressing, then this register must be initialized by configuration software. If 32-bit I/O address decoding is supported, this register specifies the upper 16 bits, corresponding to Address[31:16], of the 32-bit limit address, that specify the I/O address range. See the PCI-to-PCI Bridge Architecture Specification for additional details). Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
15-0 IO_BASE_UPPER	I/O Base Upper 16 Bits. If the I/O Base register indicates support for 16-bit I/O address decoding, then this register is implemented as a read-only register which return zero when read. If the I/O base register indicates support for 32-bit I/O addressing, then this register must be initialized by configuration software. If 32-bit I/O address decoding is supported, this register specifies the upper 16 bits, corresponding to Address[31:16], of the 32-bit base address, that specify the I/O address range. See the PCI-to-PCI Bridge Architecture Specification for additional details. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R

11.4.3.1.13 Capabilities Pointer Register. (TYPE1_CAP_PTR_REG)

11.4.3.1.13.1 Offset

W																
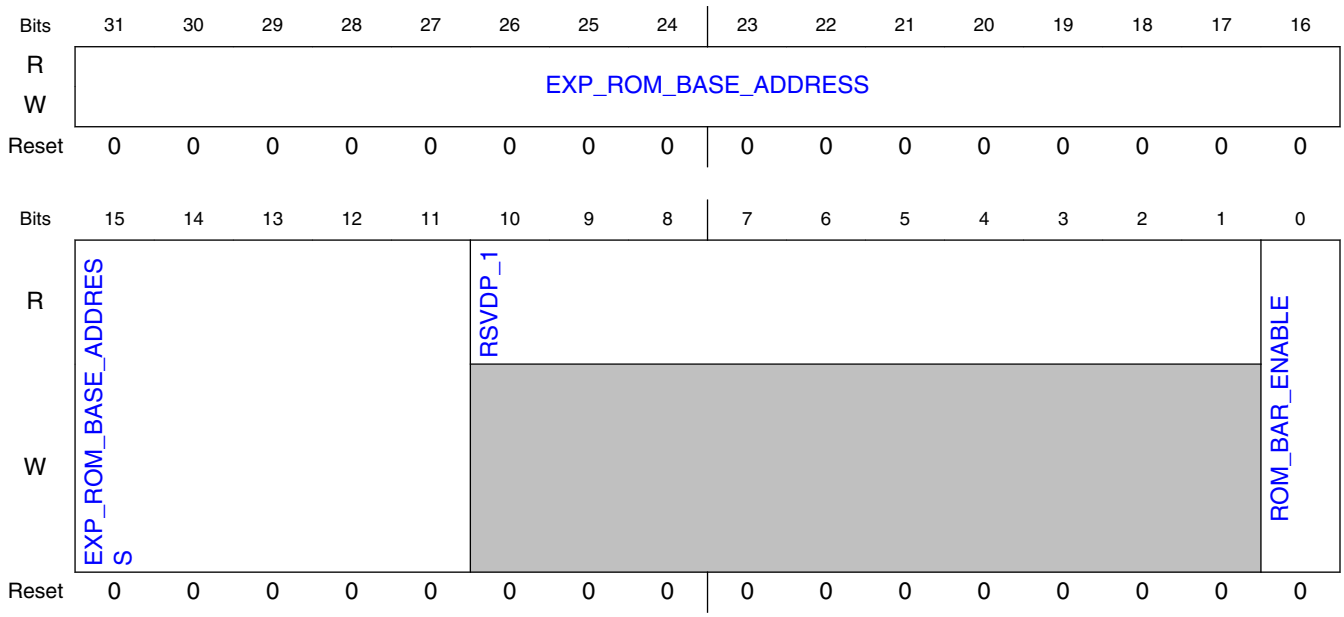
Reset	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

11.4.3.1.13.3 Fields

Field	Function
31-8 RSVDP_8	Reserved for future use.
7-0 CAP_POINTER	Capabilities Pointer. This register is used to point to a linked list of capabilities implemented by this Function. Since all PCI Express Functions are required to implement the PCI Express Capability structure, this register must point to a valid capability structure and either this structure is the PCI Express Capability structure, or a subsequent list item points to the PCI Express Capability structure. The bottom two bits are Reserved and must be set to 00b. Software must mask these bits off before using this register as a pointer in Configuration Space to the first entry of a linked list of new capabilities. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

11.4.3.1.14 Expansion ROM Base Address Register. (TYPE1_EXP_ROM_BASE_REG)



11.4.3.1.14.1 Offset

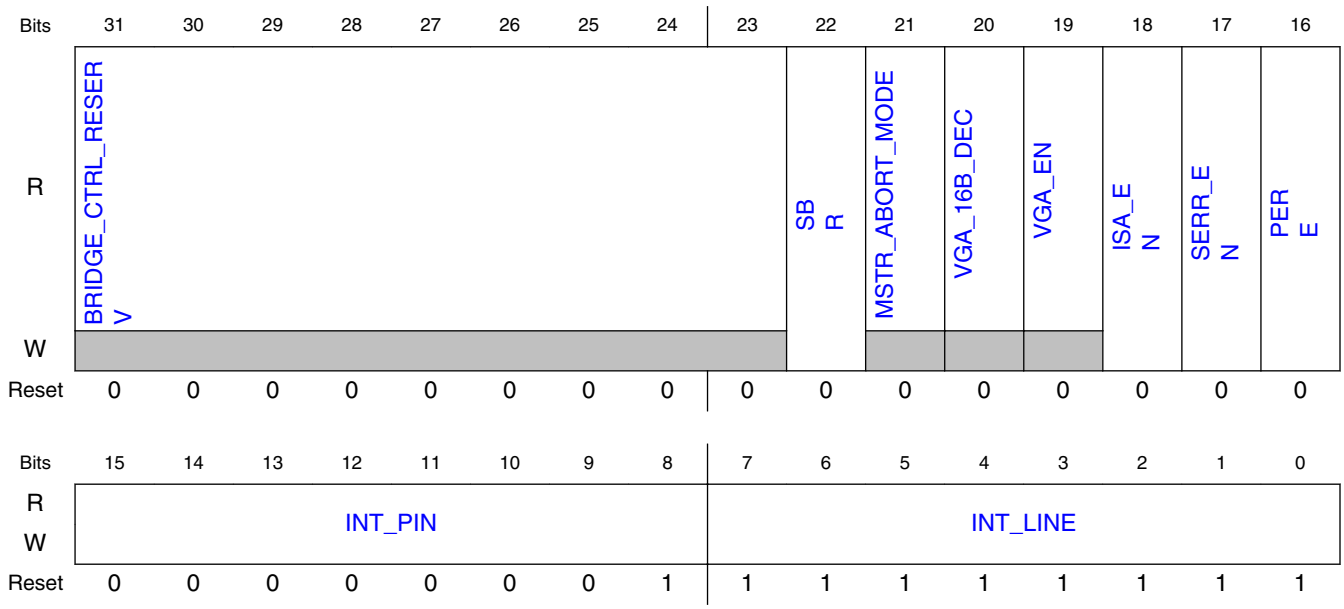
Register	Offset
TYPE1_EXP_ROM_BASE_REG	38h

11.4.3.1.14.2 Function

Expansion ROM Base Address Register. This register is defined to handle the base address and size information for this expansion ROM. The mask for this ROM BAR exists (if implemented) as a shadow register at this address. The assertion of CS2 (that is, assert the dbi_cs2 input, or the CS2 address bit for the AXI bridge) is required to write to the second register at this address.

11.4.3.1.14.3 Diagram

11.4.3.1.14.4 Fields



Field	Function
31-11 EXP_ROM_BASE_ADDRESS	Expansion ROM Base Address. Upper 21 bits of the Expansion ROM base address. The number of bits (out of these 21) that a Function actually implements depends on how much address space the Function requires. The mask for this ROM BAR exists (if implemented) as a shadow register at this address. The assertion of CS2 (that is, assert the dbi_cs2 input, or the CS2 address bit for the AXI bridge) is required to write to the second register at this address. Note: The access attributes of this field are as follows: - Dbi: R/W
10-1 RSVDP_1	Reserved for future use.
0 ROM_BAR_ENABLE	Expansion ROM Enable. This bit controls whether or not the Function accepts accesses to its expansion ROM. When this bit is 0b, the Function's expansion ROM address space is disabled. When the bit is 1b, address decoding is enabled using the parameters in the other part of the Expansion ROM Base Address register. The Memory Space Enable bit in the Command register has precedence over the Expansion ROM Enable bit. A Function must claim accesses to its expansion ROM only if both the Memory Space Enable bit and the Expansion ROM Enable bit are set. Note: The access attributes of this field are as follows: - Dbi: R/W

11.4.3.1.15 Bridge Control, Interrupt Pin, and Interrupt Line Register. (BRIDGE_CTRL_INT_PIN_INT_LINE_REG)

11.4.3.1.15.1 Offset

Register	Offset
BRIDGE_CTRL_INT_PIN_INT_LINE_REG	3Ch

11.4.3.1.15.2 Diagram

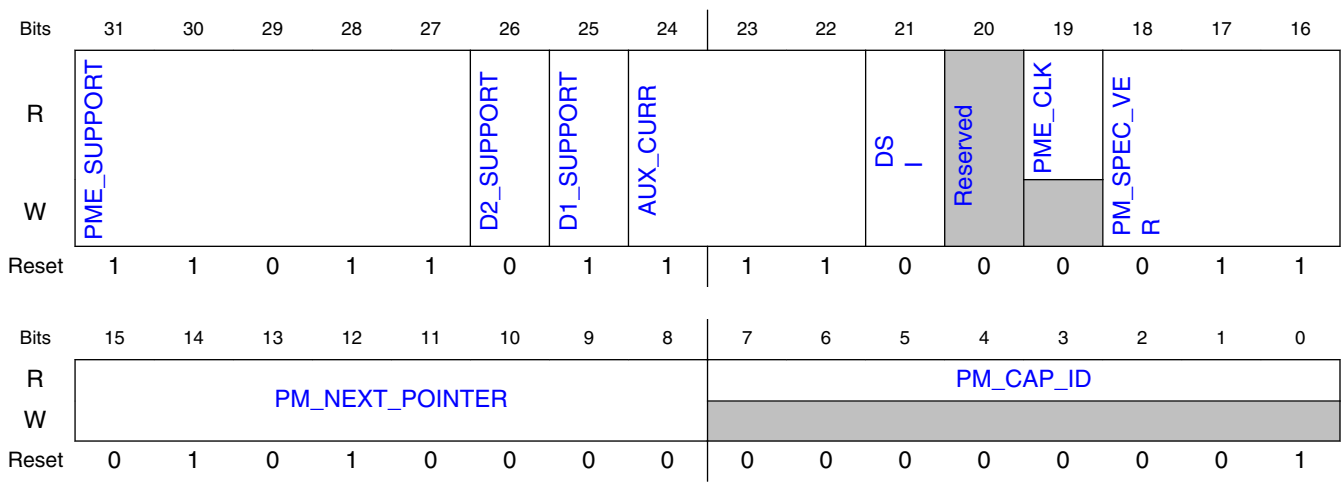
11.4.3.1.15.3 Fields

Field	Function
31-23 BRIDGE_CTRL_RESERV	Reserved
22 SBR	Secondary Bus Reset. Setting this bit triggers a hot reset on the corresponding PCI Express Port. Software must ensure a minimum reset duration (Trst) as defined in the PCI Local Bus Specification. Software and systems must honor first-access-following-reset timing requirements, unless the Readiness Notifications mechanism is used or if the Immediate Readiness bit in the relevant Function's Status Register register is set. Port configuration registers must not be changed, except as required to update Port status.
21 MSTR_ABORT_MODE	Master Abort Mode. This bit was originally described in the PCI-to-PCI Bridge Architecture Specification. Its functionality does not apply to PCI Express. The controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Dbi: R/W
20 VGA_16B_DEC	VGA 16 bit decode. This bit only has meaning if VGA Enable bit is set. This bit enables system configuration software to select between 10-bit and 16-bit I/O address decoding for all VGA I/O register accesses that are forwarded from primary to secondary. The following actions are taken based on the value of the VGA_16B_DEC bit: - 0b: Execute 10-bit address decodes on VGA I/O accesses - 1b:

Table continues on the next page...

Field	Function
	Execute 16-bit address decodes on VGA I/O accesses For Functions that do not support VGA, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Dbi: R
19 VGA_EN	VGA Enable. Modifies the response by the bridge to VGA compatible addresses. If the VGA Enable bit is set, the bridge will positively decode and forward the following accesses on the primary interface to the secondary interface (and, conversely, block the forwarding of these addresses from the secondary to primary interface): - Memory accesses in the range 000A 0000h to 000B FFFFh - I/O addresses in the first 64 KB of the I/O address space (Address[31:16] are 0000h) where Address[9:0] are in the ranges 3B0h to 3BBh and 3C0h to 3DFh (inclusive of ISA address aliases determined by the setting of VGA 16-bit Decode) If the VGA Enable bit is set, forwarding of these accesses is independent of the I/O address range and memory address ranges defined by the I/O Base and Limit registers, the Memory Base and Limit registers, and the Prefetchable Memory Base and Limit registers of the bridge. (Forwarding of these accesses is also independent of the setting of the ISA Enable bit (in the Bridge Control register) when the VGA Enable bit is set. Forwarding of these accesses is qualified by the I/O Space Enable and Memory Space Enable bits in the Command register.) The following actions are taken based on the value of the VGA_EN bit: - 0b: Do not forward VGA compatible memory and I/O addresses from the primary to the secondary interface (addresses defined above) unless they are enabled for forwarding by the defined I/O and memory address ranges - 1b: Forward VGA compatible memory and I/O addresses (addresses defined above) from the primary interface to the secondary interface (if the I/O Space Enable and Memory Space Enable bits are set) independent of the I/O and memory address ranges and independent of the ISA Enable bit For Functions that do not support VGA, the controller hardwires this bit to 0b. Note: The access attributes of this field are as follows: - Dbi: R
18 ISA_EN	ISA Enable. Modifies the response by the bridge to ISA I/O addresses. This applies only to I/O addresses that are enabled by the I/O Base and I/O Limit registers and are in the first 64 KB of I/O address space (0000 0000h to 0000 FFFFh). If this bit is set, the bridge will block any forwarding from primary to secondary of I/O transactions addressing the last 768 bytes in each 1-KB block. In the opposite direction (secondary to primary), I/O transactions will be forwarded if they address the last 768 bytes in each 1-KB block. The following actions are taken based on the value of the ISA_EN bit: - 0b: Forward downstream all I/O addresses in the address range defined by the I/O Base and I/O Limit registers - 1b: Forward upstream ISA I/O addresses in the address range defined by the I/O Base and I/O Limit registers that are in the first 64 KB of PCI I/O address space (top 768 bytes of each 1-KB block.
17 SERR_EN	SERR# Enable. This bit controls forwarding of ERR_COR, ERR_NONFATAL and ERR_FATAL from secondary to primary.
16 PERE	Parity Error Response Enable. This bit controls the logging of poisoned TLPs in the Master Data Parity Error bit in the Secondary Status register.
15-8 INT_PIN	Interrupt PIN. The Interrupt Pin register register that identifies the legacy interrupt Message(s) the Function uses. Valid values are: - 01h, 02h, 03h, and 04h: map to legacy interrupt Messages for INTA, INTB, INTC, and INTD respectively. - 00h: indicates that the Function uses no legacy interrupt Message(s). - 05h through FFh: Reserved PCI Express defines one legacy interrupt Message for a single Function device and up to four legacy interrupt Messages for a multi-Function device. For a single Function device, only INTA may be used. Any Function on a multi-Function device can use any of the INTx Messages. If a device implements a single legacy interrupt Message, it must be INTA; if it implements two legacy interrupt Messages, they must be INTA and INTB; and so forth. For a multi-Function device, all Functions may use the same INTx Message or each may have its own (up to a maximum of four Functions) or any combination thereof. A single Function can never generate an interrupt request on more than one INTx Message. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
7-0 INT_LINE	Interrupt Line. The Interrupt Line register communicates interrupt line routing information. The register must be implemented by any Function that uses an interrupt pin. Values in this register are programmed by system software and are system architecture specific. The Function itself does not use this value; rather the value in this register is used by device drivers and operating systems.

11.4.3.1.16 Power Management Capabilities Register. (CAP_ID_NXT_PTR_REG)



11.4.3.1.16.1 Offset

Register	Offset
CAP_ID_NXT_PTR_REG	40h

11.4.3.1.16.2 Function

Power Management Capabilities Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.4.3.1.16.3 Diagram

11.4.3.1.16.4 Fields

Field	Function
31-27 PME_SUPPORT	Power Management Event Support. For a description of this standard PCIe register field, see the PCI Express Specification. The read value from this field is the write value && (sys_aux_pwr_det, 1'b1, D2_SUPPORT, D1_SUPPORT, 1'b1), where D1_SUPPORT and D2_SUPPORT are fields in this register. The reset value PME_SUPPORT_n && (sys_aux_pwr_det, 1'b1, D2_SUPPORT, D1_SUPPORT, 1'b1), where PME_SUPPORT_n is a configuration parameter. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
26 D2_SUPPORT	D2 State Support. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.

Table continues on the next page...

Field	Function
25 D1_SUPPORT	D1 State Support. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
24-22 AUX_CURR	Auxiliary Current Requirements. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
21 DSI	Device Specific Initialization Bit. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
20 —	Reserved
19 PME_CLK	PCI Clock Requirement. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
18-16 PM_SPEC_VER	Power Management Spec Version. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
15-8 PM_NEXT_POINTER	Next Capability Pointer. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
7-0 PM_CAP_ID	Power Management Capability ID. For a description of this standard PCIe register field, see the PCI Express Specification.

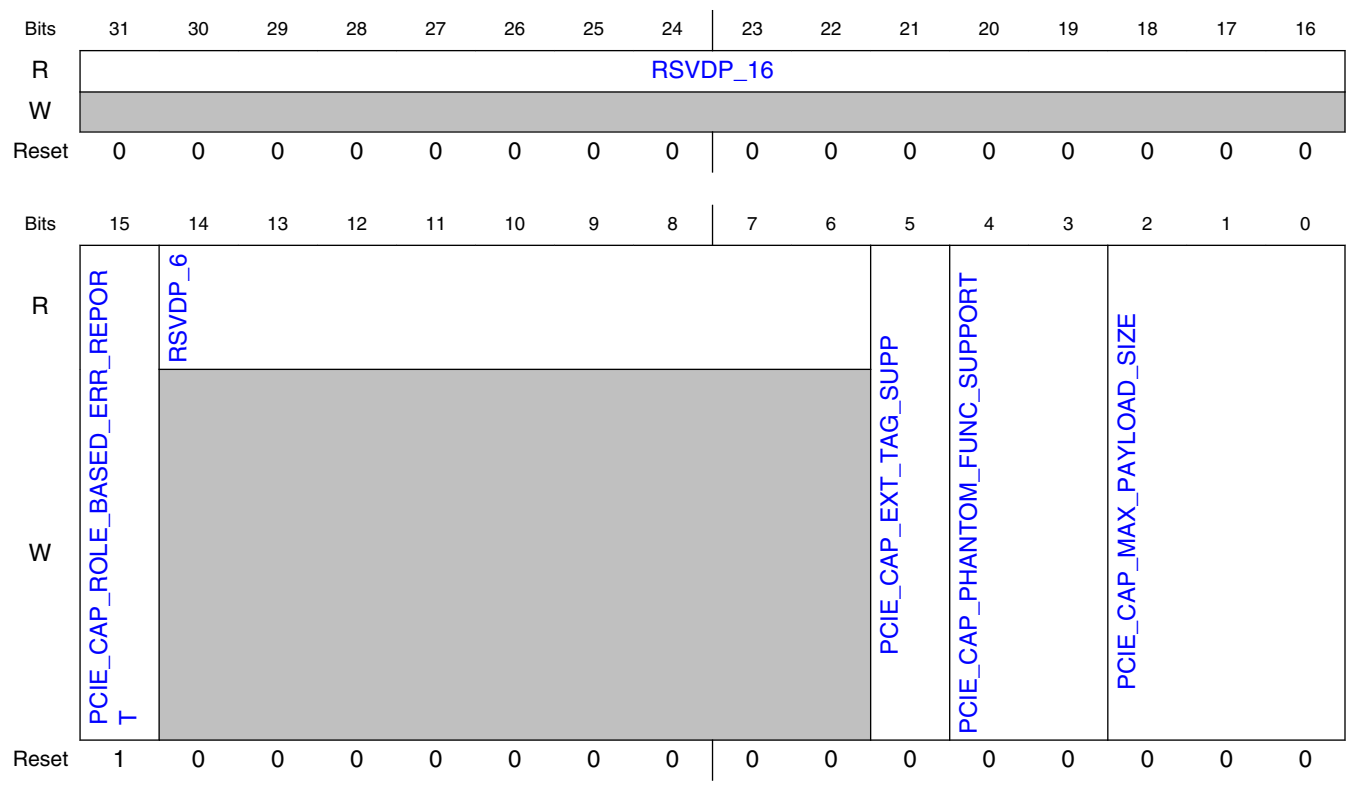
11.4.3.1.24.4 Fields

Field	Function
31 RSVDP_31	Reserved for future use.
30 RSVD	Reserved For a description of this standard PCIe register field, see the PCI Express Specification.
29-25 PCIE_INT_MSG_NUM	PCIE Interrupt Message Number. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
24 PCIE_SLOT_IMP	PCIe Slot Implemented Valid. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
23-20 PCIE_DEV_PORT_TYPE	PCIE Device/PortType. For a description of this standard PCIe register field, see the PCI Express Specification.
19-16 PCIE_CAP_REG	PCIE Capability Version Number. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
15-8 PCIE_CAP_NEXT_PTR	PCIE Next Capability Pointer. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
7-0 PCIE_CAP_ID	PCIE Capability ID. For a description of this standard PCIe register field, see the PCI Express Specification.

11.4.3.1.25 Device Capabilities Register. (DEVICE_CAPABILITIES_REG)



11.4.3.1.25.1 Offset

Register	Offset
DEVICE_CAPABILITIES_REG	74h

11.4.3.1.25.2 Function

Device Capabilities Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.4.3.1.25.3 Diagram

11.4.3.1.25.4 Fields

Field	Function
31-16	Reserved for future use.

Table continues on the next page...

Field	Function
RSVDP_16	
15 PCIE_CAP_ROLE_BASED_ERR_REPORT	Role-based Error Reporting Implemented. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
14-6 RSVDP_6	Reserved for future use.
5 PCIE_CAP_EXT_TAG_SUPP	Extended Tag Field Supported. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
4-3 PCIE_CAP_PHANTOM_FUNC_SUPPORT	Phantom Functions Supported. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
2-0 PCIE_CAP_MAX_PAYLOAD_SIZE	Max Payload Size Supported. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.

11.4.3.1.26 Device Control and Status Register. (DEVICE_CONTROL_DEVICE_STATUS)

Field	Function
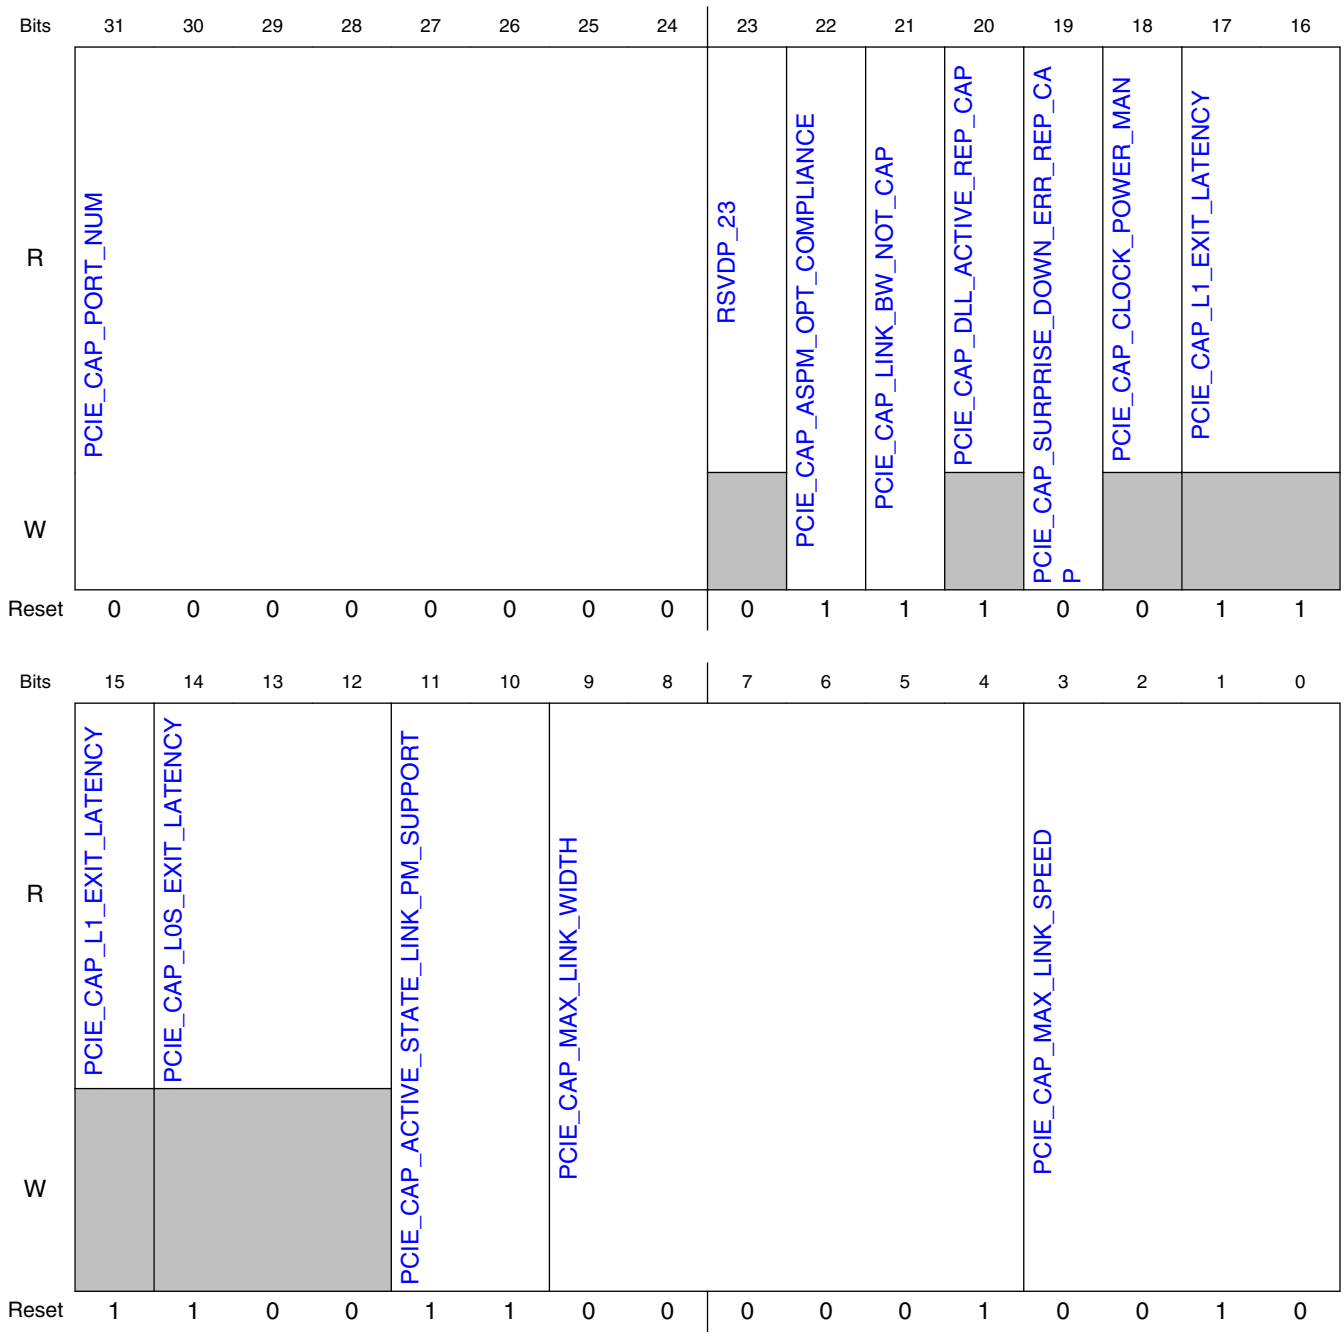
21 PCIE_CAP_TRANS_PENDING	Transactions Pending Status. For a description of this standard PCIe register field, see the PCI Express Specification.
20 PCIE_CAP_AUX_POWER_DETECTED	Aux Power Detected Status. For a description of this standard PCIe register field, see the PCI Express Specification. This bit is derived by sampling the sys_aux_pwr_det input.
19 PCIE_CAP_UNSUPPORTED_REQ_DETECTED	Unsupported Request Detected Status. For a description of this standard PCIe register field, see the PCI Express Specification.
18 PCIE_CAP_FATAL_ERR_DETECTED	Fatal Error Detected Status. For a description of this standard PCIe register field, see the PCI Express Specification.
17 PCIE_CAP_NON_FATAL_ERR_DETECTED	Non-Fatal Error Detected Status. For a description of this standard PCIe register field, see the PCI Express Specification.
16 PCIE_CAP_CORR_ERR_DETECTED	Correctable Error Detected Status. For a description of this standard PCIe register field, see the PCI Express Specification.
15 PCIE_CAP_INITIATE_FLR	Initiate Function Level Reset (for endpoints). For a description of this standard PCIe register field, see the PCI Express Specification.
14-12 PCIE_CAP_MAX_READ_REQ_SIZE	Max Read Request Size. For a description of this standard PCIe register field, see the PCI Express Specification.
11 PCIE_CAP_EN_NO_SNOOP	Enable No Snoop. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R
10 PCIE_CAP_AUX_POWER_PM_EN	Aux Power PM Enable. For a description of this standard PCIe register field, see the PCI Express Specification. This bit is derived by sampling the sys_aux_pwr_det input. Note: This register field is sticky.
9 PCIE_CAP_PHANTOM_FUNC_EN	Phantom Functions Enable. For a description of this standard PCIe register field, see the PCI Express Specification. The write value is gated with the PCIE_CAP_PHANTOM_FUNC_SUPPORT field of DEVICE_CAPABILITIES_REG. Note: The access attributes of this field are as follows: - Dbi: DEVICE_CAPABILITIES_REG.PCIE_CAP_PHANTOM_FUNC_SUPPORT ? RW : RO
8 PCIE_CAP_EXT_TAG_EN	Extended Tag Field Enable. For a description of this standard PCIe register field, see the PCI Express Specification. The write value is gated with the PCIE_CAP_EXT_TAG_SUPP field of DEVICE_CAPABILITIES_REG. Note: The access attributes of this field are as follows: - Dbi: DEVICE_CAPABILITIES_REG.PCIE_CAP_EXT_TAG_SUPP ? RW : RO

Table continues on the next page...

Field	Function
7-5 PCIE_CAP_MAX_PAYLOAD_SIZE_CS	Max Payload Size. Max_Payload_Size . This field sets maximum TLP payload size for the Function. Permissible values that can be programmed are indicated by the Max_Payload_Size Supported field (PCIE_CAP_MAX_PAYLOAD_SIZE) in the Device Capabilities register (DEVICE_CAPABILITIES_REG).
4 PCIE_CAP_EN_REL_ORDER	Enable Relaxed Ordering. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
3 PCIE_CAP_UNSUPPORT_REQ_REP_EN	Unsupported Request Reporting Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
2 PCIE_CAP_FATAL_ERR_REPORT_EN	Fatal Error Reporting Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
1 PCIE_CAP_NON_FATAL_ERR_REPORT_EN	Non-fatal Error Reporting Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
0 PCIE_CAP_CORR_ERR_REPORT_EN	Correctable Error Reporting Enable. For a description of this standard PCIe register field, see the PCI Express Specification.

11.4.3.1.27 Link Capabilities Register. (LINK_CAPABILITIES_REG)



11.4.3.1.27.1 Offset

Register	Offset
LINK_CAPABILITIES_REG	7Ch

11.4.3.1.27.2 Function

Link Capabilities Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.4.3.1.27.3 Diagram

11.4.3.1.27.4 Fields

Field	Function
31-24 PCIE_CAP_PORT_NUM	Port Number. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R

Table continues on the next page...

Field	Function
23 RSVDP_23	Reserved for future use.
22 PCIE_CAP_ASPM_OPT_COMPLIANCE	ASPM Optionality Compliance. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
21 PCIE_CAP_LINK_BW_NOT_CAP	Link Bandwidth Notification Capable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
20 PCIE_CAP_DLL_ACTIVE_REP_CAP	Data Link Layer Link Active Reporting Capable. For a description of this standard PCIe register field, see the PCI Express Specification.
19 PCIE_CAP_SURPRISE_DOWN_ERR_REP_CAP	Surprise Down Error Reporting Capable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
18 PCIE_CAP_CLOCK_POWER_MAN	Clock Power Management. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
17-15 PCIE_CAP_L1_EXIT_LATENCY	L1 Exit Latency. For a description of this standard PCIe register field, see the PCI Express Specification. There are two each of these register fields, this one and a shadow one at the same address. The Common Clock bit (PCIE_CAP_COMMON_CLK_CONFIG) of the Link Control Register (LINK_CONTROL_LINK_STATUS_REG) determines which one is used by the controller and which one is accessed by a read request. Common Clock operation is supported (possible) in the controller when one or more of the following expressions is true: - CX_NFTS !=CX_COMM_NFTS - DEFAULT_L0S_EXIT_LATENCY !=DEFAULT_COMM_L0S_EXIT_LATENCY - DEFAULT_L1_EXIT_LATENCY !=DEFAULT_COMM_L1_EXIT_LATENCY Common Clock operation is enabled in the controller when you set the Common Clock bit (PCIE_CAP_COMMON_CLK_CONFIG) of the Link Control Register (LINK_CONTROL_LINK_STATUS_REG). The assertion of CS2 (that is, assert the dbi_cs2 input, or the CS2 address bit for the AXI bridge) is required to write to the shadow field at this location. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
14-12 PCIE_CAP_L0S_EXIT_LATENCY	LOs Exit Latency. For a description of this standard PCIe register field, see the PCI Express Specification. There are two each of these register fields, this one and a shadow one at the same address. The Common Clock bit (PCIE_CAP_COMMON_CLK_CONFIG) of the Link Control Register (LINK_CONTROL_LINK_STATUS_REG) determines which one is used by the controller and which one is accessed by a read request. Common Clock operation is supported (possible) in the controller when one or more of the following expressions is true: - CX_NFTS !=CX_COMM_NFTS - DEFAULT_L0S_EXIT_LATENCY !=DEFAULT_COMM_L0S_EXIT_LATENCY - DEFAULT_L1_EXIT_LATENCY !=DEFAULT_COMM_L1_EXIT_LATENCY Common Clock operation is enabled in the controller when you set the Common Clock bit (PCIE_CAP_COMMON_CLK_CONFIG) of the Link Control Register (LINK_CONTROL_LINK_STATUS_REG). The assertion of CS2 (that is, assert the dbi_cs2 input, or the CS2 address bit for the AXI bridge) is required to write to the shadow field at this location. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.

Table continues on the next page...

Field	Function
11-10 PCIE_CAP_ACTIVE_STATE_LINK_PM_SUPPORT	Level of ASPM (Active State Power Management) Support. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
9-4 PCIE_CAP_MAX_LINK_WIDTH	Maximum Link Width. For a description of this standard PCIe register field, see the PCI Express Specification. In M-PCIe mode, the reset and dynamic values of this field are calculated by the controller. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.
3-0 PCIE_CAP_MAX_LINK_SPEED	Maximum Link Speed. For a description of this standard PCIe register field, see the PCI Express Specification. In M-PCIe mode, the reset and dynamic values of this field are calculated by the controller. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R Note: This register field is sticky.

Field	Function
31	Link Autonomous Bandwidth Status. For a description of this standard PCIe register field, see the PCI Express Specification. The write value is gated with the PCIE_CAP_LINK_BW_NOT_CAP field in LINK_CAPABILITIES_REG.

Table continues on the next page...

Field	Function
PCIE_CAP_LINK_AUTO_BW_STATUS	
30 PCIE_CAP_LINK_BW_MAN_STATUS	Link Bandwidth Management Status. For a description of this standard PCIe register field, see the PCI Express Specification. The write value is gated with the PCIE_CAP_LINK_BW_NOT_CAP field in LINK_CAPABILITIES_REG.
29 PCIE_CAP_DLL_ACTIVE	Data Link Layer Active. For a description of this standard PCIe register field, see the PCI Express Specification.
28 PCIE_CAP_SLOT_CLK_CONFIG	Slot Clock Configuration. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
27 PCIE_CAP_LINK_TRAINING	LTSSM is in Configuration or Recovery State. For a description of this standard PCIe register field, see the PCI Express Specification.
26 RSVDP_26	Reserved for future use.
25-20 PCIE_CAP_NEGO_LINK_WIDTH	Negotiated Link Width. For a description of this standard PCIe register field, see the PCI Express Specification.
19-16 PCIE_CAP_LINK_SPEED	Current Link Speed. For a description of this standard PCIe register field, see the PCI Express Specification.
15-14 PCIE_CAP_DRS_SIGNALING_CONTROL	DRS Signaling Control. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: LINK_CAPABILITIES2_REG.DRS_SUPPORTED ? RW : RO
13-12 RSVDP_12	Reserved for future use.
11 PCIE_CAP_LINK_AUTO_BW_INT_EN	Link Autonomous Bandwidth Management Interrupt Enable. For a description of this standard PCIe register field, see the PCI Express Specification. The write value is gated with the PCIE_CAP_LINK_BW_NOT_CAP field in LINK_CAPABILITIES_REG. Note: The access attributes of this field are as follows: - Dbi: LINK_CAPABILITIES_REG.PCIE_CAP_LINK_BW_NOT_CAP ? RW : RO
10 PCIE_CAP_LINK_BW_MAN_INT_EN	Link Bandwidth Management Interrupt Enable. For a description of this standard PCIe register field, see the PCI Express Specification. The write value is gated with the PCIE_CAP_LINK_BW_NOT_CAP field in LINK_CAPABILITIES_REG. Note: The access attributes of this field are as follows: - Dbi: LINK_CAPABILITIES_REG.PCIE_CAP_LINK_BW_NOT_CAP ? RW : RO
9 PCIE_CAP_HW_AUTO_WIDTH_DISABLE	Hardware Autonomous Width Disable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
8	Enable Clock Power Management. For a description of this standard PCIe register field, see the PCI Express Specification. The write value is gated with the PCIE_CAP_CLOCK_POWER_MAN field in

Table continues on the next page...

Field	Function
PCIE_CAP_EN_CLK_POWER_MAN	LINK_CAPABILITIES_REG. Note: The access attributes of this field are as follows: - Dbi: LINK_CAPABILITIES_REG.PCIE_CAP_CLOCK_POWER_MAN ? RWS : ROS Note: This register field is sticky.
7 PCIE_CAP_EXTENDED_SYNCH	Extended Synch. For a description of this standard PCIe register field, see the PCI Express Specification.
6 PCIE_CAP_COMMON_CLK_CONFIG	Common Clock Configuration. For a description of this standard PCIe register field, see the PCI Express Specification.
5 PCIE_CAP_RETRAIN_LINK	Initiate Link Retrain. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: see description
4 PCIE_CAP_LINK_DISABLE	Initiate Link Disable. For a description of this standard PCIe register field, see the PCI Express Specification. In a DSP that supports crosslink, the controller gates the write value with the CROSS_LINK_EN field in PORT_LINK_CTRL_OFF. Note: The access attributes of this field are as follows: - Dbi: CX_CROSSLINK_ENABLE=1 && PORT_LINK_CTRL_OFF.CROSS_LINK_EN=1|| CX_CROSSLINK_ENABLE=0 && dsp=1? RW : RO
3 PCIE_CAP_RCB	Read Completion Boundary (RCB). Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W else R
2 RSVDP_2	Reserved for future use.
1-0 PCIE_CAP_ACTIVE_STATE_LINK_PM_CONTROL	Active State Power Management (ASPM) Control. Software must not enable L0s in either direction on a given Link unless components on both sides of the Link each support L0s; otherwise, the result is undefined. For a description of this standard PCIe register field, see the PCI Express Specification.

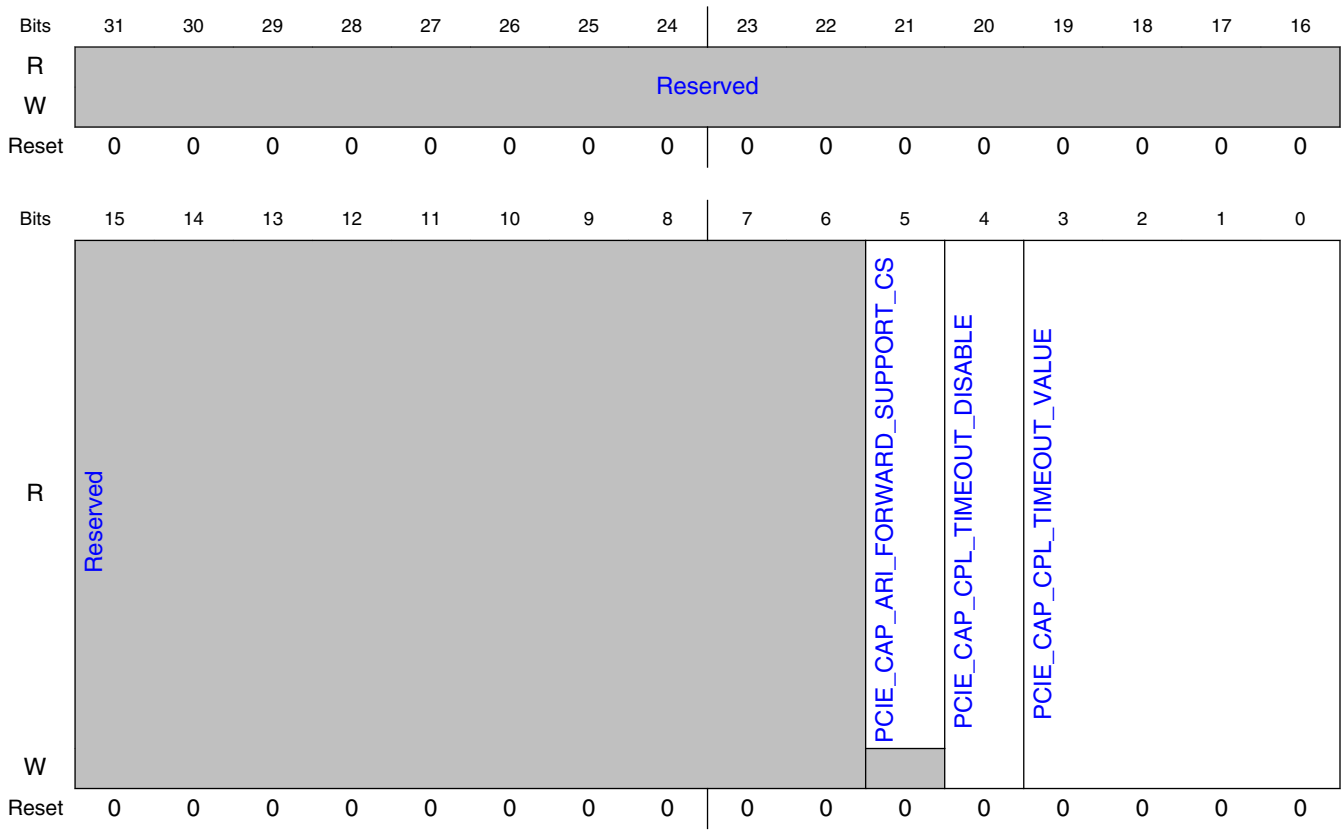
17 PCIE_CAP2_10_BIT_TAG_REQ_SUPPORT	10-Bit Tag Requester Supported. For a description of this standard PCIe register field, see the PCI Express Base Specification 4.0.
16 PCIE_CAP2_10_BIT_TAG_COMP_SUPPORT	10-Bit Tag Completer Supported. For a description of this standard PCIe register field, see the PCI Express Base Specification 4.0.
15-14 —	Reserved
13 PCIE_CAP_TPH_CMPLT_SUPPORT_1	TPH Completer Supported Bit 1. For a description of this standard PCIe register field, see the PCI Express Specification.
12 PCIE_CAP_TPH_CMPLT_SUPPORT_0	TPH Completer Supported Bit 0. For a description of this standard PCIe register field, see the PCI Express Specification.
11 PCIE_CAP_LTR_SUPP	LTR Mechanism Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
10 PCIE_CAP_NO_RO_EN_PR2PR_PAR	No Relaxed Ordering Enabled PR-PR Passing. For a description of this standard PCIe register field, see the PCI Express Specification.
9 PCIE_CAP_128_CAS_CPL_SUPP	128 Bit CAS Completer Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
8 PCIE_CAP_64_ATOMIC_CPL_SUPP	64 Bit AtomicOp Completer Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
7 PCIE_CAP_32_ATOMIC_CPL_SUPP	32 Bit AtomicOp Completer Supported. For a description of this standard PCIe register field, see the PCI Express Specification.

Table continues on the next page...

Field	Function
6 PCIE_CAP_ATOMIC_ROUTING_SUPP	Atomic Operation Routing Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
5 PCIE_CAP_ARI_FORWARD_SUPPORT	ARI Forwarding Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
4 PCIE_CAP_CPL_TIMEOUT_DISABLE_SUPPORT	Completion Timeout Disable Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
3-0 PCIE_CAP_CPL_TIMEOUT_RANGE	Completion Timeout Ranges Supported. For a description of this standard PCIe register field, see the PCI Express Specification.

11.4.3.1.34 Device Control 2 and Status 2 Register. (DEVICE_CONTROL2_DEVICE_STATUS2_REG)



11.4.3.1.34.1 Offset

Register	Offset
DEVICE_CONTROL2_DEVICE_STATUS2_REG	98h

11.4.3.1.34.2 Function

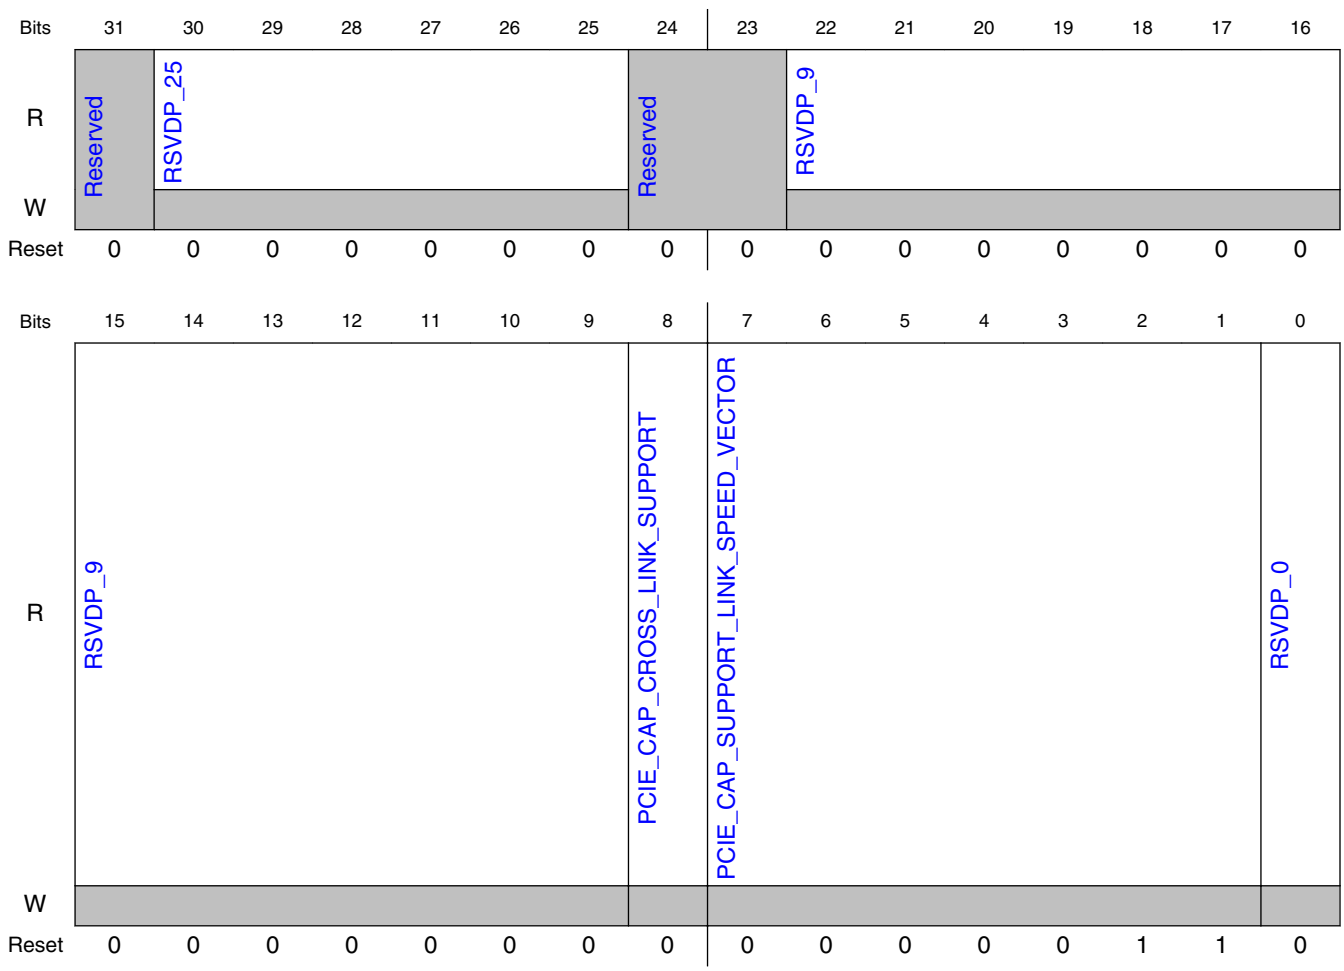
Device Control 2 and Status 2 Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.4.3.1.34.3 Diagram

11.4.3.1.34.4 Fields

Field	Function
31-6 —	Reserved
5 PCIE_CAP_ARI_FORWARD_SUPPORT_CS	ARI Forwarding Enable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
4 PCIE_CAP_CPL_TIMEOUT_DISABLE	Completion Timeout Disable. For a description of this standard PCIe register field, see the PCI Express Specification.
3-0 PCIE_CAP_CPL_TIMEOUT_VALUE	Completion Timeout Value. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W

11.4.3.1.35 Link Capabilities 2 Register. (LINK_CAPABILITIES2_REG)



11.4.3.1.35.1 Offset

Register	Offset
LINK_CAPABILITIES2_REG	9Ch

11.4.3.1.35.2 Function

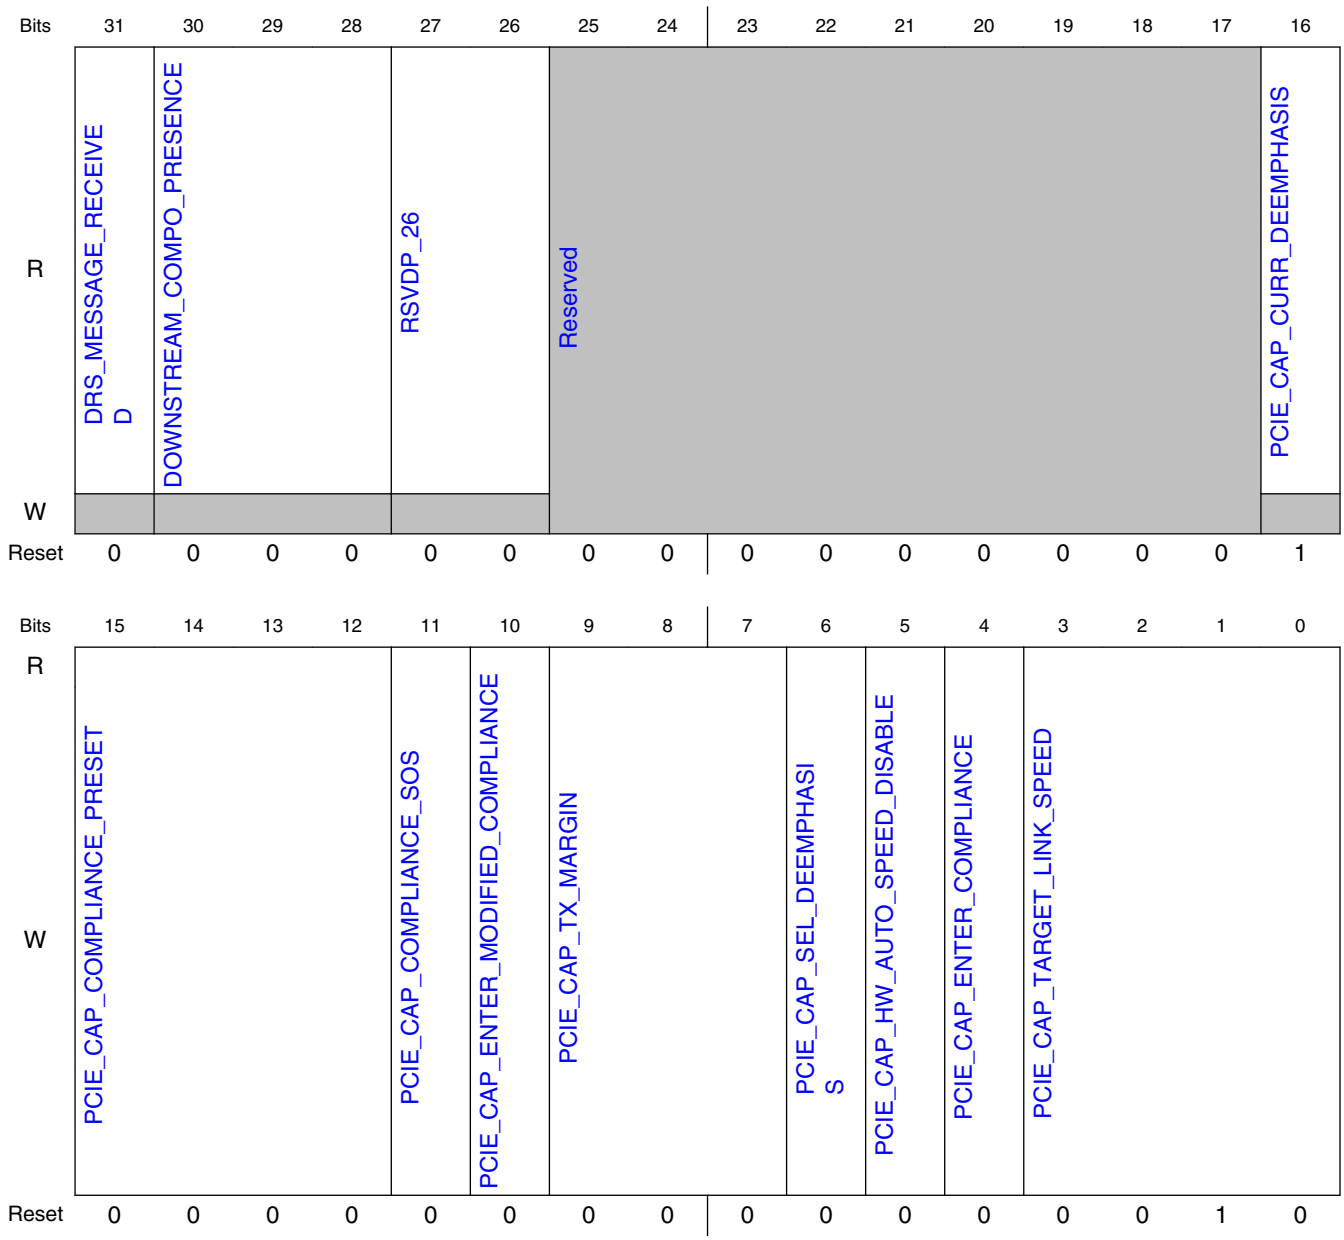
Link Capabilities 2 Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.4.3.1.35.3 Diagram

11.4.3.1.35.4 Fields

Field	Function
31 —	Reserved
30-25 RSVDP_25	Reserved for future use.
24-23 —	Reserved
22-9 RSVDP_9	Reserved for future use.
8 PCIE_CAP_CROSS_LINK_SUPPORT	Cross Link Supported. For a description of this standard PCIe register field, see the PCI Express Specification.
7-1 PCIE_CAP_SUPPORT_LINK_SPEED_VECTOR	Supported Link Speeds Vector. For a description of this standard PCIe register field, see the PCI Express Specification. This field has a default of (PCIE_CAP_MAX_LINK_SPEED == 0100) ? 0001111 : (PCIE_CAP_MAX_LINK_SPEED == 0011) ? 0000111 : (PCIE_CAP_MAX_LINK_SPEED == 0010) ? 0000011 : 0000001 where PCIE_CAP_MAX_LINK_SPEED is a field in the LINK_CAPABILITIES_REG register.
0 RSVDP_0	Reserved for future use.

11.4.3.1.36 Link Control 2 and Status 2 Register. (LINK_CONTROL2_LINK_STATUS2_REG)



11.4.3.1.36.1 Offset

Register	Offset
LINK_CONTROL2_LINK_STATUS2_REG	A0h

11.4.3.1.36.2 Function

Link Control 2 and Status 2 Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.4.3.1.36.3 Diagram

11.4.3.1.36.4 Fields

Field	Function
31 DRS_MESSAGE_RECEIVED	DRS Message Received. For a description of this standard PCIe register field, see the PCI Express Base Specification 4.0. Note: The access attributes of this field are as follows: - Dbi: RW1C
30-28	Downstream Component Presence. For a description of this standard PCIe register field, see the PCI Express Base Specification 4.0.

Table continues on the next page...

Field	Function
DOWNSTREAM_COMPO_PRESENCE	
27-26 RSVDP_26	Reserved for future use.
25-17 —	Reserved
16 PCIE_CAP_CURR_DEEMPHASIS	Current De-emphasis Level. For a description of this standard PCIe register field, see the PCI Express Specification. In M-PCIe mode this register is always 0x0. In C-PCIe mode, its contents are derived by sampling the PIPE
15-12 PCIE_CAP_COMPLIANCE_PRESET	Sets Compliance Preset/De-emphasis for 5 GT/s and 8 GT/s. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
11 PCIE_CAP_COMPLIANCE_SOS	Sets Compliance Skip Ordered Sets transmission. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
10 PCIE_CAP_ENTER_MODIFIED_COMPLIANCE	Enter Modified Compliance. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
9-7 PCIE_CAP_TX_MARGIN	Controls Transmit Margin for Debug or Compliance. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
6 PCIE_CAP_SEL_DEEMPHASIS	Controls Selectable De-emphasis for 5 GT/s. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
5 PCIE_CAP_HW_AUTO_SPEED_DISABLE	Hardware Autonomous Speed Disable. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
4 PCIE_CAP_ENTER_COMPLIANCE	Enter Compliance Mode. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
3-0 PCIE_CAP_TARGET_LINK_SPEED	Target Link Speed. For a description of this standard PCIe register field, see the PCI Express Specification. In M-PCIe mode, the contents of this field are derived from other registers. Note: This register field is sticky.

11.4.3.1.37 Advanced Error Reporting Extended Capability Header. (AER_EXT_CAP_HDR_OFF)

11.4.3.1.37.1 Offset

Register	Offset
AER_EXT_CAP_HDR_OFF	100h

11.4.3.1.37.2 Function

Advanced Error Reporting Extended Capability Header. For a description of this standard PCIe register, see the PCI Express Specification.

11.4.3.1.37.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

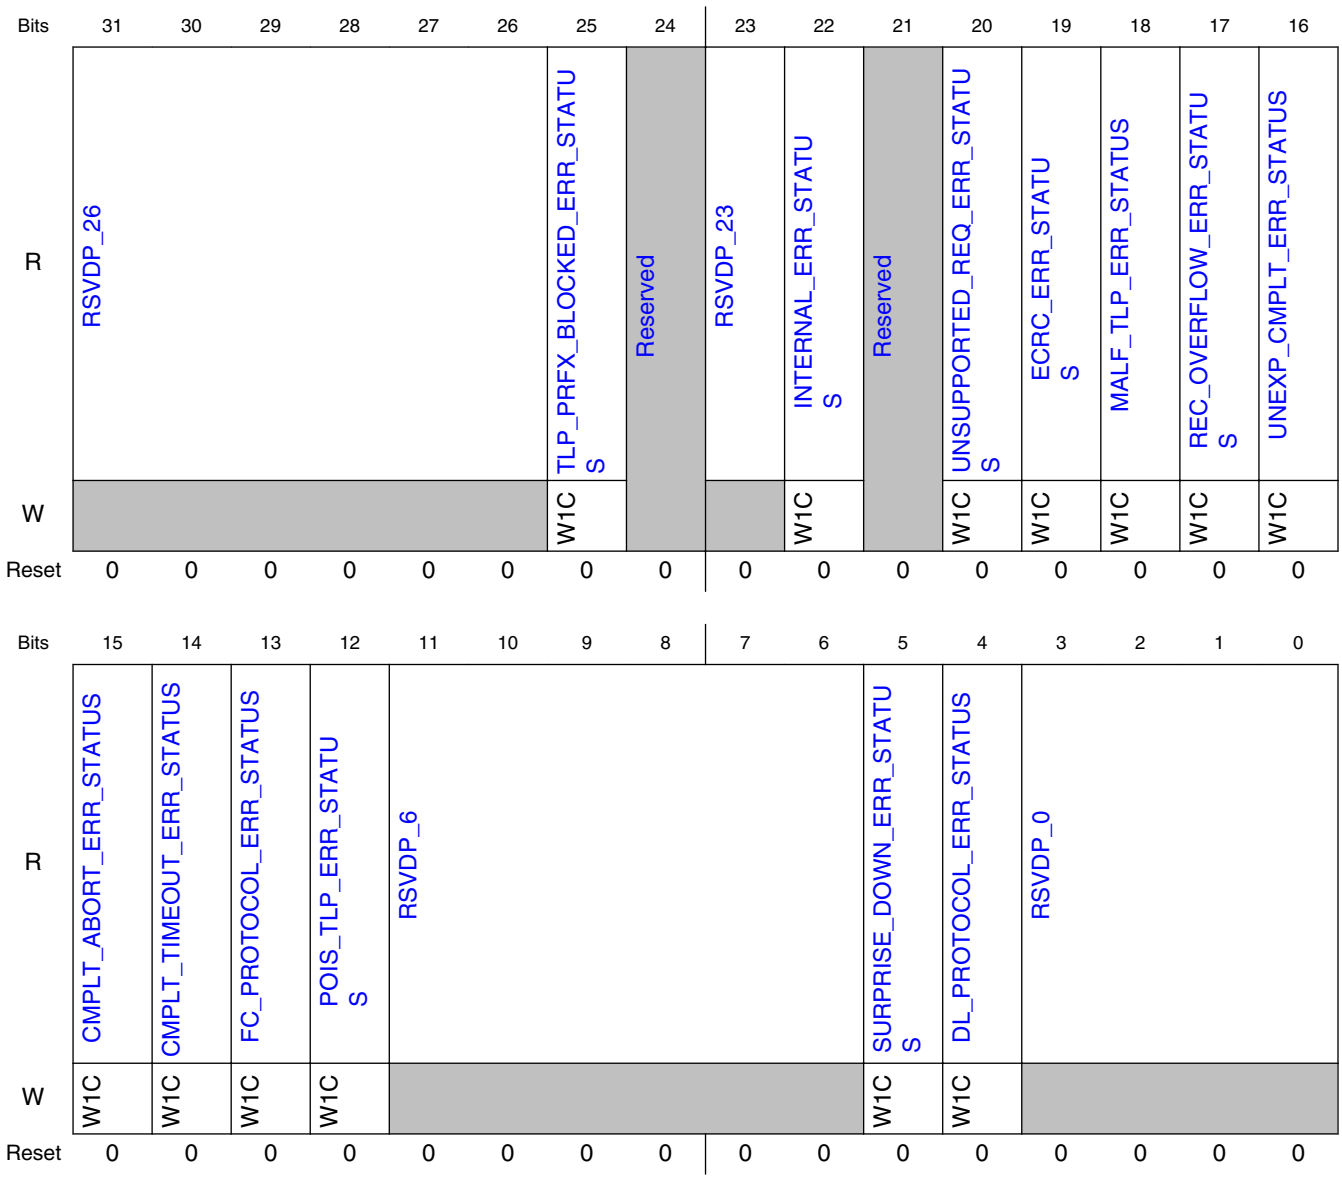
11.4.3.1.37.4 Fields

Field	Function
31-20 NEXT_OFFSET	Next Capability Offset. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
19-16 CAP_VERSION	Capability Version. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
15-0 CAP_ID	AER Extended Capability ID. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

11.4.3.1.38 Uncorrectable Error Status Register. (UNCORR_ERR_STATUS_OFF)



11.4.3.1.38.1 Offset

Register	Offset
UNCORR_ERR_STATUS_OFF	104h

11.4.3.1.38.2 Function

Uncorrectable Error Status Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.4.3.1.38.3 Diagram

11.4.3.1.38.4 Fields

Field	Function
31-26 RSVDP_26	Reserved for future use.
25 TLP_PRFX_BLOCKED_ERR_STATUS	TLP Prefix Blocked Error Status. For a description of this standard PCIe register field, see the PCI Express Specification. Note: Not supported.
24	Reserved

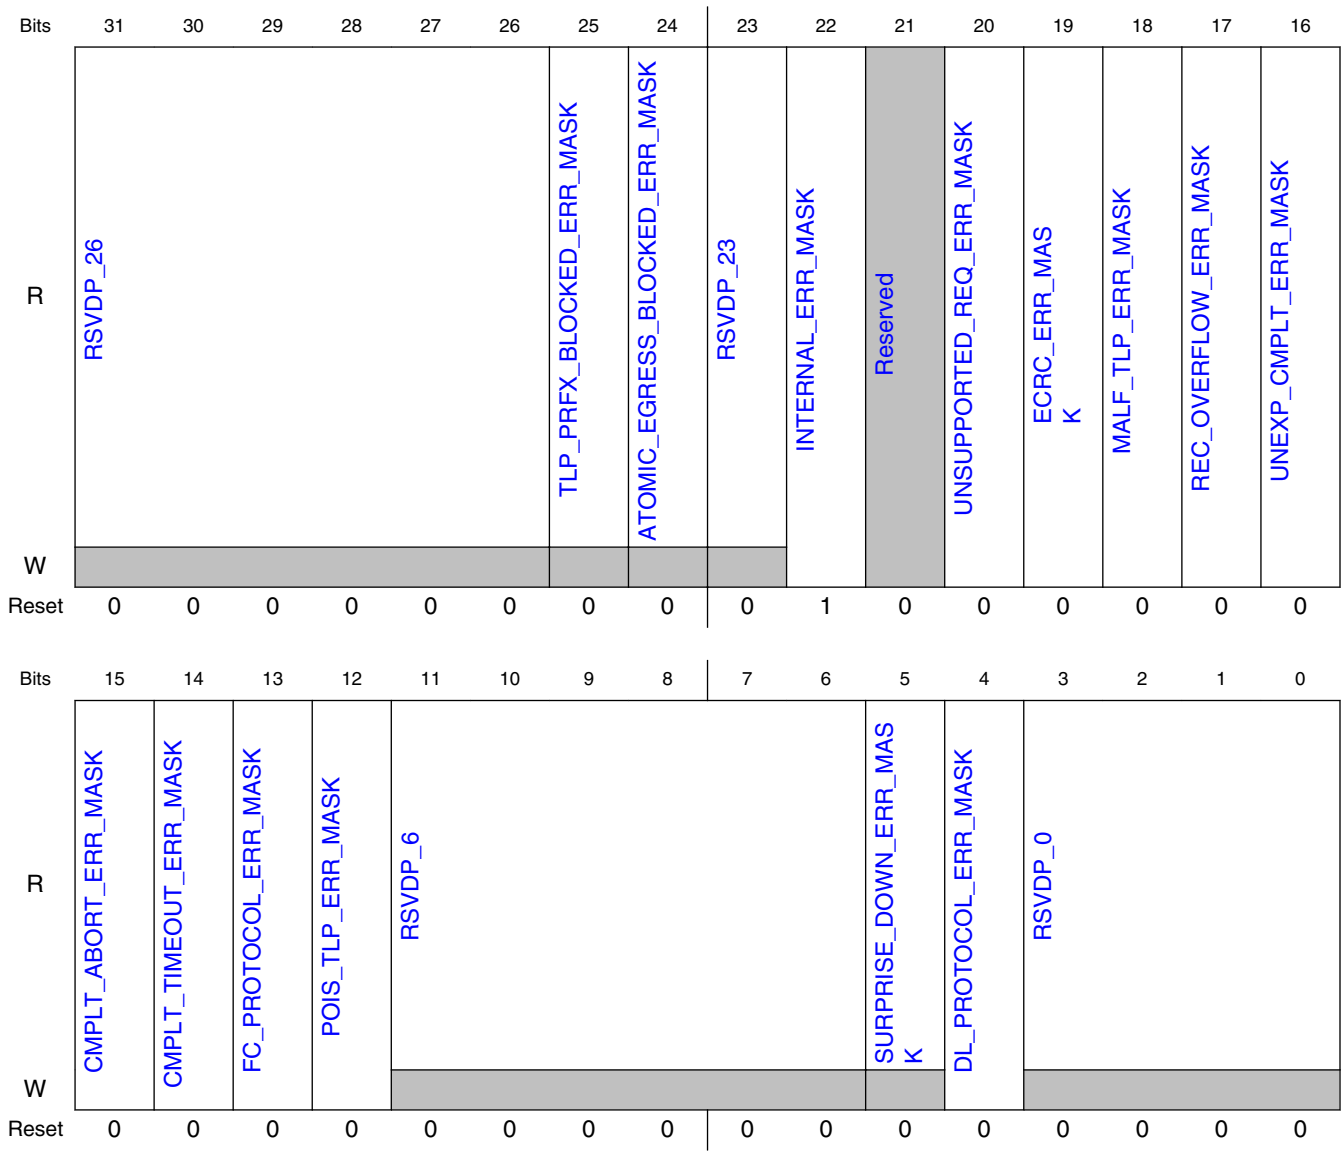
Table continues on the next page...

Field	Function
—	
23 RSVDP_23	Reserved for future use.
22 INTERNAL_ERR_STATUS	Uncorrectable Internal Error Status. For a description of this standard PCIe register field, see the PCI Express Specification. The controller sets this bit when your application asserts app_err_bus[9]. It does not set this bit when it detects internal uncorrectable internal errors such as parity and ECC failures. You should use the outputs from these errors to drive the app_err_bus[9] input. For more details, see the "Data Integrity (Wire, Datapath, and RAM Protection)" section in the Databook.
21 —	Reserved
20 UNSUPPORTED_REQ_ERR_STATUS	Unsupported Request Error Status. For a description of this standard PCIe register field, see the PCI Express Specification.
19 ECRC_ERR_STATUS	ECRC Error Status. For a description of this standard PCIe register field, see the PCI Express Specification.
18 MALF_TLP_ERR_STATUS	Malformed TLP Status. For a description of this standard PCIe register field, see the PCI Express Specification.
17 REC_OVERFLOW_ERR_STATUS	Receiver Overflow Status. For a description of this standard PCIe register field, see the PCI Express Specification.
16 UNEXP_CMPLT_ERR_STATUS	Unexpected Completion Status. For a description of this standard PCIe register field, see the PCI Express Specification.
15 CMPLT_ABORT_ERR_STATUS	Completer Abort Status. For a description of this standard PCIe register field, see the PCI Express Specification.
14 CMPLT_TIMEOUT_ERR_STATUS	Completion Timeout Status. For a description of this standard PCIe register field, see the PCI Express Specification.
13 FC_PROTOCOL_ERR_STATUS	Flow Control Protocol Error Status. For a description of this standard PCIe register field, see the PCI Express Specification.
12 POIS_TLP_ERR_STATUS	Poisoned TLP Status. For a description of this standard PCIe register field, see the PCI Express Specification.
11-6 RSVDP_6	Reserved for future use.
5	Surprise Down Error Status (Optional). For a description of this standard PCIe register field, see the PCI Express Specification.

Table continues on the next page...

Field	Function
SURPRISE_DOWN_ERR_STATUS	
4 DL_PROTOCOL_ERR_STATUS	Data Link Protocol Error Status. For a description of this standard PCIe register field, see the PCI Express Specification.
3-0 RSVDP_0	Reserved for future use.

11.4.3.1.39 Uncorrectable Error Mask Register. (UNCORR_ERR_MASK_OFF)



11.4.3.1.39.1 Offset

Register	Offset
UNCORR_ERR_MASK_OFF	108h

11.4.3.1.39.2 Function

Uncorrectable Error Mask Register. For a description of this standard PCIe register, see the PCI Express Specification.

Field	Function
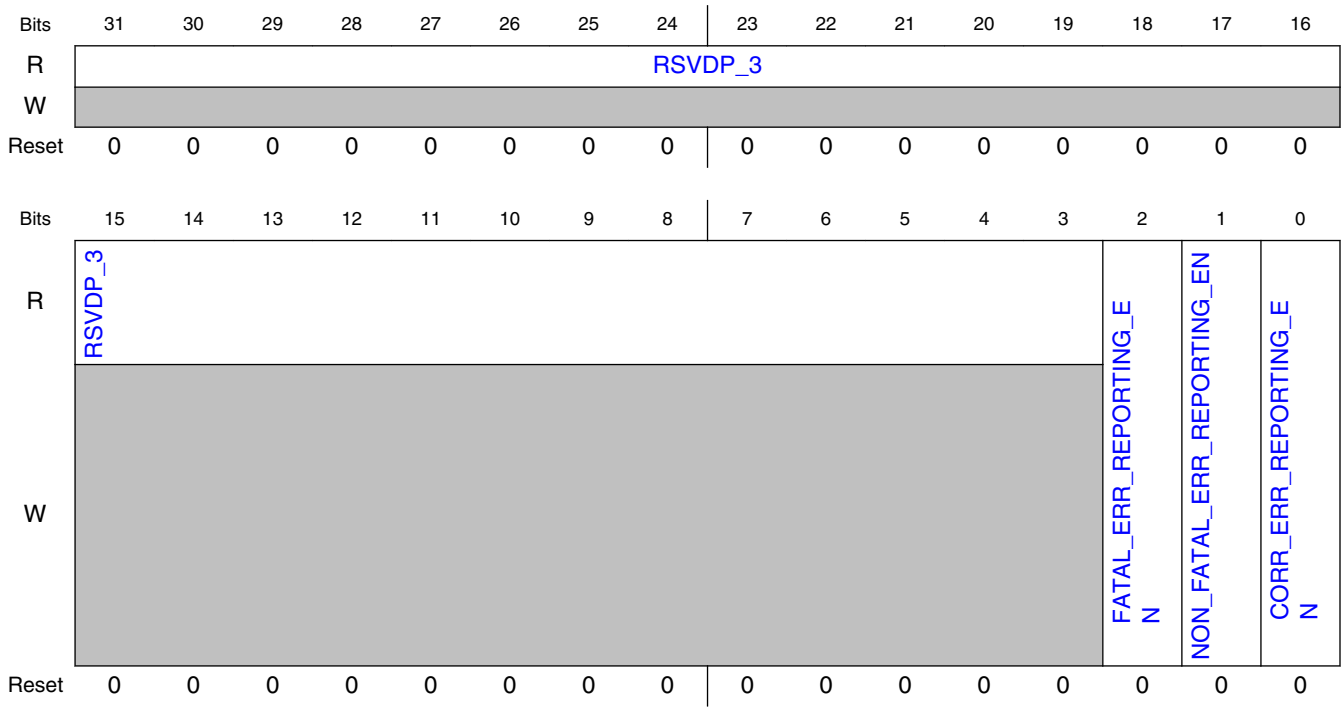
31-24 FOURTH_DWORD_FOURTH_BYTE	Byte 3 of Header log register of Fourth 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
23-16 FOURTH_DWORD_THIRD_BYTE	Byte 2 of Header log register of Fourth 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
15-8 FOURTH_DWORD_SECOND_BYTE	Byte 1 of Header log register of Fourth 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
7-0 FOURTH_DWORD_FIRST_BYTE	Byte 0 of Header log register of Fourth 32 bit Data Word. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

11.4.3.1.48 Root Error Command Register. (ROOT_ERR_CMD_OFF)



11.4.3.1.48.1 Offset

Register	Offset
ROOT_ERR_CMD_OFF	12Ch

11.4.3.1.48.2 Function

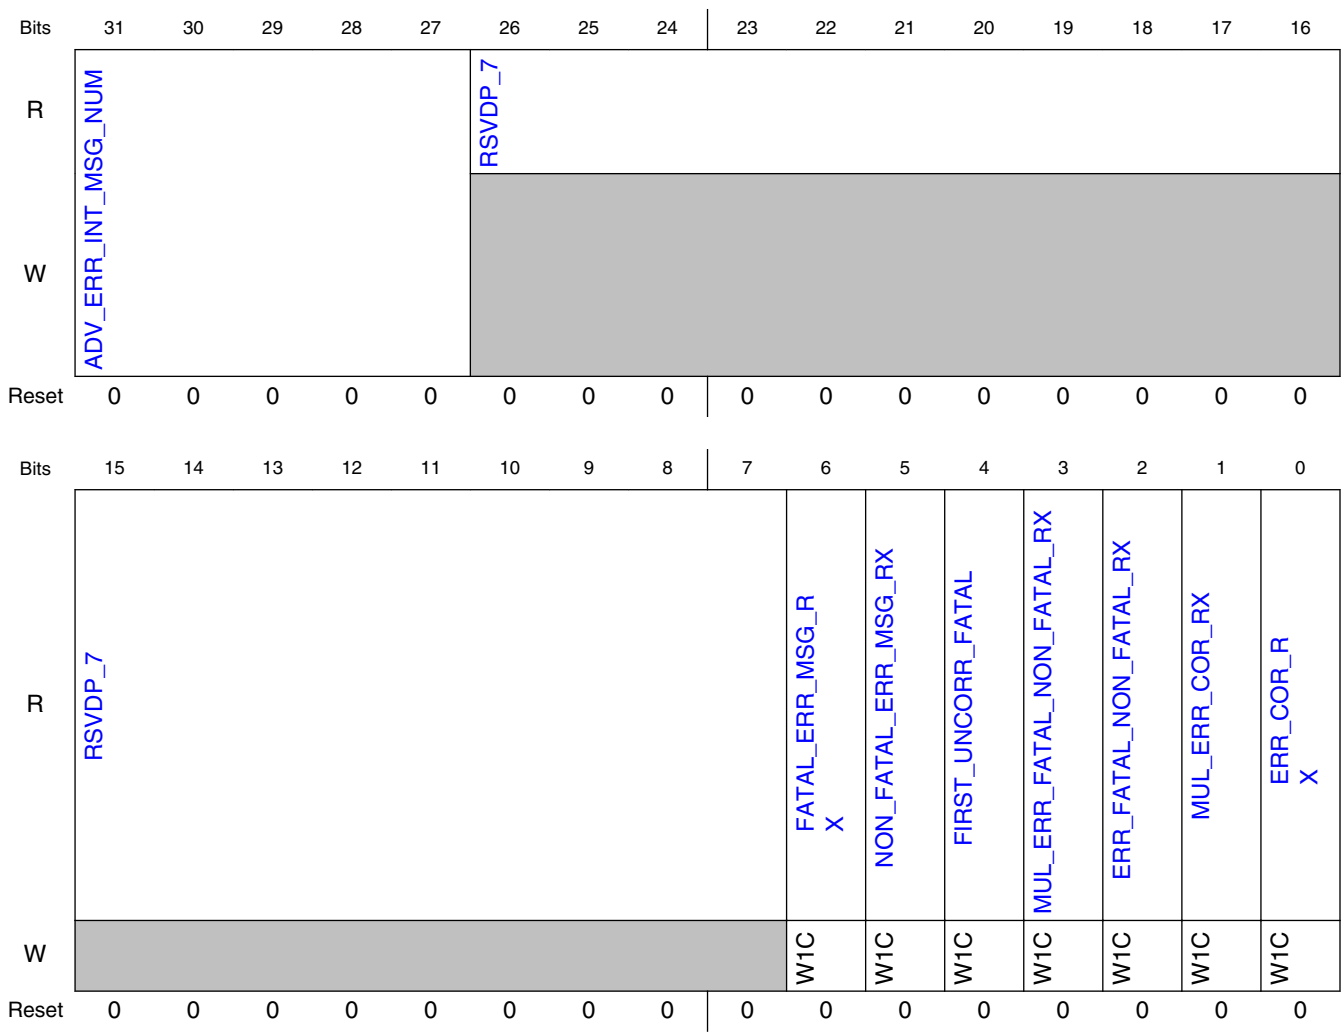
Root Error Command Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.4.3.1.48.3 Diagram

11.4.3.1.48.4 Fields

Field	Function
31-3 RSVDP_3	Reserved for future use.
2 FATAL_ERR_REPORTING_EN	Fatal Error Reporting Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
1 NON_FATAL_ERR_REPORTING_EN	Non-Fatal Error Reporting Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
0 CORR_ERR_REPORTING_EN	Correctable Error Reporting Enable. For a description of this standard PCIe register field, see the PCI Express Specification.

11.4.3.1.49 Root Error Status Register. (ROOT_ERR_STATUS_OFF)



11.4.3.1.49.1 Offset

Register	Offset
ROOT_ERR_STATUS_OFF	130h

11.4.3.1.49.2 Function

Root Error Status Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.4.3.1.49.3 Diagram

11.4.3.1.49.4 Fields

Field	Function
31-27 ADV_ERR_INT_MSG_NUM	Advanced Error Interrupt Message Number. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
26-7 RSVDP_7	Reserved for future use.
6 FATAL_ERR_MSG_RX	One or more Fatal Error Messages Received. For a description of this standard PCIe register field, see the PCI Express Specification.
5 NON_FATAL_ERR_MSG_RX	One or more Non-Fatal Error Messages Received. For a description of this standard PCIe register field, see the PCI Express Specification.
4 FIRST_UNCOR_FATAL	First Uncorrectable Error is Fatal. For a description of this standard PCIe register field, see the PCI Express Specification.
3 MUL_ERR_FATAL_NON_FATAL_RX	Multiple Fatal or Non-Fatal Errors Received. For a description of this standard PCIe register field, see the PCI Express Specification.
2 ERR_FATAL_NON_FATAL_RX	Fatal or Non-Fatal Error Received. For a description of this standard PCIe register field, see the PCI Express Specification.
1 MUL_ERR_COR_RX	Multiple Correctable Errors Received. For a description of this standard PCIe register field, see the PCI Express Specification.
0 ERR_COR_RX	Correctable Error Received. For a description of this standard PCIe register field, see the PCI Express Specification.

11.4.3.1.50 Error Source Identification Register. (ERR_SRC_ID_OFF)

11.4.3.1.50.1 Offset

Register	Offset
ERR_SRC_ID_OFF	134h

11.4.3.1.50.2 Function

Error Source Identification Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.4.3.1.50.3 Diagram

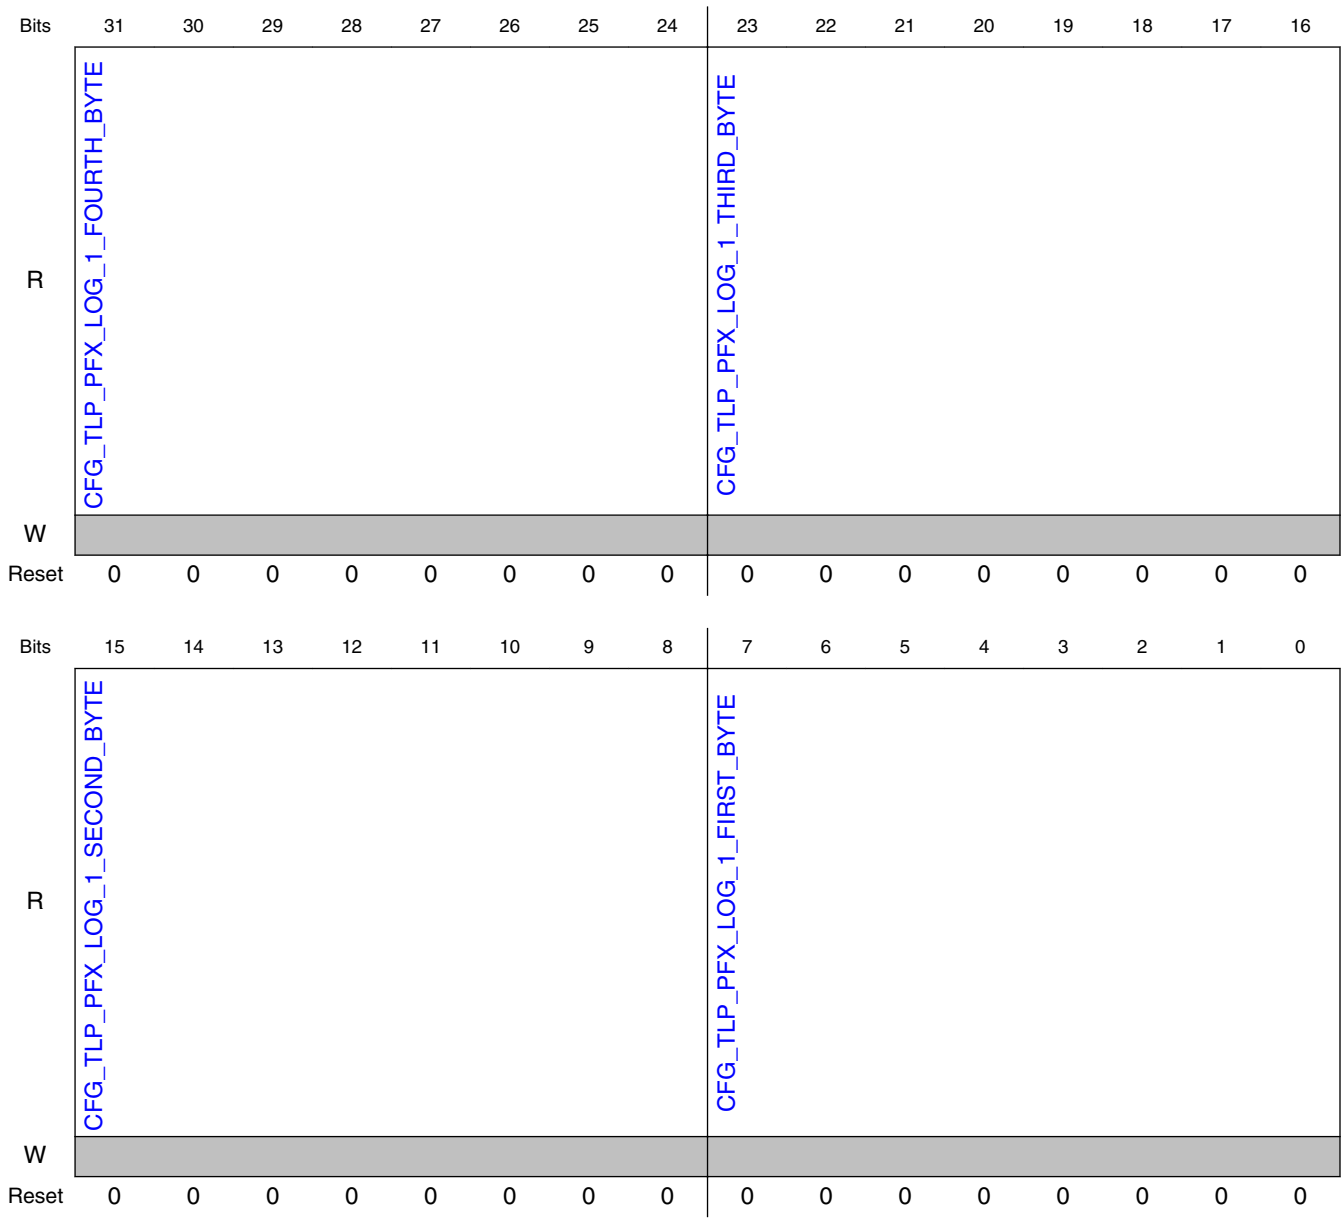
11.4.3.1.50.4 Fields

Field	Function
31-16 ERR_FATAL_NON_FATAL_SOURCE_ID	Source of Fatal/Non-Fatal Error. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
15-0 ERR_COR_SOURCE_ID	Source of Correctable Error. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

11.4.3.1.51 TLP Prefix Log Register 1. (TLP_PREFIX_LOG_1_OFF)



11.4.3.1.51.1 Offset

Register	Offset
TLP_PREFIX_LOG_1_OFF	138h

11.4.3.1.51.2 Function

TLP Prefix Log Register 1. For a description of this standard PCIe register, see the PCI Express Specification.

11.4.3.1.51.3 Diagram

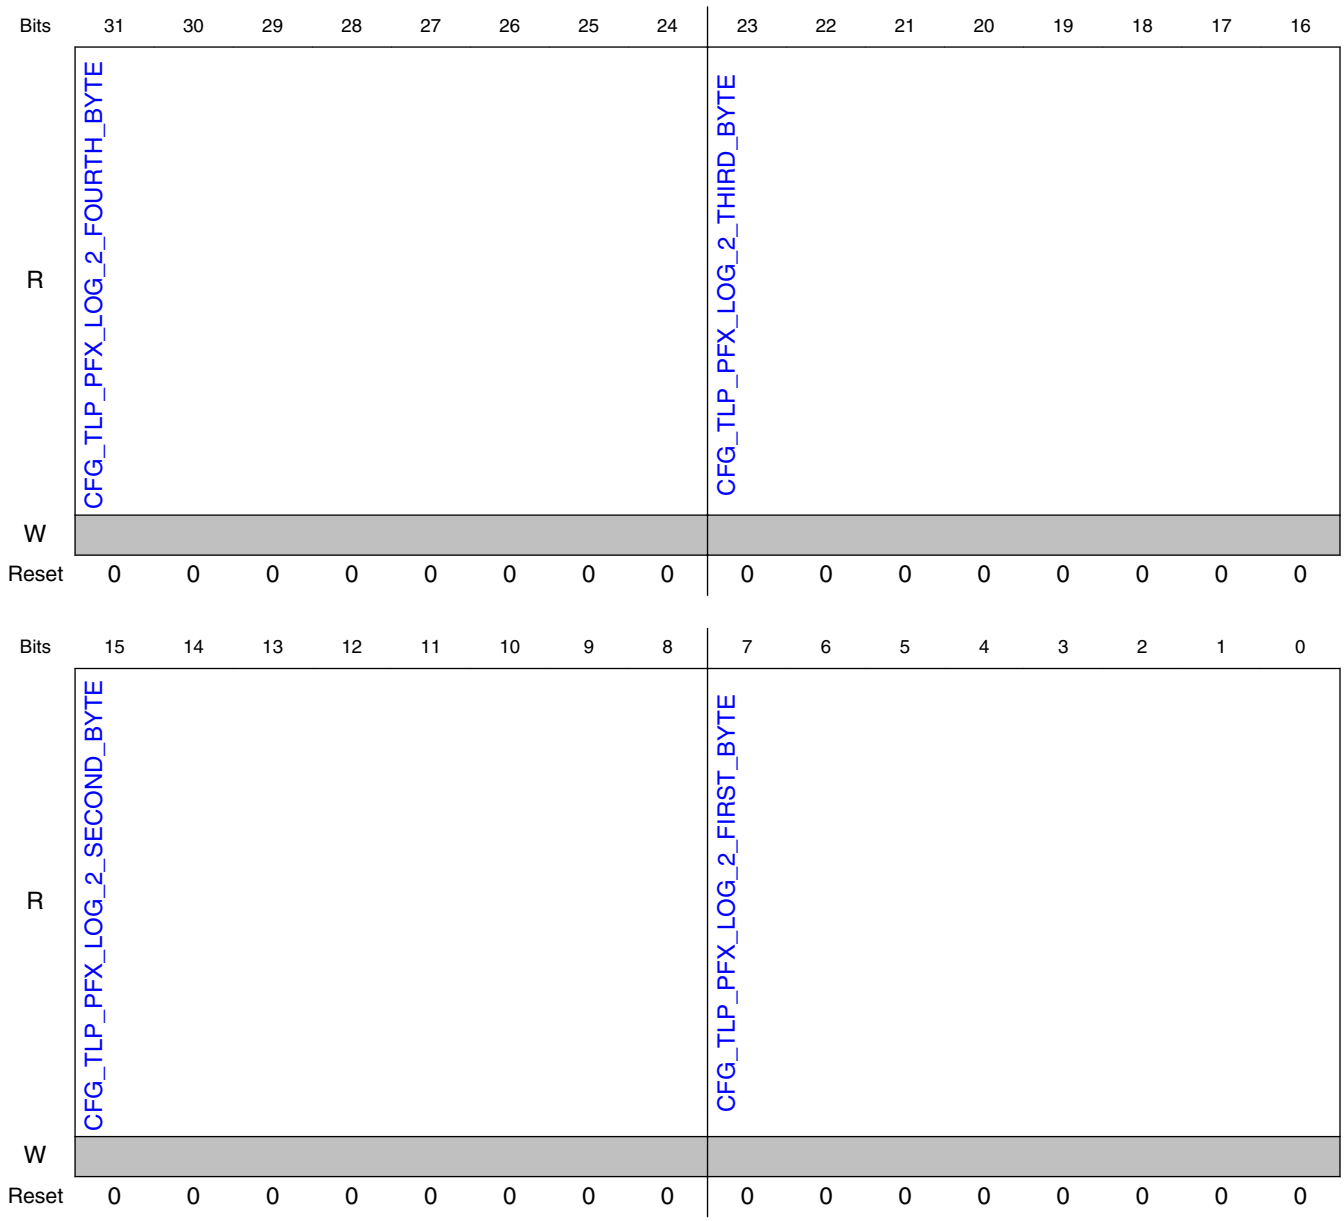
11.4.3.1.51.4 Fields

Field	Function
31-24 CFG_TLP_PFX_LOG_1_FOURTH_BYTE	Byte 3 of Error TLP Prefix Log 1. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
23-16	Byte 2 of Error TLP Prefix Log 1. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

Table continues on the next page...

Field	Function
CFG_TLP_PFX_LOG_1_THIRD_BYTE	
15-8 CFG_TLP_PFX_LOG_1_SECOND_BYTE	Byte 1 of Error TLP Prefix Log 1. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
7-0 CFG_TLP_PFX_LOG_1_FIRST_BYTE	Byte 0 of Error TLP Prefix Log 1. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

11.4.3.1.52 TLP Prefix Log Register 2. (TLP_PREFIX_LOG_2_OFF)



11.4.3.1.52.1 Offset

Register	Offset
TLP_PREFIX_LOG_2_OFF	13Ch

11.4.3.1.52.2 Function

TLP Prefix Log Register 2. For a description of this standard PCIe register, see the PCI Express Specification.

11.4.3.1.52.3 Diagram

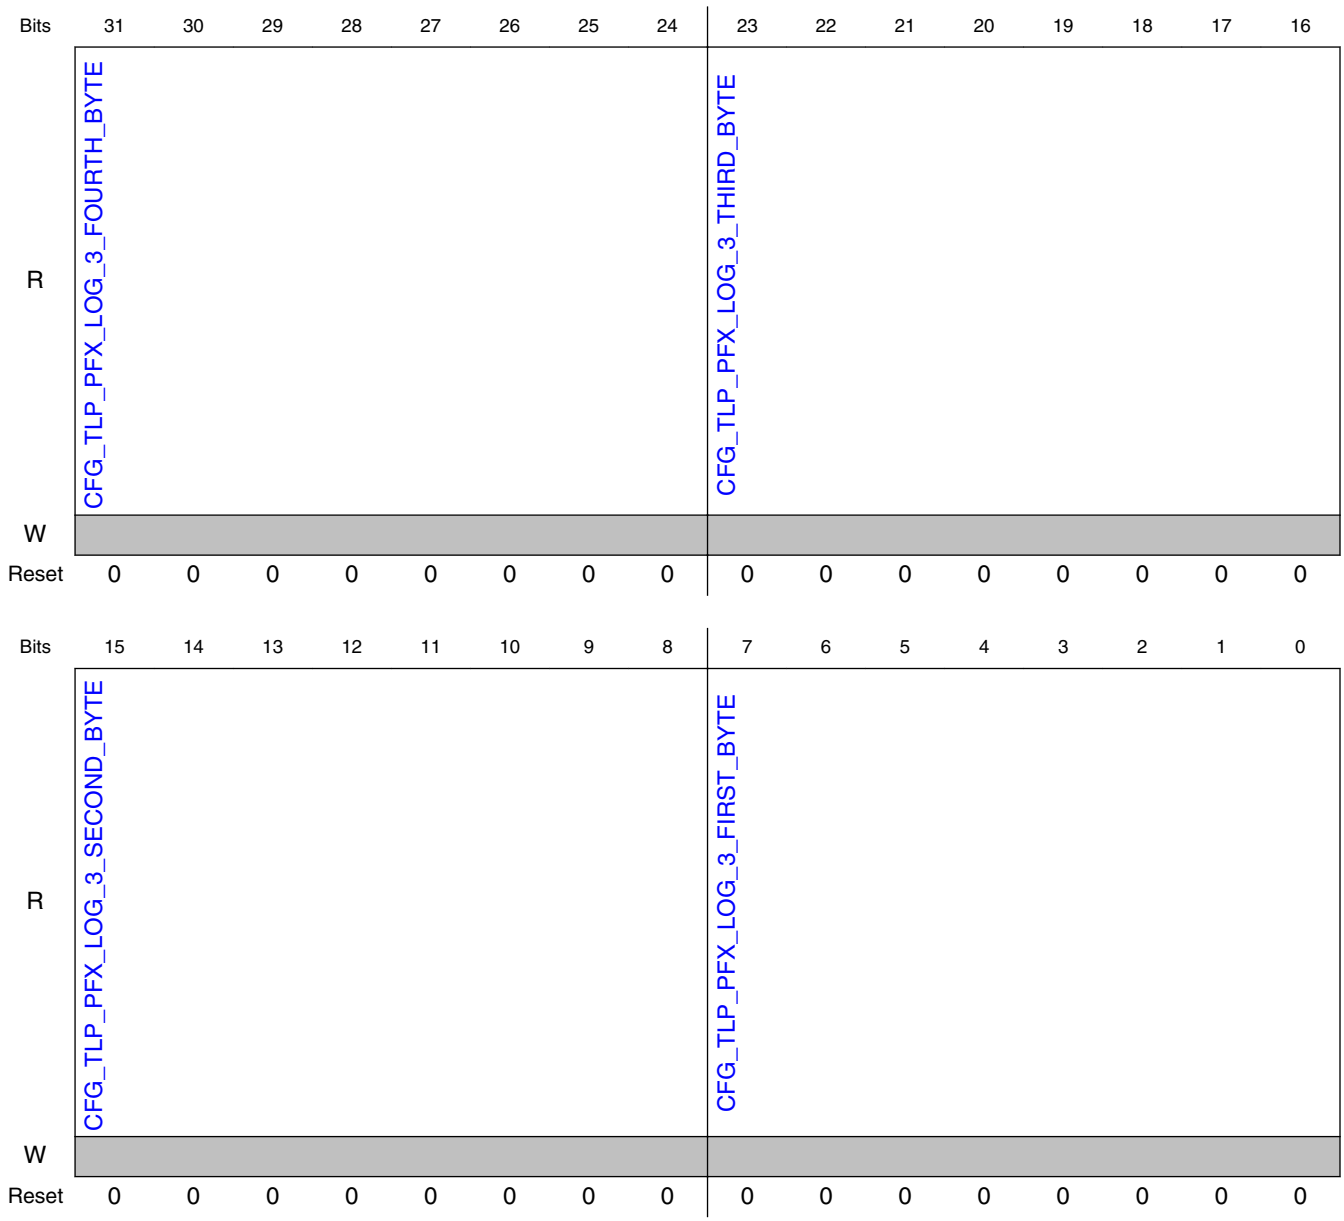
11.4.3.1.52.4 Fields

Field	Function
31-24 CFG_TLP_PFX_LOG_2_FOURTH_BYTE	Byte 3 Error TLP Prefix Log 2. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
23-16	Byte 2 Error TLP Prefix Log 2. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

Table continues on the next page...

Field	Function
CFG_TLP_PFX_LOG_2_THIRD_BYTE	
15-8 CFG_TLP_PFX_LOG_2_SECOND_BYTE	Byte 1 Error TLP Prefix Log 2. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
7-0 CFG_TLP_PFX_LOG_2_FIRST_BYTE	Byte 0 Error TLP Prefix Log 2. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

11.4.3.1.53 TLP Prefix Log Register 3. (TLP_PREFIX_LOG_3_OFF)



11.4.3.1.53.1 Offset

Register	Offset
TLP_PREFIX_LOG_3_OFF	140h

11.4.3.1.53.2 Function

TLP Prefix Log Register 3. For a description of this standard PCIe register, see the PCI Express Specification.

11.4.3.1.53.3 Diagram

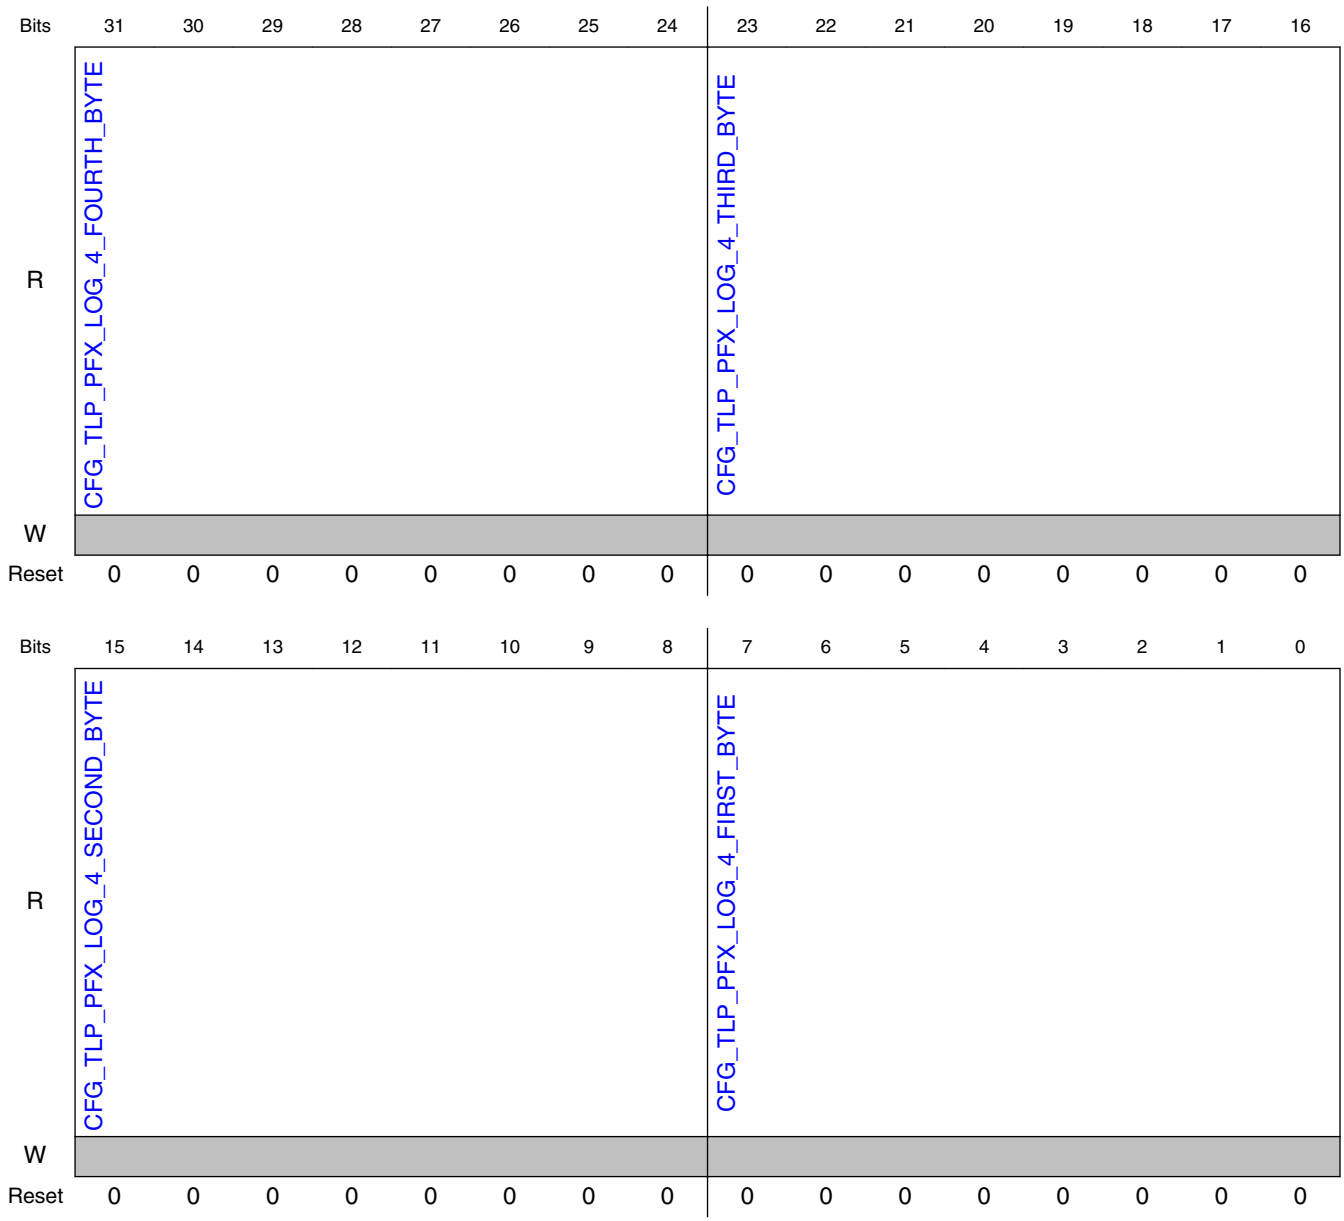
11.4.3.1.53.4 Fields

Field	Function
31-24 CFG_TLP_PFX_LOG_3_FOURTH_BYTE	Byte 3 Error TLP Prefix Log 3. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
23-16	Byte 2 Error TLP Prefix Log 3. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

Table continues on the next page...

Field	Function
CFG_TLP_PFX_LOG_3_THIRD_BYTE	
15-8 CFG_TLP_PFX_LOG_3_SECOND_BYTE	Byte 1 Error TLP Prefix Log 3. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
7-0 CFG_TLP_PFX_LOG_3_FIRST_BYTE	Byte 0 Error TLP Prefix Log 3. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

11.4.3.1.54 TLP Prefix Log Register 4. (TLP_PREFIX_LOG_4_OFF)



11.4.3.1.54.1 Offset

Register	Offset
TLP_PREFIX_LOG_4_OFF	144h

11.4.3.1.54.2 Function

TLP Prefix Log Register 4. For a description of this standard PCIe register, see the PCI Express Specification.

11.4.3.1.54.3 Diagram

11.4.3.1.54.4 Fields

Field	Function
31-24 CFG_TLP_PFX_LOG_4_FOURTH_BYTE	Byte 3 Error TLP Prefix Log 4. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
23-16	Byte 2 Error TLP Prefix Log 4. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

Table continues on the next page...

Field	Function
CFG_TLP_PFX_LOG_4_THIRD_BYTE	
15-8 CFG_TLP_PFX_LOG_4_SECOND_BYTE	Byte 1 Error TLP Prefix Log 4. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.
7-0 CFG_TLP_PFX_LOG_4_FIRST_BYTE	Byte 0 Error TLP Prefix Log 4. For a description of this standard PCIe register field, see the PCI Express Specification. Note: This register field is sticky.

11.4.3.1.55 L1 Substates Extended Capability Header. (L1SUB_CAP_HEADER_REG)

11.4.3.1.55.1 Offset

Register	Offset
L1SUB_CAP_HEADER_REG	158h

11.4.3.1.55.2 Function

L1 Substates Extended Capability Header. For a description of this standard PCIe register, see the PCI Express Specification.

11.4.3.1.55.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

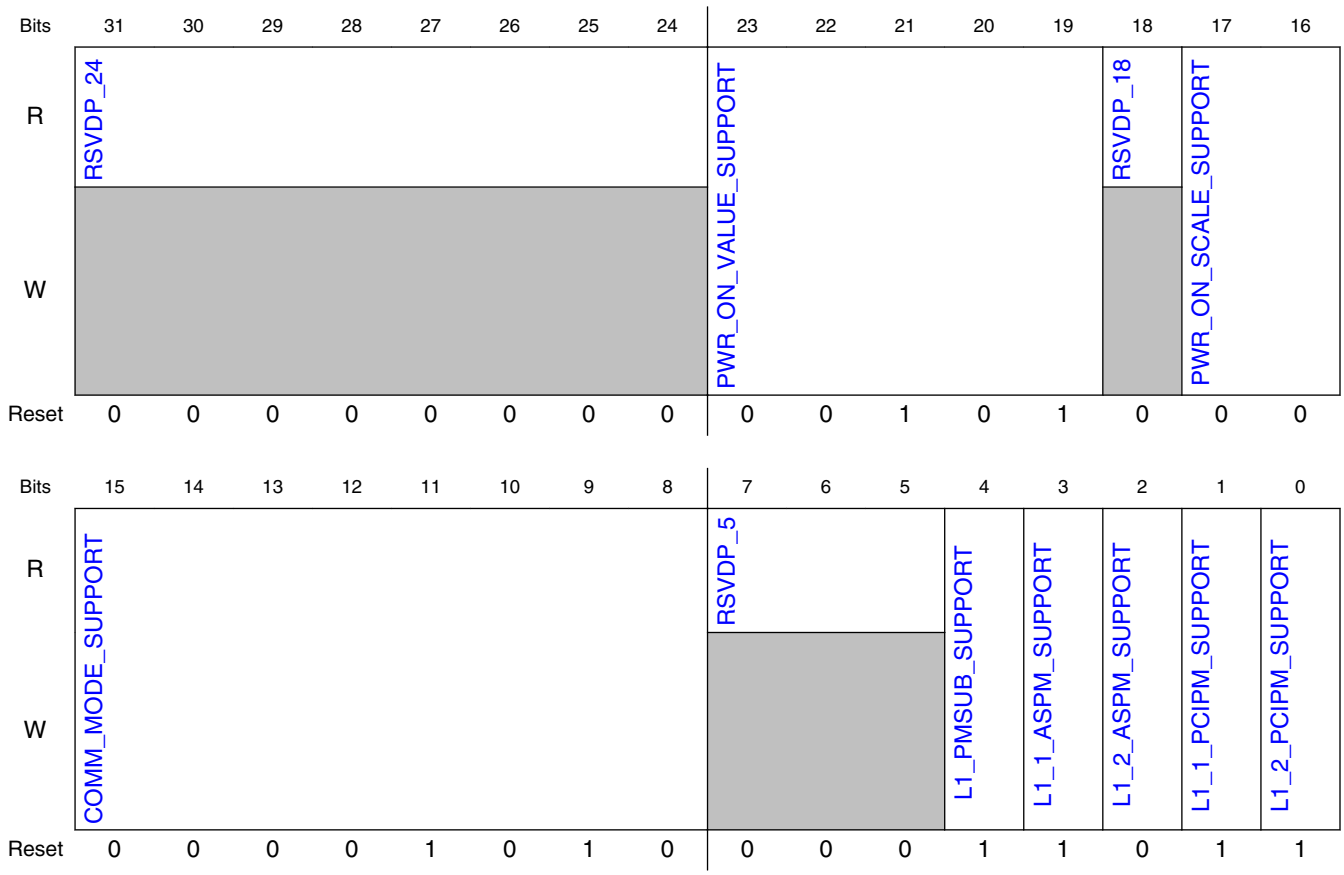
Reset	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	0

11.4.3.1.55.4 Fields

Field	Function
31-20 NEXT_OFFSET	Next Capability Offset. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
19-16 CAP_VERSION	Capability Version. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.
15-0 EXTENDED_CAP_ID	L1SUB Extended Capability ID. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: if (DBI_RO_WR_EN == 1) then R/W(sticky) else R(sticky) Note: This register field is sticky.

11.4.3.1.56 L1 Substates Capability Register. (L1SUB_CAPABILITY_REG)



11.4.3.1.56.1 Offset

Register	Offset
L1SUB_CAPABILITY_REG	15Ch

11.4.3.1.56.2 Function

L1 Substates Capability Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.4.3.1.56.3 Diagram

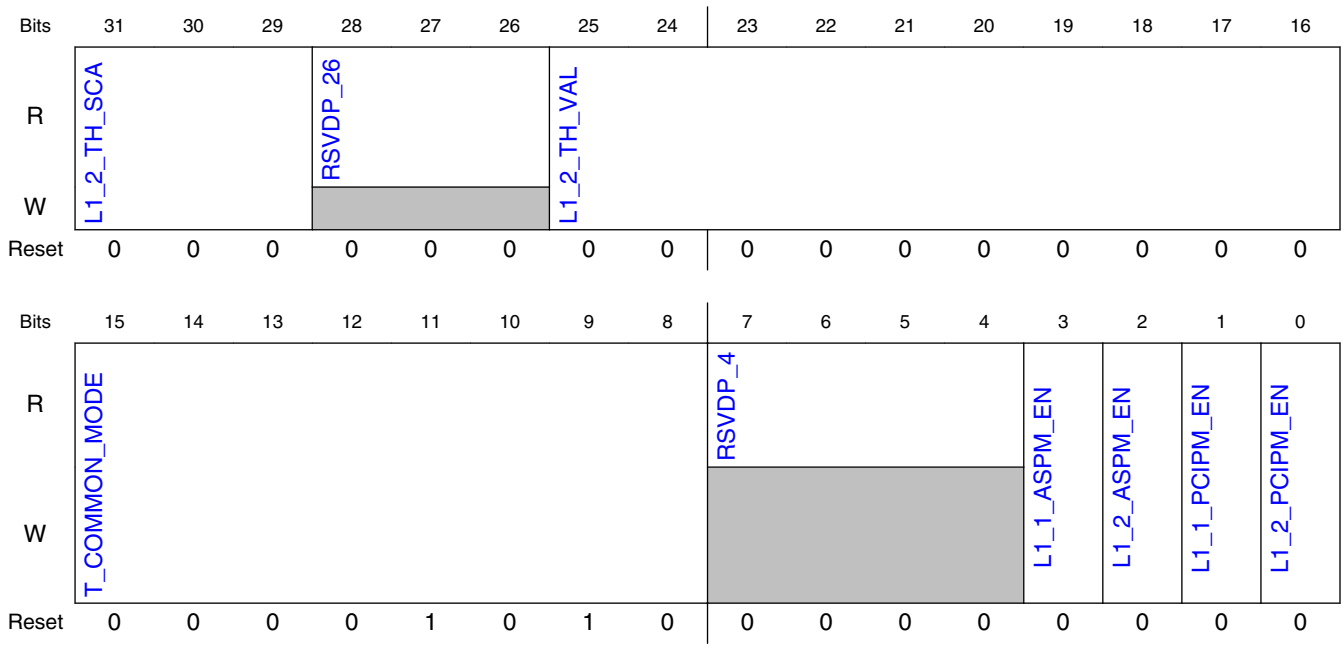
11.4.3.1.56.4 Fields

Field	Function
31-24 RSVDP_24	Reserved for future use.
23-19 PWR_ON_VALUE_SUPPORT	Port T Power On Value. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
18 RSVDP_18	Reserved for future use.
17-16 PWR_ON_SCALE_SUPPORT	Port T Power On Scale. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
15-8 COMM_MODE_SUPPORT	Port Common Mode Restore Time. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
7-5	Reserved for future use.

Table continues on the next page...

Field	Function
RSVDP_5	
4 L1_PMSUB_SUPPORT	L1 PM Substates ECN Supported. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
3 L1_1_ASPM_SUPPORT	ASPM L11 Supported. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
2 L1_2_ASPM_SUPPORT	ASPM L12 Supported. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
1 L1_1_PCIPM_SUPPORT	PCI-PM L11 Supported. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
0 L1_2_PCIPM_SUPPORT	PCI-PM L12 Supported. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W

11.4.3.1.57 L1 Substates Control 1 Register. (L1SUB_CONTROL1_REG)



11.4.3.1.57.1 Offset

Register	Offset
L1SUB_CONTROL1_REG	160h

11.4.3.1.57.2 Function

L1 Substates Control 1 Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.4.3.1.57.3 Diagram

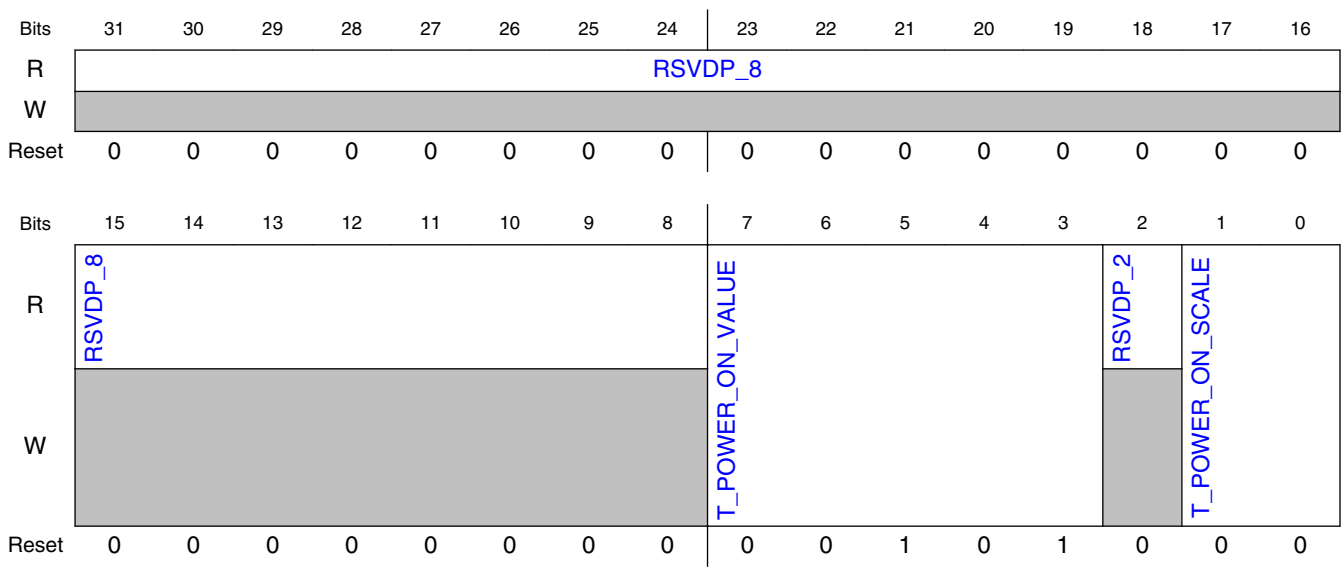
11.4.3.1.57.4 Fields

Field	Function
31-29 L1_2_TH_SCA	LTR L12 Threshold Scale. For a description of this standard PCIe register field, see the PCI Express Specification.
28-26 RSVDP_26	Reserved for future use.
25-16 L1_2_TH_VAL	LTR L12 Threshold Value. For a description of this standard PCIe register field, see the PCI Express Specification.
15-8 T_COMMON_MODE	Common Mode Restore Time. For a description of this standard PCIe register field, see the PCI Express Specification. Note: The access attributes of this field are as follows: - Dbi: R/W
7-4 RSVDP_4	Reserved for future use.
3 L1_1_ASPM_EN	ASPM L11 Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
2 L1_2_ASPM_EN	ASPM L12 Enable. For a description of this standard PCIe register field, see the PCI Express Specification.
1 L1_1_PCIPM_EN	PCI-PM L11 Enable. For a description of this standard PCIe register field, see the PCI Express Specification.

Table continues on the next page...

Field	Function
0 L1_2_PCIPM_EN	PCI-PM L12 Enable. For a description of this standard PCIe register field, see the PCI Express Specification.

11.4.3.1.58 L1 Substates Control 2 Register. (L1SUB_CONTROL2_REG)



11.4.3.1.58.1 Offset

Register	Offset
L1SUB_CONTROL2_REG	164h

11.4.3.1.58.2 Function

L1 Substates Control 2 Register. For a description of this standard PCIe register, see the PCI Express Specification.

11.4.3.1.58.3 Diagram

11.4.3.1.58.4 Fields

Field	Function
31-8	Reserved for future use.

Table continues on the next page...

Field	Function
RSVDP_8	
7-3 T_POWER_ON_VALUE	T Power On Value. For a description of this standard PCIe register field, see the PCI Express Specification.
2 RSVDP_2	Reserved for future use.
1-0 T_POWER_ON_SCALE	T Power On Scale. For a description of this standard PCIe register field, see the PCI Express Specification.

11.4.3.1.59 Ack Latency Timer and Replay Timer Register. (ACK_LATENCY_TIMER_OFF)

11.4.3.1.59.1 Offset

Register	Offset
ACK_LATENCY_TIMER_OFF	700h

11.4.3.1.59.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	REPLAY_TIME_LIMIT															
Reset	0	0	0	1	1	0	0	0	0	1	0	0	0	1	1	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ROUND_TRIP_LATENCY_TIME_LIMIT															
Reset	0	0	0	0	1	0	0	0	0	0	0	1	0	1	1	1

11.4.3.1.59.3 Fields

Field	Function
31-16 REPLAY_TIME_LIMIT	Replay Timer Limit. The replay timer expires when it reaches this limit. The controller initiates a replay upon reception of a NAK or when the replay timer expires. For more details, see "Transmit Replay". You can modify the effective timer limit with the TIMER_MOD_REPLAY_TIMER field of the TIMER_CTRL_MAX_FUNC_NUM_OFF register. After reset, the controller updates the default according to the Negotiated Link Width, Max_Payload_Size, and speed. The value is determined from Tables 3-4,

Table continues on the next page...

Field	Function
	3-5, and 3-6 of the PCIe 3.0 specification. If there is a change in the payload size or link speed, the controller will override any value that you have written to this register field, and reset the field back to the specification-defined value. It will not change the value in the TIMER_MOD_REPLAY_TIMER field of the TIMER_CTRL_MAX_FUNC_NUM_OFF register.
15-0 ROUND_TRIP_LATENCY_TIME_LIMIT	Ack Latency Timer Limit. The Ack latency timer expires when it reaches this limit. For more details, see "Ack Scheduling". You can modify the effective timer limit with the TIMER_MOD_ACK_NAK field of the TIMER_CTRL_MAX_FUNC_NUM_OFF register. After reset, the controller updates the default according to the Negotiated Link Width, Max_Payload_Size, and speed. The value is determined from Tables 3-7, 3-8, and 3-9 of the PCIe 3.0 specification. The limit must reflect the round trip latency from requester to completer. If there is a change in the payload size or link width, the controller will override any value that you have written to this register field, and reset the field back to the specification-defined value. It will not change the value in the TIMER_MOD_ACK_NAK field of the TIMER_CTRL_MAX_FUNC_NUM_OFF register.

11.4.3.1.60 Vendor Specific DLLP Register. (VENDOR_SPEC_DLLP_OFF)

11.4.3.1.60.1 Offset

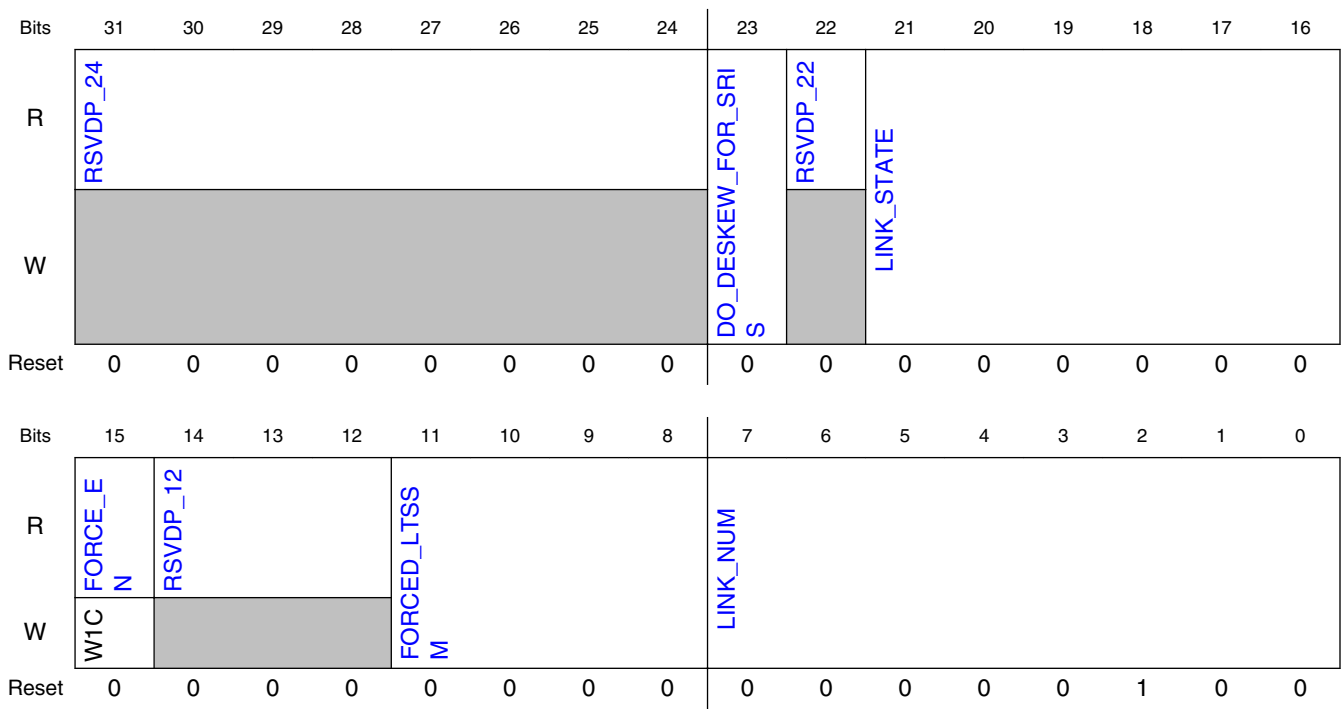
Register	Offset
VENDOR_SPEC_DLLP_OFF	704h

11.4.3.1.60.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	VENDOR_SPEC_DLLP															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	VENDOR_SPEC_DLLP															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

11.4.3.1.60.3 Fields



Field	Function
31-0 VENDOR_SPEC_DLLP	Vendor Specific DLLP Register. Used to send a specific PCI Express DLLP. Your application writes the 8-bit DLLP Type and 24-bits of Payload data into this register, then sets the field VENDOR_SPECIFIC_DLLP_REQ of PORT_LINK_CTRL_OFF to send the DLLP. - [7:0] = Type - [31:8] = Payload (24 bits) The dllp type is in bits [7:0] while the remainder is the vendor defined payload. Note: This register field is sticky.

11.4.3.1.61 Port Force Link Register. (PORT_FORCE_OFF)

11.4.3.1.61.1 Offset

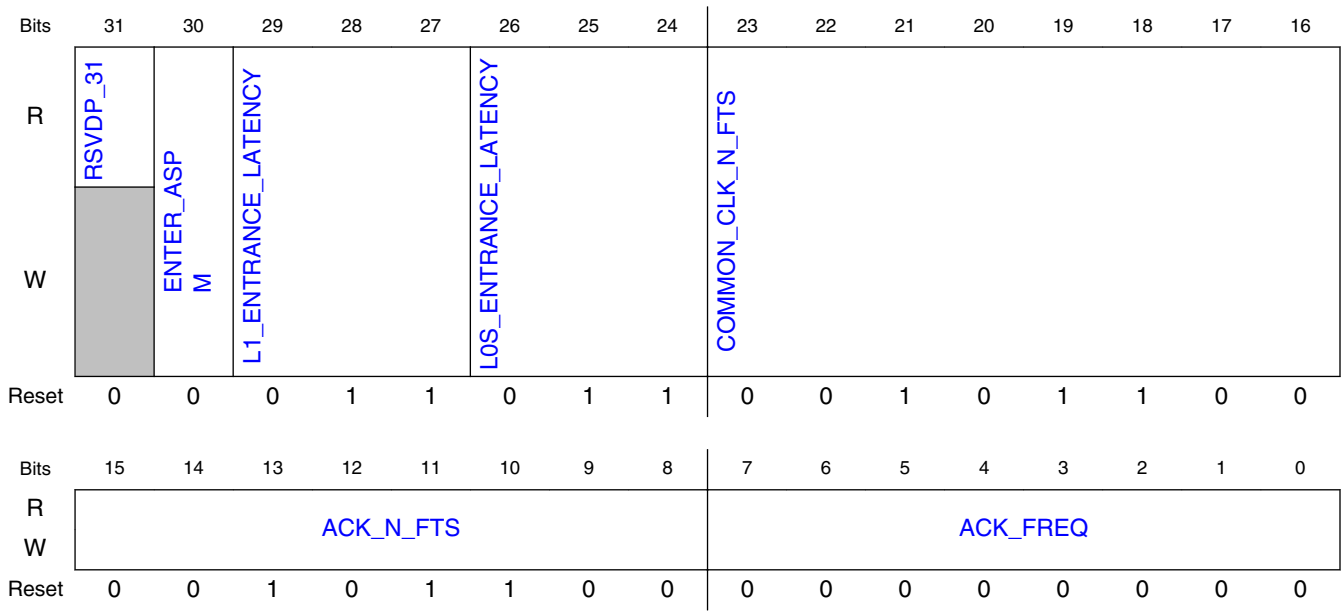
Register	Offset
PORT_FORCE_OFF	708h

11.4.3.1.61.2 Diagram

11.4.3.1.61.3 Fields

Field	Function
31-24 RSVDP_24	Reserved for future use.
23 DO_DESKEW_FOR_SRIS	Use the transitions from TS2 to Logical Idle Symbol, SKP OS to Logical Idle Symbol, and FTS Sequence to SKP OS to do deskew for SRIS instead of using received SKP OS if DO_DESKEW_FOR_SRIS is set to 1. Note: This register field is sticky.
22 RSVDP_22	Reserved for future use.

Table continues on the next page...



Field	Function
21-16 LINK_STATE	Forced LTSSM State. The LTSSM state that the controller is forced to when you set the FORCE_EN bit (Force Link). LTSSM state encoding is defined by the lts_state variable in workspace/src/Layer1/smlh_ltssm.v. Note: This register field is sticky.
15 FORCE_EN	Force Link. The controller supports a testing and debug capability to allow your software to force the LTSSM state machine into a specific state, and to force the controller to transmit a specific Link Command. Asserting this bit triggers the following actions: - Forces the LTSSM to the state specified by the Forced LTSSM State field. - Forces the controller to transmit the command specified by the Forced Link Command field. This is a self-clearing register field. Reading from this register field always returns a "0".
14-12 RSVDP_12	Reserved for future use.
11-8 FORCED_LTSSM	Forced Link Command. The link command that the controller is forced to transmit when you set FORCE_EN bit (Force Link). Link command encoding is defined by the ltssm_cmd variable in workspace/src/Layer1/smlh_ltssm.v. Note: This register field is sticky.
7-0 LINK_NUM	Link Number. Not used for endpoint. Not used for M-PCIe. Note: This register field is sticky.

11.4.3.1.62 Ack Frequency and L0-L1 ASPM Control Register. (ACK_F_ASPM_CTRL_OFF)

11.4.3.1.62.1 Offset

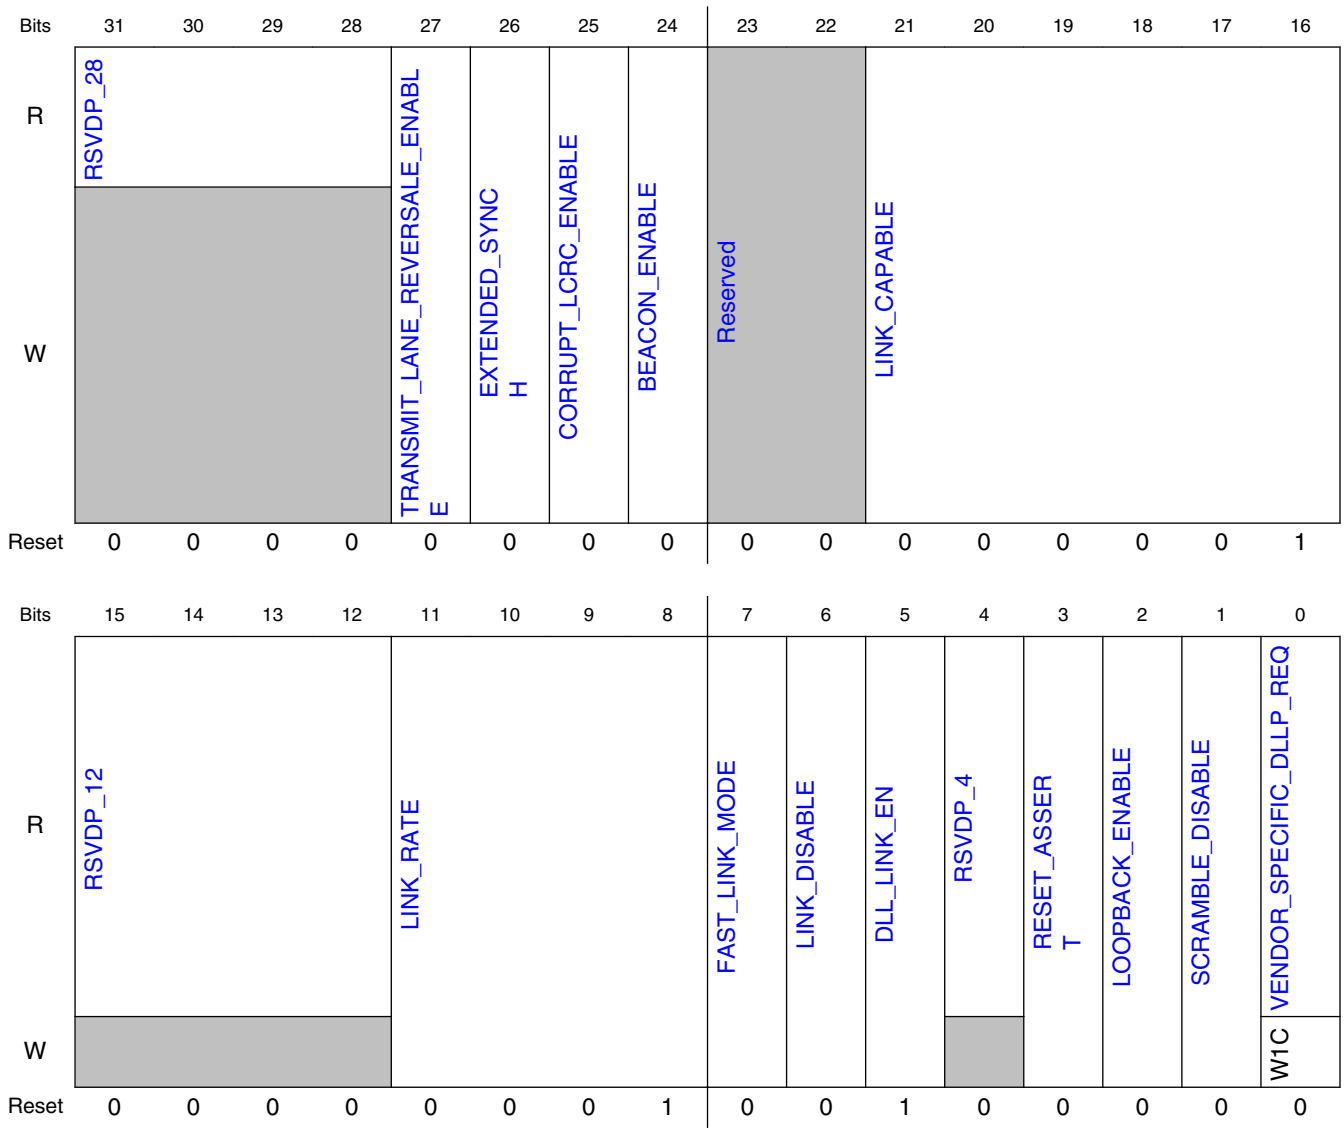
Register	Offset
ACK_F_ASPM_CTRL_OFF	70Ch

11.4.3.1.62.2 Diagram

11.4.3.1.62.3 Fields

Field	Function
31 RSVDP_31	Reserved for future use.
30 ENTER_ASPM	ASPM L1 Entry Control. - 1: Core enters ASPM L1 after a period in which it has been idle. - 0: Core enters ASPM L1 only after idle period during which both receive and transmit are in L0s. Note: This register field is sticky.
29-27 L1_ENTRANCE_LATENCY	L1 Entrance Latency. Value range is: - 000: 1 us - 001: 2 us - 010: 4 us - 011: 8 us - 100: 16 us - 101: 32 us - 110 or 111: 64 us Note: Programming this timer with a value greater that 32us has no effect unless extended sync is used, or all of the credits are infinite. Note: This register field is sticky.
26-24 L0S_ENTRANCE_LATENCY	L0s Entrance Latency. Values correspond to: - 000: 1 us - 001: 2 us - 010: 3 us - 011: 4 us - 100: 5 us - 101: 6 us - 110 or 111: 7 us This field is applicable to STALL while in L0 for M-PCIe. Note: This register field is sticky.
23-16 COMMON_CLK_N_FTS	Common Clock N_FTS. This is the N_FTS when common clock is used. The number of Fast Training Sequence ordered sets to be transmitted when transitioning from L0s to L0. The maximum number of FTS ordered-sets that a component can request is 255. This field is only writable (sticky) when all of the following configuration parameter equations are true: - CX_NFTS !=CX_COMM_NFTS - DEFAULT_L0S_EXIT_LATENCY !=DEFAULT_COMM_L0S_EXIT_LATENCY - DEFAULT_L1_EXIT_LATENCY !=DEFAULT_COMM_L1_EXIT_LATENCY The controller does not support a value of zero; a value of zero can cause the LTSSM to go into the recovery state when exiting from L0s. This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R
15-8 ACK_N_FTS	N_FTS. The number of Fast Training Sequence ordered sets to be transmitted when transitioning from L0s to L0. The maximum number of FTS ordered-sets that a component can request is 255. The controller does not support a value of zero; a value of zero can cause the LTSSM to go into the recovery state when exiting from L0s. This field is reserved (fixed to '0') for M-PCIe. Note: This register field is sticky.

Table continues on the next page...



Field	Function
7-0 ACK_FREQ	Ack Frequency. The controller accumulates the number of pending ACKs specified here (up to 255) before sending an ACK DLLP. - 0: Indicates that this Ack frequency control feature is turned off. The controller schedules a low-priority ACK DLLP for every TLP that it receives. - 1-255: Indicates that the controller will schedule a high-priority ACK after receiving this number of TLPs. It might schedule the ACK before receiving this number of TLPs, but never later. For a typical system, you do not have to modify the default setting. For more details, see "ACK/NAK Scheduling". Note: This register field is sticky.

11.4.3.1.63 Port Link Control Register. (PORT_LINK_CTRL_OFF)

11.4.3.1.63.1 Offset

Register	Offset
PORT_LINK_CTRL_OFF	710h

11.4.3.1.63.2 Diagram

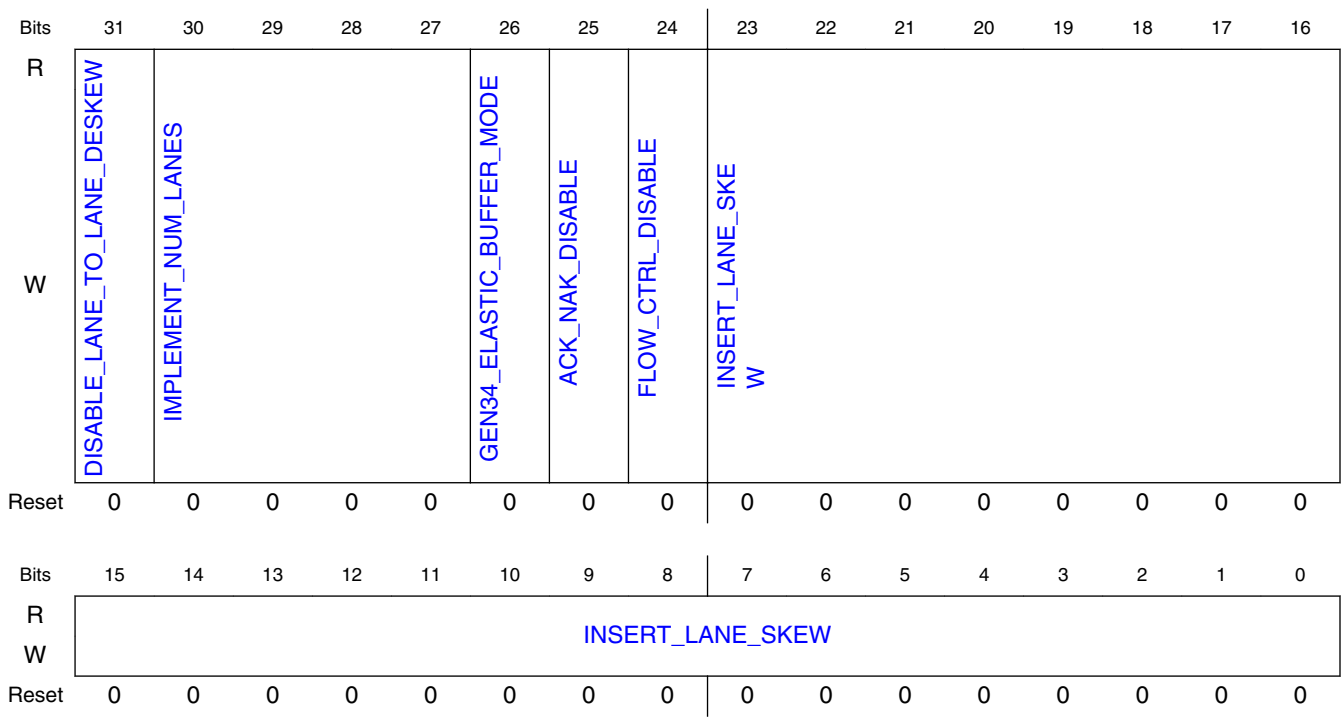
11.4.3.1.63.3 Fields

Field	Function
31-28 RSVDP_28	Reserved for future use.
27 TRANSMIT_LANE_REVERSALE_ENABLE	TRANSMIT_LANE_REVERSALE_ENABLE is an internally reserved field. Do not use. Note: This register field is sticky.
26	EXTENDED_SYNCH is an internally reserved field. Do not use. Note: This register field is sticky.

Table continues on the next page...

Field	Function
EXTENDED_SYNCH	
25 CORRUPT_LCRC_ENABLE	CORRUPT_LCRC_ENABLE is an internally reserved field. Do not use. Note: This register field is sticky.
24 BEACON_ENABLE	BEACON_ENABLE is an internally reserved field. Do not use. Note: This register field is sticky.
23-22 —	Reserved
21-16 LINK_CAPABLE	Link Mode Enable. Sets the number of lanes in the link that you want to connect to the link partner. When you have unused lanes in your system, then you must change the value in this register to reflect the number of lanes. You must also change the value in the "Predetermined Number of Lanes" field of the "Link Width and Speed Change Control Register". For more information, see "How to Tie Off Unused Lanes". For information on upsizing and downsizing the link width, see "Link Establishment". - 000001: x1 - 000011: x2 - 000111: x4 - 001111: x8 - 011111: x16 - 111111: x32 (not supported) This field is reserved (fixed to '0') for M-PCIe. Note: This register field is sticky.
15-12 RSVDP_12	Reserved for future use.
11-8 LINK_RATE	LINK_RATE is an internally reserved field. Do not use. Note: This register field is sticky.
7 FAST_LINK_MODE	Fast Link Mode. Sets all internal LTSSM millisecond timers to Fast Mode for speeding up simulation. Forces the LTSSM training (link initialization) to use shorter time-outs and to link up faster. The default scaling factor can be changed using the DEFAULT_FAST_LINK_SCALING_FACTOR parameter or through the FAST_LINK_SCALING_FACTOR field in the TIMER_CTRL_MAX_FUNC_NUM_OFF register. Fast Link Mode can also be activated by setting the diag_ctrl_bus[2] pin to '1'. For more details, see the "Fast Link Simulation Mode" section in the "Integrating the Core with the PHY or Application RTL or Verification IP" chapter of the User Guide. For M-PCIe, this field also affects Remain Hibern8 Time, Minimum Activate Time, and RRAP timeout. If this bit is set to '1', tRRAPInitiatorResponse is set to 1.88 ms(60 ms/32). Note: This register field is sticky.
6 LINK_DISABLE	LINK_DISABLE is an internally reserved field. Do not use. Note: This register field is sticky.
5 DLL_LINK_EN	DLL Link Enable. Enables link initialization. When DLL Link Enable =0, the controller does not transmit InitFC DLLPs and does not establish a link. Note: This register field is sticky.
4 RSVDP_4	Reserved for future use.
3 RESET_ASSERT	Reset Assert. Triggers a recovery and forces the LTSSM to the hot reset state (downstream port only). Note: This register field is sticky.
2 LOOPBACK_ENABLE	Loopback Enable. Turns on loopback. For more details, see "Loopback". For M-PCIe, to force the master to enter Digital Loopback mode, you must set this field to "1" during Configuration.start state(initial discovery/configuration). M-PCIe doesn't support loopback mode from L0 state - only from Configuration.start. Note: This register field is sticky.
1 SCRAMBLE_DISABLE	Scramble Disable. Turns off data scrambling. Note: This register field is sticky.

Table continues on the next page...



Field	Function
0 VENDOR_SPECIFIC_DLLP_REQ	Vendor Specific DLLP Request. When software writes a '1' to this bit, the controller transmits the DLLP contained in the VENDOR_SPEC_DLLP field of VENDOR_SPEC_DLLP_OFF. Reading from this self-clearing register field always returns a '0'.

11.4.3.1.64 Lane Skew Register. (LANE_SKEW_OFF)

11.4.3.1.64.1 Offset

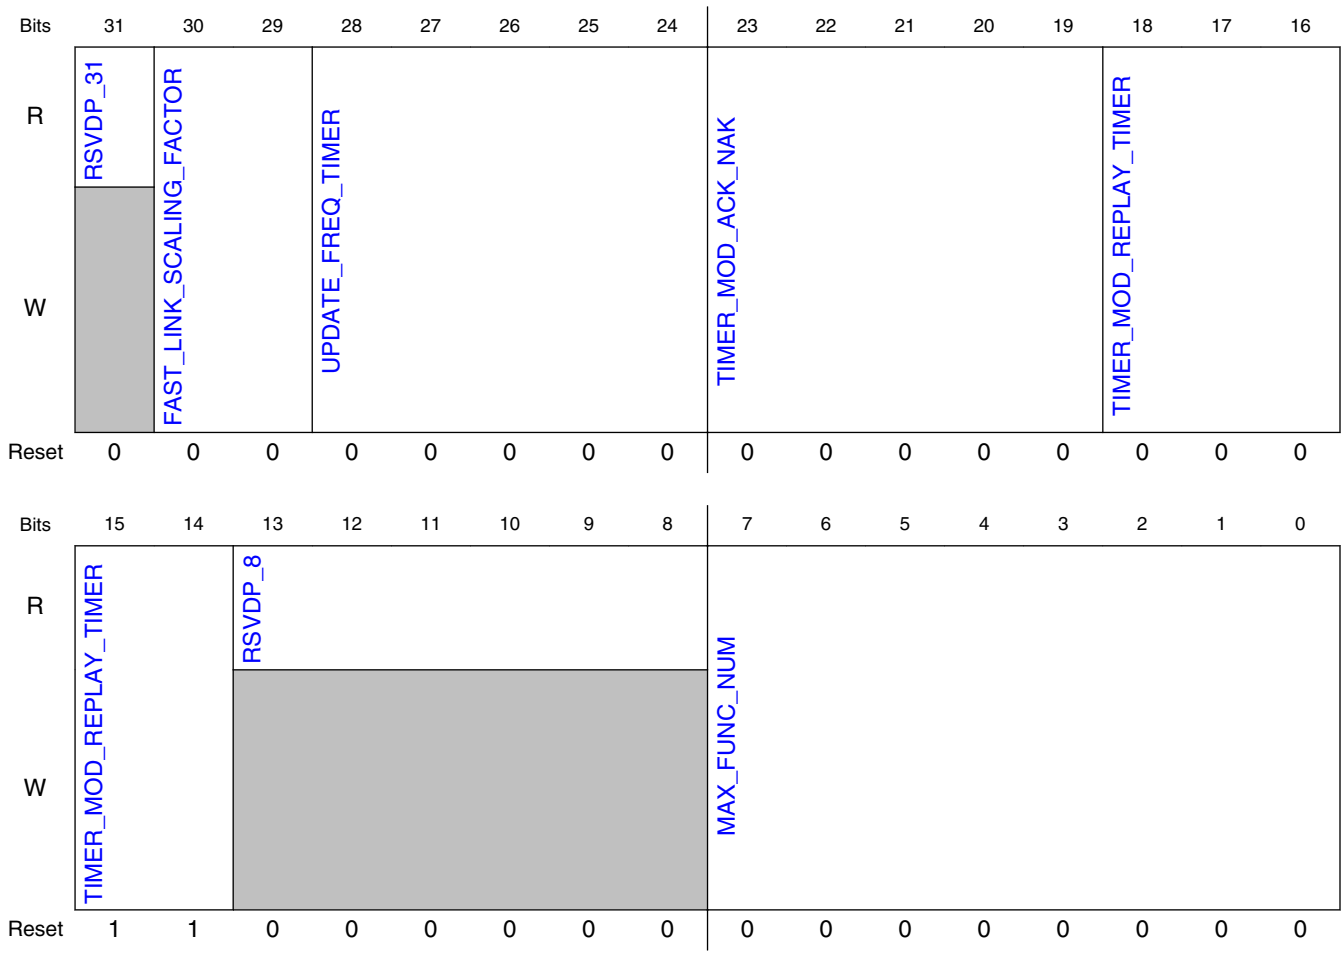
Register	Offset
LANE_SKEW_OFF	714h

11.4.3.1.64.2 Diagram

11.4.3.1.64.3 Fields

Field	Function
31	Disable Lane-to-Lane Deskew. Causes the controller to disable the internal Lane-to-Lane deskew logic. Note: This register field is sticky.

Table continues on the next page...



Field	Function
DISABLE_LANE_TO_LANE_DESKEW	
30-27 IMPLEMENT_NUM_LANES	Implementation-specific Number of Lanes. Set the implementation-specific number of lanes. Allowed values are: - 4'b0000: 1 lane - 4'b0001: 2 lanes - 4'b0011: 4 lanes - 4'b0111: 8 lanes - 4'b1111: 16 lanes The number of lanes to be used when in Loopback Master. The number of lanes programmed must be equal to or less than the valid number of lanes set in LINK_CAPABLE field. You must configure this field before initiating Loopback by writing in the LOOPBACK_ENABLE field. The controller will transition from Loopback.Entry to Loopback.Active after receiving two consecutive TS1 Ordered Sets with the Loopback bit asserted on the implementation specific number of lanes configured in this field. Note: This register field is sticky.
26 GEN34_ELASTIC_BUFFER_MODE	Selects Elasticity Buffer operating mode in Gen3 or Gen4 rate: 0: Nominal Half Full Buffer mode 1: Nominal Empty Buffer Mode This register bit only affects Gen3 or Gen4 operating rate. For Gen1 or Gen2 operating rate the Elasticity Buffer operating mode is always the Nominal Half Full Buffer mode. Note: This register field is sticky.
25 ACK_NAK_DISABLE	Ack/Nak Disable. Prevents the controller from sending ACK and NAK DLLPs. Note: This register field is sticky.
24 FLOW_CTRL_DISABLE	Flow Control Disable. Prevents the controller from sending FC DLLPs. Note: This register field is sticky.
23-0 INSERT_LANE_SKEW	INSERT_LANE_SKEW is an internally reserved field. Do not use. Note: This register field is sticky.

11.4.3.1.65 Timer Control and Max Function Number Register. (TIMER_CTRL_MAX_FUNC_NUM_OFF)

11.4.3.1.65.1 Offset

Register	Offset
TIMER_CTRL_MAX_FUNC_NUM_OFF	718h

11.4.3.1.65.2 Diagram

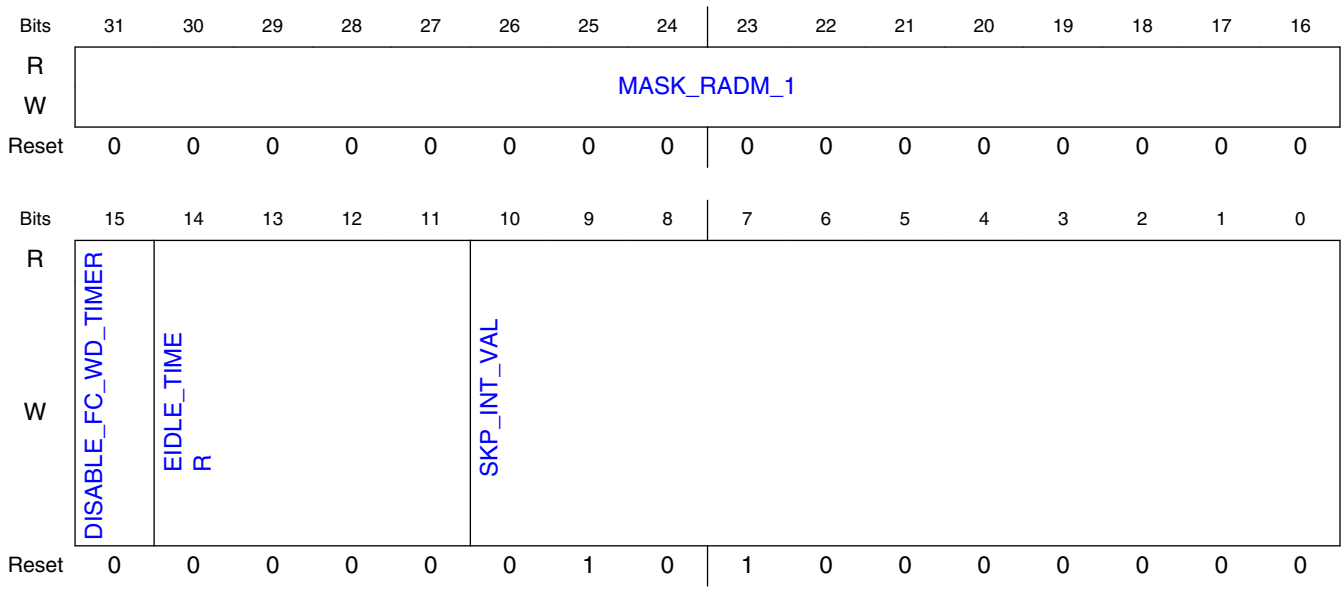
11.4.3.1.65.3 Fields

Field	Function
31 RSVDP_31	Reserved for future use.
30-29 FAST_LINK_SCALING_FACTOR	Fast Link Timer Scaling Factor. Sets the scaling factor of LTSSM timer when FAST_LINK_MODE field in PORT_LINK_CTRL_OFF is set to '1'. - 0: Scaling Factor is 1024 (1ms is 1us) - 1: Scaling Factor is 256 (1ms is 4us) - 2: Scaling Factor is 64 (1ms is 16us) - 3: Scaling Factor is 16 (1ms is 64us) Default is set by the hidden configuration parameter DEFAULT_FAST_LINK_SCALING_FACTOR which defaults to '0'. Not used for M-PCIe. Note: This register field is sticky.
28-24 UPDATE_FREQ_TIMER	UPDATE_FREQ_TIMER is an internally reserved field. Do not use. Note: This register field is sticky.
23-19 TIMER_MOD_ACK_NAK	Ack Latency Timer Modifier. Increases the timer value for the Ack latency timer in increments of 64 clock cycles. A value of "0" represents no modification to the timer value. For more details, see the ROUND_TRIP_LATENCY_TIME_LIMIT field of the ACK_LATENCY_TIMER_OFF register. Note: This register field is sticky.

Table continues on the next page...

Field	Function
18-14 TIMER_MOD_REPLAY_TIMER	Replay Timer Limit Modifier. Increases the time-out value for the replay timer in increments of 64 clock cycles at Gen1 or Gen2 speed, and in increments of 256 clock cycles at Gen3 speed. A value of "0" represents no modification to the timer limit. For more details, see the REPLAY_TIME_LIMIT field of the ACK_LATENCY_TIMER_OFF register. At Gen3 speed, the controller automatically changes the value of this field to DEFAULT_GEN3_REPLAY_ADJ. For M-PCIe, this field increases the time-out value for the replay timer in increments of 64 clock cycles at HS-Gear1, HS-Gear2, or HS-Gear3 speed. Note: This register field is sticky.
13-8 RSVDP_8	Reserved for future use.
7-0 MAX_FUNC_NUM	Maximum function number that can be used in a request. Configuration requests targeted at function numbers above this value are returned with UR (unsupported request). Note: This register field is sticky.

11.4.3.1.66 Symbol Timer Register and Filter Mask 1 Register. (SYMBOL_TIMER_FILTER_1_OFF)



11.4.3.1.66.1 Offset

Register	Offset
SYMBOL_TIMER_FILTER_1_OFF	71Ch

11.4.3.1.66.2 Function

Symbol Timer Register and Filter Mask 1 Register. The Filter Mask 1 Register modifies the RADM filtering and error handling rules. For more details, see the "Receive Filtering" section. In each case, '0' applies the associated filtering rule and '1' masks the associated filtering rule.

11.4.3.1.66.3 Diagram

11.4.3.1.66.4 Fields

Field	Function
31-16 MASK_RADM_1	Filter Mask 1. The Filter Mask 1 Register modifies the RADM filtering and error handling rules. For more details, see the "Receive Filtering" section. In each case, '0' applies the associated filtering rule and '1' masks the associated filtering rule. [31]: CX_FLT_MASK_RC_CFG_DISCARD - 0: For RADM RC filter to not allow CFG transaction being received - 1: For RADM RC filter to allow CFG transaction being received [30]: CX_FLT_MASK_RC_IO_DISCARD - 0: For RADM RC filter to not allow IO transaction being received - 1: For RADM RC filter to allow IO transaction being received [29]: CX_FLT_MASK_MSG_DROP - 0: Drop MSG TLP (except for Vendor MSG). Send decoded message on the SII. - 1: Do not Drop MSG (except for Vendor MSG). Send message TLPs to your application on TRGT1 and send decoded message on the SII. - The default for this bit is the inverse of FLT_DROP_MSG. That is, if FLT_DROP_MSG =1, then the default of this bit is "0" (drop message TLPs). This bit only controls message TLPs other than Vendor MSGs. Vendor MSGs are controlled by Filter Mask Register 2, bits [1:0]. The controller never passes ATS Invalidate messages to the SII interface regardless of this filter rule setting. The controller passes all ATS Invalidate messages to TRGT1 (or AXI bridge master), as they are too big for the SII. [28]: CX_FLT_MASK_CPL_ECRC_DISCARD - Only used when completion queue is advertised with infinite credits and is in store-and-forward mode. - 0: Discard completions with ECRC errors - 1: Allow completions with ECRC errors to be passed up - Reserved field for SW. [27]: CX_FLT_MASK_ECRC_DISCARD - 0: Discard TLPs with ECRC errors - 1: Allow TLPs with ECRC errors to be passed up [26]: CX_FLT_MASK_CPL_LEN_MATCH - 0: Enforce length match for completions; a violation results in cpl_abort, and possibly AER of unexp_cpl_err - 1: MASK length match for completions [25]: CX_FLT_MASK_CPL_ATTR_MATCH - 0: Enforce attribute match for completions; a violation results in a malformed TLP error, and possibly AER of unexp_cpl_err, cpl_rcvd_ur, cpl_rcvd_ca - 1: Mask attribute match for completions [24]: CX_FLT_MASK_CPL_TC_MATCH - 0: Enforce Traffic Class match for completions; a violation results in a malformed TLP error, and possibly AER of unexp_cpl_err, cpl_rcvd_ur, cpl_rcvd_ca - 1: Mask Traffic Class match for completions [23]: CX_FLT_MASK_CPL_FUNC_MATCH - 0: Enforce function match for completions; a violation results in cpl_abort, and possibly AER of unexp_cpl_err, cpl_rcvd_ur, cpl_rcvd_ca - 1: Mask function match for completions [22]: CX_FLT_MASK_CPL_REQID_MATCH - 0: Enforce Req. Id match for completions; a violation result in cpl_abort, and possibly AER of unexp_cpl_err, cpl_rcvd_ur, cpl_rcvd_ca - 1: Mask Req. Id match for completions [21]: CX_FLT_MASK_CPL_TAGERR_MATCH - 0: Enforce Tag Error Rules for

Table continues on the next page...

Field	Function
	completions; a violation result in cpl_abort, and possibly AER of unexp_cpl_err, cpl_rcvd_ur, cpl_rcvd_ca - 1: Mask Tag Error Rules for completions [20]: CX_FLT_MASK_LOCKED_RD_AS_UR - 0: Treat locked Read TLPs as UR for EP; Supported for RC - 1: Treat locked Read TLPs as Supported for EP; UR for RC [19]: CX_FLT_MASK_CFG_TYPE1_REQ_AS_UR - 0: Treat CFG type1 TLPs as UR for EP; Supported for RC - 1: Treat CFG type1 TLPs as Supported for EP; UR for RC - When CX_SRIOV_ENABLE is set then this bit is set to allow the filter to process Type 1 Config requests if the EP consumes more than one bus number. [18]: CX_FLT_MASK_UR_OUTSIDE_BAR - 0: Treat out-of-bar TLPs as UR - 1: Do not treat out-of-bar TLPs as UR [17]: CX_FLT_MASK_UR_POIS - 0: Treat poisoned request TLPs as UR - 1: Do not treat poisoned request TLPs as UR - The native controller always passes poisoned completions to your application except when you are using the DMA read channel. [16]: CX_FLT_MASK_UR_FUNC_MISMATCH - 0: Treat Function MisMatched TLPs as UR - 1: Do not treat Function MisMatched TLPs as UR Note: This register field is sticky.
15 DISABLE_FC_WD_TIMER	Disable FC Watchdog Timer. Note: This register field is sticky.
14-11 EIDLE_TIMER	EIDLE_TIMER is an internally reserved field. Do not use. Note: This register field is sticky.
10-0 SKP_INT_VAL	SKP Interval Value. The number of symbol times to wait between transmitting SKP ordered sets. Note that the controller actually waits the number of symbol times in this register plus 1 between transmitting SKP ordered sets. Your application must program this register accordingly. For example, if 1536 were programmed into this register (in a 250 MHz controller), then the controller actually transmits SKP ordered sets once every 1537 symbol times. The value programmed to this register is actually clock ticks and not symbol times. In a 125 MHz controller, programming the value programmed to this register should be scaled down by a factor of 2 (because one clock tick = two symbol times in this case). Note: This value is not used at Gen3 speed; the skip interval is hardcoded to 370 blocks. For M-PCIe configurations, if the 2K_PPM_DISABLED field in the M-PCIe Configuration Attribute is changed, then this field is changed automatically as follows. - 2K_PPM_DISABLED=1: 1280 / CX_NB - 2K_PPM_DISABLED=0: 228/CX_NB You need to set this field again if necessary when 2K_PPM_DISABLED is changed. Note: This register field is sticky.

11.4.3.1.67 Filter Mask 2 Register. (FILTER_MASK_2_OFF)

11.4.3.1.67.1 Offset

Register	Offset
FILTER_MASK_2_OFF	720h

11.4.3.1.67.2 Function

Filter Mask 2 Register. This register modifies the RADM filtering and error handling rules. For more details, see the "Receive Filtering" section. In each case, '0' applies the associated filtering rule and '1' masks the associated filtering rule.

11.4.3.1.67.3 Diagram

Field	Function
31 TIMER_MOD_FLOW_CONTROL_EN	FC Latency Timer Override Enable. When this bit is set, the value from the "FC Latency Timer Override Value" field in this register will override the FC latency timer value that the controller calculates according to the PCIe specification. Note: This register field is sticky.
30-29 RSVDP_29	Reserved for future use.

Table continues on the next page...

Field	Function
28-16 TIMER_MOD_FLOW_CONTROL	FC Latency Timer Override Value. When you set the "FC Latency Timer Override Enable" in this register, the value in this field will override the FC latency timer value that the controller calculates according to the PCIe specification. For more details, see "Flow Control". Note: This register field is sticky.
15 RX_SERIALIZATION_Q_READ_ERR	Receive Serialization Read Error. Indicates the serialization queue has attempted to read an incorrectly formatted TLP.
14 RX_SERIALIZATION_Q_WRITE_ERR	Receive Serialization Queue Write Error. Indicates insufficient buffer space available to write to the serialization queue.
13 RX_SERIALIZATION_Q_NON_EMPTY	Receive Serialization Queue Not Empty. Indicates there is data in the serialization queue.
12-4 RSVDP_4	Reserved for future use.
3 RX_QUEUE_OVERFLOW	Receive Credit Queue Overflow. Indicates insufficient buffer space available to write to the P/NP/CPL credit queue.
2 RX_QUEUE_NON_EMPTY	Receive Credit Queue Not Empty. Indicates there is data in one or more of the receive buffers.
1 TX_RETRY_BUFFER_NE	Transmit Retry Buffer Not Empty. Indicates that there is data in the transmit retry buffer.
0 RX_TLP_FC_CREDIT_NON_RETURN	Received TLP FC Credits Not Returned. Indicates that the controller has received a TLP but has not yet sent an UpdateFC DLLP indicating that the credits for that TLP have been restored by the receiver at the other end of the link.

19-12 VC0_CPL_HEADER_CREDIT	VC0 Completion Header Credits. The number of initial Completion header credits for VC0, used only in the segmented-buffer configuration. Note: The access attributes of this field are as follows: - Dbi: R (sticky) Note: This register field is sticky.
11-0 VC0_CPL_DATA_CREDIT	VC0 Completion Data Credits. The number of initial Completion data credits for VC0, used only in the segmented-buffer configuration. Note: The access attributes of this field are as follows: - Dbi: R (sticky) Note: This register field is sticky.

11.4.3.1.79 Link Width and Speed Change Control Register. (GEN2_CTRL_OFF)

11.4.3.1.79.1 Offset

Register	Offset
GEN2_CTRL_OFF	80Ch

11.4.3.1.79.2 Diagram

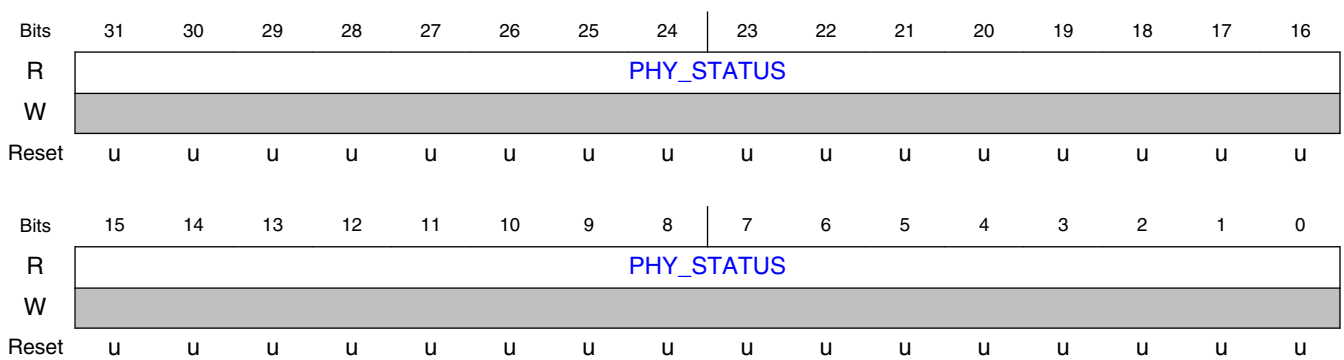
11.4.3.1.79.3 Fields

Field	Function
31-22 RSVDP_22	Reserved for future use.
21 GEN1_EI_INFERENCE	Electrical Idle Inference Mode at Gen1 Rate. Programmable mode to determine inferred electrical idle (EI) in Recovery.Speed or Loopback.Active (as slave) state at Gen1 speed by looking for a "1" value on RxElecIdle instead of looking for a "0" on RxValid. If the PHY fails to deassert the RxValid signal in Recovery.Speed or Loopback.Active (because of corrupted EIOS for example), then EI cannot be inferred successfully in the controller by just detecting the condition RxValid=0. - 0: Use RxElecIdle signal to infer Electrical Idle - 1: Use RxValid signal to infer Electrical Idle Note: This register field is sticky.
20 SEL_DEEMPHASIS	Used to set the de-emphasis level for upstream ports. This bit selects the level of de-emphasis the link operates at. - 0: -6 dB - 1: -3.5 dB This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
19 CONFIG_TX_COMP_RX	Config Tx Compliance Receive Bit. When set to 1, signals LTSSM to transmit TS ordered sets with the compliance receive bit assert (equal to "1"). This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
18 CONFIG_PHY_TX_CHANGE	Config PHY Tx Swing. Controls the PHY transmitter voltage swing level. The controller drives the mac_phy_txswing output from this register bit field. - 0: Full Swing - 1: Low Swing This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
17 DIRECT_SPEED_CHANGE	Directed Speed Change. Writing "1" to this field instructs the LTSSM to initiate a speed change to Gen2 or Gen3 after the link is initialized at Gen1 speed. When the speed change occurs, the controller will clear the contents of this field; and a read to this field by your software will return a "0". To manually initiate the speed change: - Write to LINK_CONTROL2_LINK_STATUS2_REG . PCIE_CAP_TARGET_LINK_SPEED in the local device - Deassert this field - Assert this field If you set the default of this field using the DEFAULT_GEN2_SPEED_CHANGE configuration parameter to "1", then the speed change is initiated automatically after link up, and the controller clears the contents of this field. If you want to prevent this automatic speed change, then write a lower speed value to the Target Link Speed field of the Link Control 2 register (LINK_CONTROL2_LINK_STATUS2_OFF . PCIE_CAP_TARGET_LINK_SPEED) through the DBI before link up. This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W
16 AUTO_LANE_FLIP_CTRL_EN	Enable Auto flipping of the lanes. You must set the CX_AUTO_LANE_FLIP_CTRL_EN configuration parameter to include the hardware for this feature in the controller. For more details, see the 'Lane Reversal' appendix in the Databook. This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
15-13 PRE_DET_LANE	Predetermined Lane for Auto Flip. This field defines which physical lane is connected to logical Lane0 by the flip operation performed in Detect. Allowed values are: - 3'b000: Connect logical Lane0 to physical lane 0 or CX_NL-1 or CX_NL/2-1 or CX_NL/4-1 or CX_NL/8-1, depending on which lane is detected - 3'b001: Connect logical Lane0 to physical lane 1 - 3'b010: Connect logical Lane0 to physical lane 3 - 3'b011: Connect logical Lane0 to physical lane 7 - 3'b100: Connect logical Lane0 to physical lane 15 This field is used to restrict the receiver detect procedure to a particular lane when the default detect and polling procedure performed on all lanes cannot be successful. A notable example of when it is useful to program this field to a value different from the default, is when a lane is asymmetrically broken, that is, it is detected in Detect LTSSM state but it cannot exit Electrical Idle in Polling LTSSM state. Note: This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
12-8 NUM_OF_LANES	Predetermined Number of Lanes. Defines the number of lanes which are connected and not bad. Used to limit the effective link width to ignore 'broken" or "unused" lanes that detect a receiver. Indicates the number of lanes to check for exit from Electrical Idle in Polling.Active and L2.Idle. It is possible that the LTSSM might detect a receiver on a bad or broken lane during the Detect Substate. However, it is also

Table continues on the next page...

Field	Function
	possible that such a lane might also fail to exit Electrical Idle and therefore prevent a valid link from being configured. This value is referred to as the "Predetermined Number of Lanes" in section 4.2.6.2.1 of the PCI Express Base 3.0 Specification, revision 1.0. Encoding is as follows: - 0x01: 1 lane - 0x02: 2 lanes - 0x03: 3 lanes - .. When you have unused lanes in your system, then you must change the value in this register to reflect the number of lanes. You must also change the value in the "Link Mode Enable" field of PORT_LINK_CTRL_OFF. The value in this register is normally the same as the encoded value in PORT_LINK_CTRL_OFF. If you find that one of your used lanes is bad then you must reduce the value in this register. For more information, see "How to Tie Off Unused Lanes." For information on upsizing and downsizing the link width, see "Link Establishment." This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.
7-0 FAST_TRAINING_SEQ	Sets the Number of Fast Training Sequences (N_FTS) that the controller advertises as its N_FTS during Gen2 or Gen3 link training. This value is used to inform the link partner about the PHY's ability to recover synchronization after a low power state. The number should be provided by the PHY vendor. Do not set N_FTS to zero; doing so can cause the LTSSM to go into the recovery state when exiting from L0s. This field is reserved (fixed to '0') for M-PCIe. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.

11.4.3.1.80 PHY Status Register. (PHY_STATUS_OFF)



11.4.3.1.80.1 Offset

Register	Offset
PHY_STATUS_OFF	810h

11.4.3.1.80.2 Function

PHY Status Register. Memory mapped register from phy_cfg_status GPIO input pins.

11.4.3.1.80.3 Diagram

11.4.3.1.80.4 Fields

Field	Function
31-0 PHY_STATUS	PHY Status. Data received directly from the phy_cfg_status bus. These is a GPIO register reflecting the values on the static phy_cfg_status input signals. The usage is left completely to the user and does not in any way influence controller functionality. You can use it for any static sideband status signalling requirements that you have for your PHY. This field is reserved (fixed to '0') for M-PCIe. Note: This register field is sticky.

11.4.3.1.81 PHY Control Register. (PHY_CONTROL_OFF)

11.4.3.1.81.1 Offset

Register	Offset
PHY_CONTROL_OFF	814h

11.4.3.1.81.2 Function

PHY Control Register. Memory mapped register to cfg_phy_control GPIO output pins.

R W	MSI_CTRL_ADDR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

11.4.3.1.83.3 Fields

Field	Function
31-0 MSI_CTRL_ADDR	Integrated MSI Reception Module Address. System specified address for MSI memory write transaction termination. Within the AXI Bridge, every received Memory Write request is examined to see if it targets the MSI Address that has been specified in this register; and also to see if it satisfies the definition of an MSI interrupt request. When these conditions are satisfied the Memory Write request is marked as an MSI request. Note: This register field is sticky.

11.4.3.1.84 Integrated MSI Reception Module Upper Address Register. (MSI_CTRL_UPPER_ADDR_OFF)

11.4.3.1.84.1 Offset

Register	Offset
MSI_CTRL_UPPER_ADDR_OFF	824h

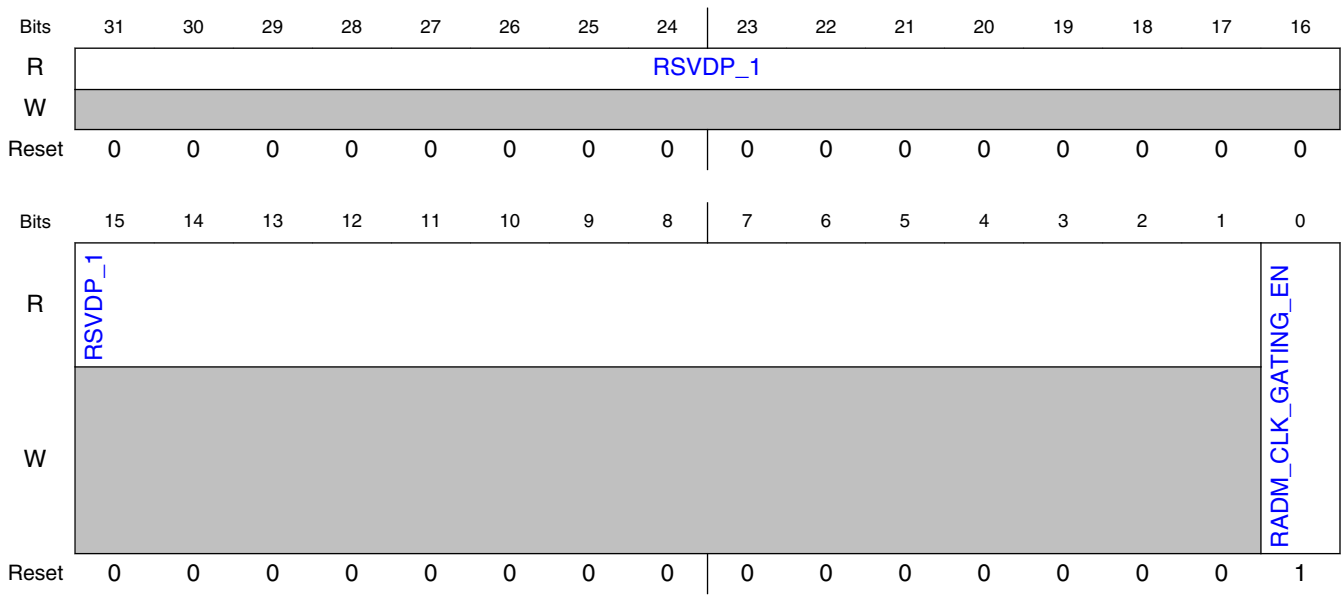
11.4.3.1.110 RADM clock gating enable control register. (CLOCK_GATING_CTRL_OFF)



11.4.3.1.110.1 Offset

Register	Offset
CLOCK_GATING_CTRL_OFF	88Ch

11.4.3.1.110.2 Function

RADM clock gating enable control register. Using this register you can disable the RADM clock gating feature. The DWC_pcie_clk_rst.v modules uses the en_radm_clk_g output to gate core_clk and create the radm_clk_g clock input. The controller de-asserts the en_radm_clk_g output when there is no Rx traffic, Rx queues and pre/post-queue pipelines are empty, RADM completion LUT is empty, and there are no FLR actions pending. You must set the RADM_CLK_GATING_EN field to enable this functionality; otherwise the en_radm_clk_g output will always be set to '1'.

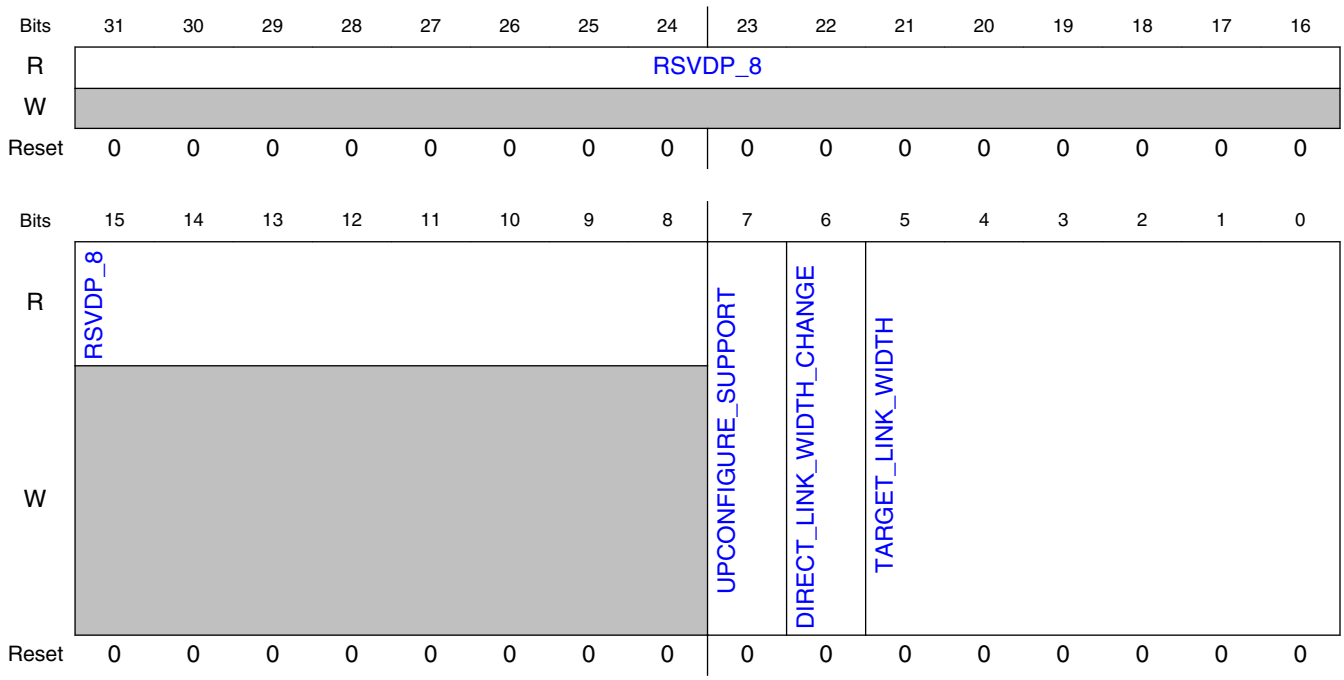
11.4.3.1.113.3 Fields

Field	Function
31-6 RSVDP_6	Reserved for future use.
5 ARI_DEVICE_NUMBER	When ARI is enabled, this field enables use of the device ID. Note: This register field is sticky.
4 —	Reserved
3	Enables Simplified Replay Timer (Gen4). For more details, see "Transmit Replay" in the Controller Operations chapter of the Databook. Simplified Replay Timer Values are: - A value from 24,000 to 31,000

Table continues on the next page...

Field	Function
SIMPLIFIED_REPLAY_TIMER	Symbol Times when Extended Synch is 0b. - A value from 80,000 to 100,000 Symbol Times when Extended Synch is 1b. Must not be changed while link is in use. Note: This register field is sticky.
2 UR_CA_MASK_4_TRGT1	This field only applies to request TLPs (with UR filtering status) that you have chosen to forward to the application (when you set DEFAULT_TARGET in this register). - When you set this field to '1', the core suppresses error logging, Error Message generation, and CPL generation (for non-posted requests). - For more details, refer to the "Advanced Error Handling For Received TLPs" chapter of the Databook. You should set this if you have set the Default Target port logic register to '1'. Default is CX_MASK_UR_CA_4_TRGT1 configuration parameter. Note: This register field is sticky.
1 DEFAULT_TARGET	Default target a received IO or MEM request with UR/CA/CRS is sent to by the controller. - 0: The controller drops all incoming I/O or MEM requests (after corresponding error reporting). A completion with UR status will be generated for non-posted requests. - 1: The controller forwards all incoming I/O or MEM requests with UR/CA/CRS status to your application For more details, see "ECRC Handling" and "Request TLP Routing Rules" in "Receive Routing" section of the "Controller Operations" chapter of the Databook. Default value is DEFAULT_TARGET configuration parameter. Note: This register field is sticky.
0 DBI_RO_WR_EN	Write to RO Registers Using DBI. When you set this field to "1", then some RO and HwInit bits are writable from the local application through the DBI. For more details, see "Writing to Read-Only Registers." Note: This register field is sticky.

11.4.3.1.114 UpConfigure Multi-lane Control Register. (MULTI_LANE_CONTROL_OFF)



11.4.3.1.114.1 Offset

Register	Offset
MULTI_LANE_CONTROL_OFF	8C0h

11.4.3.1.114.2 Function

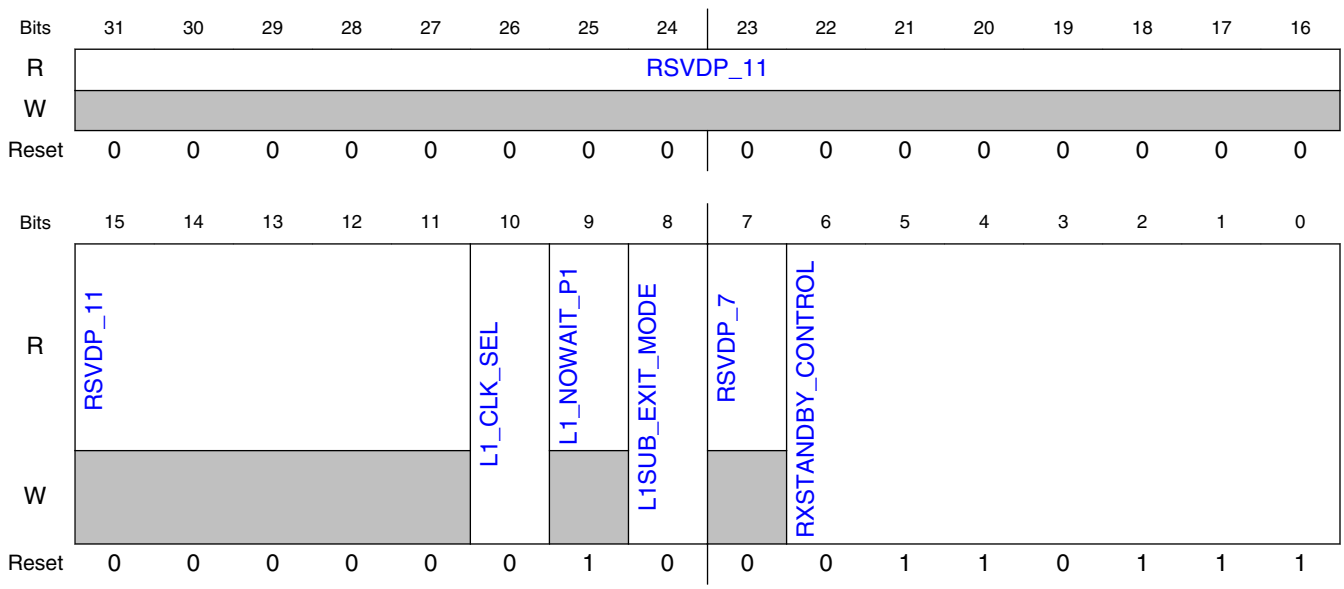
UpConfigure Multi-lane Control Register. Used when upsizing or downsizing the link width through Configuration state without bringing the link down. For more details, see the "Link Establishment" section in the "Controller Operations" chapter of the Databook.

11.4.3.1.114.3 Diagram

11.4.3.1.114.4 Fields

Field	Function
31-8 RSVDP_8	Reserved for future use.
7 UPCONFIGURE_SUPPORT	Upconfigure Support. The controller sends this value as the Link Upconfigure Capability in TS2 Ordered Sets in Configuration.Complete state. This field is reserved (fixed to '0') for M-PCIe. Note: This register field is sticky.
6 DIRECT_LINK_WIDTH_CHANGE	Directed Link Width Change. The controller always moves to Configuration state through Recovery state when this bit is set to '1'. - If the upconfigure_capable variable is '1' and the PCIE_CAP_HW_AUTO_WIDTH_DISABLE bit in LINK_CONTROL_LINK_STATUS_REG is '0', the controller starts upconfigure or autonomous width downsizing (to the TARGET_LINK_WIDTH value) in the Configuration state. - If TARGET_LINK_WIDTH value is 0x0, the controller does not start upconfigure or autonomous width downsizing in the Configuration state. The controller self-clears this field when the controller accepts this request. This field is reserved (fixed to '0') for M-PCIe.
5-0 TARGET_LINK_WIDTH	Target Link Width. Values correspond to: - 6'b000000: Core does not start upconfigure or autonomous width downsizing in the Configuration state. - 6'b000001: x1 - 6'b000010: x2 - 6'b000100: x4 - 6'b001000: x8 - 6'b010000: x16 - 6'b100000: x32 This field is reserved (fixed to '0') for M-PCIe.

11.4.3.1.115 PHY Interoperability Control Register. (PHY_INTEROP_CTRL_OFF)



11.4.3.1.115.1 Offset

Register	Offset
PHY_INTEROP_CTRL_OFF	8C4h

11.4.3.1.115.2 Function

PHY Interoperability Control Register. This register is reserved for internal use. You should not write to this register and change the default unless specifically instructed by Synopsys support.

11.4.3.1.115.3 Diagram

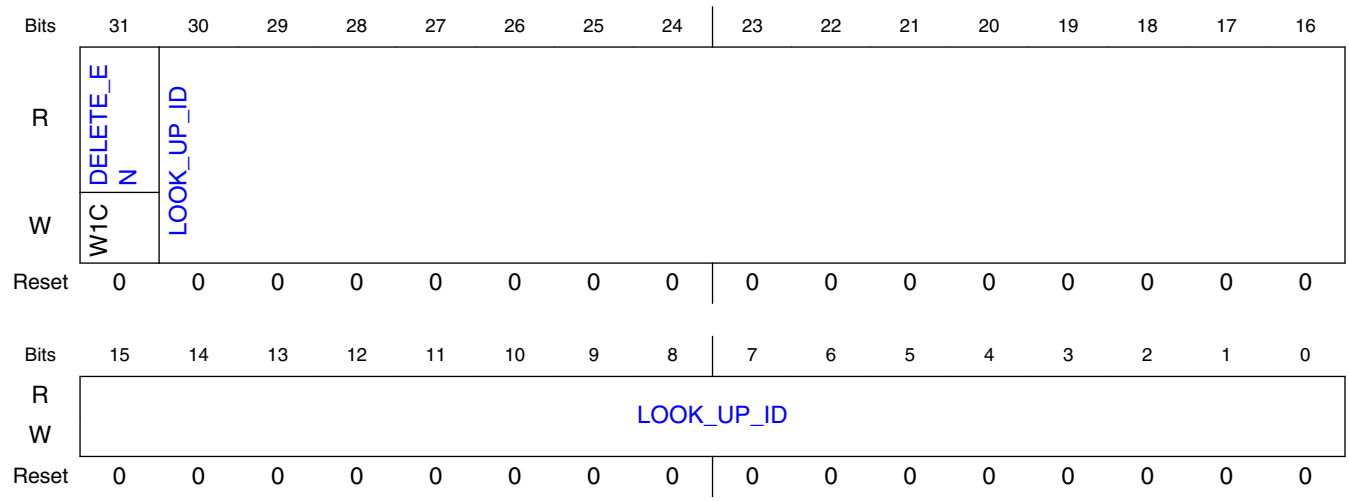
11.4.3.1.115.4 Fields

Field	Function
31-11 RSVDP_11	Reserved for future use.
10 L1_CLK_SEL	L1 Clock control bit. - 1: Controller does not request aux_clk switch and core_clk gating in L1. - 0: Controller requests aux_clk switch and core_clk gating in L1. Note: This register field is sticky.
9 L1_NOWAIT_P1	L1 entry control bit. - 1: Core does not wait for PHY to acknowledge transition to P1 before entering L1. - 0: Core waits for the PHY to acknowledge transition to P1 before entering L1. Note: The access attributes of this field are as follows: - Dbi: R/W (sticky) Note: This register field is sticky.

Table continues on the next page...

Field	Function
8 L1SUB_EXIT_MODE	L1 Exit Control Using phy_mac_pclkack_n. - 1: Core exits L1 without waiting for the PHY to assert phy_mac_pclkack_n. - 0: Core waits for the PHY to assert phy_mac_pclkack_n before exiting L1. Note: This register field is sticky.
7 RSVDP_7	Reserved for future use.
6-0 RXSTANDBY_CONTROL	Rxstandby Control. Bits 0..5 determine if the controller asserts the RxStandby signal (mac_phy_rxstandby) in the indicated condition. Bit 6 enables the controller to perform the RxStandby/ RxStandbyStatus handshake. - [0]: Rx EIOS and subsequent T TX-IDLE-MIN - [1]: Rate Change - [2]: Inactive lane for upconfigure/downconfigure - [3]: PowerDown=P1orP2 - [4]: RxL0s.Idle - [5]: EI Infer in L0 - [6]: Execute RxStandby/RxStandbyStatus Handshake This field is reserved (fixed to '0') for M-PCIe. Note: This register field is sticky.

11.4.3.1.116 TRGT_CPL_LUT Delete Entry Control register. (TRGT_CPL_LUT_DELETE_ENTRY_OFF)



11.4.3.1.116.1 Offset

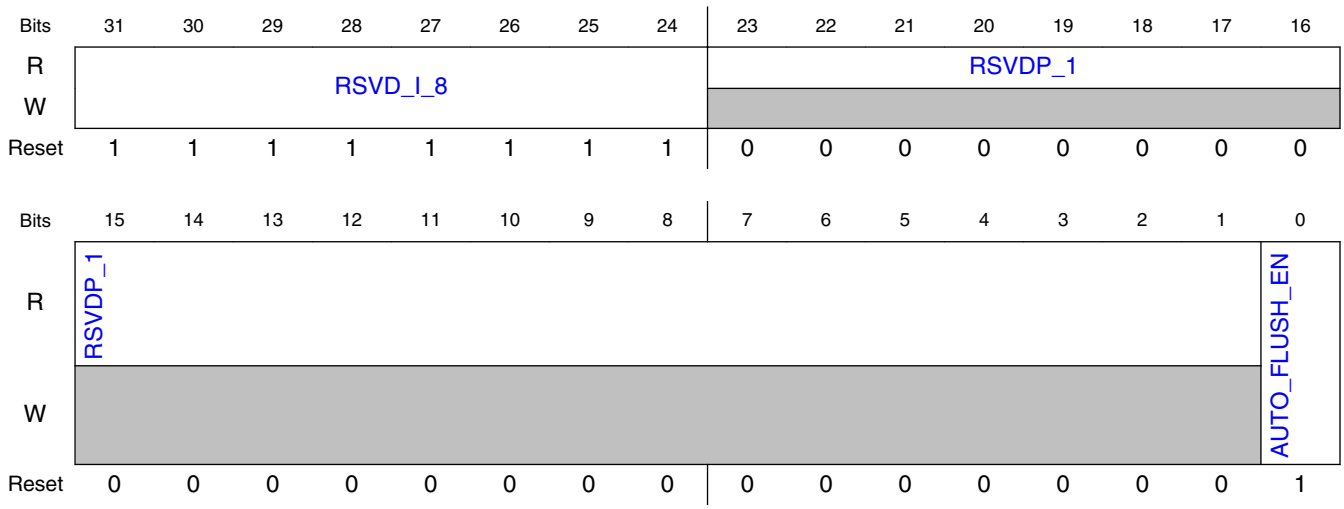
Register	Offset
TRGT_CPL_LUT_DELETE_ENTRY_OFF	8C8h

11.4.3.1.116.2 Function

TRGT_CPL_LUT Delete Entry Control register. Using this register you can delete one entry in the target completion LUT. You should only use this register when you know that your application will never send the completion because of an FLR or any other reason. Note:: The target completion LUT (and associated target completion timeout event) is watching for completions (from your application on XALI0/1/2 or AXI master read channel) corresponding to previously received non-posted requests from the PCIe wire.

11.4.3.1.116.3 Diagram

11.4.3.1.116.4 Fields



Field	Function
31 DELETE_EN	This is a one-shot bit. A '1' write to this bit triggers the deletion of the target completion LUT entry that is specified in the LOOK_UP_ID field. This is a self-clearing register field. Reading from this register field always returns a '0'.
30-0 LOOK_UP_ID	This number selects one entry to delete of the TRGT_CPL_LUT.

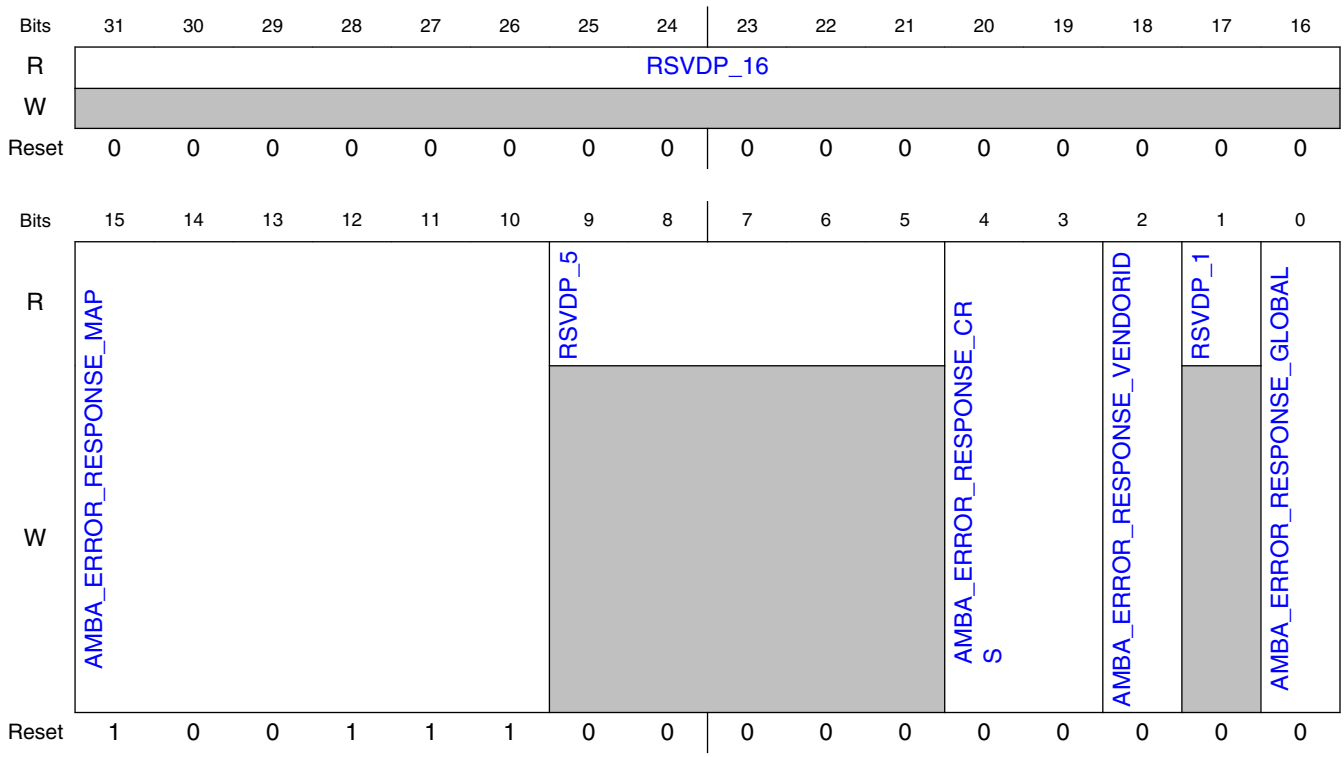
11.4.3.1.117 Link Reset Request Flush Control Register. (LINK_FLUSH_CONTROL_OFF)

11.4.3.1.117.1 Offset

Register	Offset
LINK_FLUSH_CONTROL_OFF	8CCh

11.4.3.1.117.2 Diagram

11.4.3.1.117.3 Fields



Field	Function
31-24 RSVD_I_8	This is an internally reserved field. Do not use. Note: This register field is sticky.
23-1 RSVDP_1	Reserved for future use.
0 AUTO_FLUSH_EN	Enables automatic flushing of pending requests before sending the reset request to the application logic to reset the PCIe controller and the AXI Bridge. The flushing process is initiated if any of the following events occur: - Hot reset request. A downstream port (DSP) can "hot reset" an upstream port (USP) by sending two consecutive TS1 ordered sets with the hot reset bit asserted. - Warm (Soft) reset request. Generated when exiting from D3 to D0 and cfg_pm_no_soft_rst=0. - Link down reset request. A high to low transition on smlh_req_rst_not indicates the link has gone down and the controller is requesting a reset. If you disable automatic flushing, your application is responsible for resetting the PCIe controller and the AXI Bridge. For more details see "Warm and Hot Resets" section in the Architecture chapter of the Databook. Note: This register field is sticky.

11.4.3.1.118 AXI Bridge Slave Error Response Register. (AMBA_ERROR_RESPONSE_DEFAULT_OFF)

11.4.3.1.118.1 Offset

Register	Offset
AMBA_ERROR_RESPONSE_DEFAULT_OFF	8D0h

11.4.3.1.118.2 Diagram

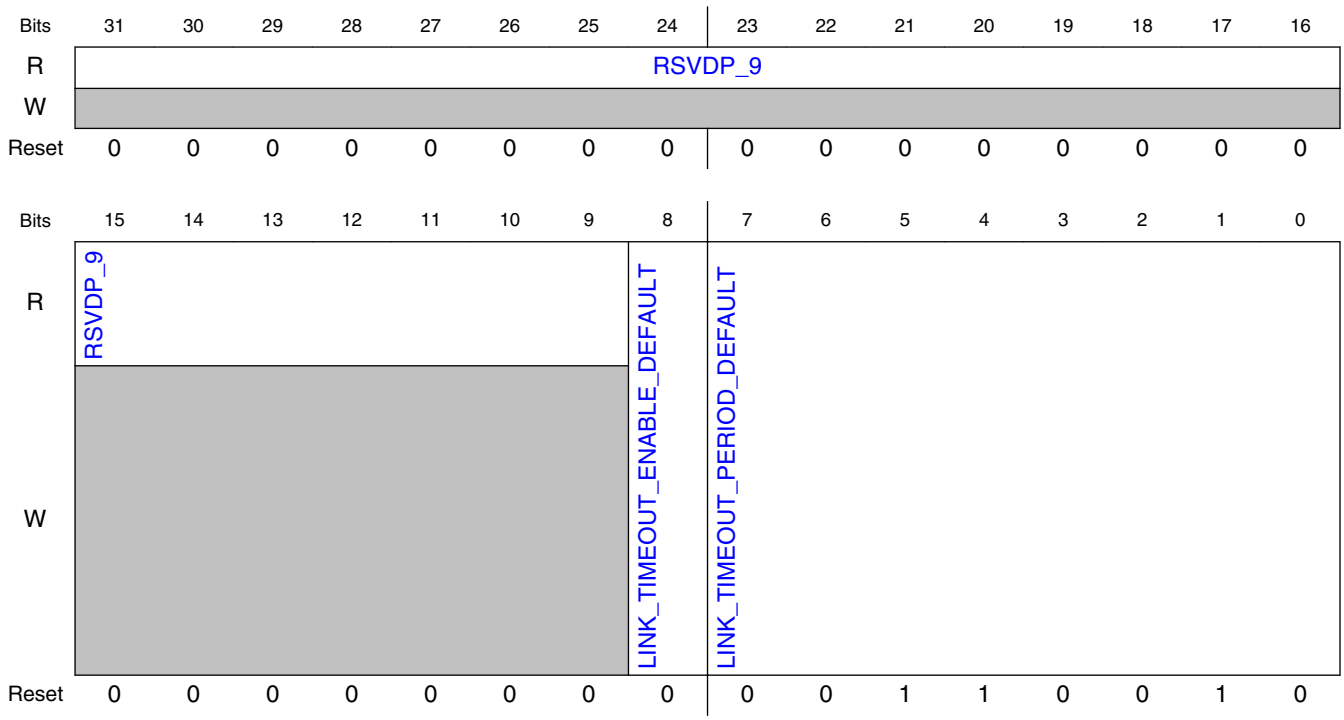
11.4.3.1.118.3 Fields

Field	Function
31-16 RSVDP_16	Reserved for future use.
15-10 AMBA_ERROR_RESPONSE_MAP	AXI Slave Response Error Map. Allows you to selectively map the errors received from the PCIe completion (for non-posted requests) to the AXI slave responses, slv_rresp or slv_bresp. The recommended setting is SLVERR. CRS is always mapped to OKAY. - [0] - 0: UR (unsupported request) -> DECERR - 1: UR (unsupported request) -> SLVERR - [1] - 0: CRS (configuration retry status) -> DECERR - 1: CRS (configuration retry status) -> SLVERR - [2] - 0: CA (completer abort) -> DECERR - 1: CA (completer abort) -> SLVERR - [3]: Reserved - [4]: Reserved - [5]: - 0: Completion Timeout -> DECERR - 1: Completion Timeout -> SLVERR The AXI bridge internally drops (processes internally but not passed to your application) a completion that has been marked by the Rx filter as UC or MLF, and does not pass its status directly down to the slave interface. It waits for a timeout and then signals "Completion Timeout" to the slave interface. The controller sets the AXI slave read databus to 0xFFFF for all error responses. Note: This register field is sticky.
9-5 RSVDP_5	Reserved for future use.
4-3 AMBA_ERROR_RESPONSE_CRS	CRS Slave Error Response Mapping. Determines the AXI slave response for CRS completions. For more details see "Error Handling" in the AXI chapter of the Databook. AHB: - always returns OKAY AXI: - 00: OKAY - 01: OKAY with all FFFF_FFFF data for all CRS completions - 10: OKAY with FFFF_0001 data for CRS completions to vendor ID read requests, OKAY with FFFF_FFFF data for all other CRS completions - 11: SLVERR/DECERR (the AXI_ERROR_RESPONSE_MAP field determines the PCIe-to-AXI Slave error response mapping) Note: This register field is sticky.

Table continues on the next page...

Field	Function
2 AMBA_ERROR_RESPONSE_VENDORID	Vendor ID Non-existent Slave Error Response Mapping. Determines the AXI slave response for errors on reads to non-existent Vendor ID register. For more details see "Error Handling" in the AXI chapter of the Databook. AHB: - 0: OKAY (with FFFF data). The controller ignores the setting in the bit when bit 0 of this register is '0'. - 1: ERROR AXI: - 0: OKAY (with FFFF data). - 1: SLVERR/DECERR (the AXI_ERROR_RESPONSE_MAP field determines the PCIe-to-AXI Slave error response mapping) Note: This register field is sticky.
1 RSVDP_1	Reserved for future use.
0 AMBA_ERROR_RESPONSE_GLOBAL	Global Slave Error Response Mapping. Determines the AXI slave response for all error scenarios on non-posted requests. For more details see "Error Handling" in the AXI chapter of the Databook. AHB: - 0: OKAY (with FFFF data for non-posted requests) and ignore the setting in bit [2] of this register. - 1: ERROR for normal link (data) accesses and look at bit [2] for other scenarios. AXI: - 0: OKAY (with FFFF data for non-posted requests) - 1: SLVERR/DECERR (the AXI_ERROR_RESPONSE_MAP field determines the PCIe-to-AXI Slave error response mapping) The error response mapping is not applicable to Non-existent Vendor ID register reads. Note: This register field is sticky.

11.4.3.1.119 Link Down AXI Bridge Slave Timeout Register. (AMBA_LINK_TIMEOUT_OFF)



11.4.3.1.119.1 Offset

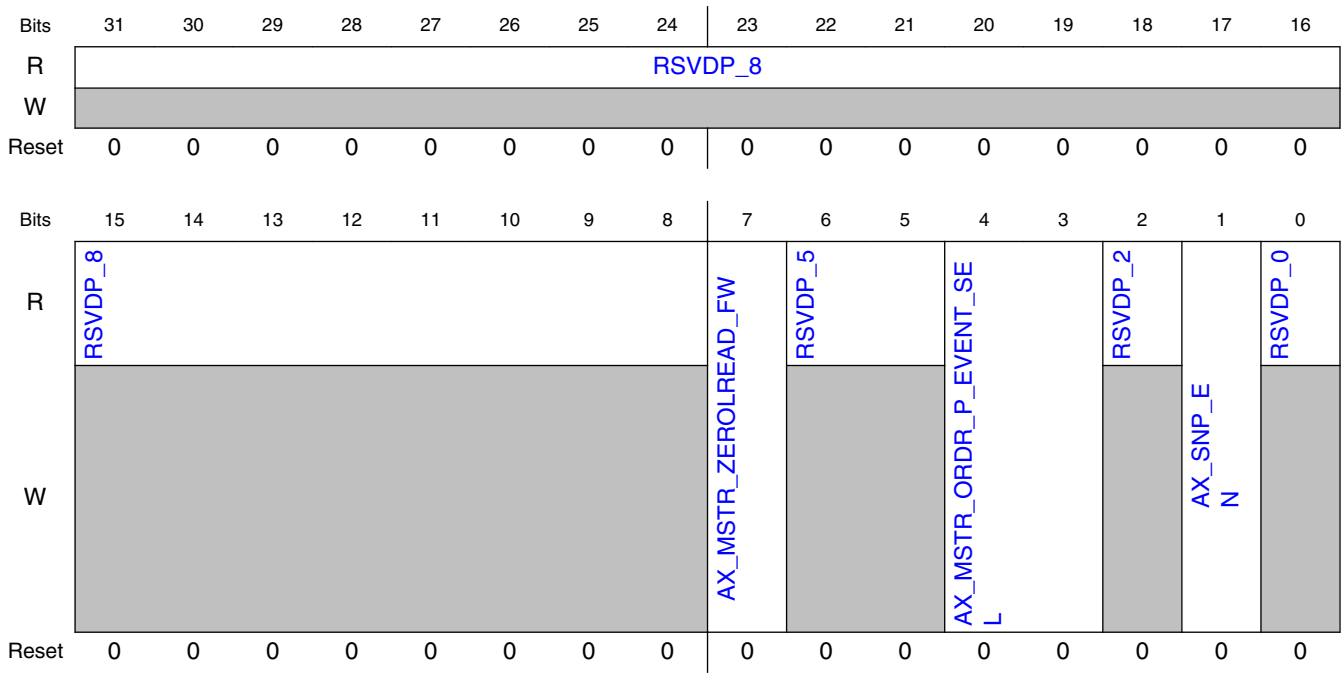
Register	Offset
AMBA_LINK_TIMEOUT_OFF	8D4h

11.4.3.1.119.2 Function

Link Down AXI Bridge Slave Timeout Register. If your application AXI master issues outbound requests to the AXI bridge slave interface before the PCIe link is operational, the controller starts a "flush" timer. The timeout value of the timer is set by this register. The timer will timeout and then flush the bridge TX request queues after this amount of time. The timer counts when there are pending outbound AXI slave interface (or DMA) requests and the PCIe TX link is not transmitting any of these requests. For more details, see the "AXI Bridge Initialization, Clocking and Reset" section in the AXI chapter of the Databook.

11.4.3.1.119.3 Diagram

11.4.3.1.119.4 Fields



Field	Function
31-9 RSVDP_9	Reserved for future use.
8 LINK_TIMEOUT_ENABLE_DEFAULT	Disable Flush. You can disable the flush feature by setting this field to "1". Note: This register field is sticky.
7-0 LINK_TIMEOUT_PERIOD_DEFAULT	Timeout Value (ms). The timer will timeout and then flush the bridge TX request queues after this amount of time. The timer counts when there are pending outbound AXI slave interface requests and the PCIe TX link is not transmitting any of these requests. The timer is clocked by core_clk. For an M-PCIe configuration: - Time unit of this field is 4 ms. - Margin of error for RateA clock is < 1%. - Margin of error for RateB clock is between 16% and 17%. Note: This register field is sticky.

11.4.3.1.120 AMBA Ordering Control. (AMBA_ORDERING_CTRL_OFF)

11.4.3.1.120.1 Offset

Register	Offset
AMBA_ORDERING_CTRL_OFF	8D8h

11.4.3.1.120.2 Diagram

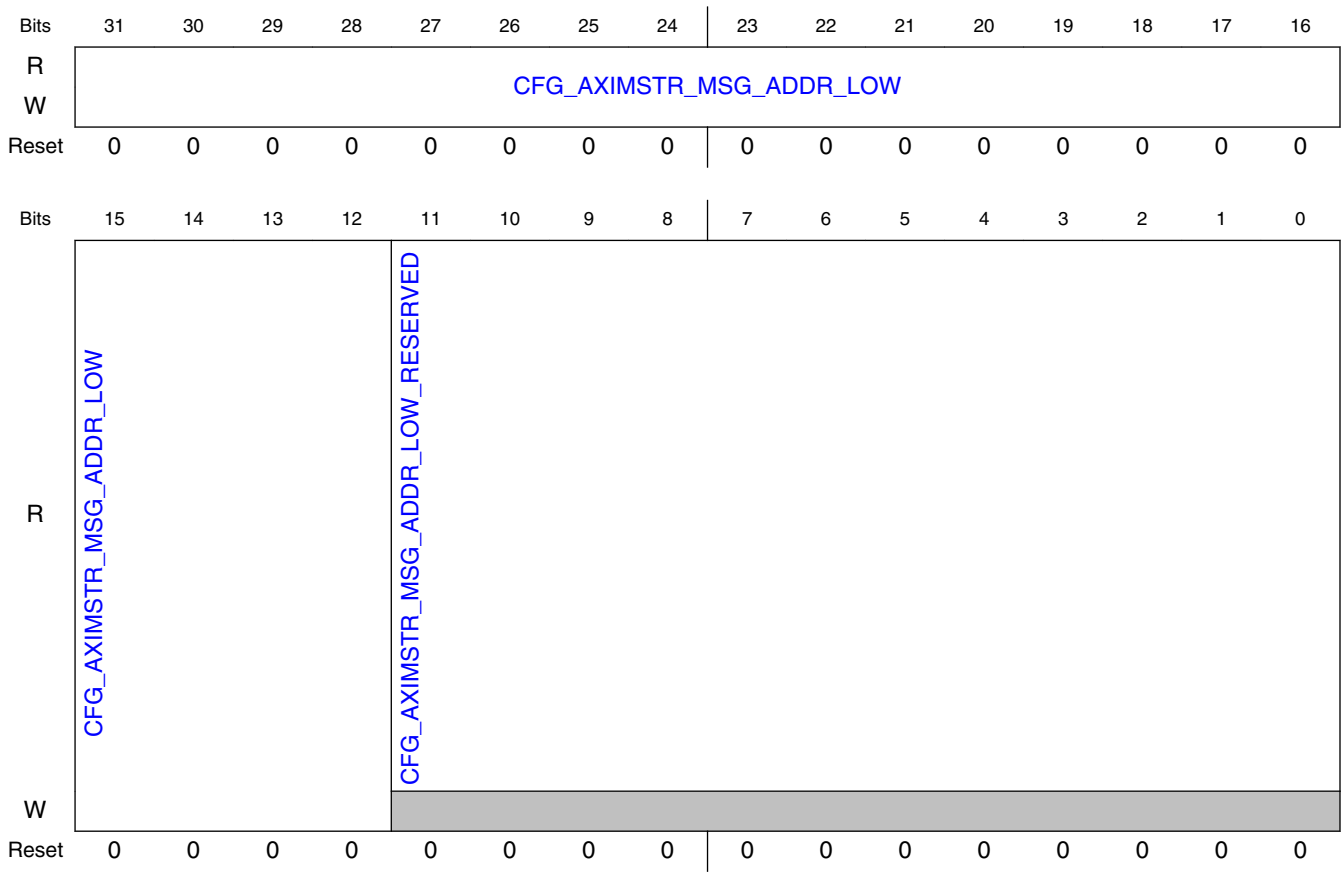
11.4.3.1.120.3 Fields

Field	Function
31-8 RSVDP_8	Reserved for future use.
7 AX_MSTR_ZEROLREAD_FW	AXI Master Zero Length Read Forward to the application. The DW PCIe controller AXI bridge is able to terminate in order with the Posted transactions the zero length read, implementing the PCIe express flush semantics of the Posted transactions. - 0x0: The zero length Read is terminated at the DW PCIe AXI bridge master - 0x1: The zero length Read is forward to the application.
6-5 RSVDP_5	Reserved for future use.
4-3 AX_MSTR_ORDR_P_EVENT_SEL	AXI Master Posted Ordering Event Selector. This field selects how the master interface determines when a P write is completed when enforcing the PCIe ordering rule, "NP must not pass P" at the AXI Master Interface. The AXI protocol does not support ordering between channels. Therefore, NP reads can pass P on your AXI bus fabric. This can result in an ordering violation when the read overtakes a P that is going to the same address. Therefore, the bridge master does not issue any NP requests until all outstanding P writes reach their destination. It does this by waiting for the all of the write responses on

Table continues on the next page...

Field	Function
	the B channel. This can affect the performance of the master read channel. For scenarios where the interconnect serializes the AXI master "AW", "W" and "AR" channels,you can increase the performance by reducing the need to wait until the complete Posted transaction has effectively reached the application slave. - 00: B'last event: wait for the all of the write responses on the B channel thereby ensuring that the complete Posted transaction has effectively reached the application slave (default). - 01: AW'last event: wait until the complete Posted transaction has left the AXI address channel at the bridge master. - 10: W'last event: wait until the complete Posted transaction has left the AXI data channel at the bridge master. - 11: Reserved Note 2: This setting will not affect: - MSI interrupt catcher and P data ordering. This is always driven by the B'last event. - DMA read engine TLP ordering. This is always driven by the B'last event. - NP write transactions which are always serialized with P write transactions.
2 RSVDP_2	Reserved for future use.
1 AX_SNP_EN	AXI Serialize Non-Posted Requests Enable. This field enables the AXI Bridge to serialize same ID Non-Posted Read/Write Requests on the wire. Serialization implies one outstanding same ID NP Read or Write on the wire and used to avoid AXI RAR and WAW hazards at the remote link partner. For more details, see the "Optional Serialization of AXI Slave Non-posted Requests" section in the AXI chapter of the Databook.
0 RSVDP_0	Reserved for future use.

11.4.3.1.121 Lower 20 bits of the programmable AXI address where Messages coming from wire are mapped to. (AXI_MSTR_MSG_ADDR_LOW_OFF)



11.4.3.1.121.1 Offset

Register	Offset
AXI_MSTR_MSG_ADDR_LOW_OFF	8F0h

11.4.3.1.121.2 Function

Lower 20 bits of the programmable AXI address where Messages coming from wire are mapped to. Bits [11:0] of the register are tied to zero for the address to be 4k-aligned. In previous releases, the third and fourth DWORDs of a message (Msg/MsgD) TLP header were delivered though the AXI master address bus (mstr_awaddr). These DWORDS are now supplied through the mstr_awmisc_info_hdr_34dw[63:0] output; and the value on mstr_awaddr is driven to the value you have programmed into the AXI_MSTR_MSG_ADDR_LOW_OFF and AXI_MSTR_MSG_ADDR_HIGH_OFF registers.

11.4.3.1.121.3 Diagram

11.4.3.1.121.4 Fields

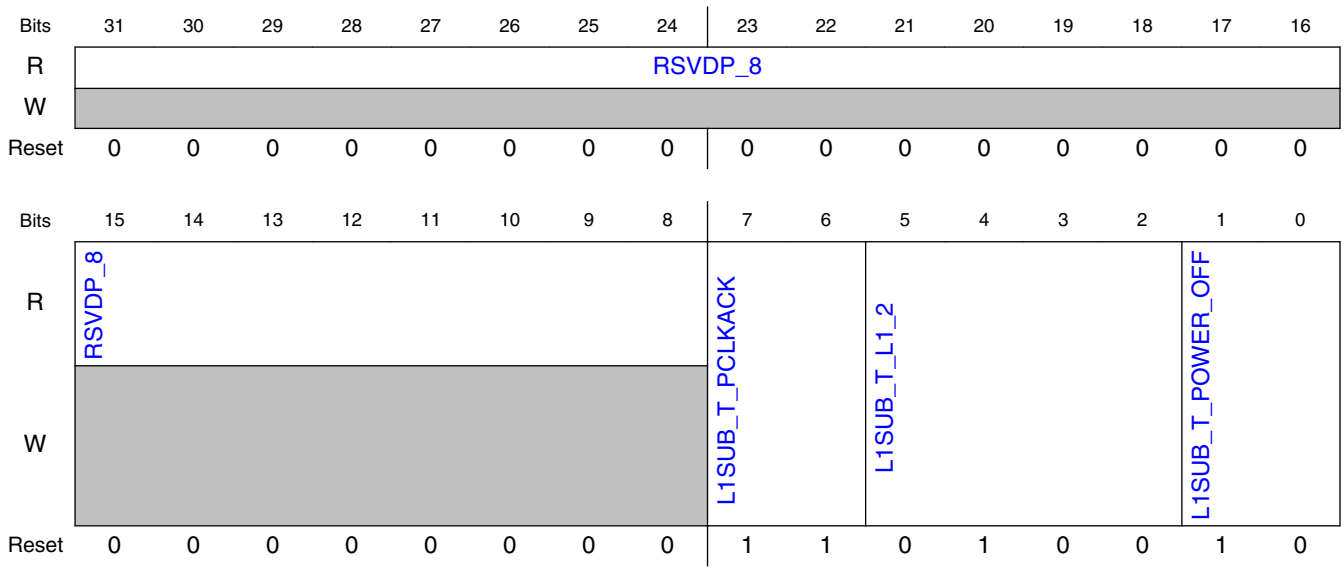
11.4.3.1.125.3 Fields



Field	Function
31-10 RSVDP_10	Reserved for future use.
9-0 AUX_CLK_FREQ	The aux_clk frequency in MHz. This value is used to provide a 1 us reference for counting time during low-power states with aux_clk when the PHY has removed the pipe_clk. Frequencies lower than 1 MHz are possible but with a loss of accuracy in the time counted. If the actual frequency (f) of aux_clk does not exactly match the programmed frequency (f_prog), then there is an error in the time counted by the controller that can be expressed in percentage as: err% = (f_prog/f-1)*100. For example if f=2.5 MHz and f_prog=3 MHz, then err% =(3/2.5-1)*100 =20%, meaning that the time counted by the controller on aux_clk will be 20% greater than the time in us programmed in the corresponding time register (for example T_POWER_ON). Note: This register field is sticky.

11.4.3.1.126 L1 Substates Timing Register. (L1_SUBSTATES_OFF)

11.4.3.1.126.1 Offset

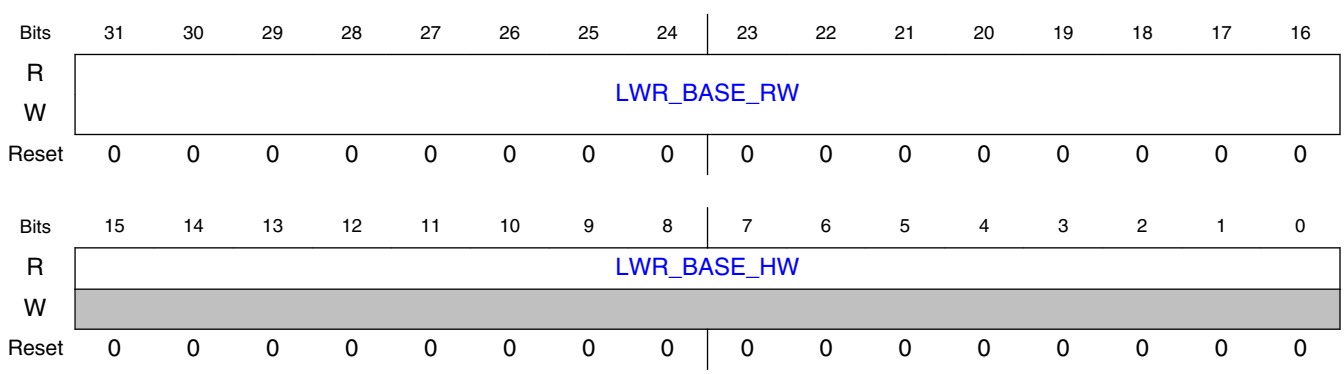
11.4.3.1.128.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 —	Reserved
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_MODE	CFG Shift Mode. The iATU uses bits [27:12] of the untranslated address (on the XALI0/1/2 interface or AXI slave interface address) to form the BDF number of the outgoing CFG TLP. This supports the Enhanced Configuration Address Mapping (ECAM) mechanism (Section 7.2.2 of the PCI Express Base 3.1 Specification, revision 1.0) by allowing all outgoing I/O and MEM TLPs (that have been translated to CFG) to be mapped from memory space into any 256 MB region of the PCIe configuration space. Note: This register field is sticky.
27 DMA_BYPASS	DMA Bypass Mode. Allows request TLPs which are initiated by the DMA controller to pass through the iATU untranslated. Note: This field is reserved for the SW product. You must set it to '0'. Note: This register field is sticky.
26-24 —	Reserved
23 HEADER_SUBSTITUTE_EN	Header Substitute Enable. When enabled and region address is matched, the iATU fully substitutes bytes 8-11 (for 3 DWORD header) or bytes 12-15 (for 4 DWORD header) of the outbound TLP header with the contents of the LWR_TARGET_RW field in IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i. - 1: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register is used to fill bytes 8-to-11 (for 3 DWORD header) or bytes 12-to-15 (for 4 DWORD header) of the translated TLP header. - 0: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register forms the new address of the translated region. Note: This register field is sticky.
22 INHIBIT_PAYLOAD	Inhibit TLP Payload Data for TLP's in Matched Region; assign iATU region to be TLP without data. When enabled and region address is matched, the iATU marks all TLPs as having no payload data by forcing the TLP header Fmt[1] bit =0, regardless of the application inputs such as slv_wstrb. - 1: Fmt[1] =0 so that only TLP type without data is sent. For example, a Msg instead of MsgD will be sent. - 0: Fmt[1] =0/1 so that TLPs with or without data can be sent. Note: This register field is sticky.
21 —	Reserved
20 SNP	Serialize Non-Posted Requests. In this mode, when the AXI Bridge is populated, same AXI ID Non-Posted Read/Write Requests are transmitted on the wire if there are no other same ID Non-Posted Requests outstanding. Note: This register field is sticky.
19 FUNC_BYPASS	Function Number Translation Bypass. In this mode, the function number of the translated TLP is taken from your application transmit interface and not from the CTRL_1_FUNC_NUM field of the "iATU Control 1 Register" or the VF_NUMBER field of the "iATU Control 3 Register." Note: This register field is sticky.
18-17 —	Reserved
16 TAG_SUBSTITUTE_EN	TAG Substitute Enable. When enabled and region address is matched, the iATU substitutes the TAG field of the outbound TLP header with the contents of the TAG field in this register. The expected usage scenario is translation from AXI MWr to Vendor Defined Msg/MsgD. Note (CX_TPH_ENABLE=1): TAG substitution for MWr will not occur because this field (byte 6) in the TLP header is the ST field. ST substitution can still take place using the MSG_CODE field in IATU_REGION_CTRL_2_OFF_OUTBOUND_i. Note: This register field is sticky.

Table continues on the next page...

Field	Function
15-8 TAG	TAG. The substituted TAG field (byte 6) in the outgoing TLP header when TAG_SUBSTITUTE_EN is set. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs (Message Code). When the address of an outbound TLP is matched to this region, and the translated TLP TYPE field is Msg or MsgD; then the message field of the TLP is changed to the value in this register. Memory TLPs: (ST;Steering Tag). When the ST field of an outbound TLP is matched to this region, and the translated TLP TYPE field targets memory space; then the ST field of the TLP is changed to the value in this register. Only Valid when the CX_TPH_ENABLE configuration parameter is 1. Note: This register field is sticky.

11.4.3.1.129 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_OUTBOUND_0)



11.4.3.1.129.1 Offset

Register	Offset
IATU_LWR_BASE_ADDR_OFF_OUTBOUND_0	30_0008h

11.4.3.1.129.2 Function

iATU Lower Base Address Register. The Minimum Size of iATU Region configuration parameter (Value Range: 4 kB, 8 kB, 16 kB, 32 kB, 64 kB defaults to 64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower 16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower log2(Minimum Size of iATU Region) bits are zero.

11.4.3.1.129.3 Diagram

11.4.3.1.129.4 Fields

Field	Function
31-16 LWR_BASE_RW	Forms bits [31:n] of the start address of the address region to be translated. n is log2(Minimum Size of iATU Region) Note: This register field is sticky.
15-0 LWR_BASE_HW	Forms bits [n-1:0] of the start address of the address region to be translated. The start address must be aligned to a Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. n is log2(Minimum Size of iATU Region)

11.4.3.1.130 iATU Upper Base Address Register. (IATU_UPPER_BASE_ADDR_OFF_OUTBOUND_0)

11.4.3.1.130.1 Offset

Register	Offset
IATU_UPPER_BASE_ADDR_OFF_OUTBOUND_0	30_000Ch

11.4.3.1.130.2 Diagram

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

11.4.3.1.132.3 Fields

Field	Function
31-0 LWR_TARGET_RW_OUTBOUND	When HEADER_SUBSTITUTE_EN in IATU_REGION_CTRL_2_OFF_OUTBOUND_ is '0' (normal operation): - LWR_TARGET_RW[31:n] forms MSB's of the Lower Target part of the new address of the translated region; - LWR_TARGET_RW[n-1:0] are not used. (The start address must be aligned to a Minimum Size of iATU Region kB boundary, so the lower bits of the start address of the new address of the translated region (bits n-1:0) are always '0'). - n is log2(Minimum Size of iATU Region). When HEADER_SUBSTITUTE_EN in IATU_REGION_CTRL_2_OFF_OUTBOUND_i is '1': - LWR_TARGET_RW[31:0] forms bytes 8-11 (for 3 dword header) or bytes 12-15 (for 4 dword header) of the outbound TLP header. Usage scenarios include the transmission of Vendor Defined Messages where the controller determines the content of bytes 12 to 15 of the TLP header. Note: This register field is sticky.

11.4.3.1.133 iATU Upper Target Address Register. (IATU_UPPER_TARGET_ADDR_OFF_OUTBOUND_0)

11.4.3.1.133.1 Offset

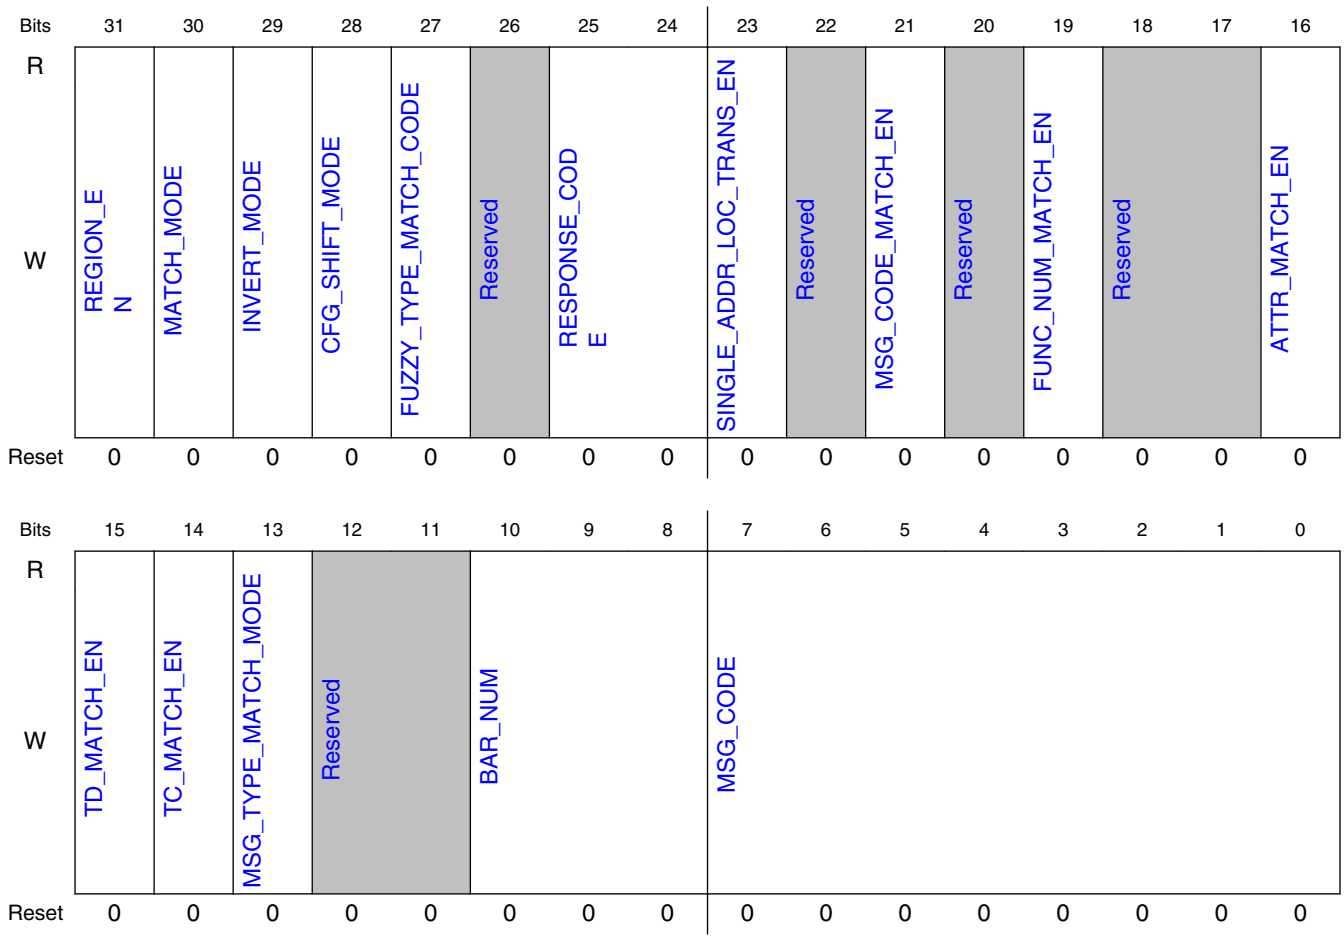
IATU_REGION_CTRL_1_OFF_INBOUND_0	30_0100h

11.4.3.1.134.2 Diagram

11.4.3.1.134.3 Fields

Field	Function
31-23 —	Reserved
22-20 CTRL_1_FUNC_NUM	Function Number. - MEM-I/O: When the Address and BAR matching logic in the controller indicate that a MEM-I/O transaction matches a BAR in the function corresponding to this value, then address translation proceeds. This check is only performed if the "Function Number Match Enable" bit of the "iATU Control 2 Register" is set. - CFG0/CFG1: When the destination function number as specified in the routing ID of the TLP header matches the function, then address translation proceeds. This check is only performed if the "Function Number Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
19-14 —	Reserved
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the maximum ATU Region size is determined by Maximum Size of iATU Region When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved
10-9 ATTR	When the ATTR field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "ATTR Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.

Table continues on the next page...



Field	Function
8 TD	When the TD field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TD Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
7-5 TC	When the TC field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TC Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
4-0 TYPE	When the TYPE field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). Note: This register field is sticky.

11.4.3.1.135 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFF_INBOUND_0)

11.4.3.1.135.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFF_INBOUND_0	30_0104h

11.4.3.1.135.2 Diagram

11.4.3.1.135.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 MATCH_MODE	Match Mode. Determines Inbound matching mode for TLPs. The mode depends on the type of TLP that is received as follows: For MEM-I/O TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU operates using addresses as in the outbound direction. The Region Base and Limit Registers must be setup. - 1:BAR Match Mode. BAR matching is used. The "BAR Number" field is relevant. Not used for RC. For CFG0 TLPs, this field is interpreted as follows: - 0: Routing ID Match Mode. The iATU interprets the Routing ID (Bytes 8 to 11 of TLP header) as an address. This corresponds to the upper 16 bits of the address in MEM-I/O transactions. The Routing ID of the TLP must be within the base and limit of the iATU region for matching to proceed. - 1: Accept Mode. The iATU accepts all CFG0 transactions as address matches. The routing ID in the CFG0 TLP is ignored. This is useful as all received CFG0 TLPs should be processed regardless of the Bus number. For MSG/MSGD TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU treats the third dword and fourth dword of the inbound MSG/MSGD TLP as an address and it is matched against the Region Base and Limit Registers. - 1: Vendor ID Match Mode. This mode is relevant for ID-routed Vendor Defined Messages. The iATU ignores the Routing ID (Bus, Device, Function) in bits [31:16] of the third dword of the TLP header, but matches

Table continues on the next page...

Field	Function
	against the Vendor ID in bits [15:0] of the third dword of the TLP header. Bits [15:0] of the Region Upper Base register should be programmed with the required Vendor ID. The lower Base and Limit Register should be programmed to translate TLPs based on vendor specific information in the fourth dword of the TLP header. - If SINGLE_ADDRESS_LOCATION_TRANSLATE_EN = 1 AND MSG_TYPE_MATCH_MODE = 1, then Match Mode is ignored. Note: This register field is sticky.
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_MODE	CFG Shift Mode. This is useful for CFG transactions where the PCIe configuration mechanism maps bits [27:12] of the address to the bus/device and function number. This allows a CFG configuration space to be located in any 256MB window of your application memory space using a 28-bit effective address. Shifts bits [31:16] of the untranslated address to form bits [27:12] of the translated address. Note: This register field is sticky.
27 FUZZY_TYPE_MATCH_CODE	Fuzzy Type Match Mode. When enabled, the iATU relaxes the matching of the TLP TYPE field against the expected TYPE field so that - CfgRd0 and CfgRd1 TLPs are seen as identical. Similarly with CfgWr0 and CfgWr1. - MWr, MRd and MRdLk TLPs are seen as identical - The Routing field of Msg/MsgD TLPs is ignored - FetchAdd, Swap and CAS are seen as identical. For example, CFG0 in the TYPE field in the "iATU Control 1 Register" matches against an inbound CfgRd0, CfgRd1, CfgWr0 or CfgWr1 TLP. Note: This register field is sticky.
26 —	Reserved
25-24 RESPONSE_CODE	Response Code. Defines the type of response to give for accesses matching this region. This overrides the normal RADM filter response. Note that this feature is not available for any region where Single Address Location Translate is enabled. - 00 - Normal RADM filter response is used. - 01 - Unsupported request (UR) - 10 - Completer abort (CA) - 11 - Not used / undefined / reserved. Note: This register field is sticky.
23 SINGLE_ADDR_LOC_TRANS_EN	Single Address Location Translate Enable. When enabled, Rx TLPs can be translated to a single address location as determined by the target address register of the iATU region. The main usage scenario is translation of Messages (such as Vendor Defined or ATS Messages) to MWr TLPs when the AXI bridge is enabled. Note: This register field is sticky.
22 —	Reserved
21 MSG_CODE_MATCH_EN	Message Code Match Enable (Msg TLPS). Ensures that a successful message Code TLP field comparison match (see Message Code field of the "iATU Control 2 Register") occurs (in MSG transactions) for address translation to proceed. ST Match Enable (Mem TLPs). Ensures that a successful ST TLP field comparison match (see ST field of the "iATU Control 2 Register") occurs (in MEM transactions) for address translation to proceed. Only Valid when the CX_TPH_ENABLE configuration parameter is 1 Note: This register field is sticky.
20 —	Reserved
19 FUNC_NUM_MATCH_EN	Function Number Match Enable. Ensures that a successful Function Number TLP field comparison match (see Function Number field of the "iATU Control 1 Register") occurs (in MEM-I/O and CFG0/CFG1 transactions) for address translation to proceed. Note: This register field is sticky.
18-17 —	Reserved
16 ATTR_MATCH_EN	ATTR Match Enable. Ensures that a successful ATTR TLP field comparison match (see ATTR field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.

Table continues on the next page...

Field	Function
15 TD_MATCH_EN	TD Match Enable. Ensures that a successful TD TLP field comparison match (see TD field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
14 TC_MATCH_EN	TC Match Enable. Ensures that a successful TC TLP field comparison match (see TC field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
13 MSG_TYPE_MATCH_MODE	Message Type Match Mode. When enabled, and if single address location translate enable is set, then inbound TLPs of type MSG/MSGd which match the type field of the iatu_region_ctrl_1_OFF_inbound register (=>TYPE[4:3]=2'b10) will be translated. Message type match mode overrides any value of MATCH_MODE field in this register. Usage scenarios for this are translation of VDM or ATS messages when AXI bridge is configured on client interface. Note: This register field is sticky.
12-11 —	Reserved
10-8 BAR_NUM	BAR Number. When the BAR number of an inbound MEM or IO TLP " that is matched by the normal internal BAR address matching mechanism " is the same as this field, address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Match Mode" bit of the "iATU Control 2 Register" is set. - 000b - BAR0 - 001b - BAR1 - 010b - BAR2 - 011b - BAR3 - 100b - BAR4 - 101b - BAR5 - 110b - ROM - 111b - reserved - IO translation would require either 00100b or 00101b in the inbound TLP TYPE; the BAR Number set in the range 000b - 101b and that BAR configured as an IO BAR. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs: (Message Code). When the TYPE field of an inbound Msg/MsgD TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Message Code Match Enable" bit of the "iATU Control 2 Register" is set. Memory TLPs: (ST;Steering Tag). When the ST field of an inbound TLP is matched to this value, then address translation proceeds. This check is only performed if the "ST Match Enable" bit of the "iATU Control2 Register" is set. The setting is independent of the setting of the TH field. Only Valid when the CX_TPH_ENABLE configuration parameter is 1. Note: This register field is sticky.

11.4.3.1.136 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_INBOUND_0)

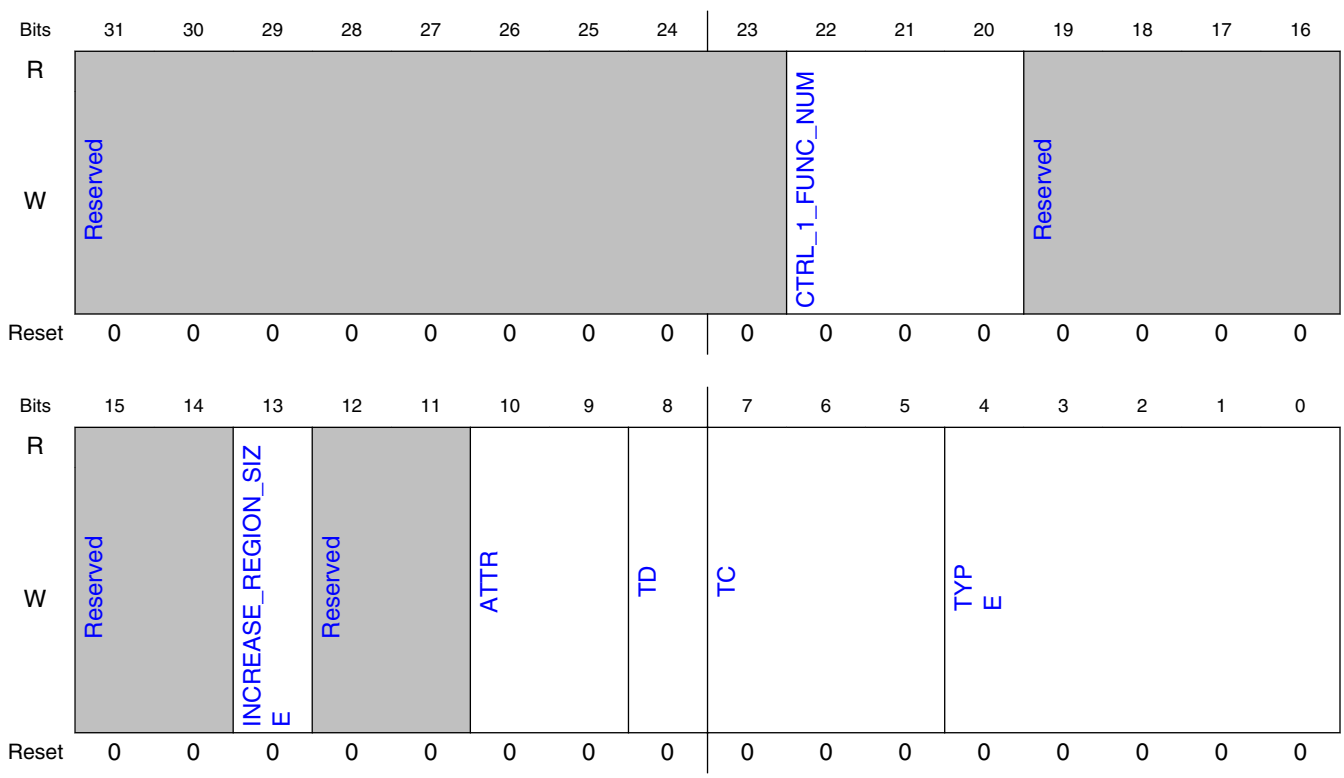
IATU_LWR_TARGET_ADDR_OFF_INBOUND_0	30_0114h

11.4.3.1.139.2 Diagram

11.4.3.1.139.3 Fields

Field	Function
31-16 LWR_TARGET_RW	Forms MSB's of the Lower Target part of the new address of the translated region. These bits are always '0'. - Field size depends on log2(Minimum Size of iATU Region) in address match mode. - Field size depends on log2(BAR_MASK+1) in BAR match mode. Note: This register field is sticky.

Table continues on the next page...



Field	Function
15-0 LWR_TARGET_HW	Forms the LSB's of the Lower Target part of the new address of the translated region. The start address must be aligned to a Minimum Size of iATU Region kB boundary (in address match mode); and to the Bar size boundary (in BAR match mode) so that these bits are always '0'. If the BAR is smaller than the iATU region size, then the iATU target address must align to the iATU region size; otherwise it must align to the BAR size. A write to this location is ignored by the PCIe controller. - Field size depends on log2(Minimum Size of iATU Region) in address match mode. - Field size depends on log2(BAR_MASK+1) in BAR match mode.

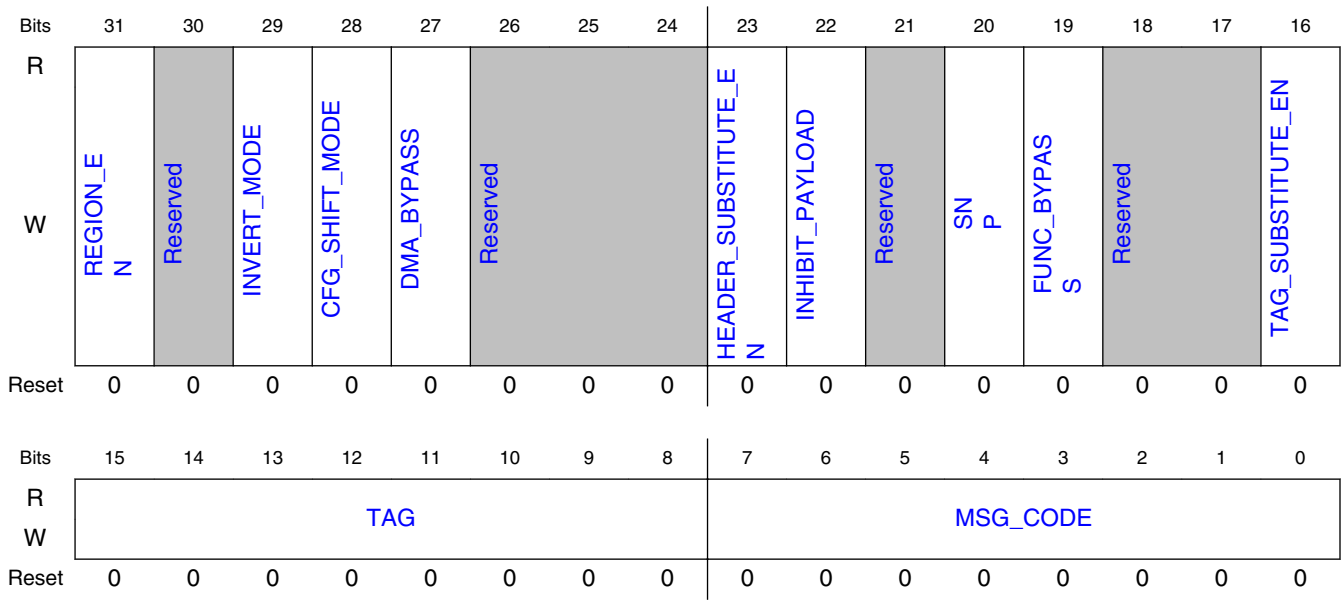
11.4.3.1.140 iATU Region Control 1 Register. (IATU_REGION_CTRL_1_OFF_OUTBOUND_1)

11.4.3.1.140.1 Offset

Register	Offset
IATU_REGION_CTRL_1_OFF_OUTBOUND_1	30_0200h

11.4.3.1.140.2 Diagram

11.4.3.1.140.3 Fields



Field	Function
31-23 —	Reserved
22-20 CTRL_1_FUNC_NUM	Function Number. - When the address of an outbound TLP is matched to this region and the FUNC_BYPASS field in the "iATU Control 2 Register" is '0', then the function number used in generating the function part of the requester ID (RID) field of the TLP is taken from this 5-bit register. The value in this register must be 0x0 unless multifunction operation in the controller is enabled (CX_NFUNC > 1). - When you are using the AXI Bridge, then this field is swapped before AXI decomposition occurs so that the correct "Max_Read_Request_Size" and "Max_Payload_Size" values are used. Note: This register field is sticky.
19-14 —	Reserved
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the maximum ATU Region size is determined by Maximum Size of iATU Region When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved
10-9 ATTR	When the address of an outbound TLP is matched to this region, then the ATTR field of the TLP is changed to the value in this register. Note: This register field is sticky.
8 TD	When the address of an outbound TLP is matched to this region, then the TD field of the TLP is changed to the value in this register. Note: This register field is sticky.
7-5 TC	When the address of an outbound TLP is matched to this region, then the TC field of the TLP is changed to the value in this register. Note: This register field is sticky.
4-0 TYPE	When the address of an outbound TLP is matched to this region, then the TYPE field of the TLP is changed to the value in this register. Note: This register field is sticky.

11.4.3.1.141 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFF_OUTBOUND_1)

11.4.3.1.141.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFF_OUTBOUND_1	30_0204h

11.4.3.1.141.2 Diagram

11.4.3.1.141.3 Fields

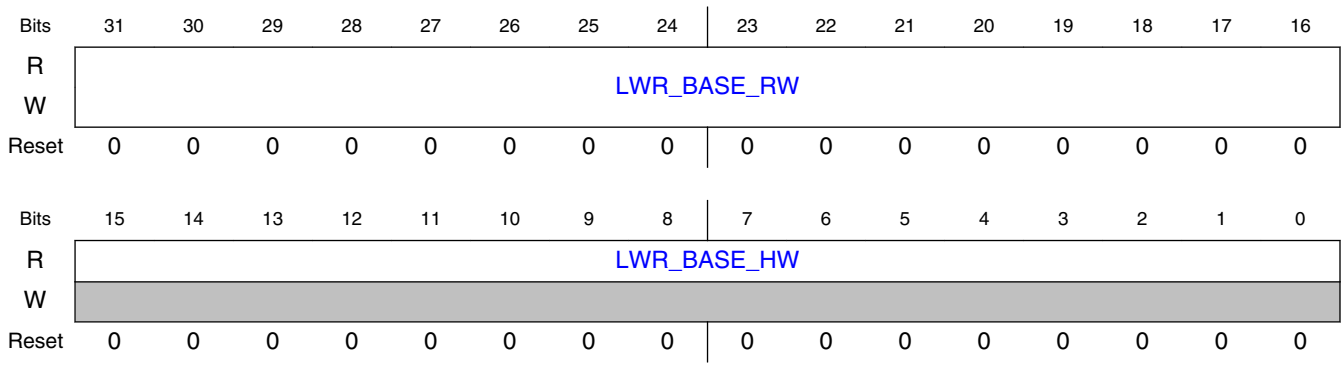
Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 —	Reserved
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_MODE	CFG Shift Mode. The iATU uses bits [27:12] of the untranslated address (on the XALI0/1/2 interface or AXI slave interface address) to form the BDF number of the outgoing CFG TLP. This supports the Enhanced Configuration Address Mapping (ECAM) mechanism (Section 7.2.2 of the PCI Express Base 3.1 Specification, revision 1.0) by allowing all outgoing I/O and MEM TLPs (that have been translated to CFG) to be mapped from memory space into any 256 MB region of the PCIe configuration space. Note: This register field is sticky.
27 DMA_BYPASS	DMA Bypass Mode. Allows request TLPs which are initiated by the DMA controller to pass through the iATU untranslated. Note: This field is reserved for the SW product. You must set it to '0'. Note: This register field is sticky.
26-24 —	Reserved
23 HEADER_SUBSTITUTE_EN	Header Substitute Enable. When enabled and region address is matched, the iATU fully substitutes bytes 8-11 (for 3 DWORD header) or bytes 12-15 (for 4 DWORD header) of the outbound TLP header with the contents of the LWR_TARGET_RW field in IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i. - 1: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register is used to fill bytes 8-to-11 (for 3 DWORD header) or bytes 12-to-15 (for 4 DWORD header) of the translated TLP header. - 0: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register forms the new address of the translated region. Note: This register field is sticky.

Table continues on the next page...

Field	Function
22 INHIBIT_PAYLOAD	Inhibit TLP Payload Data for TLP's in Matched Region; assign iATU region to be TLP without data. When enabled and region address is matched, the iATU marks all TLPs as having no payload data by forcing the TLP header Fmt[1] bit =0, regardless of the application inputs such as slv_wstrb. - 1: Fmt[1] =0 so that only TLP type without data is sent. For example, a Msg instead of MsgD will be sent. - 0: Fmt[1] =0/1 so that TLPs with or without data can be sent. Note: This register field is sticky.
21 —	Reserved
20 SNP	Serialize Non-Posted Requests. In this mode, when the AXI Bridge is populated, same AXI ID Non-Posted Read/Write Requests are transmitted on the wire if there are no other same ID Non-Posted Requests outstanding. Note: This register field is sticky.
19 FUNC_BYPASS	Function Number Translation Bypass. In this mode, the function number of the translated TLP is taken from your application transmit interface and not from the CTRL_1_FUNC_NUM field of the "iATU Control 1 Register" or the VF_NUMBER field of the "iATU Control 3 Register." Note: This register field is sticky.
18-17 —	Reserved
16 TAG_SUBSTITUTE_EN	TAG Substitute Enable. When enabled and region address is matched, the iATU substitutes the TAG field of the outbound TLP header with the contents of the TAG field in this register. The expected usage scenario is translation from AXI MWr to Vendor Defined Msg/MsgD. Note (CX_TPH_ENABLE=1): TAG substitution for MWr will not occur because this field (byte 6) in the TLP header is the ST field. ST substitution can still take place using the MSG_CODE field in IATU_REGION_CTRL_2_OFF_OUTBOUND_i. Note: This register field is sticky.
15-8 TAG	TAG. The substituted TAG field (byte 6) in the outgoing TLP header when TAG_SUBSTITUTE_EN is set. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs (Message Code). When the address of an outbound TLP is matched to this region, and the translated TLP TYPE field is Msg or MsgD; then the message field of the TLP is changed to the value in this register. Memory TLPs: (ST;Steering Tag). When the ST field of an outbound TLP is matched to this region, and the translated TLP TYPE field targets memory space; then the ST field of the TLP is changed to the value in this register. Only Valid when the CX_TPH_ENABLE configuration parameter is 1. Note: This register field is sticky.

11.4.3.1.142 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_OUTBOUND_1)

11.4.3.1.142.1 Offset



Register	Offset
IATU_LWR_BASE_ADDR_OFF_OUTBOUND_1	30_0208h

11.4.3.1.142.2 Function

iATU Lower Base Address Register. The Minimum Size of iATU Region configuration parameter (Value Range: 4 kB, 8 kB, 16 kB, 32 kB, 64 kB defaults to 64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower

16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower log2(Minimum Size of iATU Region) bits are zero.

11.4.3.1.142.3 Diagram

11.4.3.1.142.4 Fields

Field	Function
31-16 LWR_BASE_RW	Forms bits [31:n] of the start address of the address region to be translated. n is log2(Minimum Size of iATU Region) Note: This register field is sticky.
15-0 LWR_BASE_HW	Forms bits [n-1:0] of the start address of the address region to be translated. The start address must be aligned to a Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. n is log2(Minimum Size of iATU Region)

11.4.3.1.143 iATU Upper Base Address Register. (IATU_UPPER_BASE_ADDR_OFF_OUTBOUND_1)

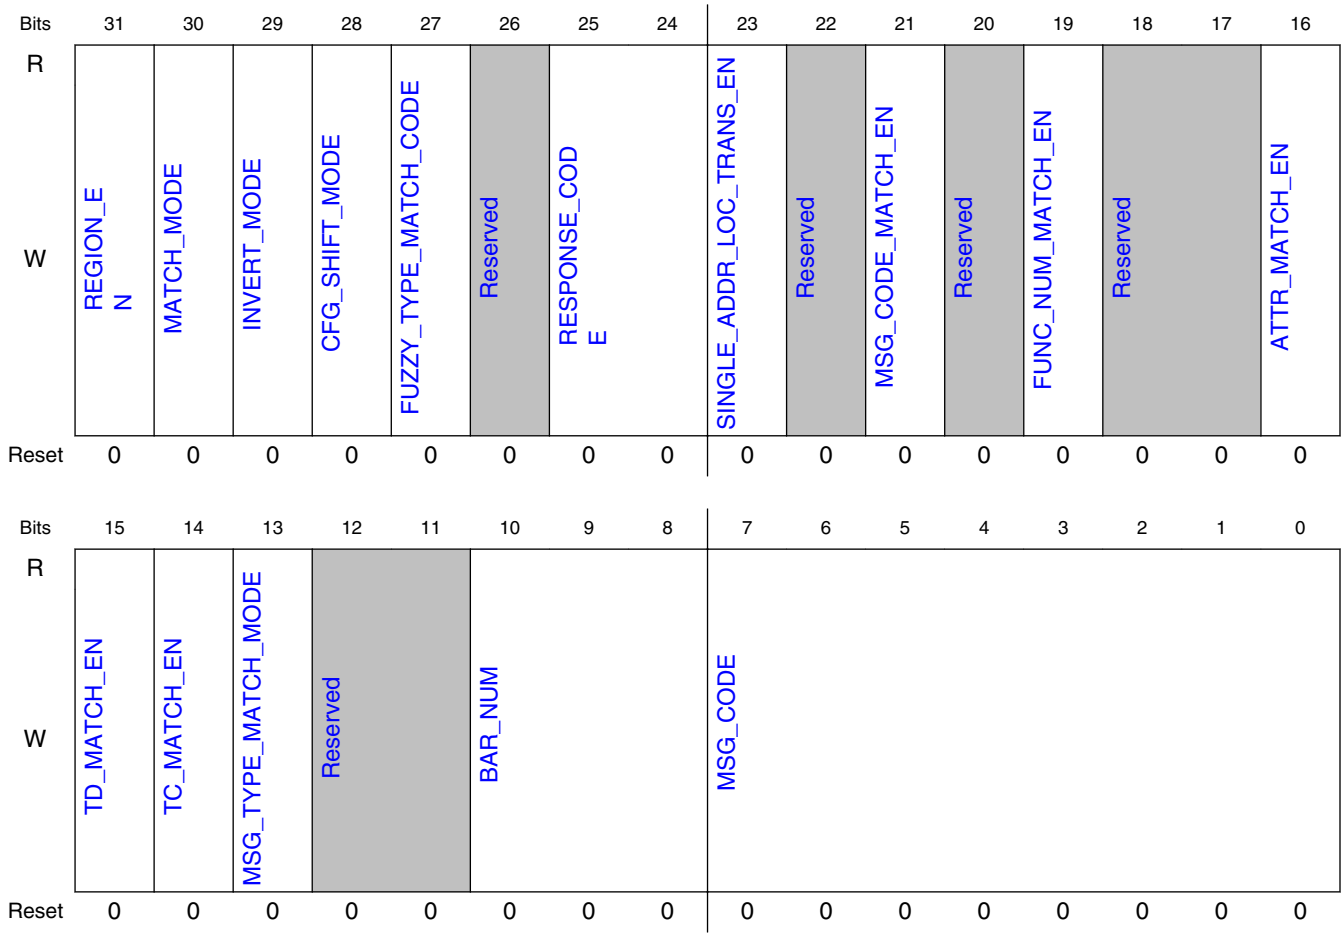
11.4.3.1.147.3 Fields

Field	Function
31-23 —	Reserved
22-20 CTRL_1_FUNC_NUM	Function Number. - MEM-I/O: When the Address and BAR matching logic in the controller indicate that a MEM-I/O transaction matches a BAR in the function corresponding to this value, then address translation proceeds. This check is only performed if the "Function Number Match Enable" bit of the "iATU Control 2 Register" is set. - CFG0/CFG1: When the destination function number as specified in the routing ID of the TLP header matches the function, then address translation proceeds. This check is only performed if the

Table continues on the next page...



Field	Function
	"Function Number Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
19-14 —	Reserved
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the maximum ATU Region size is determined by Maximum Size of iATU Region When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved
10-9 ATTR	When the ATTR field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "ATTR Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
8 TD	When the TD field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TD Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
7-5 TC	When the TC field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TC Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
4-0 TYPE	When the TYPE field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). Note: This register field is sticky.

11.4.3.1.148 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFF_INBOUND_1)

11.4.3.1.148.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFF_INBOUND_1	30_0304h

11.4.3.1.148.2 Diagram

11.4.3.1.148.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 MATCH_MODE	Match Mode. Determines Inbound matching mode for TLPs. The mode depends on the type of TLP that is received as follows: For MEM-I/O TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU operates using addresses as in the outbound direction. The Region Base and Limit Registers must be setup. - 1:BAR Match Mode. BAR matching is used. The "BAR Number" field is relevant. Not used for RC. For CFG0 TLPs, this field is interpreted as follows: - 0: Routing ID Match Mode. The iATU interprets the Routing ID (Bytes 8 to 11 of TLP header) as an address. This corresponds to the upper 16 bits of the address in MEM-I/O transactions. The Routing ID of the TLP must be within the base and limit of the iATU region for matching to proceed. - 1: Accept Mode. The iATU accepts all CFG0 transactions as address matches. The routing ID in the CFG0 TLP is ignored. This is useful as all received CFG0 TLPs should be processed regardless of the Bus number. For MSG/MSGD TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU treats the third dword and fourth dword of the inbound MSG/MSGD TLP as an address and it is matched against the Region Base and Limit Registers. - 1: Vendor ID Match Mode. This mode is relevant for ID-routed Vendor Defined Messages. The iATU ignores the Routing ID (Bus, Device, Function) in bits [31:16] of the third dword of the TLP header, but matches

Table continues on the next page...

Field	Function
	against the Vendor ID in bits [15:0] of the third dword of the TLP header. Bits [15:0] of the Region Upper Base register should be programmed with the required Vendor ID. The lower Base and Limit Register should be programmed to translate TLPs based on vendor specific information in the fourth dword of the TLP header. - If SINGLE_ADDRESS_LOCATION_TRANSLATE_EN = 1 AND MSG_TYPE_MATCH_MODE = 1, then Match Mode is ignored. Note: This register field is sticky.
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_MODE	CFG Shift Mode. This is useful for CFG transactions where the PCIe configuration mechanism maps bits [27:12] of the address to the bus/device and function number. This allows a CFG configuration space to be located in any 256MB window of your application memory space using a 28-bit effective address. Shifts bits [31:16] of the untranslated address to form bits [27:12] of the translated address. Note: This register field is sticky.
27 FUZZY_TYPE_MATCH_CODE	Fuzzy Type Match Mode. When enabled, the iATU relaxes the matching of the TLP TYPE field against the expected TYPE field so that - CfgRd0 and CfgRd1 TLPs are seen as identical. Similarly with CfgWr0 and CfgWr1. - MWr, MRd and MRdLk TLPs are seen as identical - The Routing field of Msg/MsgD TLPs is ignored - FetchAdd, Swap and CAS are seen as identical. For example, CFG0 in the TYPE field in the "iATU Control 1 Register" matches against an inbound CfgRd0, CfgRd1, CfgWr0 or CfgWr1 TLP. Note: This register field is sticky.
26 —	Reserved
25-24 RESPONSE_CODE	Response Code. Defines the type of response to give for accesses matching this region. This overrides the normal RADM filter response. Note that this feature is not available for any region where Single Address Location Translate is enabled. - 00 - Normal RADM filter response is used. - 01 - Unsupported request (UR) - 10 - Completer abort (CA) - 11 - Not used / undefined / reserved. Note: This register field is sticky.
23 SINGLE_ADDR_LOC_TRANS_EN	Single Address Location Translate Enable. When enabled, Rx TLPs can be translated to a single address location as determined by the target address register of the iATU region. The main usage scenario is translation of Messages (such as Vendor Defined or ATS Messages) to MWr TLPs when the AXI bridge is enabled. Note: This register field is sticky.
22 —	Reserved
21 MSG_CODE_MATCH_EN	Message Code Match Enable (Msg TLPS). Ensures that a successful message Code TLP field comparison match (see Message Code field of the "iATU Control 2 Register") occurs (in MSG transactions) for address translation to proceed. ST Match Enable (Mem TLPs). Ensures that a successful ST TLP field comparison match (see ST field of the "iATU Control 2 Register") occurs (in MEM transactions) for address translation to proceed. Only Valid when the CX_TPH_ENABLE configuration parameter is 1 Note: This register field is sticky.
20 —	Reserved
19 FUNC_NUM_MATCH_EN	Function Number Match Enable. Ensures that a successful Function Number TLP field comparison match (see Function Number field of the "iATU Control 1 Register") occurs (in MEM-I/O and CFG0/CFG1 transactions) for address translation to proceed. Note: This register field is sticky.
18-17 —	Reserved
16 ATTR_MATCH_EN	ATTR Match Enable. Ensures that a successful ATTR TLP field comparison match (see ATTR field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.

Table continues on the next page...

Field	Function
15 TD_MATCH_EN	TD Match Enable. Ensures that a successful TD TLP field comparison match (see TD field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
14 TC_MATCH_EN	TC Match Enable. Ensures that a successful TC TLP field comparison match (see TC field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
13 MSG_TYPE_MATCH_MODE	Message Type Match Mode. When enabled, and if single address location translate enable is set, then inbound TLPs of type MSG/MSGd which match the type field of the iatu_region_ctrl_1_OFF_inbound register (=>TYPE[4:3]=2'b10) will be translated. Message type match mode overrides any value of MATCH_MODE field in this register. Usage scenarios for this are translation of VDM or ATS messages when AXI bridge is configured on client interface. Note: This register field is sticky.
12-11 —	Reserved
10-8 BAR_NUM	BAR Number. When the BAR number of an inbound MEM or IO TLP " that is matched by the normal internal BAR address matching mechanism " is the same as this field, address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Match Mode" bit of the "iATU Control 2 Register" is set. - 000b - BAR0 - 001b - BAR1 - 010b - BAR2 - 011b - BAR3 - 100b - BAR4 - 101b - BAR5 - 110b - ROM - 111b - reserved - IO translation would require either 00100b or 00101b in the inbound TLP TYPE; the BAR Number set in the range 000b - 101b and that BAR configured as an IO BAR. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs: (Message Code). When the TYPE field of an inbound Msg/MsgD TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Message Code Match Enable" bit of the "iATU Control 2 Register" is set. Memory TLPs: (ST;Steering Tag). When the ST field of an inbound TLP is matched to this value, then address translation proceeds. This check is only performed if the "ST Match Enable" bit of the "iATU Control2 Register" is set. The setting is independent of the setting of the TH field. Only Valid when the CX_TPH_ENABLE configuration parameter is 1. Note: This register field is sticky.

11.4.3.1.149 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_INBOUND_1)

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
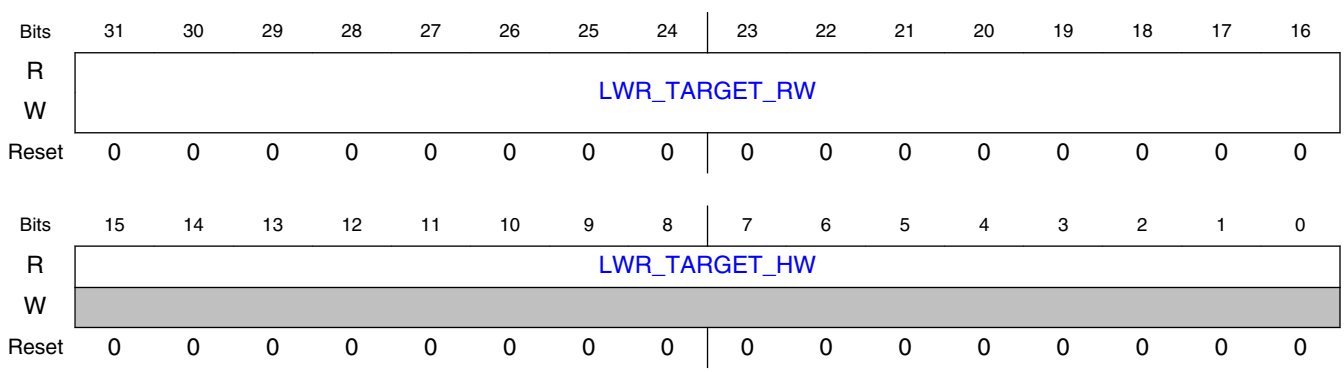
R	LIMIT_ADDR_HW															
W																
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

11.4.3.1.151.3 Fields



Field	Function
31-16 LIMIT_ADDR_RW	Forms upper bits of the end address of the address region to be translated. The end address must be aligned to a Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. Note: This register field is sticky.
15-0 LIMIT_ADDR_HW	Forms lower bits of the end address of the address region to be translated. The end address must be aligned to a Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller.

11.4.3.1.152 iATU Lower Target Address Register. (IATU_LWR_TARGET_ADDR_OFF_INBOUND_1)

11.4.3.1.152.1 Offset

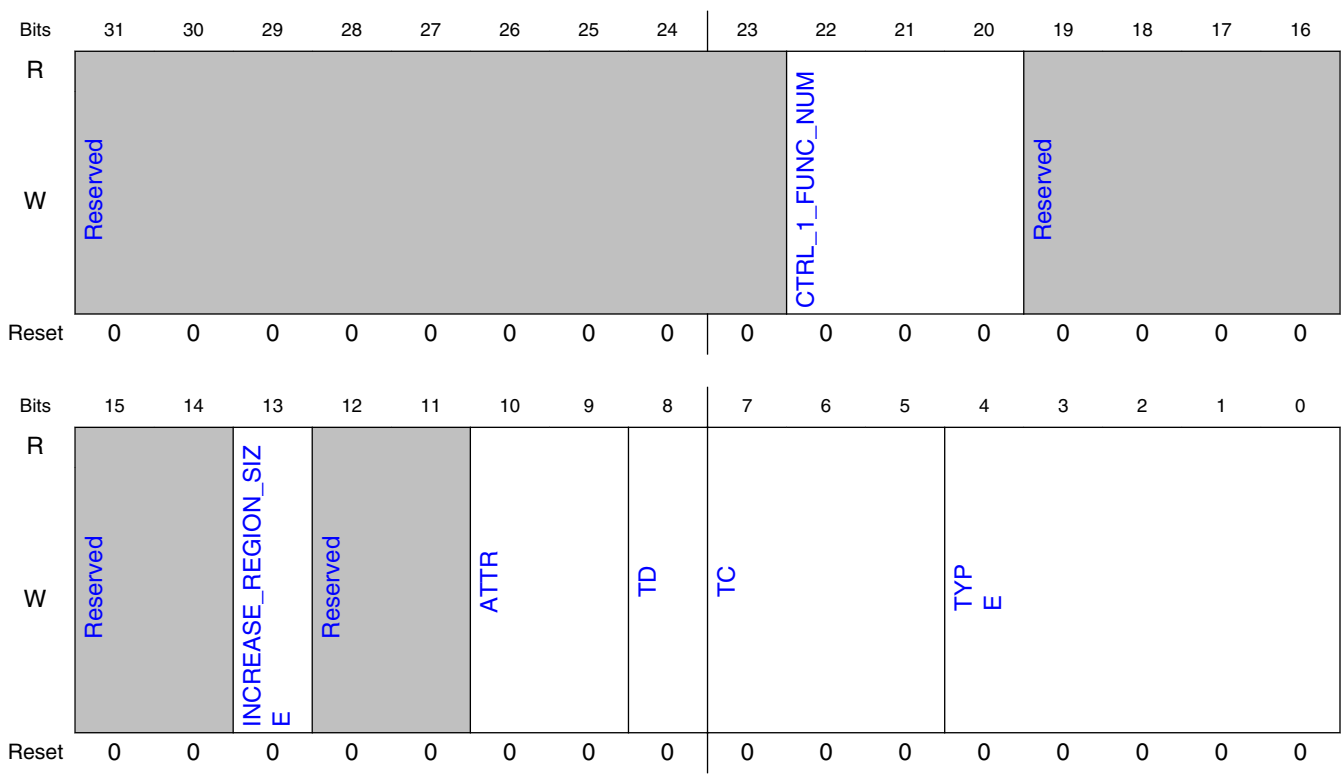
Register	Offset
IATU_LWR_TARGET_ADDR_OFF_INBOUND_1	30_0314h

11.4.3.1.152.2 Diagram

11.4.3.1.152.3 Fields

Field	Function
31-16 LWR_TARGET_RW	Forms MSB's of the Lower Target part of the new address of the translated region. These bits are always '0'. - Field size depends on log2(Minimum Size of iATU Region) in address match mode. - Field size depends on log2(BAR_MASK+1) in BAR match mode. Note: This register field is sticky.

Table continues on the next page...



Field	Function
15-0 LWR_TARGET_HW	Forms the LSB's of the Lower Target part of the new address of the translated region. The start address must be aligned to a Minimum Size of iATU Region kB boundary (in address match mode); and to the Bar size boundary (in BAR match mode) so that these bits are always '0'. If the BAR is smaller than the iATU region size, then the iATU target address must align to the iATU region size; otherwise it must align to the BAR size. A write to this location is ignored by the PCIe controller. - Field size depends on log2(Minimum Size of iATU Region) in address match mode. - Field size depends on log2(BAR_MASK+1) in BAR match mode.

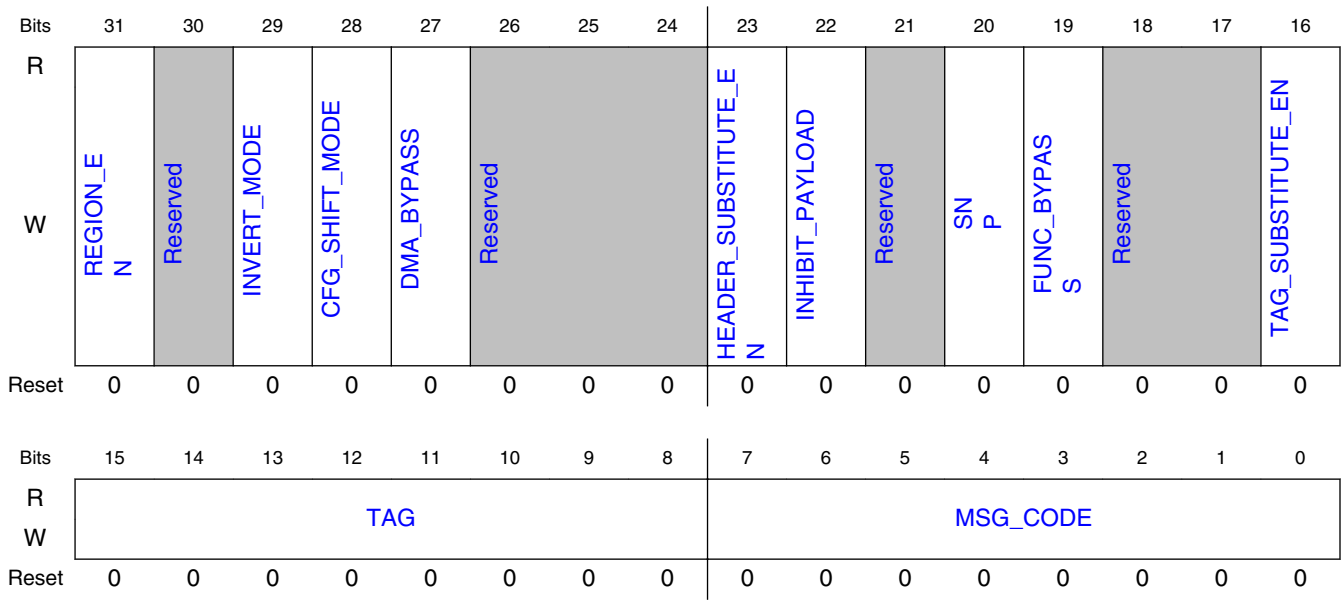
11.4.3.1.153 iATU Region Control 1 Register. (IATU_REGION_CTRL_1_OFF_OUTBOUND_2)

11.4.3.1.153.1 Offset

Register	Offset
IATU_REGION_CTRL_1_OFF_OUTBOUND_2	30_0400h

11.4.3.1.153.2 Diagram

11.4.3.1.153.3 Fields



Field	Function
31-23 —	Reserved
22-20 CTRL_1_FUNC_NUM	Function Number. - When the address of an outbound TLP is matched to this region and the FUNC_BYPASS field in the "iATU Control 2 Register" is '0', then the function number used in generating the function part of the requester ID (RID) field of the TLP is taken from this 5-bit register. The value in this register must be 0x0 unless multifunction operation in the controller is enabled (CX_NFUNC > 1). - When you are using the AXI Bridge, then this field is swapped before AXI decomposition occurs so that the correct "Max_Read_Request_Size" and "Max_Payload_Size" values are used. Note: This register field is sticky.
19-14 —	Reserved
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the maximum ATU Region size is determined by Maximum Size of iATU Region When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved
10-9 ATTR	When the address of an outbound TLP is matched to this region, then the ATTR field of the TLP is changed to the value in this register. Note: This register field is sticky.
8 TD	When the address of an outbound TLP is matched to this region, then the TD field of the TLP is changed to the value in this register. Note: This register field is sticky.
7-5 TC	When the address of an outbound TLP is matched to this region, then the TC field of the TLP is changed to the value in this register. Note: This register field is sticky.
4-0 TYPE	When the address of an outbound TLP is matched to this region, then the TYPE field of the TLP is changed to the value in this register. Note: This register field is sticky.

11.4.3.1.154 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFF_OUTBOUND_2)

11.4.3.1.154.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFF_OUTBOUND_2	30_0404h

11.4.3.1.154.2 Diagram

11.4.3.1.154.3 Fields

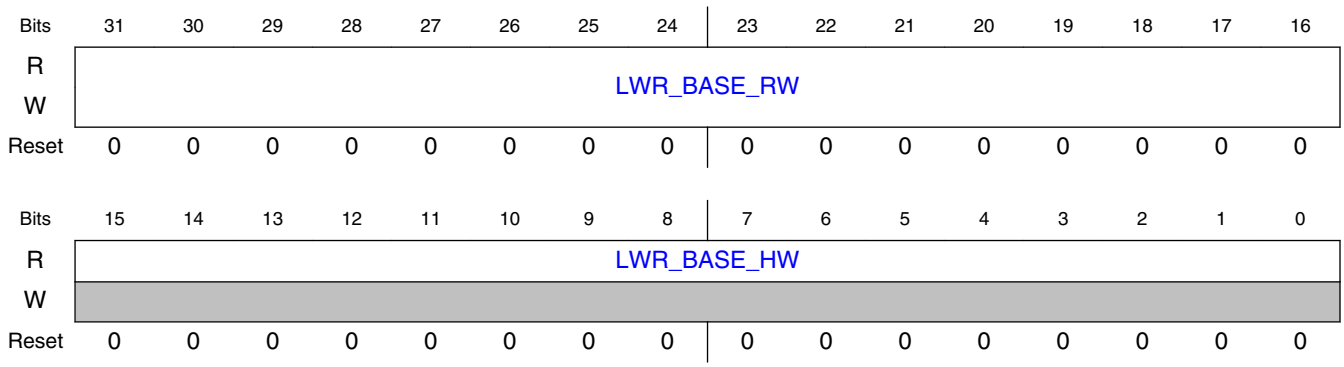
Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 —	Reserved
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_MODE	CFG Shift Mode. The iATU uses bits [27:12] of the untranslated address (on the XALI0/1/2 interface or AXI slave interface address) to form the BDF number of the outgoing CFG TLP. This supports the Enhanced Configuration Address Mapping (ECAM) mechanism (Section 7.2.2 of the PCI Express Base 3.1 Specification, revision 1.0) by allowing all outgoing I/O and MEM TLPs (that have been translated to CFG) to be mapped from memory space into any 256 MB region of the PCIe configuration space. Note: This register field is sticky.
27 DMA_BYPASS	DMA Bypass Mode. Allows request TLPs which are initiated by the DMA controller to pass through the iATU untranslated. Note: This field is reserved for the SW product. You must set it to '0'. Note: This register field is sticky.
26-24 —	Reserved
23 HEADER_SUBSTITUTE_EN	Header Substitute Enable. When enabled and region address is matched, the iATU fully substitutes bytes 8-11 (for 3 DWORD header) or bytes 12-15 (for 4 DWORD header) of the outbound TLP header with the contents of the LWR_TARGET_RW field in IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i. - 1: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register is used to fill bytes 8-to-11 (for 3 DWORD header) or bytes 12-to-15 (for 4 DWORD header) of the translated TLP header. - 0: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register forms the new address of the translated region. Note: This register field is sticky.

Table continues on the next page...

Field	Function
22 INHIBIT_PAYLOAD	Inhibit TLP Payload Data for TLP's in Matched Region; assign iATU region to be TLP without data. When enabled and region address is matched, the iATU marks all TLPs as having no payload data by forcing the TLP header Fmt[1] bit =0, regardless of the application inputs such as slv_wstrb. - 1: Fmt[1] =0 so that only TLP type without data is sent. For example, a Msg instead of MsgD will be sent. - 0: Fmt[1] =0/1 so that TLPs with or without data can be sent. Note: This register field is sticky.
21 —	Reserved
20 SNP	Serialize Non-Posted Requests. In this mode, when the AXI Bridge is populated, same AXI ID Non-Posted Read/Write Requests are transmitted on the wire if there are no other same ID Non-Posted Requests outstanding. Note: This register field is sticky.
19 FUNC_BYPASS	Function Number Translation Bypass. In this mode, the function number of the translated TLP is taken from your application transmit interface and not from the CTRL_1_FUNC_NUM field of the "iATU Control 1 Register" or the VF_NUMBER field of the "iATU Control 3 Register." Note: This register field is sticky.
18-17 —	Reserved
16 TAG_SUBSTITUTE_EN	TAG Substitute Enable. When enabled and region address is matched, the iATU substitutes the TAG field of the outbound TLP header with the contents of the TAG field in this register. The expected usage scenario is translation from AXI MWr to Vendor Defined Msg/MsgD. Note (CX_TPH_ENABLE=1): TAG substitution for MWr will not occur because this field (byte 6) in the TLP header is the ST field. ST substitution can still take place using the MSG_CODE field in IATU_REGION_CTRL_2_OFF_OUTBOUND_i. Note: This register field is sticky.
15-8 TAG	TAG. The substituted TAG field (byte 6) in the outgoing TLP header when TAG_SUBSTITUTE_EN is set. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs (Message Code). When the address of an outbound TLP is matched to this region, and the translated TLP TYPE field is Msg or MsgD; then the message field of the TLP is changed to the value in this register. Memory TLPs: (ST;Steering Tag). When the ST field of an outbound TLP is matched to this region, and the translated TLP TYPE field targets memory space; then the ST field of the TLP is changed to the value in this register. Only Valid when the CX_TPH_ENABLE configuration parameter is 1. Note: This register field is sticky.

11.4.3.1.155 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_OUTBOUND_2)

11.4.3.1.155.1 Offset



Register	Offset
IATU_LWR_BASE_ADDR_OFF_OUTBOUND_2	30_0408h

11.4.3.1.155.2 Function

iATU Lower Base Address Register. The Minimum Size of iATU Region configuration parameter (Value Range: 4 kB, 8 kB, 16 kB, 32 kB, 64 kB defaults to 64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower

16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower log2(Minimum Size of iATU Region) bits are zero.

11.4.3.1.155.3 Diagram

11.4.3.1.155.4 Fields

Field	Function
31-16 LWR_BASE_RW	Forms bits [31:n] of the start address of the address region to be translated. n is log2(Minimum Size of iATU Region) Note: This register field is sticky.
15-0 LWR_BASE_HW	Forms bits [n-1:0] of the start address of the address region to be translated. The start address must be aligned to a Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. n is log2(Minimum Size of iATU Region)

11.4.3.1.156 iATU Upper Base Address Register. (IATU_UPPER_BASE_ADDR_OFF_OUTBOUND_2)

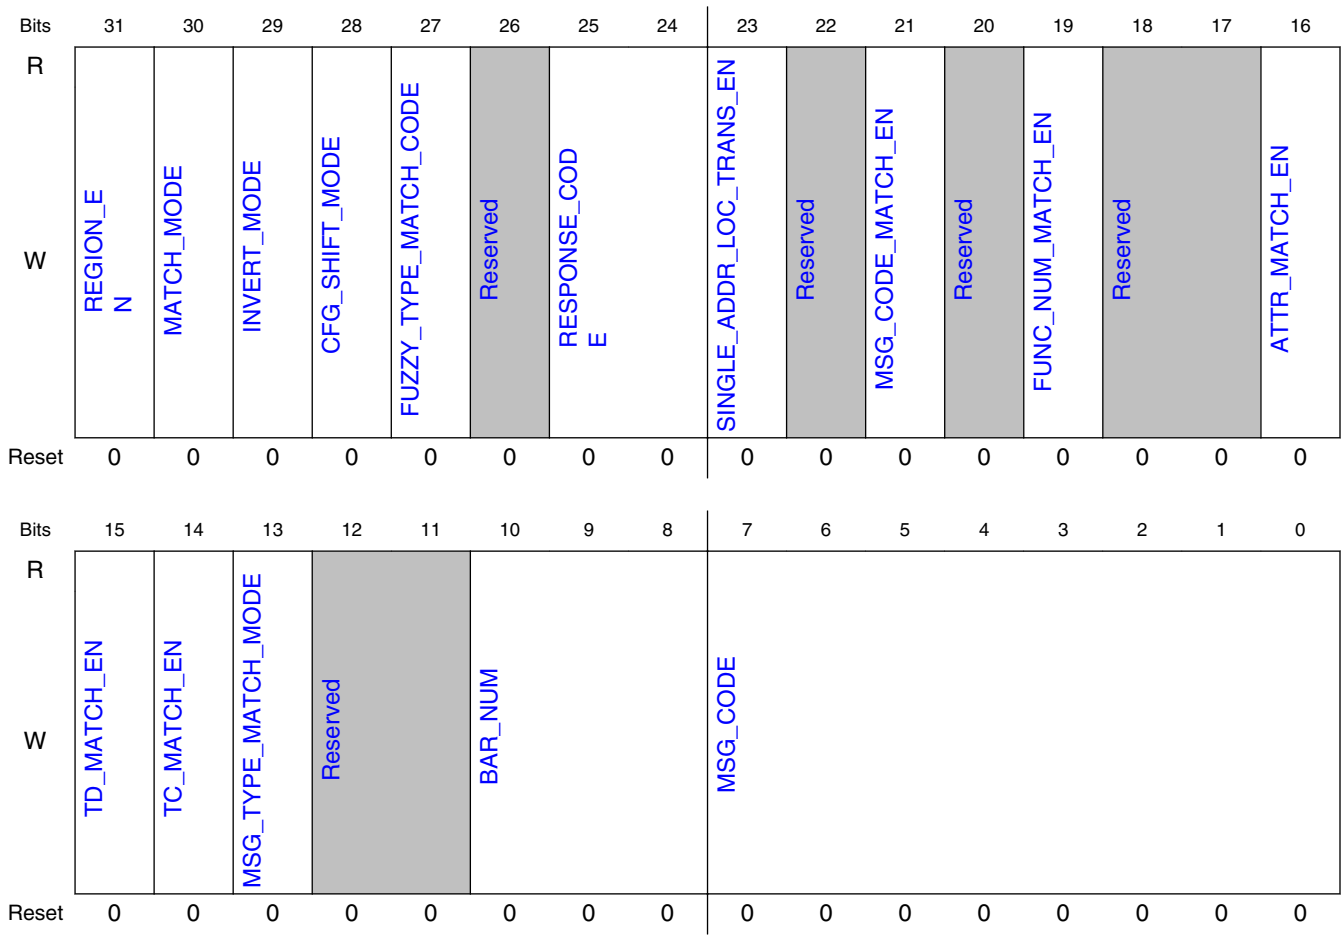
11.4.3.1.160.3 Fields

Field	Function
31-23 —	Reserved
22-20 CTRL_1_FUNC_NUM	Function Number. - MEM-I/O: When the Address and BAR matching logic in the controller indicate that a MEM-I/O transaction matches a BAR in the function corresponding to this value, then address translation proceeds. This check is only performed if the "Function Number Match Enable" bit of the "iATU Control 2 Register" is set. - CFG0/CFG1: When the destination function number as specified in the routing ID of the TLP header matches the function, then address translation proceeds. This check is only performed if the

Table continues on the next page...



Field	Function
	"Function Number Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
19-14 —	Reserved
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the maximum ATU Region size is determined by Maximum Size of iATU Region When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved
10-9 ATTR	When the ATTR field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "ATTR Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
8 TD	When the TD field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TD Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
7-5 TC	When the TC field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TC Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
4-0 TYPE	When the TYPE field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). Note: This register field is sticky.

11.4.3.1.161 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFF_INBOUND_2)

11.4.3.1.161.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFF_INBOUND_2	30_0504h

11.4.3.1.161.2 Diagram

11.4.3.1.161.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 MATCH_MODE	Match Mode. Determines Inbound matching mode for TLPs. The mode depends on the type of TLP that is received as follows: For MEM-I/O TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU operates using addresses as in the outbound direction. The Region Base and Limit Registers must be setup. - 1:BAR Match Mode. BAR matching is used. The "BAR Number" field is relevant. Not used for RC. For CFG0 TLPs, this field is interpreted as follows: - 0: Routing ID Match Mode. The iATU interprets the Routing ID (Bytes 8 to 11 of TLP header) as an address. This corresponds to the upper 16 bits of the address in MEM-I/O transactions. The Routing ID of the TLP must be within the base and limit of the iATU region for matching to proceed. - 1: Accept Mode. The iATU accepts all CFG0 transactions as address matches. The routing ID in the CFG0 TLP is ignored. This is useful as all received CFG0 TLPs should be processed regardless of the Bus number. For MSG/MSGD TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU treats the third dword and fourth dword of the inbound MSG/MSGD TLP as an address and it is matched against the Region Base and Limit Registers. - 1: Vendor ID Match Mode. This mode is relevant for ID-routed Vendor Defined Messages. The iATU ignores the Routing ID (Bus, Device, Function) in bits [31:16] of the third dword of the TLP header, but matches

Table continues on the next page...

Field	Function
	against the Vendor ID in bits [15:0] of the third dword of the TLP header. Bits [15:0] of the Region Upper Base register should be programmed with the required Vendor ID. The lower Base and Limit Register should be programmed to translate TLPs based on vendor specific information in the fourth dword of the TLP header. - If SINGLE_ADDRESS_LOCATION_TRANSLATE_EN = 1 AND MSG_TYPE_MATCH_MODE = 1, then Match Mode is ignored. Note: This register field is sticky.
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_MODE	CFG Shift Mode. This is useful for CFG transactions where the PCIe configuration mechanism maps bits [27:12] of the address to the bus/device and function number. This allows a CFG configuration space to be located in any 256MB window of your application memory space using a 28-bit effective address. Shifts bits [31:16] of the untranslated address to form bits [27:12] of the translated address. Note: This register field is sticky.
27 FUZZY_TYPE_MATCH_CODE	Fuzzy Type Match Mode. When enabled, the iATU relaxes the matching of the TLP TYPE field against the expected TYPE field so that - CfgRd0 and CfgRd1 TLPs are seen as identical. Similarly with CfgWr0 and CfgWr1. - MWr, MRd and MRdLk TLPs are seen as identical - The Routing field of Msg/MsgD TLPs is ignored - FetchAdd, Swap and CAS are seen as identical. For example, CFG0 in the TYPE field in the "iATU Control 1 Register" matches against an inbound CfgRd0, CfgRd1, CfgWr0 or CfgWr1 TLP. Note: This register field is sticky.
26 —	Reserved
25-24 RESPONSE_CODE	Response Code. Defines the type of response to give for accesses matching this region. This overrides the normal RADM filter response. Note that this feature is not available for any region where Single Address Location Translate is enabled. - 00 - Normal RADM filter response is used. - 01 - Unsupported request (UR) - 10 - Completer abort (CA) - 11 - Not used / undefined / reserved. Note: This register field is sticky.
23 SINGLE_ADDR_LOC_TRANS_EN	Single Address Location Translate Enable. When enabled, Rx TLPs can be translated to a single address location as determined by the target address register of the iATU region. The main usage scenario is translation of Messages (such as Vendor Defined or ATS Messages) to MWr TLPs when the AXI bridge is enabled. Note: This register field is sticky.
22 —	Reserved
21 MSG_CODE_MATCH_EN	Message Code Match Enable (Msg TLPS). Ensures that a successful message Code TLP field comparison match (see Message Code field of the "iATU Control 2 Register") occurs (in MSG transactions) for address translation to proceed. ST Match Enable (Mem TLPs). Ensures that a successful ST TLP field comparison match (see ST field of the "iATU Control 2 Register") occurs (in MEM transactions) for address translation to proceed. Only Valid when the CX_TPH_ENABLE configuration parameter is 1 Note: This register field is sticky.
20 —	Reserved
19 FUNC_NUM_MATCH_EN	Function Number Match Enable. Ensures that a successful Function Number TLP field comparison match (see Function Number field of the "iATU Control 1 Register") occurs (in MEM-I/O and CFG0/CFG1 transactions) for address translation to proceed. Note: This register field is sticky.
18-17 —	Reserved
16 ATTR_MATCH_EN	ATTR Match Enable. Ensures that a successful ATTR TLP field comparison match (see ATTR field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.

Table continues on the next page...

Field	Function
15 TD_MATCH_EN	TD Match Enable. Ensures that a successful TD TLP field comparison match (see TD field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
14 TC_MATCH_EN	TC Match Enable. Ensures that a successful TC TLP field comparison match (see TC field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
13 MSG_TYPE_MATCH_MODE	Message Type Match Mode. When enabled, and if single address location translate enable is set, then inbound TLPs of type MSG/MSGd which match the type field of the iatu_region_ctrl_1_OFF_inbound register (=>TYPE[4:3]=2'b10) will be translated. Message type match mode overrides any value of MATCH_MODE field in this register. Usage scenarios for this are translation of VDM or ATS messages when AXI bridge is configured on client interface. Note: This register field is sticky.
12-11 —	Reserved
10-8 BAR_NUM	BAR Number. When the BAR number of an inbound MEM or IO TLP " that is matched by the normal internal BAR address matching mechanism " is the same as this field, address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Match Mode" bit of the "iATU Control 2 Register" is set. - 000b - BAR0 - 001b - BAR1 - 010b - BAR2 - 011b - BAR3 - 100b - BAR4 - 101b - BAR5 - 110b - ROM - 111b - reserved - IO translation would require either 00100b or 00101b in the inbound TLP TYPE; the BAR Number set in the range 000b - 101b and that BAR configured as an IO BAR. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs: (Message Code). When the TYPE field of an inbound Msg/MsgD TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Message Code Match Enable" bit of the "iATU Control 2 Register" is set. Memory TLPs: (ST;Steering Tag). When the ST field of an inbound TLP is matched to this value, then address translation proceeds. This check is only performed if the "ST Match Enable" bit of the "iATU Control2 Register" is set. The setting is independent of the setting of the TH field. Only Valid when the CX_TPH_ENABLE configuration parameter is 1. Note: This register field is sticky.

11.4.3.1.162 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_INBOUND_2)

11.4.3.1.162.1 Offset

Register	Offset
IATU_LWR_BASE_ADDR_OFF_INBOUND_2	30_0508h

11.4.3.1.162.2 Function

iATU Lower Base Address Register. The Minimum Size of iATU Region configuration parameter (Value Range: 4 kB, 8 kB, 16 kB, 32 kB, 64 kB defaults to 64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower 16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower log2(Minimum Size of iATU Region) bits are zero.

11.4.3.1.162.3 Diagram

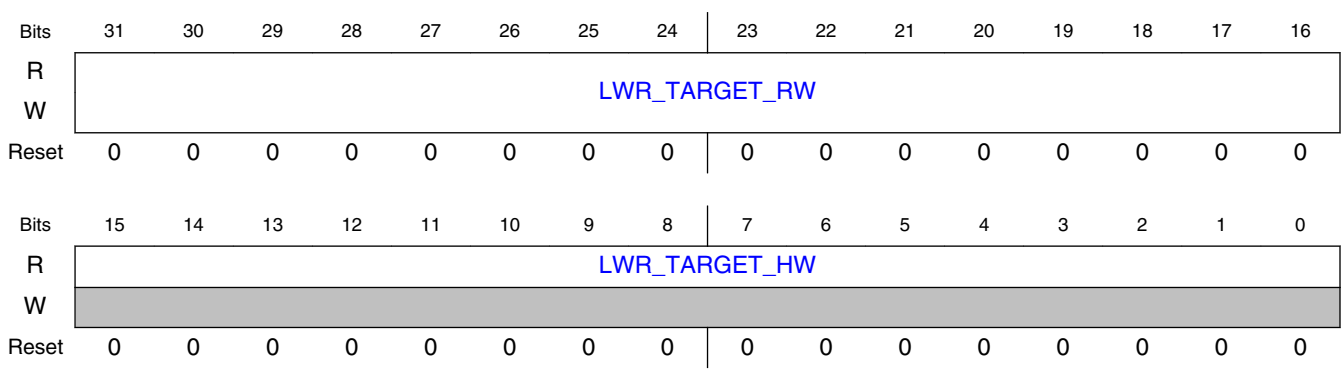
11.4.3.1.164.3 Fields



Field	Function
31-16 LIMIT_ADDR_RW	Forms upper bits of the end address of the address region to be translated. The end address must be aligned to a Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. Note: This register field is sticky.
15-0 LIMIT_ADDR_HW	Forms lower bits of the end address of the address region to be translated. The end address must be aligned to a Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller.

11.4.3.1.165 iATU Lower Target Address Register. (IATU_LWR_TARGET_ADDR_OFF_INBOUND_2)

11.4.3.1.165.1 Offset

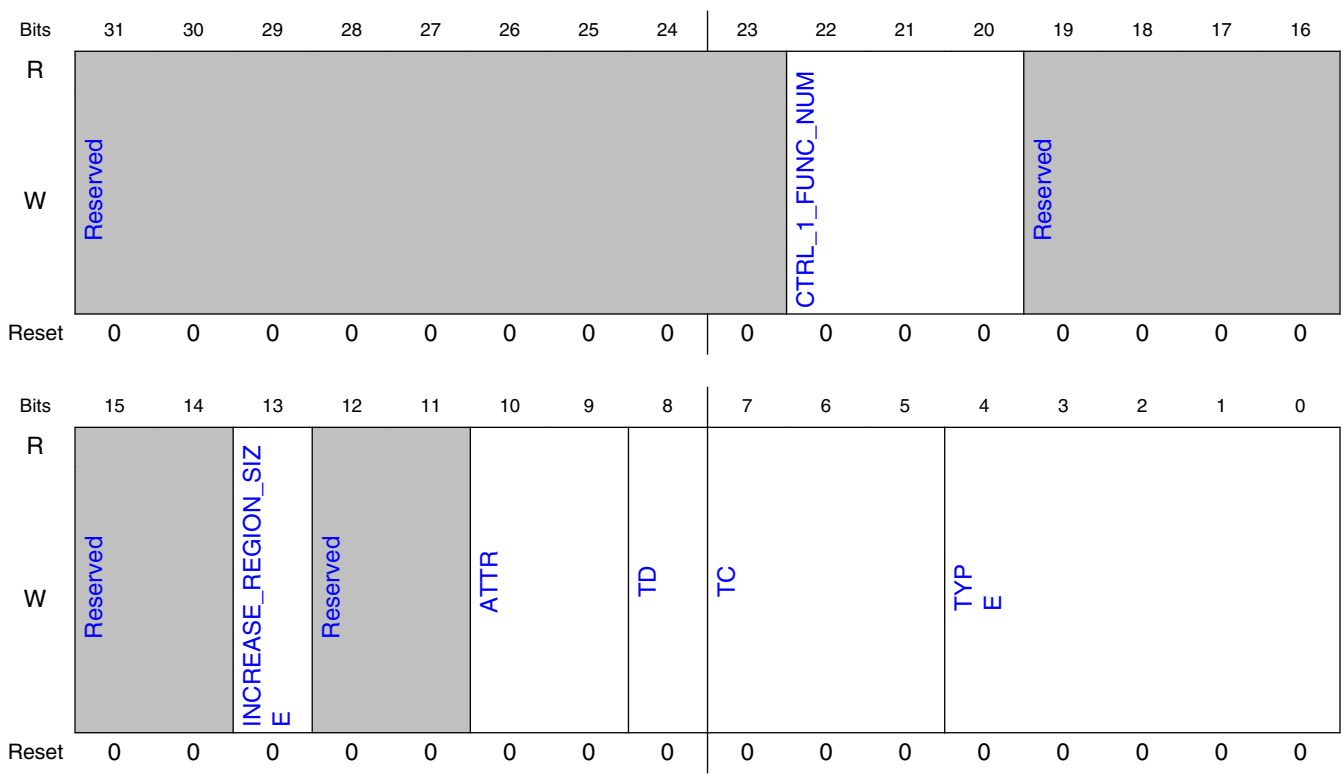
Register	Offset
IATU_LWR_TARGET_ADDR_OFF_INBOUND_2	30_0514h

11.4.3.1.165.2 Diagram

11.4.3.1.165.3 Fields

Field	Function
31-16 LWR_TARGET_RW	Forms MSB's of the Lower Target part of the new address of the translated region. These bits are always '0'. - Field size depends on log2(Minimum Size of iATU Region) in address match mode. - Field size depends on log2(BAR_MASK+1) in BAR match mode. Note: This register field is sticky.

Table continues on the next page...



Field	Function
15-0 LWR_TARGET_HW	Forms the LSB's of the Lower Target part of the new address of the translated region. The start address must be aligned to a Minimum Size of iATU Region kB boundary (in address match mode); and to the Bar size boundary (in BAR match mode) so that these bits are always '0'. If the BAR is smaller than the iATU region size, then the iATU target address must align to the iATU region size; otherwise it must align to the BAR size. A write to this location is ignored by the PCIe controller. - Field size depends on log2(Minimum Size of iATU Region) in address match mode. - Field size depends on log2(BAR_MASK+1) in BAR match mode.

11.4.3.1.166 iATU Region Control 1 Register. (IATU_REGION_CTRL_1_OFF_OUTBOUND_3)

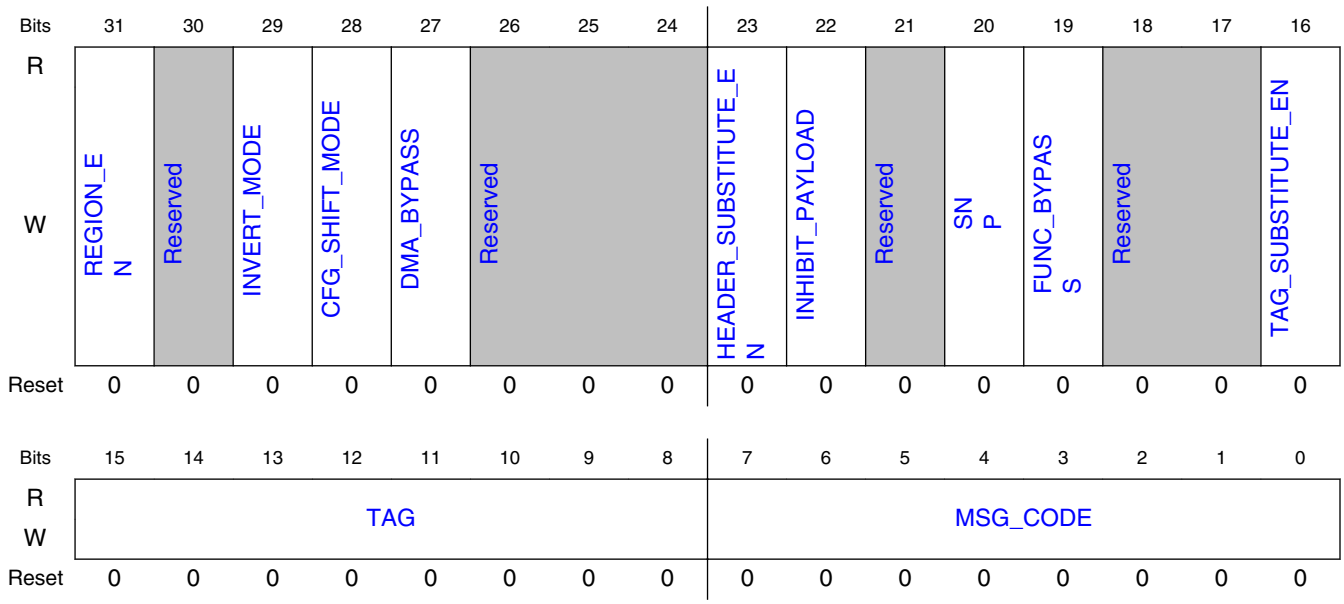
Register	Offset
IATU_REGION_CTRL_1_OFF_OUTBOUND_3	30_0600h

11.4.3.1.166.2 Diagram

11.4.3.1.166.3 Fields



Field	Function
31-23 —	Reserved
22-20 CTRL_1_FUNC_NUM	Function Number. - When the address of an outbound TLP is matched to this region and the FUNC_BYPASS field in the "iATU Control 2 Register" is '0', then the function number used in generating the function part of the requester ID (RID) field of the TLP is taken from this 5-bit register. The value in this register must be 0x0 unless multifunction operation in the controller is enabled (CX_NFUNC > 1). - When you are using the AXI Bridge, then this field is swapped before AXI decomposition occurs so that the correct "Max_Read_Request_Size" and "Max_Payload_Size" values are used. Note: This register field is sticky.
19-14 —	Reserved
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the maximum ATU Region size is determined by Maximum Size of iATU Region When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved
10-9 ATTR	When the address of an outbound TLP is matched to this region, then the ATTR field of the TLP is changed to the value in this register. Note: This register field is sticky.
8 TD	When the address of an outbound TLP is matched to this region, then the TD field of the TLP is changed to the value in this register. Note: This register field is sticky.
7-5 TC	When the address of an outbound TLP is matched to this region, then the TC field of the TLP is changed to the value in this register. Note: This register field is sticky.
4-0 TYPE	When the address of an outbound TLP is matched to this region, then the TYPE field of the TLP is changed to the value in this register. Note: This register field is sticky.

11.4.3.1.167 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFF_OUTBOUND_3)

11.4.3.1.167.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFF_OUTBOUND_3	30_0604h

11.4.3.1.167.2 Diagram

11.4.3.1.167.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 —	Reserved
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_MODE	CFG Shift Mode. The iATU uses bits [27:12] of the untranslated address (on the XALI0/1/2 interface or AXI slave interface address) to form the BDF number of the outgoing CFG TLP. This supports the Enhanced Configuration Address Mapping (ECAM) mechanism (Section 7.2.2 of the PCI Express Base 3.1 Specification, revision 1.0) by allowing all outgoing I/O and MEM TLPs (that have been translated to CFG) to be mapped from memory space into any 256 MB region of the PCIe configuration space. Note: This register field is sticky.
27 DMA_BYPASS	DMA Bypass Mode. Allows request TLPs which are initiated by the DMA controller to pass through the iATU untranslated. Note: This field is reserved for the SW product. You must set it to '0'. Note: This register field is sticky.
26-24 —	Reserved
23 HEADER_SUBSTITUTE_EN	Header Substitute Enable. When enabled and region address is matched, the iATU fully substitutes bytes 8-11 (for 3 DWORD header) or bytes 12-15 (for 4 DWORD header) of the outbound TLP header with the contents of the LWR_TARGET_RW field in IATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i. - 1: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register is used to fill bytes 8-to-11 (for 3 DWORD header) or bytes 12-to-15 (for 4 DWORD header) of the translated TLP header. - 0: LWR_TARGET_RW in the iATU_LWR_TARGET_ADDR_OFF_OUTBOUND_i register forms the new address of the translated region. Note: This register field is sticky.

Table continues on the next page...

Field	Function
22 INHIBIT_PAYLOAD	Inhibit TLP Payload Data for TLP's in Matched Region; assign iATU region to be TLP without data. When enabled and region address is matched, the iATU marks all TLPs as having no payload data by forcing the TLP header Fmt[1] bit =0, regardless of the application inputs such as slv_wstrb. - 1: Fmt[1] =0 so that only TLP type without data is sent. For example, a Msg instead of MsgD will be sent. - 0: Fmt[1] =0/1 so that TLPs with or without data can be sent. Note: This register field is sticky.
21 —	Reserved
20 SNP	Serialize Non-Posted Requests. In this mode, when the AXI Bridge is populated, same AXI ID Non-Posted Read/Write Requests are transmitted on the wire if there are no other same ID Non-Posted Requests outstanding. Note: This register field is sticky.
19 FUNC_BYPASS	Function Number Translation Bypass. In this mode, the function number of the translated TLP is taken from your application transmit interface and not from the CTRL_1_FUNC_NUM field of the "iATU Control 1 Register" or the VF_NUMBER field of the "iATU Control 3 Register." Note: This register field is sticky.
18-17 —	Reserved
16 TAG_SUBSTITUTE_EN	TAG Substitute Enable. When enabled and region address is matched, the iATU substitutes the TAG field of the outbound TLP header with the contents of the TAG field in this register. The expected usage scenario is translation from AXI MWr to Vendor Defined Msg/MsgD. Note (CX_TPH_ENABLE=1): TAG substitution for MWr will not occur because this field (byte 6) in the TLP header is the ST field. ST substitution can still take place using the MSG_CODE field in IATU_REGION_CTRL_2_OFF_OUTBOUND_i. Note: This register field is sticky.
15-8 TAG	TAG. The substituted TAG field (byte 6) in the outgoing TLP header when TAG_SUBSTITUTE_EN is set. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs (Message Code). When the address of an outbound TLP is matched to this region, and the translated TLP TYPE field is Msg or MsgD; then the message field of the TLP is changed to the value in this register. Memory TLPs: (ST;Steering Tag). When the ST field of an outbound TLP is matched to this region, and the translated TLP TYPE field targets memory space; then the ST field of the TLP is changed to the value in this register. Only Valid when the CX_TPH_ENABLE configuration parameter is 1. Note: This register field is sticky.

11.4.3.1.168 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_OUTBOUND_3)

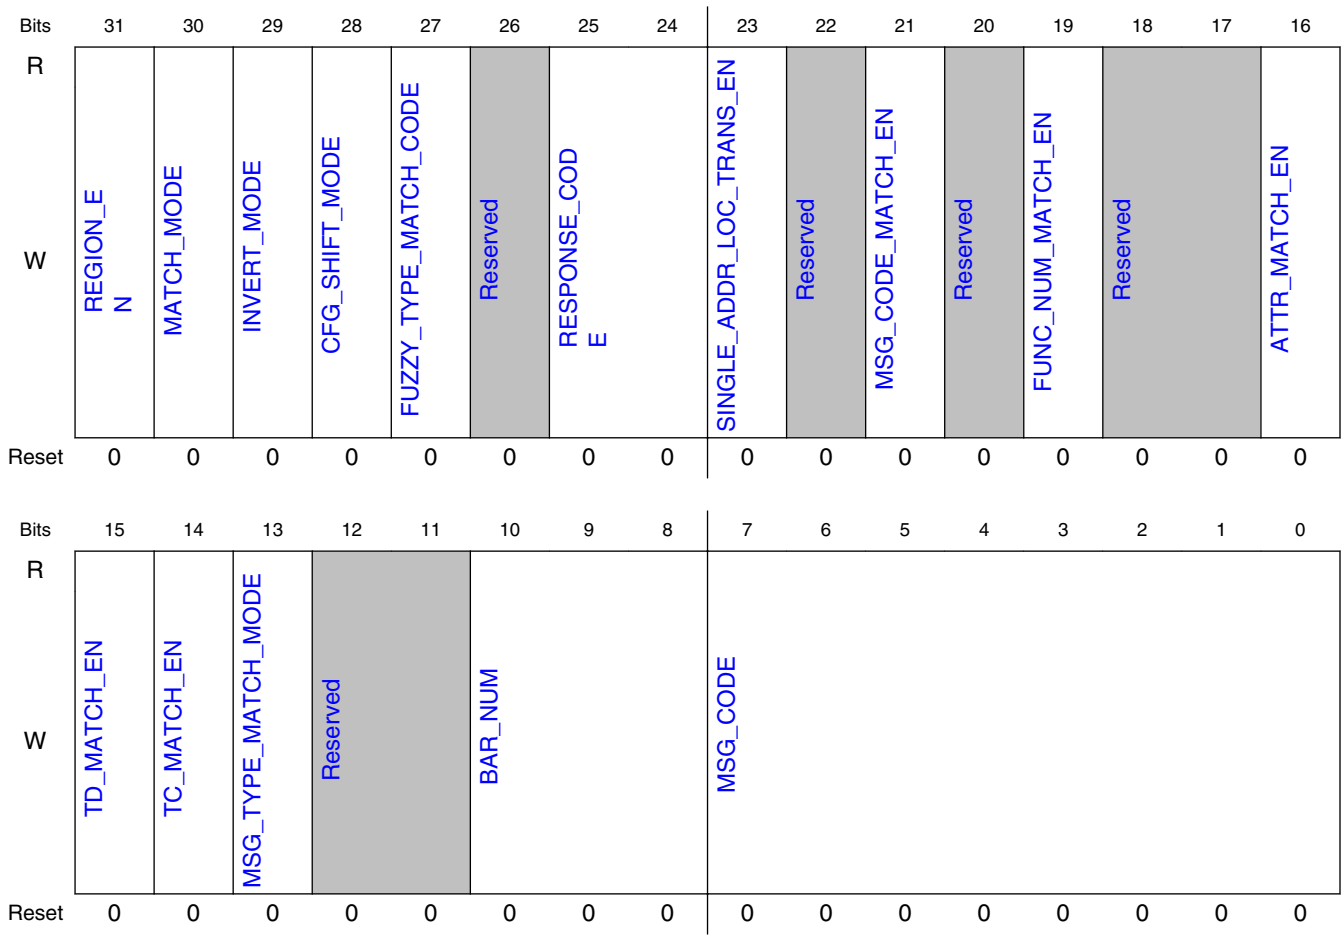
11.4.3.1.173.3 Fields

Field	Function
31-23 —	Reserved
22-20 CTRL_1_FUNC_NUM	Function Number. - MEM-I/O: When the Address and BAR matching logic in the controller indicate that a MEM-I/O transaction matches a BAR in the function corresponding to this value, then address translation proceeds. This check is only performed if the "Function Number Match Enable" bit of the "iATU Control 2 Register" is set. - CFG0/CFG1: When the destination function number as specified in the routing ID of the TLP header matches the function, then address translation proceeds. This check is only performed if the

Table continues on the next page...



Field	Function
	"Function Number Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
19-14 —	Reserved
13 INCREASE_REGION_SIZE	Increase the maximum ATU Region size. When set, the maximum ATU Region size is determined by Maximum Size of iATU Region When clear, the maximum ATU Region size is 4 GB (default). Note: This register field is sticky.
12-11 —	Reserved
10-9 ATTR	When the ATTR field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "ATTR Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
8 TD	When the TD field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TD Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
7-5 TC	When the TC field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "TC Match Enable" bit of the "iATU Control 2 Register" is set. Note: This register field is sticky.
4-0 TYPE	When the TYPE field of an inbound TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). Note: This register field is sticky.

11.4.3.1.174 iATU Region Control 2 Register. (IATU_REGION_CTRL_2_OFF_INBOUND_3)

11.4.3.1.174.1 Offset

Register	Offset
IATU_REGION_CTRL_2_OFF_INBOUND_3	30_0704h

11.4.3.1.174.2 Diagram

11.4.3.1.174.3 Fields

Field	Function
31 REGION_EN	Region Enable. This bit must be set to '1' for address translation to take place. Note: This register field is sticky.
30 MATCH_MODE	Match Mode. Determines Inbound matching mode for TLPs. The mode depends on the type of TLP that is received as follows: For MEM-I/O TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU operates using addresses as in the outbound direction. The Region Base and Limit Registers must be setup. - 1:BAR Match Mode. BAR matching is used. The "BAR Number" field is relevant. Not used for RC. For CFG0 TLPs, this field is interpreted as follows: - 0: Routing ID Match Mode. The iATU interprets the Routing ID (Bytes 8 to 11 of TLP header) as an address. This corresponds to the upper 16 bits of the address in MEM-I/O transactions. The Routing ID of the TLP must be within the base and limit of the iATU region for matching to proceed. - 1: Accept Mode. The iATU accepts all CFG0 transactions as address matches. The routing ID in the CFG0 TLP is ignored. This is useful as all received CFG0 TLPs should be processed regardless of the Bus number. For MSG/MSGD TLPs, this field is interpreted as follows: - 0: Address Match Mode. The iATU treats the third dword and fourth dword of the inbound MSG/MSGD TLP as an address and it is matched against the Region Base and Limit Registers. - 1: Vendor ID Match Mode. This mode is relevant for ID-routed Vendor Defined Messages. The iATU ignores the Routing ID (Bus, Device, Function) in bits [31:16] of the third dword of the TLP header, but matches

Table continues on the next page...

Field	Function
	against the Vendor ID in bits [15:0] of the third dword of the TLP header. Bits [15:0] of the Region Upper Base register should be programmed with the required Vendor ID. The lower Base and Limit Register should be programmed to translate TLPs based on vendor specific information in the fourth dword of the TLP header. - If SINGLE_ADDRESS_LOCATION_TRANSLATE_EN = 1 AND MSG_TYPE_MATCH_MODE = 1, then Match Mode is ignored. Note: This register field is sticky.
29 INVERT_MODE	Invert Mode. When set the address matching region is inverted. Therefore, an address match occurs when the untranslated address is in the region outside the defined range (Base Address to Limit Address). Note: This register field is sticky.
28 CFG_SHIFT_MODE	CFG Shift Mode. This is useful for CFG transactions where the PCIe configuration mechanism maps bits [27:12] of the address to the bus/device and function number. This allows a CFG configuration space to be located in any 256MB window of your application memory space using a 28-bit effective address. Shifts bits [31:16] of the untranslated address to form bits [27:12] of the translated address. Note: This register field is sticky.
27 FUZZY_TYPE_MATCH_CODE	Fuzzy Type Match Mode. When enabled, the iATU relaxes the matching of the TLP TYPE field against the expected TYPE field so that - CfgRd0 and CfgRd1 TLPs are seen as identical. Similarly with CfgWr0 and CfgWr1. - MWr, MRd and MRdLk TLPs are seen as identical - The Routing field of Msg/MsgD TLPs is ignored - FetchAdd, Swap and CAS are seen as identical. For example, CFG0 in the TYPE field in the "iATU Control 1 Register" matches against an inbound CfgRd0, CfgRd1, CfgWr0 or CfgWr1 TLP. Note: This register field is sticky.
26 —	Reserved
25-24 RESPONSE_CODE	Response Code. Defines the type of response to give for accesses matching this region. This overrides the normal RADM filter response. Note that this feature is not available for any region where Single Address Location Translate is enabled. - 00 - Normal RADM filter response is used. - 01 - Unsupported request (UR) - 10 - Completer abort (CA) - 11 - Not used / undefined / reserved. Note: This register field is sticky.
23 SINGLE_ADDR_LOC_TRANS_EN	Single Address Location Translate Enable. When enabled, Rx TLPs can be translated to a single address location as determined by the target address register of the iATU region. The main usage scenario is translation of Messages (such as Vendor Defined or ATS Messages) to MWr TLPs when the AXI bridge is enabled. Note: This register field is sticky.
22 —	Reserved
21 MSG_CODE_MATCH_EN	Message Code Match Enable (Msg TLPS). Ensures that a successful message Code TLP field comparison match (see Message Code field of the "iATU Control 2 Register") occurs (in MSG transactions) for address translation to proceed. ST Match Enable (Mem TLPs). Ensures that a successful ST TLP field comparison match (see ST field of the "iATU Control 2 Register") occurs (in MEM transactions) for address translation to proceed. Only Valid when the CX_TPH_ENABLE configuration parameter is 1 Note: This register field is sticky.
20 —	Reserved
19 FUNC_NUM_MATCH_EN	Function Number Match Enable. Ensures that a successful Function Number TLP field comparison match (see Function Number field of the "iATU Control 1 Register") occurs (in MEM-I/O and CFG0/CFG1 transactions) for address translation to proceed. Note: This register field is sticky.
18-17 —	Reserved
16 ATTR_MATCH_EN	ATTR Match Enable. Ensures that a successful ATTR TLP field comparison match (see ATTR field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.

Table continues on the next page...

Field	Function
15 TD_MATCH_EN	TD Match Enable. Ensures that a successful TD TLP field comparison match (see TD field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
14 TC_MATCH_EN	TC Match Enable. Ensures that a successful TC TLP field comparison match (see TC field of the "iATU Control 1 Register") occurs for address translation to proceed. Note: This register field is sticky.
13 MSG_TYPE_MATCH_MODE	Message Type Match Mode. When enabled, and if single address location translate enable is set, then inbound TLPs of type MSG/MSGd which match the type field of the iatu_region_ctrl_1_OFF_inbound register (=>TYPE[4:3]=2'b10) will be translated. Message type match mode overrides any value of MATCH_MODE field in this register. Usage scenarios for this are translation of VDM or ATS messages when AXI bridge is configured on client interface. Note: This register field is sticky.
12-11 —	Reserved
10-8 BAR_NUM	BAR Number. When the BAR number of an inbound MEM or IO TLP " that is matched by the normal internal BAR address matching mechanism " is the same as this field, address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Match Mode" bit of the "iATU Control 2 Register" is set. - 000b - BAR0 - 001b - BAR1 - 010b - BAR2 - 011b - BAR3 - 100b - BAR4 - 101b - BAR5 - 110b - ROM - 111b - reserved - IO translation would require either 00100b or 00101b in the inbound TLP TYPE; the BAR Number set in the range 000b - 101b and that BAR configured as an IO BAR. Note: This register field is sticky.
7-0 MSG_CODE	MSG TLPs: (Message Code). When the TYPE field of an inbound Msg/MsgD TLP is matched to this value, then address translation proceeds (when all other enabled field-matches are successful). This check is only performed if the "Message Code Match Enable" bit of the "iATU Control 2 Register" is set. Memory TLPs: (ST;Steering Tag). When the ST field of an inbound TLP is matched to this value, then address translation proceeds. This check is only performed if the "ST Match Enable" bit of the "iATU Control2 Register" is set. The setting is independent of the setting of the TH field. Only Valid when the CX_TPH_ENABLE configuration parameter is 1. Note: This register field is sticky.

11.4.3.1.175 iATU Lower Base Address Register. (IATU_LWR_BASE_ADDR_OFF_INBOUND_3)

11.4.3.1.175.1 Offset

Register	Offset
IATU_LWR_BASE_ADDR_OFF_INBOUND_3	30_0708h

11.4.3.1.175.2 Function

iATU Lower Base Address Register. The Minimum Size of iATU Region configuration parameter (Value Range: 4 kB, 8 kB, 16 kB, 32 kB, 64 kB defaults to 64 kB) specifies the minimum size of an address translation region. For example, if set to 64 kB; the lower 16 bits of the Base, Limit and Target registers are zero and all address regions are aligned on 64 kB boundaries. More precisely, the lower log2(Minimum Size of iATU Region) bits are zero.

11.4.3.1.175.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
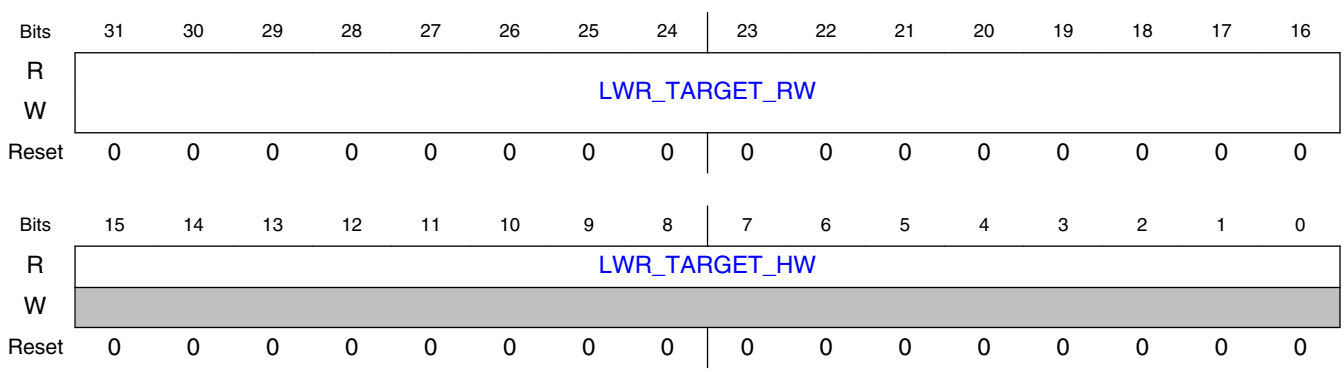
R	LIMIT_ADDR_HW															
W																
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

11.4.3.1.177.3 Fields



Field	Function
31-16 LIMIT_ADDR_RW	Forms upper bits of the end address of the address region to be translated. The end address must be aligned to a Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller. Note: This register field is sticky.
15-0 LIMIT_ADDR_HW	Forms lower bits of the end address of the address region to be translated. The end address must be aligned to a Minimum Size of iATU Region kB boundary, so these bits are always 0. A write to this location is ignored by the PCIe controller.

11.4.3.1.178 iATU Lower Target Address Register. (IATU_LWR_TARGET_ADDR_OFF_INBOUND_3)

11.4.3.1.178.1 Offset

Register	Offset
IATU_LWR_TARGET_ADDR_OFF_INBOUND_3	30_0714h

11.4.3.1.178.2 Diagram

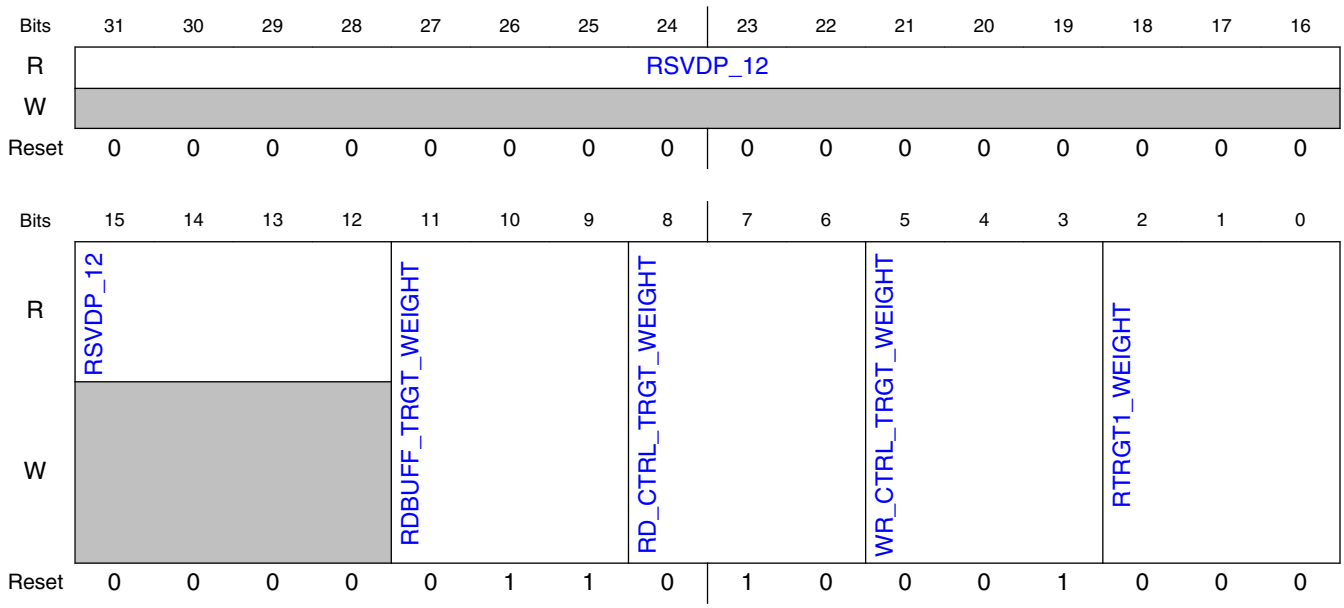
11.4.3.1.178.3 Fields

Field	Function
31-16 LWR_TARGET_RW	Forms MSB's of the Lower Target part of the new address of the translated region. These bits are always '0'. - Field size depends on log2(Minimum Size of iATU Region) in address match mode. - Field size depends on log2(BAR_MASK+1) in BAR match mode. Note: This register field is sticky.

Table continues on the next page...

Field	Function
15-0 LWR_TARGET_HW	Forms the LSB's of the Lower Target part of the new address of the translated region. The start address must be aligned to a Minimum Size of iATU Region kB boundary (in address match mode); and to the Bar size boundary (in BAR match mode) so that these bits are always '0'. If the BAR is smaller than the iATU region size, then the iATU target address must align to the iATU region size; otherwise it must align to the BAR size. A write to this location is ignored by the PCIe controller. - Field size depends on log2(Minimum Size of iATU Region) in address match mode. - Field size depends on log2(BAR_MASK+1) in BAR match mode.

11.4.3.1.179 DMA Arbitration Scheme for TRGT1 Interface. (DMA_CTRL_DATA_ARB_PRIOR_OFF)



11.4.3.1.179.1 Offset

Register	Offset
DMA_CTRL_DATA_ARB_PRIOR_OFF	38_0000h

11.4.3.1.179.2 Function

DMA Arbitration Scheme for TRGT1 Interface. This register is used to control traffic priorities among various sources that are delivered to your application through TRGT1 where 0x0 represents the highest priority. - Non-DMA Rx Requests - DMA Write Channel MRd Requests (DMA data requests and LL element/descriptor access) - DMA Read Channel MRd Requests (LL element/descriptor access) - DMA Read Channel MWr Requests Concurrent traffic from channels with same priority are sorted according to Round-Robin arbitration rules. The arbitration priority defaults to Non-DMA requests (highest), Write Channel MRd, Read Channel MRd, Read Channel MWr. For more details, see the For more details, see the Internal Architecture section in the DMA chapter of the Databook.

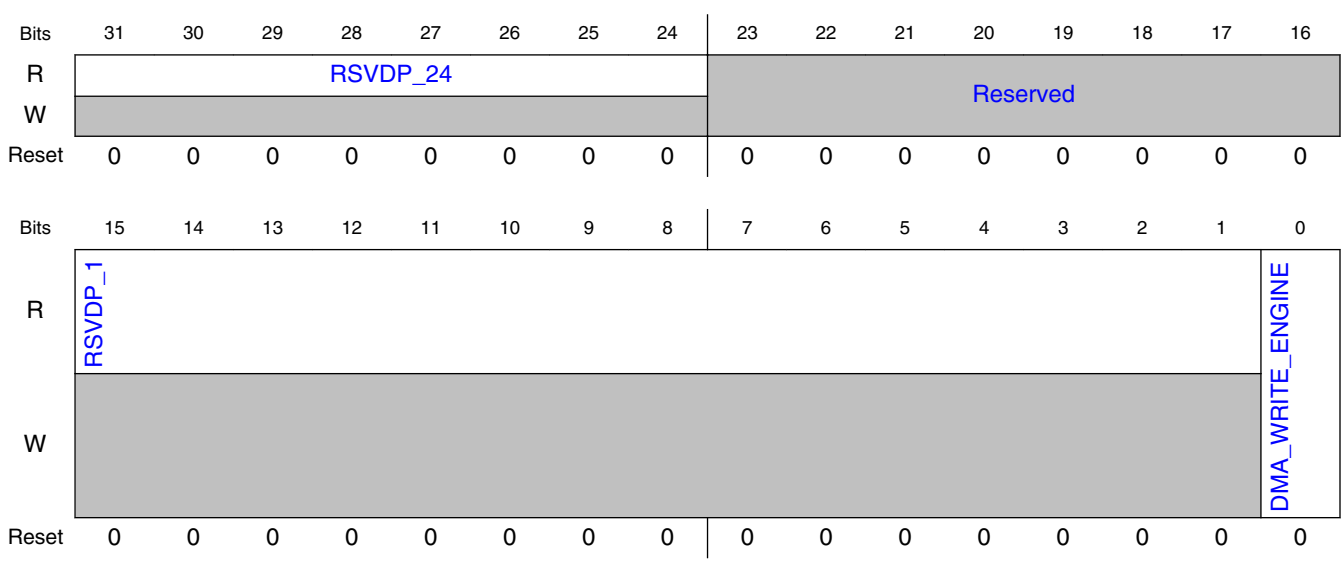
25 DIS_C2W_CACHE_RD	Disable DMA Read Channels "completion to memory write" context cache pre-fetch function. Note: For internal debugging only. Note: The access attributes of this field are as follows: - Dbi: R/W
24 DIS_C2W_CACHE_WR	Disable DMA Write Channels "completion to memory write" context cache pre-fetch function. Note: For internal debugging only. Note: The access attributes of this field are as follows: - Dbi: R/W

Table continues on the next page...



Field	Function
23-20 RSVDP_20	Reserved for future use.
19-16 NUM_DMA_RD_CHAN	Number of Read Channels. You can read this register to determine the number of read channels the DMA controller has been configured to support.
15-4 RSVDP_4	Reserved for future use.
3-0 NUM_DMA_WR_CHAN	Number of Write Channels. You can read this register to determine the number of write channels the DMA controller has been configured to support.

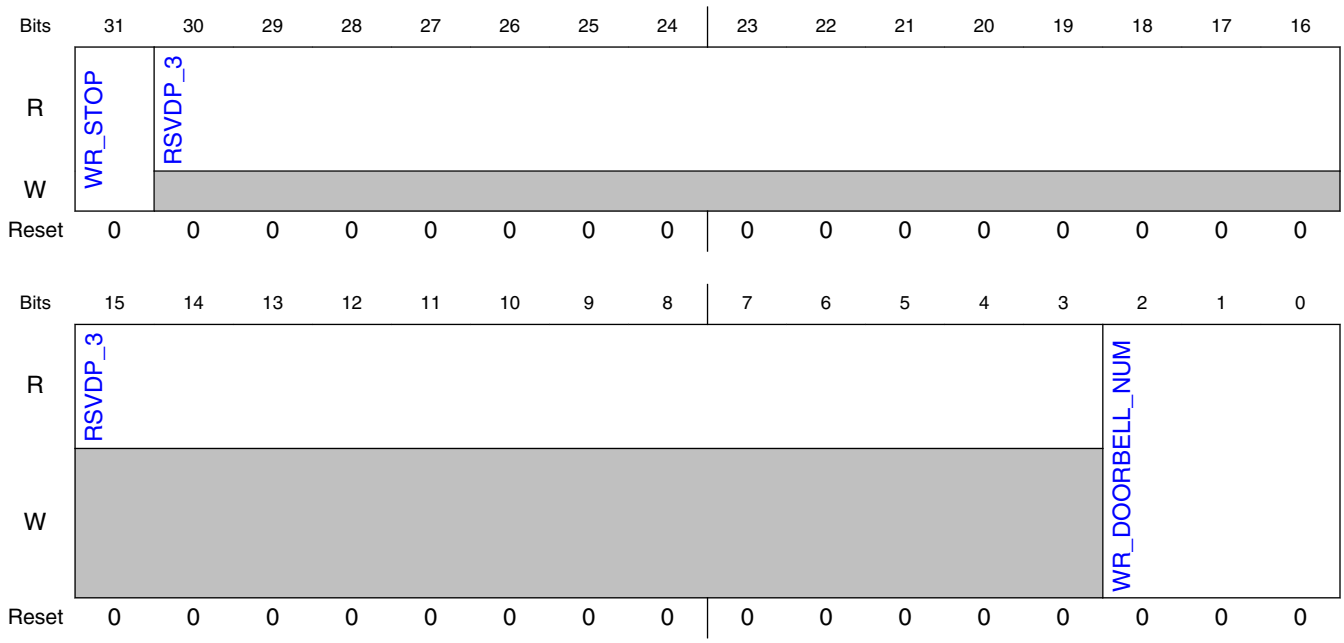
11.4.3.1.181 DMA Write Engine Enable Register. (DMA_WRITE_ENGINE_EN_OFF)

11.4.3.1.181.1 Offset

Register	Offset
DMA_WRITE_ENGINE_EN_OFF	38_000Ch

11.4.3.1.181.2 Diagram

11.4.3.1.181.3 Fields



Field	Function
31-24 RSVDP_24	Reserved for future use.
23-16 —	Reserved
15-1 RSVDP_1	Reserved for future use.
0 DMA_WRITE_ENGINE	DMA Write Engine Enable. - 1: Enable - 0: Disable (Soft Reset) For normal operation, you must initially set this bit to "1", before any other software setup actions. You do not need to toggle or rewrite to this bit during normal operation. You should set this bit to "0" when you want to "Soft Reset" the DMA controller write logic. There are three possible reasons for resetting the DMA controller write logic: - The "Abort Interrupt Status" bit is set (in the "DMA Write Interrupt Status Register" DMA_WRITE_INT_STATUS_OFF), and any of the bits is in the "DMA Write Error Status Register" (DMA_WRITE_ERR_STATUS_OFF) are set. Resetting the DMA controller write logic re-initializes the control logic, ensuring that the next DMA write transfer is executed successfully. - You have executed the procedure outlined in "Stop Bit" , after which, the "Abort Interrupt Status" bit is set and the Channel Status field (CS) of the DMA write "DMA Channel Control 1 Register " (DMA_CH_CONTROL1_OFF_WRCH_0) is set to "Stopped." Resetting the DMA controller write logic re-initializes the control logic ensuring that the next DMA write transfer is executed successfully. - During software development, when you incorrectly program the DMA write engine. To "Soft Reset" the DMA controller write logic, you must: - De-assert the DMA write engine enable bit. - Wait for the DMA to complete any in-progress TLP transfer, by waiting until a read on the DMA write engine enable bit returns a "0". - Assert the DMA write engine enable bit. This "Soft Reset" does not clear the DMA configuration registers. The DMA write transfer does not start until you write to the "DMA Write Doorbell Register" (DMA_WRITE_DOORBELL_OFF). Note: The access attributes of this field are as follows: - Dbi: R/W

11.4.3.1.182 DMA Write Doorbell Register. (DMA_WRITE_DOORBELL_OFF)

11.4.3.1.182.1 Offset

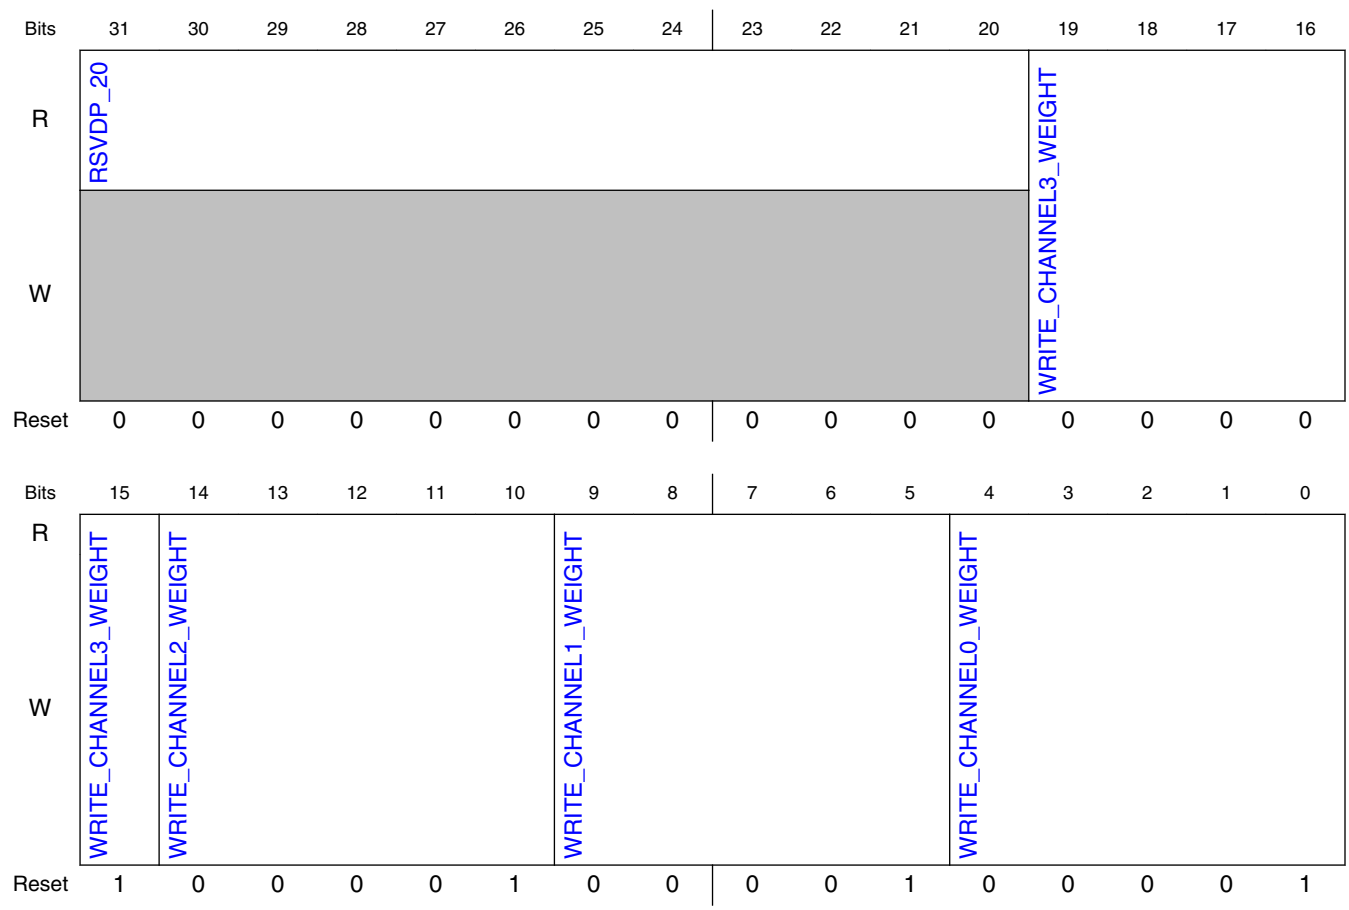
Register	Offset
DMA_WRITE_DOORBELL_OFF	38_0010h

11.4.3.1.182.2 Diagram

11.4.3.1.182.3 Fields

Field	Function
31 WR_STOP	Stop. Set in conjunction with the Doorbell Number field. The DMA write channel stops issuing requests, sets the channel status to "Stopped", and asserts the "Abort" interrupt if it is enabled. Before setting the Stop bit, you must read the channel Status field (CS) of the "DMA Channel Control 1 Register " (DMA_CH_CONTROL1_OFF_WRCH_0) to ensure that the write channel is "Running" (transferring data). For more information, see "Stopping the DMA Transfer (Software Stop)." Note: The access attributes of this field are as follows: - Dbi: R/W
30-3 RSVDP_3	Reserved for future use.
2-0 WR_DOORBELL_NUM	Doorbell Number. You must write the channel number to this register to start the DMA write transfer for that channel. The DMA detects a write to this register field even if the value of this field does not change. You do not need to toggle or write any other value to this register to start a new transfer. The range of this field is 0x0 to 0x7, and 0x0 corresponds to channel 0. Also note that a write to this field triggers the controller to exit L1 substates. Note: The access attributes of this field are as follows: - Dbi: R/W

11.4.3.1.183 DMA Write Engine Channel Arbitration Weight Low Register. (DMA_WRITE_CHANNEL_ARB_WEIGHT_LOW_OFF)



11.4.3.1.183.1 Offset

Register	Offset
DMA_WRITE_CHANNEL_ARB_WEIGHT_LOW_OFF	38_0018h

11.4.3.1.183.2 Function

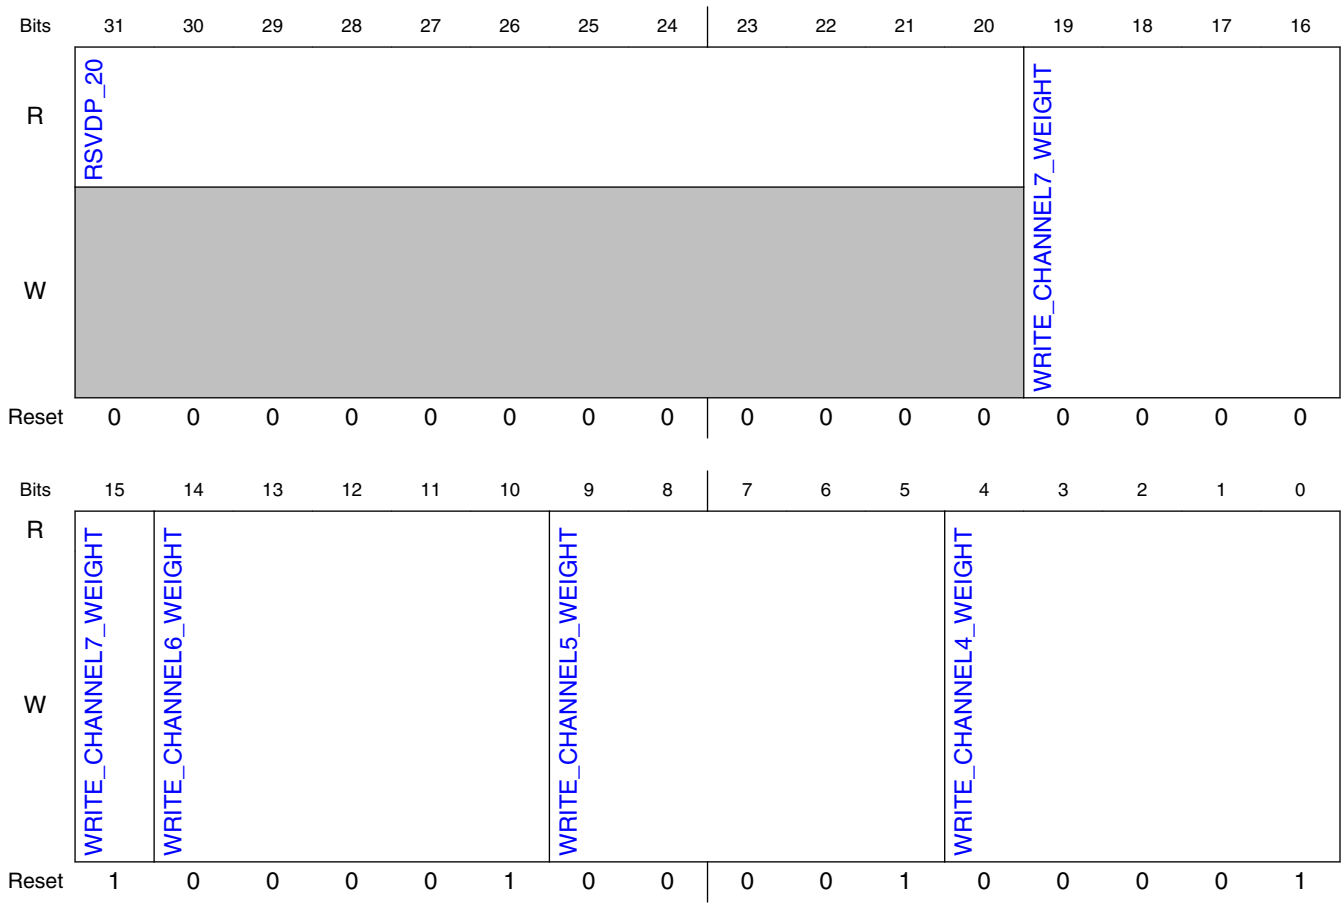
DMA Write Engine Channel Arbitration Weight Low Register. The 5-bit channel weight (for write channels 0-3) specifies the maximum number of TLP requests that the DMA can issue for that channel before it must return to the arbitration routine. When the channel weight count is reached or DMA channel request transfer size reaches zero, the WWR arbiter selects the next channel to be processed. Your software must initialize this register before ringing the doorbell. For more details, see "Multichannel Arbitration". Value range is (0-0x1F) corresponding to (1-32) transaction requests.

11.4.3.1.183.3 Diagram

11.4.3.1.183.4 Fields

Field	Function
31-20 RSVDP_20	Reserved for future use.
19-15 WRITE_CHANNEL3_WEIGHT	Channel 3 Weight. The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. A value of '0' means that one TLP is issued before moving to the next channel. Note: The access attributes of this field are as follows: - Dbi: R/W
14-10 WRITE_CHANNEL2_WEIGHT	Channel 2 Weight. The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. A value of '0' means that one TLP is issued before moving to the next channel. Note: The access attributes of this field are as follows: - Dbi: R/W
9-5 WRITE_CHANNEL1_WEIGHT	Channel 1 Weight. The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. A value of '0' means that one TLP is issued before moving to the next channel. Note: The access attributes of this field are as follows: - Dbi: R/W
4-0 WRITE_CHANNEL0_WEIGHT	Channel 0 Weight. The weight is initialized by software before ringing the doorbell. The value is used by the channel weighted round robin arbiter to select the next channel read request. A value of '0' means that one TLP is issued before moving to the next channel. Note: The access attributes of this field are as follows: - Dbi: R/W

11.4.3.1.184 DMA Write Engine Channel Arbitration Weight High Register. (DMA_WRITE_CHANNEL_ARB_WEIGHT_HIGH_OFF)



11.4.3.1.184.1 Offset

Register	Offset
DMA_WRITE_CHANNEL_ARB_WEIGHT_HIGH_OFF	38_001Ch

11.4.3.1.184.2 Function

DMA Write Engine Channel Arbitration Weight High Register. The 5-bit channel weight (for write channels 4-7) specifies the maximum number of TLP requests that the DMA can issue for that channel before it must return to the arbitration routine. When the channel weight count is reached or DMA channel request transfer size reaches zero, the WWR arbiter selects the next channel to be processed. Your software must initialize this register before ringing the doorbell. For more details, see "Multichannel Arbitration". Value range is (0-0x1F) corresponding to (1-32) transaction requests.

11.4.3.1.189.3 Fields

Field	Function
31-24 RSVDP_24	Reserved for future use.
23-16 WR_ABORT_INT_STATUS	Abort Interrupt Status. The DMA write channel has detected an error, or you manually stopped the transfer as described in "Error Handling Assistance by Remote Software". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA write interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the DMA write interrupt Clear register to clear this interrupt bit. Note: You can write to this register to emulate interrupt generation, during software or hardware testing. A write to the address triggers an interrupt, but the DMA does not set the Done or Abort bits in this register. Note: The access attributes of this field are as follows: - Dbi: R/W
15-8 RSVDP_8	Reserved for future use.
7-0 WR_DONE_INT_STATUS	Done Interrupt Status. The DMA write channel has successfully completed the DMA transfer. For more details, see "Interrupts and Error Handling". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA write interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the DMA write interrupt Clear register to clear this interrupt bit. Note: You can write to this register to emulate interrupt generation, during software or hardware testing. A write to

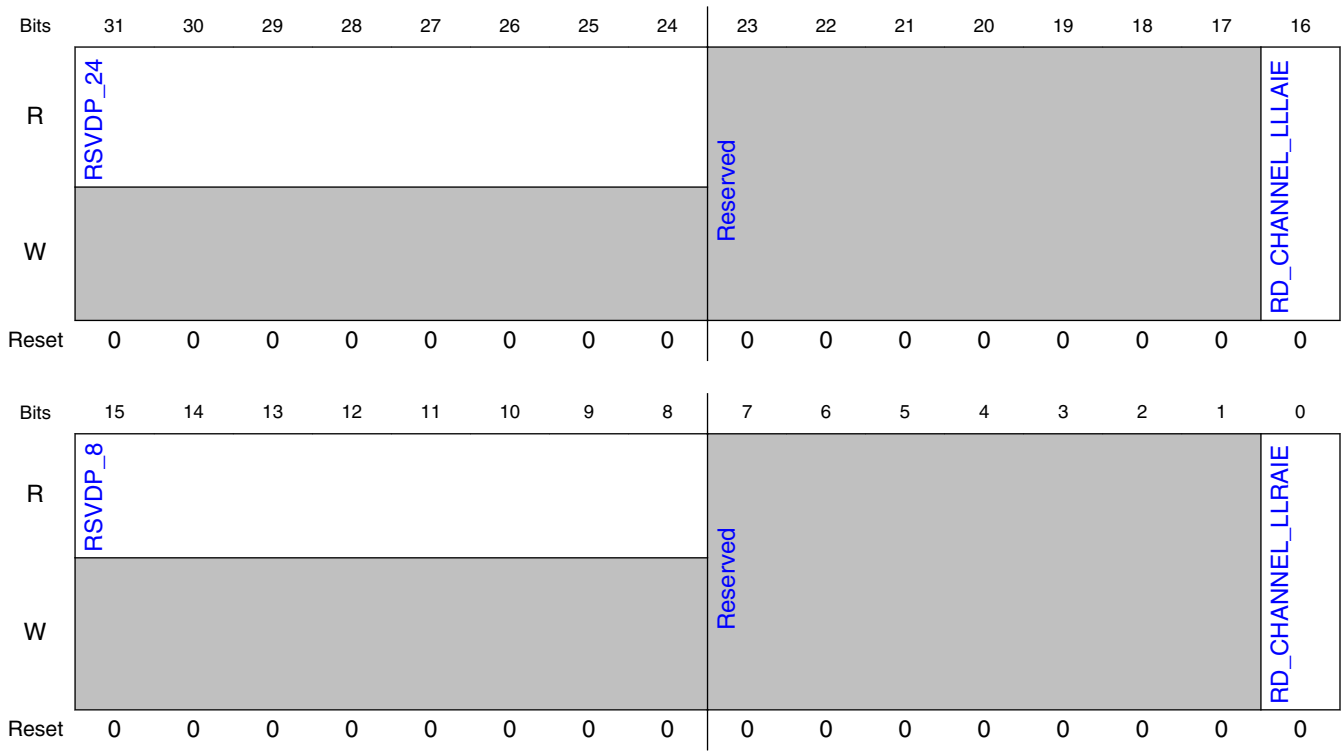
11.4.3.1.206.3 Fields

Field	Function
31-24 DATA_POISIONING	Data Poisoning. The DMA read channel has detected data poisoning in the completion from the remote device (in response to the MRd request). The DMA read channel will drop the completion and then be halted. The CX_FLT_MASK_UR_POIS filter rule does not affect this behavior. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA read interrupt Mask register has no effect on this register. - Clearing: You

Table continues on the next page...

Field	Function
	must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Read Interrupt Clear Register" (DMA_READ_INT_CLEAR_OFF) to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.
23-16 CPL_TIMEOUT	Completion Time Out. The DMA read channel has timed-out while waiting for the remote device to respond to the MRd request, or a malformed CplD has been received. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling" . - Masking: The DMA read interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Read Interrupt Clear Register" (DMA_READ_INT_CLEAR_OFF) to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.
15-8 CPL_ABORT	Completer Abort. The DMA read channel has received a PCIe completer abort completion status from the remote device in response to the MRd request. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA read interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Read Interrupt Clear Register" (DMA_READ_INT_CLEAR_OFF) to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.
7-0 UNSUPPORTED_REQ	Unsupported Request. The DMA read channel has received a PCIe unsupported request completion status from the remote device in response to the MRd request. For more details, see "Linked List Mode". Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. - Enabling: For details, see "Interrupts and Error Handling". - Masking: The DMA read interrupt Mask register has no effect on this register. - Clearing: You must write a 1'b1 to the corresponding channel bit in the Abort interrupt field of the "DMA Read Interrupt Clear Register" (DMA_READ_INT_CLEAR_OFF) to clear this error bit. Note, this also clears the other error bits for the same channel in this register and in the DMA Read Error Status Low register.

11.4.3.1.207 DMA Read Linked List Error Enable Register. (DMA_READ_LINKED_LIST_ERR_EN_OFF)



11.4.3.1.207.1 Offset

Register	Offset
DMA_READ_LINKED_LIST_ERR_EN_OFF	38_00C4h

11.4.3.1.207.2 Function

DMA Read Linked List Error Enable Register. The LIE and RIE bits in the LL element enable the channel "done" interrupts (local and remote). The LLLAIE and LLRAIE bits enable the channel "abort" interrupts (local and remote).

11.4.3.1.207.3 Diagram

11.4.3.1.207.4 Fields

Field	Function
31-24 RSVDP_24	Reserved for future use.
23-17 —	Reserved
16 RD_CHANNEL_LLLAIE	Read Channel LL Local Abort Interrupt Enable (LLLAIE). You enable the read channel Local Abort interrupt through this bit. The LIE and RIE bits in the LL element enable the read channel done interrupts. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Used in linked list mode only. For more details, see "Interrupt Handling". Note: The access attributes of this field are as follows: - Dbi: R/W
15-8 RSVDP_8	Reserved for future use.
7-1 —	Reserved
0 RD_CHANNEL_LLRAIE	Read Channel LL Remote Abort Interrupt Enable (LLRAIE). You enable the read channel Remote Abort interrupt through this bit. The LIE and RIE bits in the LL element enable the read channel done interrupts. Each bit corresponds to a DMA channel. Bit [0] corresponds to channel 0. Used in linked list mode only. For more details, see "Interrupt Handling". Note: The access attributes of this field are as follows: - Dbi: R/W

11.4.3.1.208 DMA Read Done IMWr Address Low Register. (DMA_READ_DONE_IMWR_LOW_OFF)

11.4.3.1.208.1 Offset

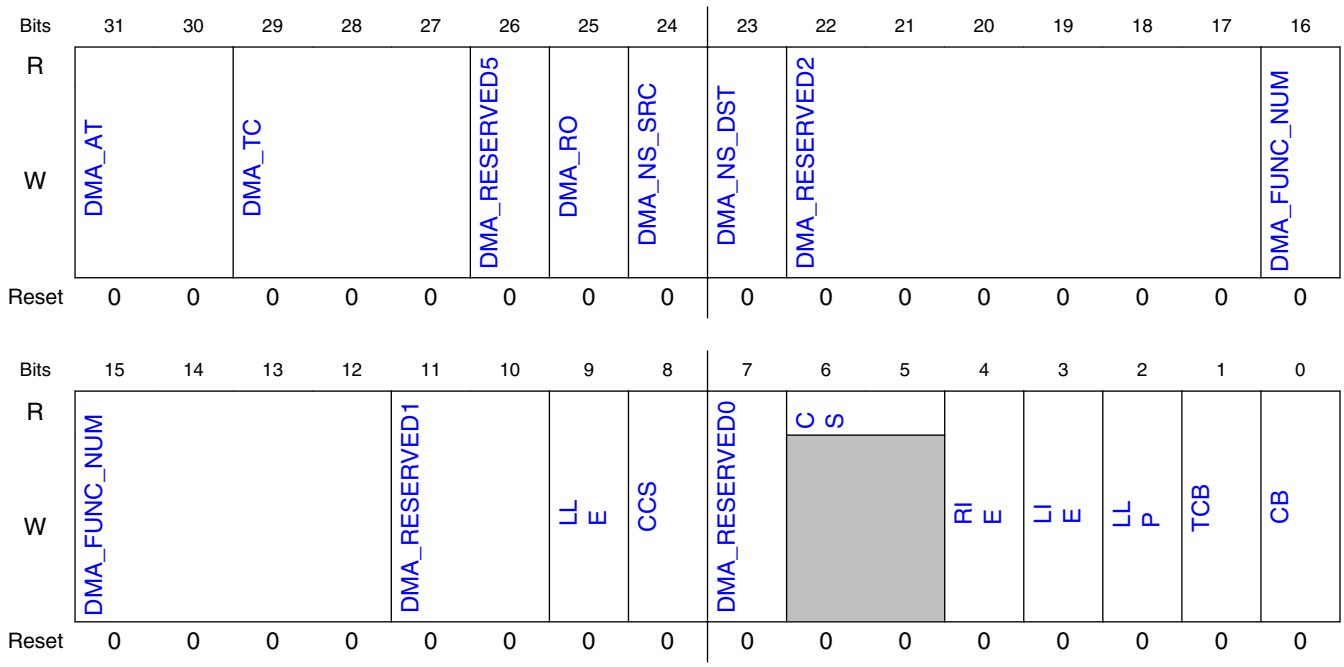
R W	RD_CHANNEL_6_DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

11.4.3.1.215.3 Fields



Field	Function
31-16 RD_CHANNEL_7_DATA	The DMA uses this field to generate the data field for the Done or Abort IMWr TLPs it generates for read channel 7. Note: The access attributes of this field are as follows: - Dbi: R/W
15-0 RD_CHANNEL_6_DATA	The DMA uses this field to generate the data field for the Done or Abort IMWr TLPs it generates for read channel 6. Note: The access attributes of this field are as follows: - Dbi: R/W

11.4.3.1.216 DMA Write Channel Control 1 Register. (DMA_CH_CONTROL1_OFF_WRCH_0)

11.4.3.1.216.1 Offset

Register	Offset
DMA_CH_CONTROL1_OFF_WRCH_0	38_0200h

11.4.3.1.216.2 Diagram

11.4.3.1.216.3 Fields

Field	Function
31-30 DMA_AT	Address Translation TLP Header Bit (AT) The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
29-27 DMA_TC	Traffic Class TLP Header Bit (TC) The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
26 DMA_RESERVED5	Reserved Note: The access attributes of this field are as follows: - Dbi: R/W
25 DMA_RO	Relaxed Ordering TLP Header Bit (RO) The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
24 DMA_NS_SRC	Source No Snoop TLP Header Bit (DMA_NS_SRC). The DMA uses this TLP header field when generating MRd (SAR addressing space) (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
23 DMA_NS_DST	Destination No Snoop TLP Header Bit (DMA_NS_DST). The DMA uses this TLP header field when generating MWr (DAR addressing space) (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
22-17 DMA_RESERVED2	Reserved Note: The access attributes of this field are as follows: - Dbi: R/W
16-12	Function Number (FN). The controller uses this field when generating the requester ID for the MRd/MWr DMA TLP. When you have enabled SR-IOV, then this field is ignored if you have set the VFE field in the

Table continues on the next page...

Field	Function
DMA_FUNC_NUM	"DMA Write Channel Control 2 Register" (DMA_CH_CONTROL2_OFF_WRCH_0). Note: The access attributes of this field are as follows: - Dbi: R/W
11-10 DMA_RESERVED1	Reserved Note: The access attributes of this field are as follows: - Dbi: R/W
9 LLE	Linked List Enable (LLE). - 0: Disable linked list operation - 1: Enable linked list operation Note: The access attributes of this field are as follows: - Dbi: R/W
8 CCS	Consumer Cycle State (CCS). Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". You must initialize this bit. The DMA updates this bit during linked list operation. Note: The access attributes of this field are as follows: - Dbi: R/W
7 DMA_RESERVED0	Reserved Note: The access attributes of this field are as follows: - Dbi: R/W
6-5 CS	Channel Status (CS). The channel status bits identify the current operational state of the DMA channel. The operation state encoding for each DMA channel is a s follows: - 00: Reserved - 01: Running. This channel is active and transferring data. - 10: Halted. An error condition has been detected, and the DMA has stopped this channel. - 11: Stopped. The DMA has transferred all data for this channel, or you have prematurely stopped this channel by writing to the Stop field of the "DMA Write Doorbell Register" (DMA_WRITE_DOORBELL_OFF) or "DMA Read Doorbell Register" (DMA_READ_DOORBELL_OFF).
4 RIE	Remote Interrupt Enable (RIE). You must set this bit to enable the generation of the Done or Abort Remote interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the RIE of the LL element. The RIE bit in a LL element only enables the Done interrupt. In non-LL mode, the RIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. Note: The access attributes of this field are as follows: - Dbi: R/W
3 LIE	Local Interrupt Enable (LIE). You must set this bit to enable the generation of the Done or Abort Local interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the LIE of the LL element. The LIE bit in a LL element only enables the Done interrupt. In non-LL mode, the LIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. Note: The access attributes of this field are as follows: - Dbi: R/W
2 LLP	Load Link Pointer (LLP). Used in linked list mode only. Indicates that this linked list element is a link element, and its LL element pointer dwords are pointing to the next (non-contiguous) element. The DMA loads this field with the LLP of the linked list element. Note: The access attributes of this field are as follows: - Dbi: R/W
1 TCB	Toggle Cycle Bit (TCB). Indicates to the DMA to toggle its interpretation of the CB. Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the TCB of the linked list element. this field is not defined in a data LL element. Note: The access attributes of this field are as follows: - Dbi: R/W
0 CB	Cycle Bit (CB). Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the CB of the linked list element. Note: The access attributes of this field are as follows: - Dbi: R/W

11.4.3.1.217 DMA Write Transfer Size Register. (DMA_TRANSFER_SIZE_OFF_WRCH_0)

11.4.3.1.217.1 Offset

Register	Offset
DMA_TRANSFER_SIZE_OFF_WRCH_0	38_0208h

11.4.3.1.217.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	DMA_TRANSFER_SIZE															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

11.4.3.1.217.3 Fields

Field	Function
31-0 DMA_TRANSFER_SIZE	DMA Transfer Size. You program this register with the size of the DMA transfer. The maximum DMA transfer size is 4Gbytes. The minimum transfer size is one byte (0x1). This field is automatically decremented by the DMA as the DMA write channel transfer progresses. This field indicates the number bytes remaining to be transferred. When all bytes are successfully transferred the current transfer size is zero. In LL mode, the DMA overwrites this register with the corresponding dword of the LL element. You can read this register to monitor the transfer progress, however in some scenarios this register is updated after a delay. For example, when less than 3 channels are doorbelled, this register is updated only after a descriptor finishes(linked list mode), or the transfer ends (non-linked list mode). Note: The access attributes of this field are as follows: - Dbi: R/W

11.4.3.1.218 DMA Write SAR Low Register. (DMA_SAR_LOW_OFF_WRCH_0)

11.4.3.1.218.1 Offset

Register	Offset
DMA_SAR_LOW_OFF_WRCH_0	38_020Ch

R W	LLP_LOW															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

11.4.3.1.222.3 Fields

Field	Function
31-0 LLP_LOW	Lower bits of the address of the linked list transfer list in local memory. Used in linked list mode only. Updated by the DMA to point to the next element in the transfer list after the previous element is consumed. - When the current element is a data element; this field is incremented by 6. - When the current element is a link element; this field is overwritten by the LL Element Pointer of the element. Note: The access attributes of this field are as follows: - Dbi: R/W

11.4.3.1.223 DMA Write Linked List Pointer High Register. (DMA_LLP_HIGH_OFF_WRCH_0)

11.4.3.1.223.1 Offset

Register	Offset
DMA_LLP_HIGH_OFF_ WRCH_0	38_0220h

R W	LLP_HIGH															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

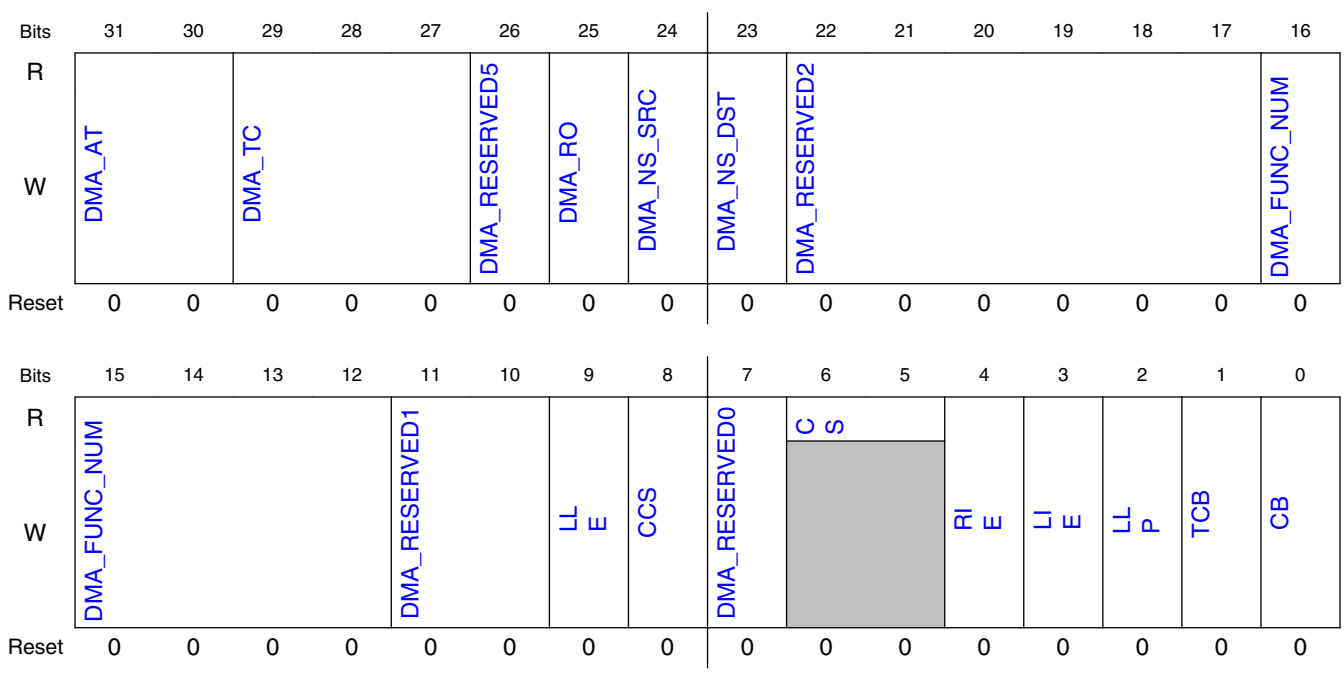
11.4.3.1.223.3 Fields



Field	Function
31-0 LLP_HIGH	Upper 32 bits of the address of the linked list transfer list in local memory. Used in linked list mode only. Updated by the DMA to point to the next element in the transfer list as elements are consumed. Note: The access attributes of this field are as follows: - Dbi: R/W

11.4.3.1.224 DMA Read Channel Control 1 Register. (DMA_CH_CONTROL1_OFF_RDCH_0)

11.4.3.1.224.1 Offset

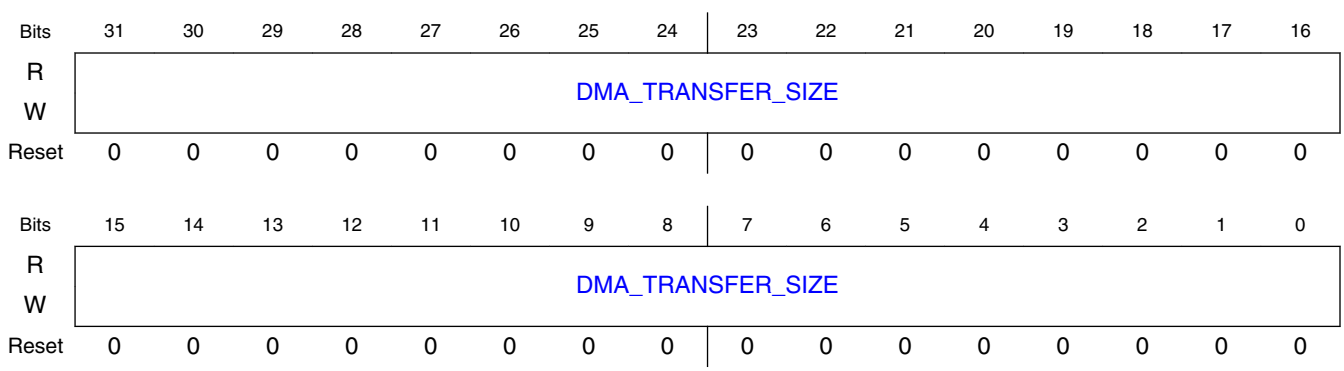
Register	Offset
DMA_CH_CONTROL1_OFF_RDCH_0	38_0300h

11.4.3.1.224.2 Diagram

11.4.3.1.224.3 Fields

Field	Function
31-30 DMA_AT	Address Translation TLP Header Bit (AT) The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
29-27 DMA_TC	Traffic Class TLP Header Bit (TC) The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
26 DMA_RESERVED5	Reserved Note: The access attributes of this field are as follows: - Dbi: R/W
25 DMA_RO	Relaxed Ordering TLP Header Bit (RO) The DMA uses this TLP header field when generating MRd/MWr (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
24 DMA_NS_SRC	Source No Snoop TLP Header Bit (DMA_NS_SRC). The DMA uses this TLP header field when generating MRd (SAR addressing space) (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
23 DMA_NS_DST	Destination No Snoop TLP Header Bit (DMA_NS_DST). The DMA uses this TLP header field when generating MWr (DAR addressing space) (not IMWr) TLPs. Note: The access attributes of this field are as follows: - Dbi: R/W
22-17 DMA_RESERVED2	Reserved Note: The access attributes of this field are as follows: - Dbi: R/W
16-12 DMA_FUNC_NUM	Function Number (FN). The controller uses this field when generating the requester ID for the MRd/MWr DMA TLP. When you have enabled SR-IOV, then this field is ignored if you have set the VFE field in the "DMA Read Channel Control 2 Register" (DMA_CH_CONTROL2_OFF_RDCH_0). Note: The access attributes of this field are as follows: - Dbi: R/W
11-10 DMA_RESERVED1	Reserved Note: The access attributes of this field are as follows: - Dbi: R/W
9 LLE	Linked List Enable (LLE). - 0: Disable linked list operation - 1: Enable linked list operation Note: The access attributes of this field are as follows: - Dbi: R/W
8 CCS	Consumer Cycle State (CCS). Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". You must initialize this bit. The DMA updates this bit during linked list operation. Note: The access attributes of this field are as follows: - Dbi: R/W
7 DMA_RESERVED0	Reserved Note: The access attributes of this field are as follows: - Dbi: R/W
6-5 CS	Channel Status (CS). The channel status bits identify the current operational state of the DMA channel. The operation state encoding for each DMA channel is a s follows: - 00: Reserved - 01: Running. This channel is active and transferring data. - 10: Halted. An error condition has been detected, and the DMA has stopped this channel. - 11: Stopped. The DMA has transferred all data for this channel, or you have prematurely stopped this channel by writing to the Stop field of the "DMA Read Doorbell Register" (DMA_WRITE_DOORBELL_OFF) or "DMA Read Doorbell Register" (DMA_READ_DOORBELL_OFF).
4 RIE	Remote Interrupt Enable (RIE). You must set this bit to enable the generation of the Done or Abort Remote interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the RIE of the LL element. The RIE bit in a LL element only enables the Done interrupt. In non-LL mode, the RIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. Note: The access attributes of this field are as follows: - Dbi: R/W

Table continues on the next page...



Field	Function
3 LIE	Local Interrupt Enable (LIE). You must set this bit to enable the generation of the Done or Abort Local interrupts. For more details, see "Interrupts and Error Handling". In LL mode, the DMA overwrites this with the LIE of the LL element. The LIE bit in a LL element only enables the Done interrupt. In non-LL mode, the LIE bit enables the Done and Abort interrupts. This field is not defined in a link LL element. Note: The access attributes of this field are as follows: - Dbi: R/W
2 LLP	Load Link Pointer (LLP). Used in linked list mode only. Indicates that this linked list element is a link element, and its LL element pointer dwords are pointing to the next (non-contiguous) element. The DMA loads this field with the LLP of the linked list element. Note: The access attributes of this field are as follows: - Dbi: R/W
1 TCB	Toggle Cycle Bit (TCB). Indicates to the DMA to toggle its interpretation of the CB. Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the TCB of the linked list element. this field is not defined in a data LL element. Note: The access attributes of this field are as follows: - Dbi: R/W
0 CB	Cycle Bit (CB). Used in linked list mode only. It is used to synchronize the producer (software) and the consumer (DMA). For more details, see "PCS-CCS-CB-TCB Producer-Consumer Synchronization". The DMA loads this field with the CB of the linked list element. Note: The access attributes of this field are as follows: - Dbi: R/W

11.4.3.1.225 DMA Read Transfer Size Register. (DMA_TRANSFER_SIZE_OFF_RDCH_0)

11.4.3.1.225.1 Offset

Register	Offset
DMA_TRANSFER_SIZE_OFF_RDCH_0	38_0308h

11.4.3.1.225.2 Diagram

11.4.3.1.225.3 Fields

Field	Function
31-0 DMA_TRANSFER_SIZE	DMA Transfer Size. You program this register with the size of the DMA transfer. The maximum DMA transfer size is 4Gbytes. The minimum transfer size is one byte (0x1). This field is automatically decremented by the DMA as the DMA read channel transfer progresses. This field indicates the number bytes remaining to be transferred. When all bytes are successfully transferred the current transfer size is zero. In LL mode, the DMA overwrites this register with the corresponding dword of the LL element. You can read this register to monitor the transfer progress, however in some scenarios this register is updated after a delay. For example, when less than 3 channels are doorbelled, this register is updated only after a descriptor finishes(linked list mode), or the transfer ends (non-linked list mode). Note: The access attributes of this field are as follows: - Dbi: R/W

11.4.3.1.226 DMA Read SAR Low Register. (DMA_SAR_LOW_OFF_RDCH_0)

11.4.3.1.226.1 Offset

Register	Offset
DMA_SAR_LOW_OFF_RDCH_0	38_030Ch

11.4.3.1.226.3 Fields

Field	Function
31-0 SRC_ADDR_REG_LOW	Source Address Register (Lower 32 bits). Indicates the next address to be read from. The DMA increments the SAR as the DMA transfer progresses. In LL mode, the DMA overwrites this with the corresponding dword of the LL element. - DMA Read: The SAR is the address of the remote memory. - DMA Read: The SAR is the address of the local memory. Note: The access attributes of this field are as follows: - Dbi: R/W

11.4.3.1.227 DMA Read SAR High Register. (DMA_SAR_HIGH_OFF_RDCH_0)

11.4.3.1.227.1 Offset

11.4.3.1.231.3 Fields

Field	Function
31-0 LLP_HIGH	Upper 32 bits of the address of the linked list transfer list in local memory. Used in linked list mode only. Updated by the DMA to point to the next element in the transfer list as elements are consumed. Note: The access attributes of this field are as follows: - Dbi: R/W

11.5 PCI Express PHY (PCIe_PHY)

11.5.1 Overview

The PCIe PHY IP core is used for PCI-Express (PCIe) applications. The transceiver in the core performs these functions:

- Serializes the 8b/10b encoded data for transmission for Gen1 and Gen2 operation, and 128b/130b encoded data for Gen3
- De-serializes the received code groups

When transmitting the data, the transceiver performs these functions:

- Accepts four 10-bit 8b/10b encoded transmit characters or four 8-bit 128b/130b encoded data
- Attaches and serializes the data to the TXP/TXN differential outputs to a maximum value of 8.0 Gb/s

When receiving the data, the transceiver performs these functions:

- Samples the received serial data on the RXP/RXN differential inputs
- Deserializes it into four 10-bit(or 8b-bit) received characters

PCIe PHY core has on-chip PLL circuitry for synthesis of the baud-rate transmitting clocks, and extraction of the retimed clocks from the received serial stream.

11.5.1.1 Block Diagram

The figure below illustrates the block diagram of a 4-lane PCIe PHY.

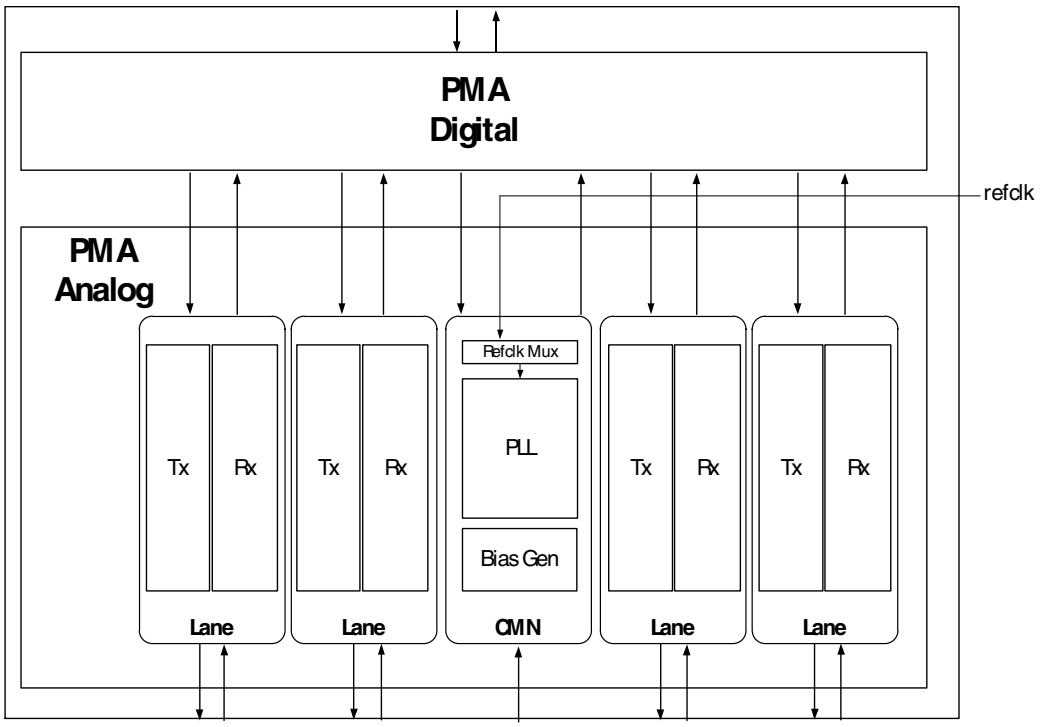

Figure 11-57. Block Diagram of PCIe PHY

The PCIe PHY comprises of one Common, four lanes of transceiver, one external reference clock in/output buffer, and PMA digital.

11.5.1.2 Features

The supported features in a Samsung PCIe PHY IP core are:

- PCI Express Base Specification 4.0 compliance
- 2.5Gb/s, 5.0Gb/s, and 8.0Gb/s Serializer/Deserializer
- PHY Interface for the PCI Express Architecture, Version 4.2 compliance
- Receiver Detection
- Spread Spectrum Clocking in Transmitter and Receiver
- Separate Refclk Independent SSC (SRIS) Architecture
- Continuous-Time Linear Equalizer and 5-tap adaptive Decision-Feedback Equalizer

11.5.2 Functional Description

The PCIe PHY comprises of a PMA analog and PMA digital. The PMA consists of:

- One CMN block

- Four lane blocks including a full-duplex transceiver,
- One external reference clock input/output (bidirectional) buffer.

In the transmitter side, the PMA Analog executes these actions:

- PMA Analog receives parallel data from PMA digital.
- The TX driver characteristics, such as amplitude and 3-tap FIR filter, are both presettable and user- controllable.

In the receiver side, the PMA executes these actions:

- Distortion on received signal due to channel loss is compensated by Continuous Time Linear Equalizer (CTLE) and Decision Feedback Equalizer (DFE).
- Clock and Data Recovery (CDR) generates frequency- and phase-aligned clock and equalized signal is deserialized to parallel data which is delivered to the PHY digital.

11.5.2.1 Common (CMN)

The CMN consists of a band-gap reference (BGR), bias generator, and PLL. Detailed information on each block is described in the following sections

11.5.2.1.1 BGR and bias generator

The BGR circuit generates high-accuracy reference voltage across PVT variation.

A bias generator makes two kinds of current, external- and internal-resistor (RMRES)-referred current, and these currents are distributed to each block in CMN and lanes. The external resistor-referred (REXT) current is generated using an 8.2KΩ resistor which is connected between the rext pad and ground outside the chip. On the other hand, the internal resistor-referred current is generated using internally integrated replica resistor to compensate resistance error across PVT variation.

11.5.2.1.2 Phase Locked Loop (PLL)

The PLL in the CMN synthesizes high-speed clock, which is used for TX serializer and RX CDR lock, from a reference clock. The reference clock can be selected from two clock sources; internal SoC reference clock and external differential reference clock.

In the PCIe PHY, the high frequency clock from PLL is used in the serialization of TX data and CDR lock acquisition and maintenance. The following are the main features of the PLL:

- Supports wide-range LC VCO from 8GHz to 10GHz
- Supports pre-defined and programmable divider setting for each PCIe specification

- Supports spread spectrum clocking (SSC) with sigma-delta modulated fractional divider.
- Supports Automatic Frequency Calibrated (AFC) oscillator setting for the desired frequency of operation
- Supports programmable charge pump current and loop filter resistance allowing for wide range of programmable loop bandwidth and peaking

11.5.2.2 Transmitter

The main features of the TX are provided below:

- Supports high voltage swing with auxiliary current-mode driver.
- Supports 3-tap FIR filter with resolution of 1/48.
- Supports 10 FIR presets (P0 to P9)
- Supports automatic TX termination resistance calibration.
- Supports electrical idle mode with either fast or low-power common-mode keep.
- Supports receiver detection.

11.5.3 Memory Map and register definition

This section includes the PCIE_PHY module memory map and descriptions of the registers.

11.5.3.1 PCIe PHY register descriptions

11.5.3.1.1 PCIe_PHY Memory map

PCIE_PHY base address: 32F0_0000h

11.6 Ethernet MAC (ENET)

11.6.1 Overview

The core implements a triple-speed 10/100/1000-Mbit/s Ethernet MAC compliant with the IEEE802.3-2002 standard. The MAC layer provides compatibility with half- or full-duplex 10/100-Mbit/s and full-duplex gigabit Ethernet LANs.

The MAC operation is fully programmable and can be used in Network Interface Card (NIC), bridging, or switching applications. The core implements the remote network monitoring (RMON) counters according to IETF RFC 2819.

The core also implements a hardware acceleration block to optimize the performance of network controllers providing TCP/IP, UDP, and ICMP protocol services. The acceleration block performs critical functions in hardware, which are typically implemented with large software overhead.

The core implements programmable embedded FIFOs that can provide buffering on the receive path for lossless flow control.

Advanced power management features are available with magic packet detection and programmable power-down modes.

A unified DMA (uDMA), internal to the ENET module, optimizes data transfer between the ENET core and the SoC, and supports an enhanced buffer descriptor programming model to support IEEE 1588 functionality.

The programmable Ethernet MAC with IEEE 1588 integrates a standard IEEE 802.3 Ethernet MAC with a time-stamping module. The IEEE 1588 standard provides accurate clock synchronization for distributed control nodes for industrial automation applications.

11.6.1.1 Block diagram

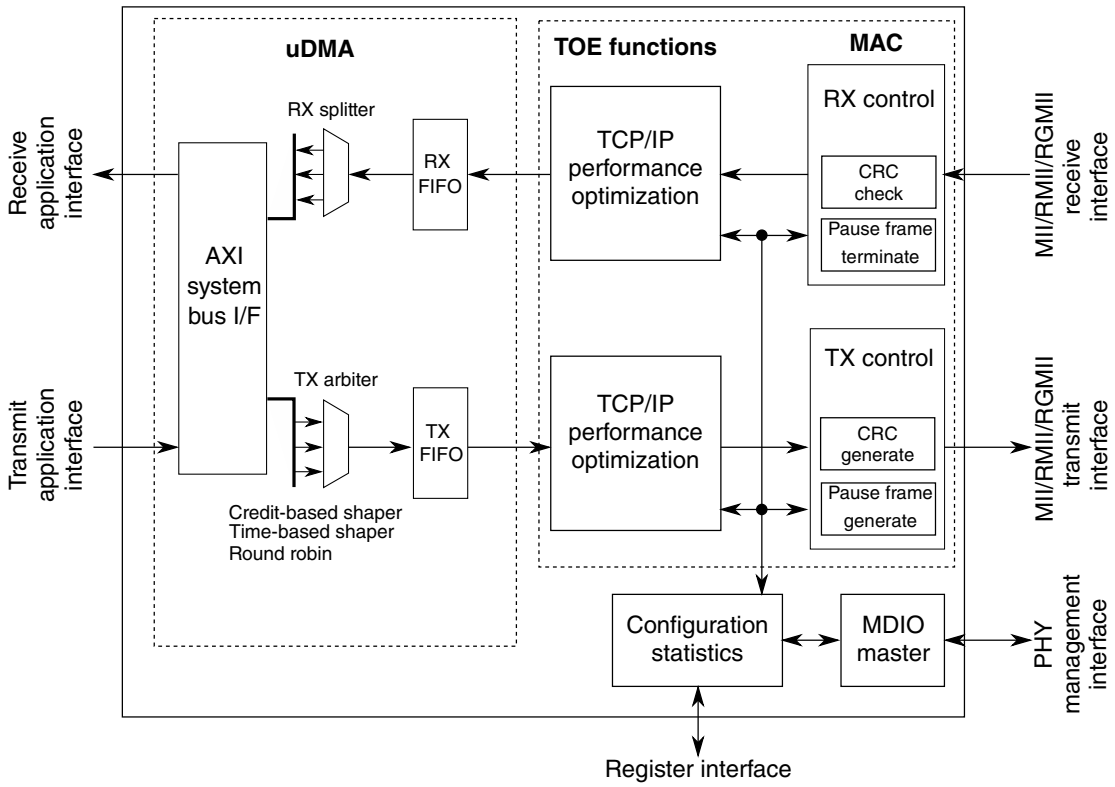

Figure 11-58. Ethernet MAC-NET core block diagram

11.6.1.2 Features

The MAC-NET core includes the following features.

11.6.1.2.1 Ethernet MAC features

- Implements the full 802.3 specification with preamble/SFD generation, frame padding generation, CRC generation and checking
- Supports zero-length preamble
- Dynamically configurable to support 10/100-Mbit/s and gigabit operation
- Supports 10/100 Mbit/s full-duplex and configurable half-duplex operation
- Supports gigabit full-duplex operation
- Compliant with the AMD magic packet detection with interrupt for node remote power management
- Seamless interface to commercial ethernet PHY devices via one of the following:
  - a 2-bit Reduced MII (RMII) operating at 50 MHz.
  - a (double data rate) 4-bit Reduced GMII (RGMII) operating at 125 MHz.
- CRC-32 checking at full speed with optional forwarding of the frame check sequence (FCS) field to the client

- CRC-32 generation and append on transmit or forwarding of user application provided FCS selectable on a per-frame basis
- In full-duplex mode:
  - Implements automated pause frame (802.3 x31A) generation and termination, providing flow control without user application intervention
  - Pause quanta used to form pause frames — dynamically programmable
  - Pause frame generation additionally controllable by user application offering flexible traffic flow control
  - Optional forwarding of received pause frames to the user application
  - Implements standard flow-control mechanism
- In half-duplex mode: provides full collision support, including jamming, backoff, and automatic retransmission
- Supports VLAN-tagged frames according to IEEE 802.1Q
- Programmable MAC address: Insertion on transmit; discards frames with mismatching destination address on receive (except broadcast and pause frames)
- Programmable promiscuous mode support to omit MAC destination address checking on receive
- Multicast and unicast address filtering on receive based on 64-entry hash table, reducing higher layer processing load
- Programmable frame maximum length providing support for any standard or proprietary frame length
- Statistics indicators for frame traffic and errors (alignment, CRC, length) and pause frames providing for IEEE 802.3 basic and mandatory management information database (MIB) package and remote network monitoring (RFC 2819)
- Simple handshake user application FIFO interface with fully programmable depth and threshold levels
- Provides separate status word for each received frame on the user interface providing information such as frame length, frame type, VLAN tag, and error information
- MII internal loopback
- MDIO master interface for PHY device configuration and management supports two programmable MDIO base addresses, and standard (IEEE 802.3 Clause 22) and extended (Clause 45) MDIO frame formats
- Supports legacy FEC buffer descriptors
- Interrupt coalescing reduces the number of interrupts generated by the MAC, reducing CPU loading
- Traffic-shaping bandwidth distribution supports credit-based and round-robin-based policies. Either policy can be combined with time-based shaping.
- AVB (Audio Video Bridging, IEEE 802.1Qav) features:
  - Credit-based bandwidth distribution policy can be combined with time-based shaping

- AVB endpoint talker and listener support
- Support for arbitration between different priority traffic (for example, AVB class A, AVB class B, and non-AVB)

11.6.1.2.2 IP protocol performance optimization features

- Operates on TCP/IP and UDP/IP and ICMP/IP protocol data or IP header only
- Enables wire-speed processing
- Supports IPv4 and IPv6
- Transparent passing of frames of other types and protocols
- Supports VLAN tagged frames according to IEEE 802.1q with transparent forwarding of VLAN tag and control field
- Automatic IP-header and payload (protocol specific) checksum calculation and verification on receive
- Automatic IP-header and payload (protocol specific) checksum generation and automatic insertion on transmit configurable on a per-frame basis
- Supports IP and TCP, UDP, ICMP data for checksum generation and checking
- Supports full header options for IPv4 and TCP protocol headers
- Provides IPv6 support to datagrams with base header only — datagrams with extension headers are passed transparently unmodifed/unchecked
- Provides statistics information for received IP and protocol errors
- Configurable automatic discard of erroneous frames
- Configurable automatic host-to-network (RX) and network-to-host (TX) byte order conversion for IP and TCP/UDP/ICMP headers within the frame
- Configurable padding remove for short IP datagrams on receive
- Configurable Ethernet payload alignment to allow for 32-bit word-aligned header and payload processing
- Programmable store-and-forward operation with clock and rate decoupling FIFOs

11.6.1.2.3 IEEE 1588 features

- Supports all IEEE 1588 frames.
- Allows reference clock to be chosen independently of network speed.

- Software-programmable precise time-stamping of ingress and egress frames
- Timer monitoring capabilities for system calibration and timing accuracy management
- Precise time-stamping of external events with programmable interrupt generation
- Programmable event and interrupt generation for external system control
- Supports hardware- and software-controllable timer synchronization.
- Provides a 4-channel IEEE 1588 timer. Each channel supports input capture and output compare using the 1588 counter.

11.6.2 Functional description

This section provides a complete functional description of the MAC-NET core.

11.6.2.1 Ethernet MAC frame formats

- Minimum length of 64 bytes
- Maximum length of 1518 bytes excluding the preamble and the start frame delimiter (SFD) bytes

An Ethernet frame consists of the following fields:

- Seven bytes preamble
- Start frame delimiter (SFD)
- Two address fields
- Length or type field
- Data field
- Frame check sequence (CRC value)

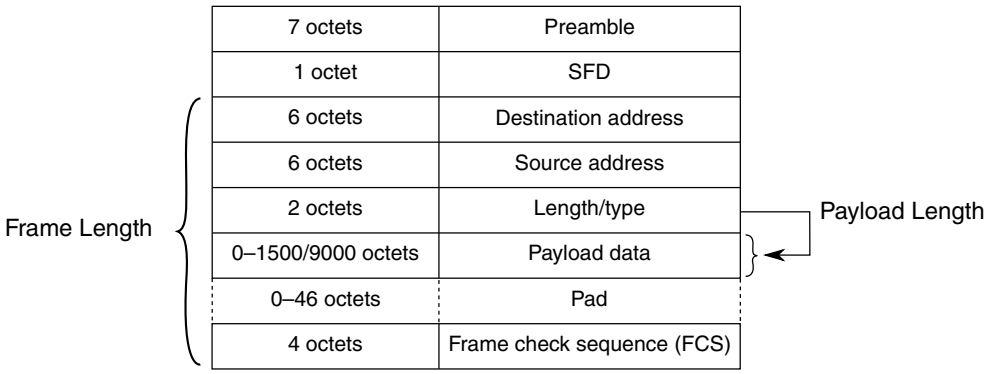

Figure 11-59. MAC frame format overview

Optionally, MAC frames can be VLAN-tagged with an additional four-byte field inserted between the MAC source address and the type/length field. VLAN tagging is defined by the IEEE P802.1q specification. VLAN-tagged frames have a maximum length of 1522 bytes, excluding the preamble and the SFD bytes.

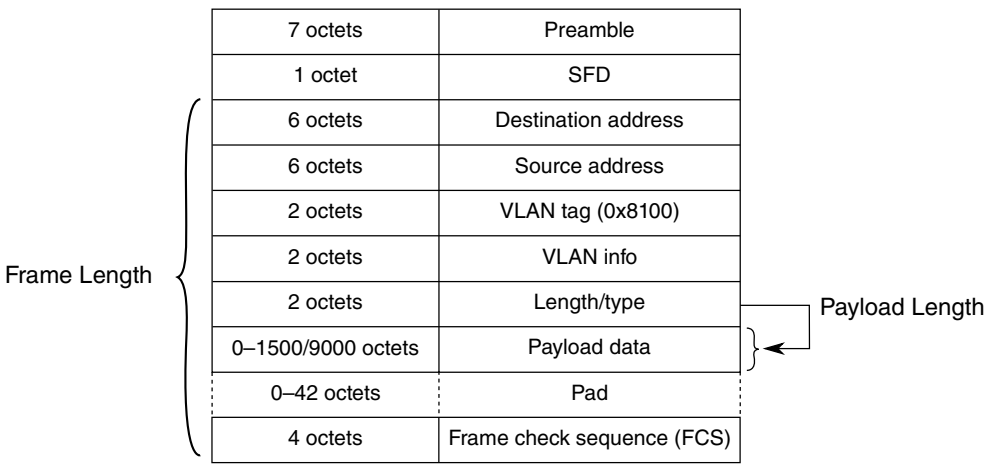

Figure 11-60. VLAN-tagged MAC frame format overview

Table 11-47. MAC frame definition

Term	Description
Frame length	Defines the length, in octets, of the complete frame without preamble and SFD. A frame has a valid length if it contains at least 64 octets and does not exceed the programmed maximum length.
Payload length	The length/type field indicates the length of the frame's payload section. The most significant byte is sent/received first. • If the length/type field is set to a value less than 46, the payload is padded so that the minimum frame length requirement (64 bytes) is met. For VLAN-tagged frames, a value less than 42 indicates a padded frame. • If the length/type field is set to a value larger than the programmed frame maximum length (e.g. 1518) it is interpreted as a type field.
Destination and source address	48-bit MAC addresses. The least significant byte is sent/received first and the first two least significant bits of the MAC address distinguish MAC frames, as detailed in MAC address check.

Note

Although the IEEE specification defines a maximum frame length, the MAC core provides the flexibility to program any value for the frame maximum length.

11.6.2.1.1 Pause Frames

The receiving device generates a pause frame to indicate a congestion to the emitting device, which should stop sending data.

Pause frames are indicated by the length/type set to 0x8808. The two first bytes of a pause frame following the type, defines a 16-bit opcode field set to 0x0001 always. A 16-bit pause quanta is defined in the frame payload bytes 2 (P1) and 3 (P2) as defined in the following table. The P1 pause quanta byte is the most significant.

Table 11-48. Pause Frame Format (Values in Hex)

1	2	3	4	5	6	7	8	9	10	11	12	13	14
55	55	55	55	55	55	55	D5	01	80	C2	00	00	01
Preamble							SFD	Multicast Destination Address					
15	16	17	18	19	20	21	22	23	24	25	26	27 –68	
00	00	00	00	00	00	88	08	00	01	hi	lo	00	
Source Address						Type		Opcode		P1	P2	pad (42)	
69	70	71	72										
26	6B	AE	0A										
CRC-32													

There is no payload length field found within a pause frame and a pause frame is always padded with 42 bytes (0x00).

If a pause frame with a pause value greater than zero (XOFF condition) is received, the MAC stops transmitting data as soon the current frame transfer is completed. The MAC stops transmitting data for the value defined in pause quanta. One pause quanta fraction refers to 512 bit times.

If a pause frame with a pause value of zero (XON condition) is received, the transmitter is allowed to send data immediately (see Full-duplex flow control operation for details).

11.6.2.1.2 Magic packets

A magic packet is a unicast, multicast, or broadcast packet, which carries a defined sequence in the payload section.

Magic packets are received and inspected only under specific conditions as described in Magic packet detection.

The defined sequence to decode a magic packet is formed with a synchronization stream which consists of six consecutive 0xFF bytes, and is followed by sequence of sixteen consecutive unicast MAC addresses of the node to be awakened.

This sequence can be located anywhere in the magic packet payload. The magic packet is formed with a standard Ethernet header, optional padding, and CRC.

11.6.2.2 IP and higher layers frame format

The following sections use the term datagram to describe the protocol specific data unit that is found within the payload section of its container entity.

For example, an IP datagram specifies the payload section of an Ethernet frame. A TCP datagram specifies the payload section within an IP datagram.

11.6.2.2.1 Ethernet types

IP datagrams are carried in the payload section of an Ethernet frame. The Ethernet frame type/length field discriminates several datagram types.

The following table lists the types of interest:

Table 11-49. Ethernet type value examples

Type	Description
0x8100	VLAN-tagged frame. The actual type is found 4 octets later in the frame.
0x0800	IPv4
0x0806	ARP
0x86DD	IPv6

11.6.2.2.2 IPv4 datagram format

The following figure shows the IP Version 4 (IPv4) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words. The first byte sent/received is the leftmost byte of the first word (in other words, version/IHL field).

The IP header can contain further options, which are always padded if necessary to guarantee the payload following the header is aligned to a 32-bit boundary.

The IP header is immediately followed by the payload, which can contain further protocol headers (for example, TCP or UDP, as indicated by the protocol field value). The complete IP datagram is transported in the payload section of an Ethernet frame.

Table 11-50. IPv4 header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Version	IHL	TOS		Length			
Fragment ID				Flags	Fragment offset		
TTL		Protocol		Header checksum			
Source address							
Destination address							
Options							

Table 11-51. IPv4 header fields

Field name	Description
Version	4-bit IP version information. 0x4 for IPv4 frames.
IHL	4-bit Internet header length information. Determines number of 32-bit words found within the IP header. If no options are present, the default value is 0x5.
TOS	Type of service/DiffServ field.
Length	Total length of the datagram in bytes, including all octets of header and payload.
Fragment ID, flags, fragment offset	Fields used for IP fragmentation.
TTL	Time-to-live. In effect, is decremented at each router arrival. If zero, datagram must be discarded.
Protocol	Identifier of protocol that follows in the datagram.
Header checksum	Checksum of IP header. For computational purposes, this field's value is zero.
Source address	Source IP address.
Destination address	Destination IP address.

11.6.2.2.3 IPv6 datagram format

The following figure shows the IP version 6 (IPv6) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words and has a fixed length of ten words (40 bytes). The next header field identifies the type of the header that follows the IPv6 header. It is defined similar to the protocol identifier within IPv4, with new definitions for identifying extension headers. These headers can be inserted between the IPv6 header and the protocol header, which will shift the protocol header accordingly.The accelerator currently only supports IPv6 without extension headers (in other words, the next header specifies TCP, UDP, or IMCP).

The first byte sent/received is the leftmost byte of the first word (in other words, version/ traffic class fields).

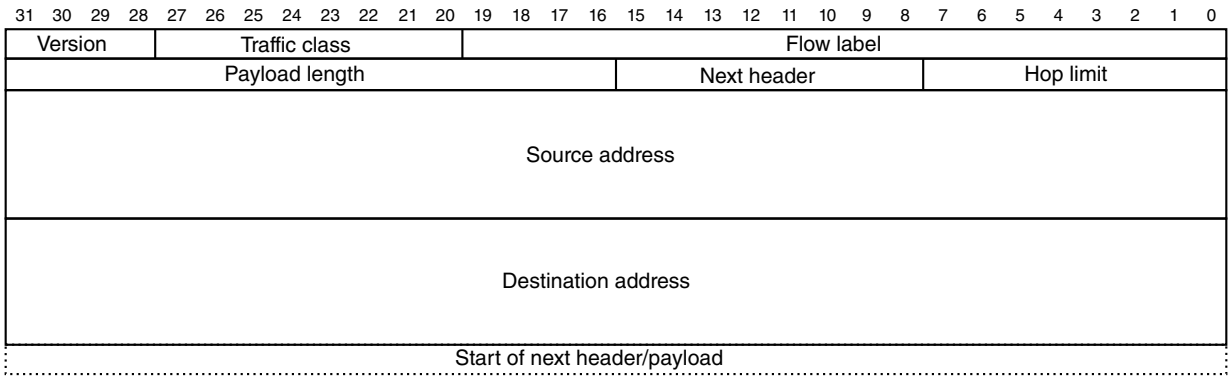

Figure 11-61. IPv6 header format

Table 11-52. IPv6 header fields

Field name	Description
Version	4-bit IP version information. 0x6 for all IPv6 frames.
Traffic class	8-bit field defining the traffic class.
Flow label	20-bit flow label identifying frames of the same flow.
Payload length	16-bit length of the datagram payload in bytes. It includes all octets following the IPv6 header.
Next header	Identifies the header that follows the IPv6 header. This can be the protocol header or any IPv6 defined extension header.
Hop limit	Hop counter, decremented by one by each station that forwards the frame. If hop limit is 0 the frame must be discarded.
Source address	128-bit IPv6 source address.
Destination address	128-bit IPv6 destination address.

11.6.2.2.4 Internet Control Message Protocol (ICMP) datagram format

An internet control message protocol (ICMP) is found following the IP header, if the protocol identifier is 1. The ICMP datagram has a four-octet header followed by additional message data.

Table 11-53. ICMP header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Type		Code		Checksum			
ICMP message data							

Table 11-54. IP header fields

Field name	Description
Type	8-bit type information
Code	8-bit code that is related to the message type
Checksum	16-bit one's complement checksum over the complete ICMP datagram

11.6.2.2.5 User Datagram Protocol (UDP) datagram format

A user datagram protocol header is found after the IP header, when the protocol identifier is 17.

The payload of the datagram is after the UDP header. The header byte order follows the conventions given for the IP header above.

Table 11-55. UDP header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source port				Destination port			
Length				Checksum			

Table 11-56. UDP header fields

Field name	Description
Source port	Source application port
Destination port	Destination application port
Length	Length of user data which immediately follows the header, including the UDP header (that is, minimum value is 8)
Checksum	Checksum over the complete datagram and some IP header information

11.6.2.2.6 TCP datagram format

A TCP header is found following the IP header, when the protocol identifier has a value of 6.

The TCP payload immediately follows the TCP header.

Table 11-57. TCP header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source port				Destination port			
Sequence number							
Acknowledgement number							
Offset	Reserved		Flags	Window			
Checksum				Urgent pointer			
Options							

Table 11-58. TCP header fields

Field name	Description
Source port	Source application port
Destination port	Destination application port
Sequence number	Transmit sequence number
Ack. number	Receive sequence number
Offset	Data offset, which is number of 32-bit words within TCP header — if no options selected, defaults to value of 5
Flags	URG, ACK, PSH, RST, SYN, FIN flags
Window	TCP receive window size information
Checksum	Checksum over the complete datagram (TCP header and data) and IP header information
Options	Additional 32-bit words for protocol options

11.6.2.3 IEEE 1588 message formats

The following sections describe the IEEE 1588 message formats.

11.6.2.3.1 Transport encapsulation

The precision time protocol (PTP) datagrams are encapsulated in Ethernet frames using the UDP/IP transport mechanism, or optionally, with the newer 1588v2 directly in Ethernet frames (layer 2).

Typically, multicast addresses are used to allow efficient distribution of the synchronization messages.

11.6.2.3.1.1 UDP/IP

The 1588 messages (v1 and v2) can be transported using UDP/IP multicast messages.

The table below shows IP multicast groups defined for PTP. The table also shows their respective MAC layer multicast address mapping according to RFC 1112 (last three octets of IP follow the fixed value of 01-00-5E).

Table 11-59. UDP/IP multicast domains

Name	IP Address	MAC Address mapping
DefaultPTPdomain	224.0.1.129	01-00-5E-00-01-81
AlternatePTPdomain1	224.0.1.130	01-00-5E-00-01-82
AlternatePTPdomain2	224.0.1.131	01-00-5E-00-01-83

Table continues on the next page...

Table 11-59. UDP/IP multicast domains (continued)

Name	IP Address	MAC Address mapping
AlternatePTPdomain3	224.0.1.132	01-00-5E-00-01-84

Table 11-60. UDP port numbers

Message type	UDP port	Note
Event	319	Used for SYNC and DELAY_REQUEST messages
General	320	All other messages (for example, follow-up, delay-response)

11.6.2.3.1.2 Native Ethernet (PTPv2)

In addition to using UDP/IP frames, IEEE 1588v2 defines a native Ethernet frame format that uses ethertype = 0x88F7. The payload of the Ethernet frame immediately contains the PTP datagram, starting with the PTPv2 header.

Besides others, version 2 adds a peer delay mechanism to allow delay measurements between individual point-to-point links along a path over multiple nodes. The following multicast domains are also defined in PTPv2.

Table 11-61. PTPv2 multicast domains

Name	MAC address
Normal messages	01-1B-19-00-00-00
Peer delay messages	01-80-C2-00-00-0E

11.6.2.3.2 PTP header

All PTP frames contain a common header that determines the protocol version and the type of message, which defines the remaining content of the message.

All multi-octet fields are transmitted in big-endian order (the most significant byte is transmitted/received first).

The last four bits of versionPTP are at the same position (second byte) for PTPv1 and PTPv2 headers. This allows accurate identification by inspecting the first two bytes of the message.

11.6.2.3.2.1 PTPv1 header

Table 11-62. Common PTPv1 message header

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	2	versionPTP = 0x0001							
2	2	versionNetwork							
4	16	subdomain							
20	1	messageType							
21	1	sourceCommunicationTechnology							
22	6	sourceUuid							
28	2	sourcePortId							
30	2	sequenceId							
32	1	control							
33	1	0x00							
34	2	flags							
36	4	reserved							

The type of message is encoded in the messageType and control fields as shown in Table 11-63 :

Table 11-63. PTPv1 message type identification

messageType	control	Message Name	Message
0x01	0x0	SYNC	Event message
0x01	0x1	DELAY_REQ	Event message
0x02	0x2	FOLLOW_UP	General message
0x02	0x3	DELAY_RESP	General message
0x02	0x4	MANAGEMENT	General message
other	other	—	Reserved

The field sequenceId is used to non-ambiguously identify a message.

11.6.2.3.2.2 PTPv2 header

Table 11-64. Common PTPv2 message header

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	1	transportSpecific				messageId			
1	1	reserved				versionPTP = 0x2			
2	2	messageLength							

Table continues on the next page...

Table 11-64. Common PTPv2 message header (continued)

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
4	1	domainNumber							
5	1	reserved							
6	2	flags							
8	8	correctionField							
16	4	reserved							
20	10	sourcePortIdentity							
30	2	sequenceId							
32	1	control							
33	1	logMeanMessageInterval							

The type of message is encoded in the field messageId as follows:

Table 11-65. PTPv2 message type identification

messageId	Message name	Message
0x0	SYNC	Event message
0x1	DELAY_REQ	Event message
0x2	PATH_DELAY_REQ	Event message
0x3	PATH_DELAY_RESP	Event message
0x4–0x7	—	Reserved
0x8	FOLLOW_UP	General message
0x9	DELAY_RESP	General message
0xa	PATH_DELAY_FOLLOW_UP	General message
0xb	ANNOUNCE	General message
0xc	SIGNALING	General message
0xd	MANAGEMENT	General message

The PTPv2 flags field contains further details on the type of message, especially if one-step or two-step implementations are used. The one- or two-step implementation is controlled by the TWO_STEP bit in the first octet of the flags field as shown below. Reserved bits are cleared.

Table 11-66. PTPv2 message flags field definitions

Bit	Name	Description
0	ALTERNATE_MASTER	See IEEE 1588 Clause 17.4
1	TWO_STEP	1 Two-step clock 0 One-step clock
2	UNICAST	1 Transport layer address uses a unicast destination address

Table continues on the next page...

Table 11-66. PTPv2 message flags field definitions (continued)

Bit	Name	Description
		0 Multicast is used
3	—	Reserved
4	—	Reserved
5	Profile specific	
6	Profile specific	
7	—	Reserved

11.6.2.4 MAC receive

The MAC receive engine performs the following tasks:

- Check frame framing
- Remove frame preamble and frame SFD field
- Discard frame based on frame destination address field
- Terminate pause frames
- Check frame length
- Remove payload padding if it exists
- Calculate and verify CRC-32
- Write received frames in the core receive FIFO

If the MAC is programmed to operate in half-duplex mode, it will also check if the frame is received with a collision.

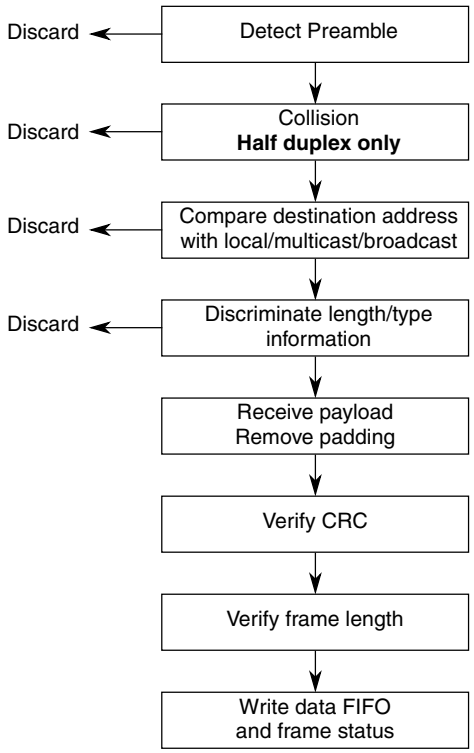

Figure 11-62. MAC receive flow

11.6.2.4.1 Collision detection in half-duplex mode

If the packet is received with a collision detected during reception of the first 64 bytes, the packet is discarded (if frame size was less than ~14 octets) or transmitted to the user application with an error and RxBD[CE] set.

11.6.2.4.2 Preamble processing

The IEEE 802.3 standard allows a maximum size of 56 bits (seven bytes) for the preamble, while the MAC core allows any preamble length, including zero length preamble.

The MAC core checks for the start frame delimiter (SFD) byte. If the next byte of the preamble, which is different from 0x55, is not 0xD5, the frame is discarded.

Although the IEEE specification dictates that the inner-packet gap should be at least 96 bits, the MAC core is designed to accept frames separated by only 64 10/100-Mbit/s operation (MII) bits.

The MAC core removes the preamble and SFD bytes.

11.6.2.4.3 MAC address check

The destination address bit 0 differentiates between multicast and unicast addresses.

- If bit 0 is 0, the MAC address is an individual (unicast) address.
- If bit 0 is 1, the MAC address defines a group (multicast) address.
- If all 48 bits of the MAC address are set, it indicates a broadcast address.

11.6.2.4.3.1 Unicast address check

If a unicast address is received, the destination MAC address is compared to the node MAC address programmed by the host in the PADDR1/2 registers.

If the destination address matches any of the programmed MAC addresses, the frame is accepted.

If Promiscuous mode is enabled (RCR[PROM] = 1) no address checking is performed and all unicast frames are accepted.

11.6.2.4.3.2 Multicast and unicast address resolution

The hash table algorithm used in the group and individual hash filtering operates as follows.

- The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits in ENET*n*_GAUR/GALR (group address hash match) or ENET*n*_IAUR/IALR (individual address hash match).
- This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63.
- The msb of the CRC result selects ENET*n*_GAUR (msb = 1) or ENET*n*_GALR (msb = 0).
- The five lsbs of the hash result select the bit within the selected register.
- If the CRC generator selects a bit set in the hash table, the frame is accepted; else, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (or 87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + 1$

If Promiscuous mode is enabled (ENET*n*_RCR[PROM] = 1) all unicast and multicast frames are accepted regardless of ENET*n*_GAUR/GALR and ENET*n*_IAUR/IALR settings.

11.6.2.4.3.3 Broadcast address reject

All broadcast frames are accepted if BC_REJ is cleared or ENET*n*_RCR[PROM] is set. If PROM is cleared when ENET*n*_RCR[BC_REJ] is set, all broadcast frames are rejected.

Table 11-67. Broadcast address reject programming

PROM	BC_REJ	Broadcast frames
0	0	Accepted
0	1	Rejected
1	0	Accepted
1	1	Accepted

11.6.2.4.3.4 Miss-bit implementation

For higher layer filtering purposes, RxBD[M] indicates an address miss when the MAC operates in promiscuous mode and accepts a frame that would otherwise be rejected.

If a group/individual hash or exact match does not occur and Promiscuous mode is enabled (RCR[PROM] = 1), the frame is accepted and the M bit is set in the buffer descriptor; otherwise, the frame is rejected.

This means the status bit is set in any of the following conditions during Promiscuous mode:

- A broadcast frame is received when BC_REJ is set
- A unicast is received that does not match either:

- Node address (PALR[PADDR1] and PAUR[PADDR2])
- Hash table for unicast (IAUR[IADDR1] and IALR[IADDR2])

- A multicast is received that does not match the GAUR[GADDR1] and GALR[GADDR2] hash table entries

11.6.2.4.4 Frame length/type verification: payload length check

If the length/type is less than 0x600 and NLC is set, the MAC checks the payload length and reports any error in the frame status word RCR[NLC] and interrupt bit EIR[PLR].

If the length/type is greater than or equal to 0x600, the MAC interprets the field as a type and no payload length check is performed.

The length check is performed on VLAN and stacked VLAN frames. If a padded frame is received, no length check can be performed due to the extended frame payload because padded frames can never have a payload length error.

11.6.2.4.5 Frame length/type verification: frame length check

When the receive frame length exceeds MAX_FL bytes, the BABR interrupt is generated and the RxBD[LG] bit is set.

The frame is not truncated unless the frame length exceeds the value programmed in ENET*n*_FTRL[TRUNC_FL]. If the frame is truncated, RxBD[TR] is set. In addition, a truncated frame always has the CRC error indication set (RxBD[CR]).

11.6.2.4.6 VLAN frames processing

VLAN frames have a length/type field set to 0x8100 immediately followed by a 16-Bit VLAN control information field.

VLAN-tagged frames are received as normal frames because the VLAN tag is not interpreted by the MAC function, and are pushed complete with the VLAN tag to the user application. If the length/type field of the VLAN-tagged frame, which is found four octets later in the frame, is less than 42, the padding is removed. In addition, the frame status word (RxBD[VLAN]) indicates that the current frame is VLAN tagged.

11.6.2.4.7 Pause frame termination

The receive engine terminates pause frames and does not transfer them to the receive FIFO. The quanta is extracted and sent to the MAC transmit path via a small internal clock rate decoupling asynchronous FIFO.

The quanta is written only if a correct CRC and frame length are detected by the control state machine. If not, the quanta is discarded and the MAC transmit path is not paused.

Valid pause frames are ignored if ENET*n*_RCR[FCE] is cleared and are forwarded to the client interface when ENET*n*_RCR[PAUFWD] is set.

11.6.2.4.8 CRC check

The CRC-32 field is checked and forwarded to the core FIFO interface if ENET*n*_RCR[CRCFWD] is cleared and ENET*n*_RCR[PADEN] is cleared. When CRCFWD is set (regardless of PADEN), the CRC-32 field is checked and terminated (not transmitted to the FIFO).

The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + 1$

The 32 bits of the CRC value are placed in the frame check sequence (FCS) field with the x^{31} term as right-most bit of the first octet. The CRC bits are thus received in the following order: x^{31}, x^{30},..., x^{1}, x^{0}.

If a CRC error is detected, the frame is marked invalid and RxBD[CR] is set.

11.6.2.4.9 Frame padding removal

When a frame is received with a payload length field set to less than 46 (42 for VLAN-tagged frames and 38 for frames with stacked VLANs), the zero padding can be removed before the frame is written into the data FIFO depending on the setting of ENET*n*_RCR[PADEN].

Note

If a frame is received with excess padding (in other words, the length field is set as mentioned above, but the frame has more than 64 octets) and padding removal is enabled, then the padding is removed as normal and no error is reported if the frame is otherwise correct (for example: good CRC, less than maximum length, and no other error).

11.6.2.4.10 Frame classification (AVB)

To support protocols such as Audio Video Bridging (AVB, IEEE 802.1Qav), normal traffic is separated from time-sensitive traffic immediately at the application interface to allow storing them in different queues for further processing. For every frame received, a

classification based on VLAN priority can be performed. When a frame is received, and it contains a VLAN tag, the priority is compared against the values set in the classification match registers (see RCMR register and the following figure.

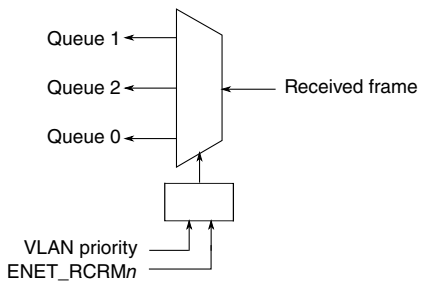

Figure 11-63. AVB frame classification

11.6.2.4.11 Receive flushing

RX flushing prevents frames in the RX FIFO from being blocked. Blocking can occur if the frame at the head of the RX FIFO cannot be forwarded because the ring it is associated with cannot accept it. This situation occurs when either the ring's RxBD[EMPTY] is not set or ENET_RDAR*n* is not set. When RX flushing is enabled, via QOS[RX_FLUSHn], the blocking frame will be flushed (discarded).

11.6.2.5 MAC transmit

Frame transmission starts when the transmit FIFO holds enough data.

After a transfer starts, the MAC transmit function performs the following tasks:

- Generates preamble and SFD field before frame transmission
- Generates XOFF pause frames if the receive FIFO reports a congestion or if ENET*n*_TCR[TFC_PAUSE] is set with ENET*n*_OPD[PAUSE_DUR] set to a non-zero value
- Generates XON pause frames if the receive FIFO congestion condition is cleared or if TFC_PAUSE is set with PAUSE_DUR cleared
- Suspends Ethernet frame transfer (XOFF) if a non-zero pause quanta is received from the MAC receive path
- Adds padding to the frame if required
- Calculates and appends CRC-32 to the transmitted frame
- Sends the frame with correct inter-packet gap (IPG) (deferring)

When the MAC is configured to operate in half-duplex mode, the following additional tasks are performed:

- Collision detection
- Frame retransmit after back-off timer expires

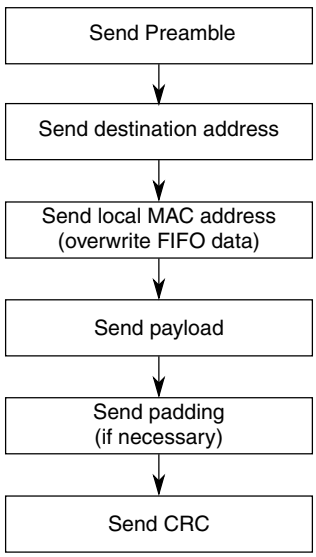

Figure 11-64. Frame transmit overview

11.6.2.5.1 Frame payload padding

The IEEE specification defines a minimum frame length of 64 bytes.

If the frame sent to the MAC from the user application has a size smaller than 60 bytes, the MAC automatically adds padding bytes (0x00) to comply with the Ethernet minimum frame length specification. Transmit padding is always performed and cannot be disabled.

If the MAC is not allowed to append a CRC (TxBD[TC] = 1), the user application is responsible for providing frames with a minimum length of 64 octets.

11.6.2.5.2 MAC address insertion

On each frame received from the core transmit FIFO interface, the source MAC address is either:

- Replaced by the address programmed in the PADDR1/2 fields (ENET*n*_TCR[ADDINS] = 1)
- Transparently forwarded to the Ethernet line (ENET*n*_TCR[ADDINS] = 0)

11.6.2.5.3 CRC-32 generation

The CRC-32 field is optionally generated and appended at the end of a frame.

The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32}+ x^{26}+ x^{23}+ x^{22}+ x^{16}+ x^{12}+ x^{11}+ x^{10}+ x^{8}+ x^{7}+ x^{5}+ x^{4}+ x^{2}+ x^{1}+ 1$

The 32 bits of the CRC value are placed in the FCS field so that the x^{31} term is the right-most bit of the first octet. The CRC bits are thus transmitted in the following order: x^{31}, x^{30},..., x^{1}, x^{0}.

11.6.2.5.4 Inter-packet gap (IPG)

In full-duplex mode, after frame transmission and before transmission of a new frame, an IPG (programmed in ENET*n*_TIPG) is maintained. The minimum IPG can be programmed between 8 and 26 byte-times (64 and 208 bit-times).

In half-duplex mode, the core constantly monitors the line. Actual transmission of the data onto the network occurs only if it has been idle for a 96-bit time period, and any back-off time requirements have been satisfied. In accordance with the standard, the core begins to measure the IPG from CRS/GMII_CRS de-assertion.

11.6.2.5.5 Collision detection and handling — half-duplex operation only

A collision occurs on a half-duplex network when concurrent transmissions from two or more nodes take place. During transmission, the core monitors the line condition and detects a collision when the PHY device asserts COL.

When the core detects a collision while transmitting, it stops transmission of the data and transmits a 32-bit jam pattern. If the collision is detected during the preamble or the SFD transmission, the jam pattern is transmitted after completing the SFD, which results in a minimum 96-bit fragment. The jam pattern is a fixed pattern that is not compared to the actual frame CRC, and has a very low probability (0.532) of having a jam pattern identical to the CRC.

If a collision occurs before transmission of 64 bytes (including preamble and SFD), the MAC core waits for the backoff period and retransmits the packet data (stored in a 64-byte re-transmit buffer) that has already been sent on the line. The backoff period is generated from a pseudo-random process (truncated binary exponential backoff).

If a collision occurs after transmission of 64 bytes (including preamble and SFD), the MAC discards the remainder of the frame, optionally sets the LC interrupt bit, and sets TxBD[LCE].

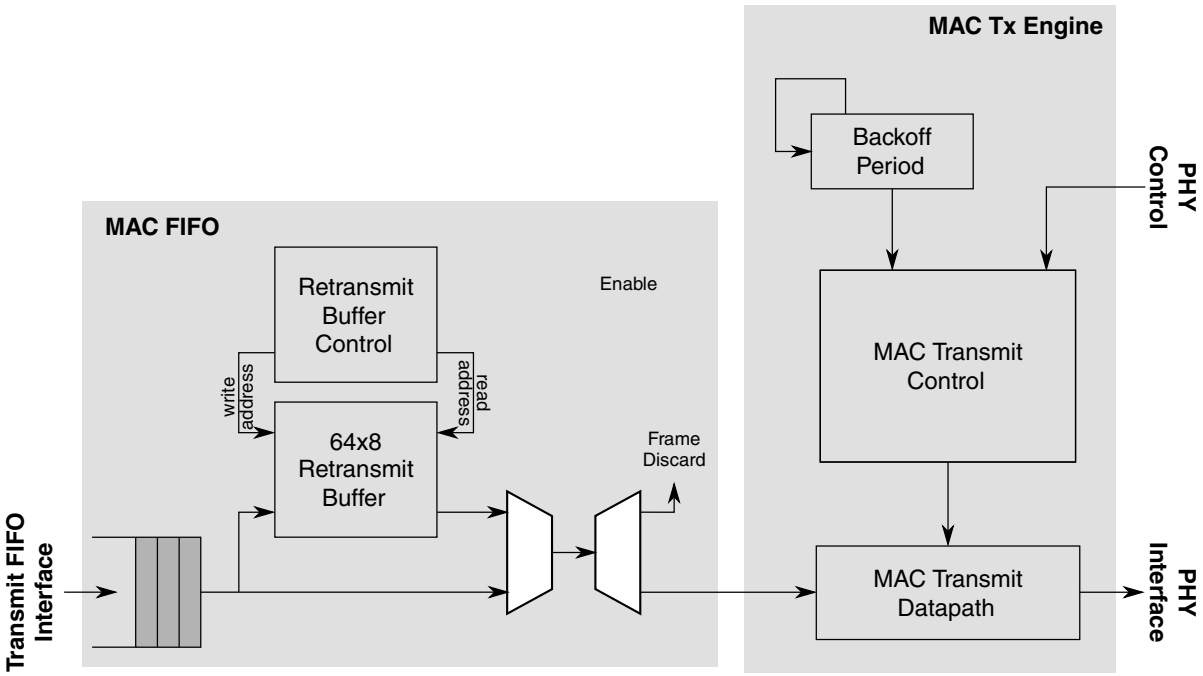

Figure 11-65. Packet re-transmit overview

The backoff time is represented by an integer multiple of slot times. One slot is equal to a 512-bit time period. The number of the delay slot times, before the n^{th} re-transmission attempt, is chosen as a uniformly-distributed random integer in the range:

- $0 < r < 2^k$
- $k = \min(n, N)$; where n is the number of retransmissions and $N = 10$

For example, after the first collision, the backoff period is 0 or 1 slot time. If a collision occurs on the first retransmission, the backoff period is 0, 1, 2, or 3, and so on.

The maximum backoff time (in 512-bit time slots) is limited by N = 10 as specified in the IEEE 802.3 standard.

If a collision occurs after 16 consecutive retransmissions, the core reports an excessive collision condition (ENET*n*_EIR[RL] interrupt field and TxBD[EE]) and discards the current packet from the FIFO.

In networks violating the standard requirements, a collision may occur after transmission of the first 64 bytes. In this case, the core stops the current packet transmission and discards the rest of the packet from the transmit FIFO. The core resumes transmission with the next packet available in the core transmit FIFO.

warning

Ethernet PHYs that support the SQE Test, or "heartbeat,"
feature must disable this feature. When this feature is enabled,

the PHY asserts the collision signal after a frame is transmitted to indicate to the ENET that the PHY's collision logic is working. This may cause data corruption in the next frame from the ENET. This corrupted frame contains up to 21 zero bytes which start somewhere within the MAC destination address field. The ENET, however, will still generate a good FCS (CRC-32) but with corrupted data.

11.6.2.5.6 Rate limiting / traffic shaping support

The MAC-NET supports two methods to optimize frame traffic for either time-sensitive AVB frames (Class A and Class B) or best-effort non-AVB frames:

- Round-robin scheme
- Credit-based traffic shaping

To ensure that sufficient bandwidth is allocated for the AVB frames, the credit-based shaper must be used. Either method can be combined with a time-based shaper to ensure that a frame is always transmitted in its correct time slot.

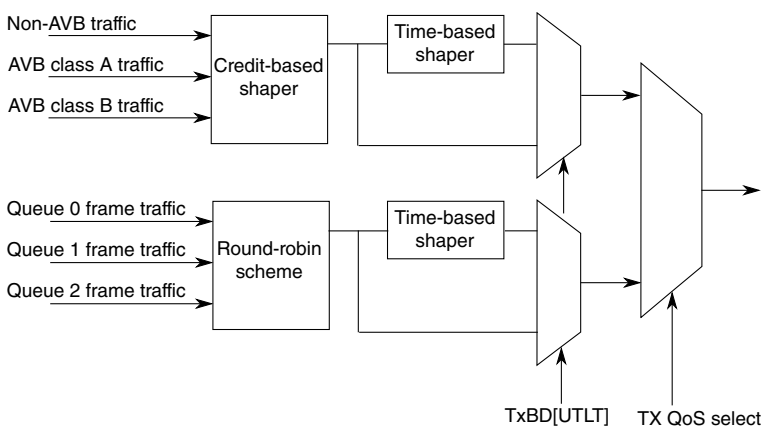

Figure 11-66. Transmit arbitration schemes

11.6.2.5.6.1 Round-robin policy

In the round-robin QoS scheme, each queue is given an equal opportunity to transmit one frame. For example, if queue *n* has a frame to transmit, the queue transmits its frame. After queue *n* has transmitted its frame, or if queue *n* does not have a frame to transmit, queue *n*+1 is then allowed to transmit its frame, and so on.

11.6.2.5.6.2 Credit-based shaper

The AVB credit based shaper acts independently, per class, to control the bandwidth distribution between normal traffic and time-sensitive traffic with respect to the total link bandwidth available. As per the IEEE 802.1Q, the maximum bandwidth distribution that can be allocated for the time-sensitive frames is 75%. The following example uses 70% for AVB frames and 30% for non-AVB frames:

Table 11-68. Bandwidth allocation example

AVB Class A	50%
AVB Class B	20%
non-AVB frames	30%
Total	100%

See DMACFG register for information on how to allocate bandwidth. The following figure shows how frame traffic is controlled within the MAC-NET core.

11.6.2.5.6.3 Time-based shaper

The time-based shaper enables the user to specify when a frame can be transmitted. It is always used in combination with either the round-robin scheme or the credit-based shaper. Use of the time-based shaper can ensure that frames are always transmitted in the correct time slot.

11.6.2.5.6.3.1 Time-based shaper example

Time-based shaping involves the following procedure:

1. Read the current value of the timer. See ATVR register and ATCR register.
2. Calculate the frame launch time and write this value to the TLT field of the frame's TxBD. See Enhanced transmit buffer descriptor.
3. Instruct the ENET to use the TLT by setting TxBD[UTLT].

The frame will be fetched and transmitted only if TxBD[TLT] is less than the current value of the timer. In other words, the timer must be past, that is, be greater than, the transmit launch time before the frame will be fetched and transmitted.

The transmit launch time must be not be greater than the current value of ENET_ATVR + (0.5 × ENET_ATPER). This means the application can not prepare frames with launch times beyond ENET_ATVR + (0.5 × ENET_ATPER). Because ENET_ATVR wraps, calculate TLT using the equation

$$(ENET_ATVR + (0.5 \times ENET_ATPER)) \bmod ENET_ATPER$$

For example, if ENET_ATPER is set to the recommended value of 1,000,000,000 ns (one second), then the user must not prepare future frames with launch times greater than (500,000,000 + ENET_ATVR).

As a specific example, if the current value of ENET_ATVR is 100,000, then you can prepare the following frames:

1. Frame 1 TxBD[TLT] = 100,000ns + 125,000ns
2. Frame 2 TxBD[TLT] = 100,000ns + 250,000ns
3. And so on

11.6.2.6 Full-duplex flow control operation

Three conditions are handled by the core's flow control engine:

- Remote device congestion — The remote device connected to the same Ethernet segment as the core reports congestion and requests that the core stop sending data.
- Core FIFO congestion — When the core's receive FIFO reaches a user-programmable threshold (RX section empty), the core sends a pause frame back to the remote device requesting the data transfer to stop.
- Local device congestion — Any device connected to the core can request (typically, via the host processor) the remote device to stop transmitting data.

11.6.2.6.1 Remote device congestion

When the MAC transmit control gets a valid pause quanta from the receive path and if ENET*n*_RCR[FCE] is set, the MAC transmit logic:

- Completes the transfer of the current frame.
- Stops sending data for the amount of time specified by the pause quanta in 512 bit time increments.
- Sets ENET*n*_TCR[RFC_PAUSE].

Frame transfer resumes when the time specified by the quanta expires and if no new quanta value is received, or if a new pause frame with a quanta value set to 0x0000 is received. The MAC also resets RFC_PAUSE to zero.

If ENET*n*_RCR[FCE] cleared, the MAC ignores received pause frames.

Optionally and independent of ENET*n*_RCR[FCE], pause frames are forwarded to the client interface if PAUFWD is set.

11.6.2.6.2 Local device/FIFO congestion

The MAC transmit engine generates pause frames when the local receive FIFO is not able to receive more than a pre-defined number of words (FIFO programmable threshold) or when pause frame generation is requested by the local host processor.

- To generate a pause frame, the host processor sets ENET*n*_TCR[TFC_PAUSE]. A single pause frame is generated when the current frame transfer is completed and TFC_PAUSE is automatically cleared. Optionally, an interrupt is generated.
- An XOFF pause frame is generated when the receive FIFO asserts its section empty flag (internal). An XOFF pause frame is generated automatically, when the current frame transfer completes.
- An XON pause frame is generated when the receive FIFO deasserts its section empty flag (internal). An XON pause frame is generated automatically, when the current frame transfer completes.

When an XOFF pause frame is generated, the pause quanta (payload byte P1 and P2) is filled with the value programmed in ENET*n*_OPD[PAUSE_DUR].

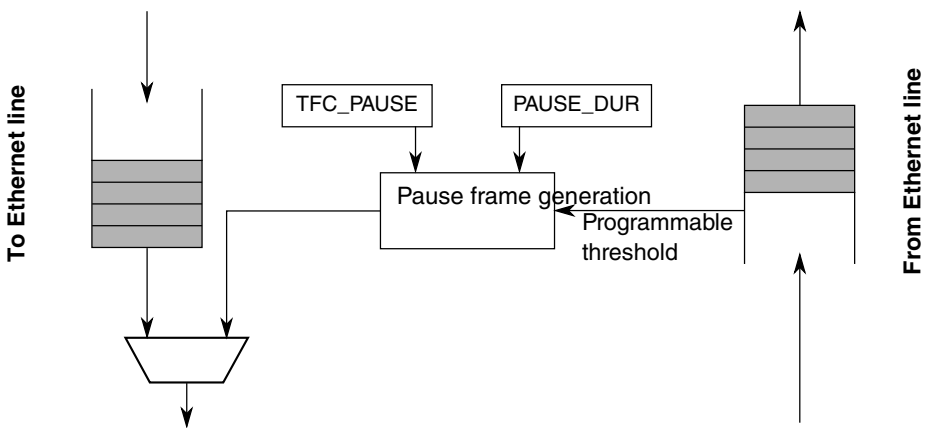

Figure 11-67. Pause frame generation overview

Note

Although the flow control mechanism should prevent any FIFO overflow on the MAC core receive path, the core receive FIFO is protected. When an overflow is detected on the receive FIFO, the current frame is truncated with an error indication set in the frame status word. The frame should subsequently be discarded by the user application.

11.6.2.7 Magic packet detection

Magic packet detection wakes a node that is put in power-down mode by the node management agent. Magic packet detection is supported only if the MAC is configured in sleep mode.

11.6.2.7.1 Sleep mode

To put the MAC in Sleep mode, set ENET*n*_ECR[SLEEP]. At the same time ENET*n*_ECR[MAGICEN] should also be set to enable magic packet detection.

In addition, if ENET is enabled, write 1 to ENET*n*_ECR[SLEEP] before entering into low power mode.

When the MAC is in Sleep mode:

- The transmit logic is disabled.
- The FIFO receive/transmit functions are disabled.
- The receive logic is kept in Normal mode, but it ignores all traffic from the line except magic packets. They are detected so that a remote agent can wake the node.

11.6.2.7.2 Magic packet detection

The core is designed to detect magic packets (See "Magic Packets" topics) with the destination address set to:

- Any multicast address
- The broadcast address
- The unicast address programmed in PADDR1/2

When a magic packet is detected, EIR[WAKEUP] is set and none of the statistic registers are incremented.

11.6.2.7.3 Wakeup

When a magic packet is detected, indicated by ENET*n*_EIR[WAKEUP], ENET*n*_ECR[SLEEP] should be cleared to resume normal operation of the MAC. Clearing the SLEEP bit automatically masks ENET*n*_ECR[MAGICEN], disabling magic packet detection.

11.6.2.8 IP accelerator functions

The following sections describe the IP accelerator functions.

11.6.2.8.1 Checksum calculation

The IP and ICMP, TCP, UDP checksums are calculated with one's complement arithmetic summing up 16-bit values.

- For ICMP, the checksum is calculated over the complete ICMP datagram, in other words without IP header.
- For TCP and UDP, the checksums contain the header and data sections and values from the IP header, which can be seen as a pseudo-header that is not actually present in the data stream.

Table 11-69. IPv4 pseudo-header for checksum calculation

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source address							
Destination address							
Zero		Protocol		TCP/UDP length			

Table 11-70. IPv6 pseudo-header for checksum calculation

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source address							
Destination address							
TCP/UDP length							
Zero						Next header	

The TCP/UDP length value is the length of the TCP or UDP datagram, which is equal to the payload of an IP datagram. It is derived by subtracting the IP header length from the complete IP datagram length that is given in the IP header (IPv4), or directly taken from the IP header (IPv6). The protocol field is the corresponding value from the IP header. The Zero fields are all zeroes.

For IPv6, the complete 128-bit addresses are considered. The next header value identifies the upper layer protocol as either TCP or UDP. It may differ from the next header value of the IPv6 header if extension headers are inserted before the protocol header.

The checksum calculation uses 16-bit words in network byte order: The first byte sent/received is the MSB, and the second byte sent/received is the LSB of the 16-bit value to add to the checksum. If the frame ends on an odd number of bytes, a zero byte is appended for checksum calculation only, and is not actually transmitted.

11.6.2.8.2 Additional padding processing

According to IEEE 802.3, any Ethernet frame must have a minimum length of 64 octets.

The MAC usually removes padding on receive when a frame with length information is received. Because IP frames have a type value instead of length, the MAC does not remove padding for short IP frames, as it is not aware of the frame contents.

The IP accelerator function can be configured to remove the Ethernet padding bytes that might follow the IP datagram.

On transmit, the MAC automatically adds padding as necessary to fill any frame to a 64-byte length.

11.6.2.8.3 32-bit Ethernet payload alignment

The data FIFOs allow inserting two additional arbitrary bytes in front of a frame. This extends the 14-byte Ethernet header to a 16-byte header, which leads to alignment of the Ethernet payload, following the Ethernet header, on a 32-bit boundary.

This function can be enabled for transmit and receive independently with the corresponding SHIFT16 bits in the ENET*n*_TACC and ENET*n*_RACC registers.

When enabled, the valid frame data is arranged as shown in Table 11-71.

Table 11-71. 64-bit interface data structure with SHIFT16 enabled

63 56	55 48	47 40	39 32	31 24	23 16	15 8	7 0
Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0	Any value	Any value
Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8	Byte 7	Byte 6
...							

11.6.2.8.3.1 Receive processing

When ENET*n*_RACC[SHIFT16] is set, each frame is received with two additional bytes in front of the frame.

The user application must ignore these first two bytes and find the first byte of the frame in bits 23–16 of the first word from the RX FIFO.

Note

SHIFT16 must be set during initialization and kept set during the complete operation, because it influences the FIFO write behavior.

11.6.2.8.3.2 Transmit processing

When ENET*n*_TACC[SHIFT16] is set, the first two bytes of the first word written (bits 15–0) are discarded immediately by the FIFO write logic.

The SHIFT16 bit can be enabled/disabled for each frame individually if required, but can be changed only between frames.

11.6.2.8.4 Received frame discard

Because the receive FIFO must be operated in store and forward mode (ENET*n*_RSFL cleared), received frames can be discarded based on the following errors:

- The MAC function receives the frame with an error:
  - The frame has an invalid payload length
  - Frame length is greater than MAX_FL
  - Frame received with a CRC-32 error
  - Frame truncated due to receive FIFO overflow
  - Frame is corrupted as PHY signaled an error (RX_ERR asserted during reception)
- An IP frame is detected and the IP header checksum is wrong
- An IP frame with a valid IP header and a valid IP header checksum is detected, the protocol is known but the protocol-specific checksum is wrong

If one of the errors occurs and the IP accelerator function is configured to discard frames (ENET*n*_RACC), the frame is automatically discarded. Statistics are maintained normally and are not affected by this discard function.

11.6.2.8.5 IPv4 fragments

When an IPv4 IP fragment frame is received, only the IP header is inspected and its checksum verified. 32-bit alignment operates the same way on fragments as it does on normal IP frames, as specified above.

The IP fragment frame payload is not inspected for any protocol headers. As such, a protocol header would only exist in the very first fragment. To assist in protocol-specific checksum verification, the one's-complement sum is calculated on the IP payload (all bytes following the IP header) and provided with the frame status word.

The frame fragment status field (RxBD[FRAG]) is set to indicate a fragment reception, and the one's-complement sum of the IP payload is available in RxBD[Payload checksum].

Note

After all fragments have been received and reassembled, the application software can take advantage of the payload checksum delivered with the frame's status word to calculate the protocol-specific checksum of the datagram.

For example, if a TCP payload is delivered by multiple IP fragments, the application software can calculate the pseudo-header checksum value from the first fragment, and add the payload checksums delivered with the status for all fragments to verify the TCP datagram checksum.

11.6.2.8.6 IPv6 support

The following sections describe the IPv6 support.

11.6.2.8.6.1 Receive processing

An Ethernet frame of type 0x86DD identifies an IP Version 6 frame (IPv6) frame. If an IPv6 frame is received, the first IP header is inspected (first ten words), which is available in every IPv6 frame.

If the receive SHIFT16 function is enabled, the IP header is aligned on a 32-bit boundary allowing more efficient processing (see 32-bit Ethernet payload alignment).

For TCP and UDP datagrams, the pseudo-header checksum calculation is performed and verified.

To assist in protocol-specific checksum verification, the one's-complement sum is always calculated on the IP payload (all bytes following the IP header) and provided with the frame status word. For example, if extension headers were present, their sums can be subtracted in software from the checksum to isolate the TCP/UDP datagram checksum, if required.

11.6.2.8.6.2 Transmit processing

For IPv6 transmission, the SHIFT16 function is supported to process 32-bit aligned datagrams.

IPv6 has no IP header checksum; therefore, the IP checksum insertion configuration is ignored.

The protocol checksum is inserted only if the next header of the IP header is a known protocol (TCP, UDP, or ICMP). If a known protocol is detected, the checksum over all bytes following the IP header is calculated and inserted in the correct position.

The pseudo-header checksum calculation is performed for TCP and UDP datagrams accordingly.

11.6.2.9 Resets and stop controls

The following sections describe the resets and stop controls.

11.6.2.9.1 Hardware reset

To reset the Ethernet module, set ENET*n*_ECR[RESET].

11.6.2.9.2 Soft reset

When ENET*n*_ECR[ETHER_EN] is cleared during operation, the following occurs:

- uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers.
- A currently ongoing transmit is terminated by asserting GMII/TXER to the PHY.
- A currently ongoing transmit FIFO write from the application is terminated by stopping the write to the FIFO, and all further data from the application is ignored. All subsequent writes are ignored until re-enabled.
- A currently ongoing receive FIFO read is terminated. The RxBD has arbitrary values in this case.

11.6.2.9.3 Hardware freeze

When the processor enters debug mode and ECR[DBGEN] is set, the MAC enters a freeze state where it stops all transmit and receive activities gracefully.

The following happens when the MAC enters hardware freeze:

- A currently ongoing receive transaction on the receive application interface is completed as normal. No further frames are read from the FIFO.
- A currently ongoing transmit transaction on the transmit application interface is completed as normal (in other words, until writing end-of-packet (EOP)).
- A currently ongoing frame receive is completed normally, after which no further frames are accepted from the RMII/GMII.
- A currently ongoing frame transmit is completed normally, after which no further frames are transmitted.

11.6.2.9.4 Graceful stop

During a graceful stop, any currently ongoing transactions are completed normally and no further frames are accepted. The MAC can resume from a graceful stop without the need for a reset (for example, clearing ETHER_EN is not required).

The following conditions lead to a graceful stop of the MAC transmit or receive datapaths.

11.6.2.9.4.1 Graceful transmit stop (GTS)

When gracefully stopped, the MAC is no longer reading frame data from the transmit FIFO and has completed any ongoing transmission.

In any of the following conditions, the transmit datapath stops after an ongoing frame transmission has been completed normally.

- ENET*n*_TCR[GTS] is set by software.
- ENET*n*_TCR[TFC_PAUSE] is set by software requesting a pause frame transmission. The status (and register bit) is cleared after the pause frame has been sent.
- A pause frame was received stopping the transmitter. The stopped situation is terminated when the pause timer expires or a pause frame with zero quanta is received.

- MAC is placed in Sleep mode by software or the processor entering Stop mode (see Sleep mode).
- The MAC is in Hardware Freeze mode.

When the transmitter has reached its stopped state, the following events occur:

- The GRA interrupt is asserted, when transitioned into stopped state.
- In Hardware Freeze mode, the GRA interrupt does not wait for the application write completion and asserts when the transmit state machine (in other words, line side of TX FIFO) reaches its stopped state.

11.6.2.9.4.2 Graceful receive stop (GRS)

When gracefully stopped, the MAC is no longer writing frames into the receive FIFO.

The receive datapath stops after any ongoing frame reception has been completed normally, if any of the following conditions occur:

- MAC is placed in Sleep mode either by the software or the processor is in Stop mode). The MAC continues to receive frames and search for magic packets if enabled (see Magic packet detection). However, no frames are written into the receive FIFO, and therefore are not forwarded to the application.
- The MAC is in Hardware Freeze mode. The MAC does not accept any frames from the RMII/GMII.

When the receive datapath is stopped, the following events occur:

- If the RX is in the stopped state, RCR[GRS] is set
- The GRA interrupt is asserted when the transmitter and receiver are stopped
- Any ongoing receive transaction to the application (RX FIFO read) continues normally until the frame end of package (EOP) is reached. After this, the following occurs:
  - When Sleep mode is active, all further frames are discarded, flushing the RX FIFO
  - In Hardware Freeze mode, no further frames are delivered to the application and they stay in the receive FIFO.

Note

The assertion of GRS does not wait for an ongoing FIFO read transaction on the application side of the FIFO (FIFO read).

11.6.2.9.4.3 Graceful stop interrupt (GRA)

The graceful stopped interrupt (GRA) is asserted for the following conditions:

- In Sleep mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- In Hardware Freeze mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- The MAC transmit datapath is stopped for any other condition (GTS, TFC_PAUSE, pause received).

The GRA interrupt is triggered only once when the stopped state is entered. If the interrupt is cleared while the stop condition persists, no further interrupt is triggered.

11.6.2.10 IEEE 1588 functions

To allow for IEEE 1588 or similar time synchronization protocol implementations, the MAC is combined with a time-stamping module to support precise time-stamping of incoming and outgoing frames. Set ENET*n*_ECR[EN1588] to enable 1588 support.

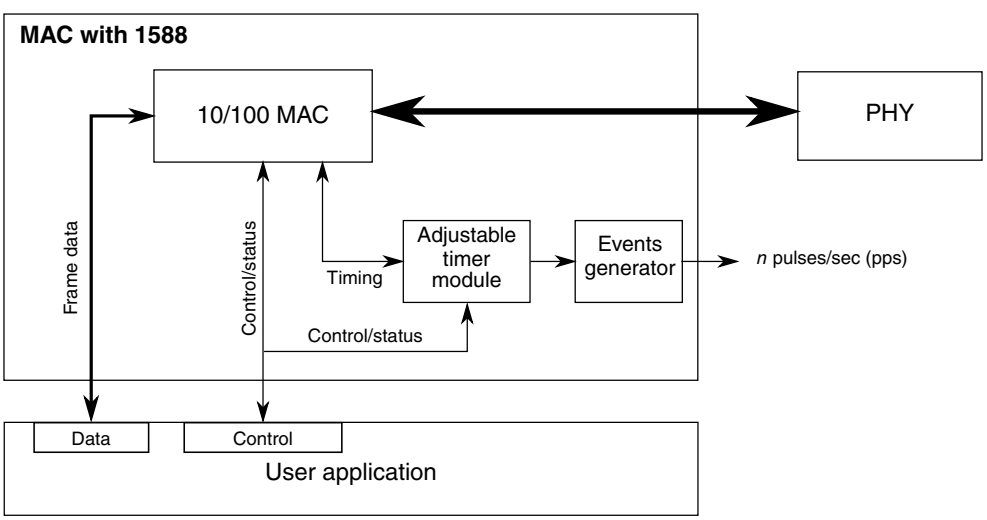

Figure 11-68. IEEE 1588 functions overview

11.6.2.10.1 Adjustable timer module

The adjustable timer module (TSM) implements the free-running counter (FRC), which generates the timestamps. The FRC operates with the time-stamping clock, which can be set to any value depending on your system requirements.

Through dedicated correction logic, the timer can be adjusted to allow synchronization to a remote master and provide a synchronized timing reference to the local system. The timer can be configured to cause an interrupt after a fixed time period, to allow synchronization of software timers or perform other synchronized system functions.

The timer is typically used to implement a period of one second; hence, its value ranges from 0 to (1×10^9)-1. The period event can trigger an interrupt, and software can maintain the seconds and hours time values as necessary.

11.6.2.10.1.1 Adjustable timer implementation

The adjustable timer consists of a programmable counter/accumulator and a correction counter. The periods of both counters and their increment rates are freely configurable, allowing very fine tuning of the timer.

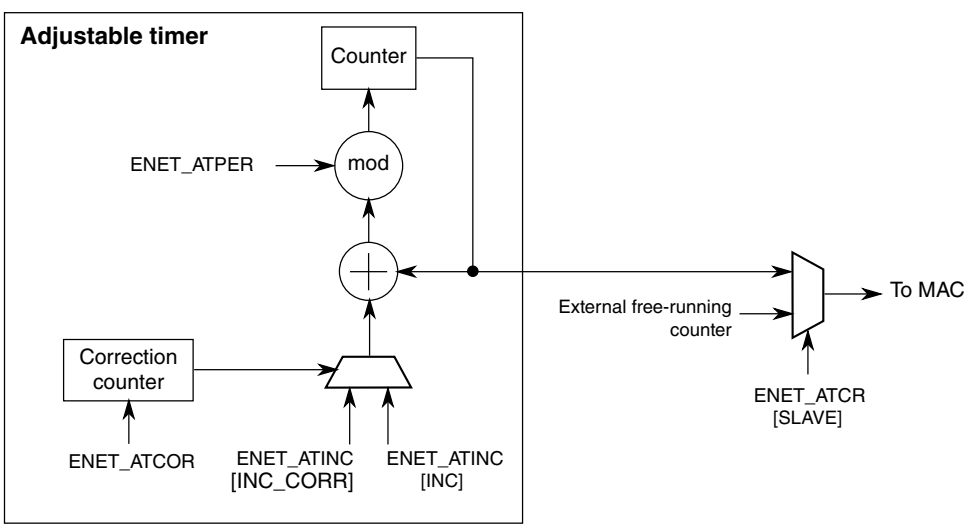

Figure 11-69. Adjustable timer implementation detail

The counter produces the current time. During each time-stamping clock cycle, a constant value is added to the current time as programmed in ENET*n*_ATINC. The value depends on the chosen time-stamping clock frequency. For example, if it operates at 125 MHz, setting the increment to eight represents 8 ns.

The period, configured in ENET*n*_ATPER, defines the modulo when the counter wraps. In a typical implementation, the period is set to 1×10^9 so that the counter wraps every second, and hence all timestamps represent the absolute nanoseconds within the one

second period. When the period is reached, the counter wraps to start again respecting the period modulo. This means it does not necessarily start from zero, but instead the counter is loaded with the value (Current + Inc –(1×10^9)), assuming the period is set to 1×10^9.

The correction counter operates fully independently, and increments by one with each time-stamping clock cycle. When it reaches the value configured in ENET*n*_ATCOR, it restarts and instructs the timer once to increment by the correction value, instead of the normal value.

The normal and correction increments are configured in ENET*n*_ATINC. To speed up the timer, set the correction increment more than the normal increment value. To slow down the timer, set the correction increment less than the normal increment value.

The correction counter only defines the distance of the corrective actions, not the amount. This allows very fine corrections and low jitter (in the range of 1 ns) independent of the chosen clock frequency.

By enabling slave mode (ENET*n*_ATCR[SLAVE] = 1), the timer is ignored and the current time is externally provided from one of the external modules. See the Chip Configuration details for which clock source is used. This is useful if multiple modules within the system must operate from a single timer. When slave mode is enabled, you still must set ENET*n*_ATINC[INC] to the value of the master, since it is used for internal comparisons.

11.6.2.10.2 Transmit timestamping

Only 1588 event frames need to be time-stamped on transmit. The client application (for example, the MAC driver) should detect 1588 event frames and set TxBD[TS] together with the frame.

If TxBD[TS] is set, the MAC records the timestamp for the frame in ENET*n*_ATSTMP. ENET*n*_EIR[TS_AVAIL] is set to indicate that a new timestamp is available.

Software implements a handshaking procedure by setting TxBD[TS] when it transmits the frame for which a timestamp is needed, and then waits for ENET*n*_EIR[TS_AVAIL] to determine when the timestamp is available. The timestamp is then read from ENET*n*_ATSTMP. This is done for all event frames. Other frames do not use TxBD[TS] and, therefore, do not interfere with the timestamp capture.

11.6.2.10.3 Receive timestamping

When a frame is received, the MAC latches the value of the timer when the frame's start of frame delimiter (SFD) field is detected, and provides the captured timestamp on RxBD[1588 timestamp]. This is done for all received frames.

11.6.2.10.4 Time synchronization

The adjustable timer module is available to synchronize the local clock of a node to a remote master. It implements a free running 32-bit counter, and also contains an additional correction counter.

The correction counter increases or decreases the rate of the free running counter, enabling very fine granular changes of the timer for synchronization, yet adding only very low jitter when performing corrections.

The application software implements, in a slave scenario, the required control algorithm, setting the correction to compensate for local oscillator drifts and locking the timer to the remote master clock on the network.

The timer and all timestamp-related information should be configured to show the true nanoseconds value of a second (in other words, the timer is configured to have a period of one second). Hence, the values range from 0 to (1×10^9)–1. In this application, the seconds counter is implemented in software using an interrupt function that is executed when the nanoseconds counter wraps at 1×10^9.

11.6.2.10.5 Input Capture and Output Compare

The Input Capture Output Compare block can be used to provide precise hardware timing for input and output events.

11.6.2.10.5.1 Input capture

The TCCR*n* capture registers latch the time value when the corresponding external event occurs. An event can be a rising-, falling-, or either-edge of one of the 1588_TMR*n* signals. An event will cause the corresponding TCSR*n*[TF] timer flag to be set, indicating that an input capture has occurred. If the corresponding interrupt is enabled with the TCSR*n*[TIE] field, an interrupt can be generated.

11.6.2.10.5.2 Output compare

The TCCR*n* compare registers are loaded with the time at which the corresponding event should occur. When the ENET free-running counter value matches the output compare reference value in the TCCR*n* register, the corresponding flag, TCSR*n*[TF], is set, indicating that an output compare has occurred. The corresponding interrupt, if enabled by TCSR*n*[TIE], will be generated.The corresponding 1588_TMR*n* output signal will be asserted according to TCSR*n*[TMODE].

NOTE

If TSCR*n*[TMODE] is set to 10X1b or 1010b then the timer output pin toggle-on-overflow will occur only when PINPER, PEREN, and EN bits of the ATCR register are one.

11.6.2.10.5.3 DMA requests

A DMA request can be enabled by setting TCSR*n*[TDRE]. The corresponding DMA request is generated when the TCSR*n*[TF] timer flag is set. When the DMA has completed, the corresponding TCSRn[TF] flag is cleared.

11.6.2.11 FIFO thresholds

The core FIFO thresholds are fully programmable to dynamically change the FIFO operation.

For example, store and forward transfer can be enabled by a simple change in the FIFO threshold registers.

The thresholds are defined in 64-bit words.

The receive and transmit FIFOs both have a depth of 1024 words.

11.6.2.11.1 Receive FIFO

Four programmable thresholds are available, which can be set to any value to control the core operation as follows.

Table 11-72. Receive FIFO thresholds definition

Register	Description
ENET*n*_RSFL [RX_SECTION_FULL]	When the FIFO level reaches the ENET*n*_RSFL value, the MAC status signal is asserted to indicate that data is available in the receive FIFO (cut-through operation). Once asserted, if the FIFO empties below the threshold set with ENET*n*_RAEM and if the end-of-frame is not yet stored in the FIFO, the status signal is deasserted again. If a frame has a size smaller than the threshold (in other words, an end-of-frame is available for the frame), the status is also asserted. To enable store and forward on the receive path, clear ENET*n*_RSFL. The MAC status signal is asserted only when a complete frame is stored in the receive FIFO. When programming a non-zero value to ENET*n*_RSFL (cut-through operation) it should be greater than ENET*n*_RAEM.
ENET*n*_RAEM [RX_ALMOST_EMPTY]	When the FIFO level reaches the ENET*n*_RAEM value, and the end-of-frame has not been received, the core receive read control stops the FIFO read (and subsequently stops transferring data to the MAC client application).

Table continues on the next page...

Table 11-72. Receive FIFO thresholds definition (continued)

Register	Description
	It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO. Set ENET*n*_RAEM to a minimum of six.
ENET*n*_RAFL [RX_ALMOST_FULL]	When the FIFO level approaches the maximum and there is no more space remaining for at least ENETn_RAFL number of words, the MAC control logic stops writing data in the FIFO and truncates the receive frame to avoid FIFO overflow. The corresponding error status is set when the frame is delivered to the application. Set ENET*n*_RAFL to a minimum of 4.
ENET*n*_RSEM [RX_SECTION_EMPTY]	When the FIFO level reaches the ENET*n*_RSEM value, an indication is sent to the MAC transmit logic, which generates an XOFF pause frame. This indicates FIFO congestion to the remote Ethernet client. When the FIFO level goes below the value programmed in ENET*n*_RSEM, an indication is sent to the MAC transmit logic, which generates an XON pause frame. This indicates the FIFO congestion is cleared to the remote Ethernet client. Clearing ENET*n*_RSEM disables any pause frame generation.

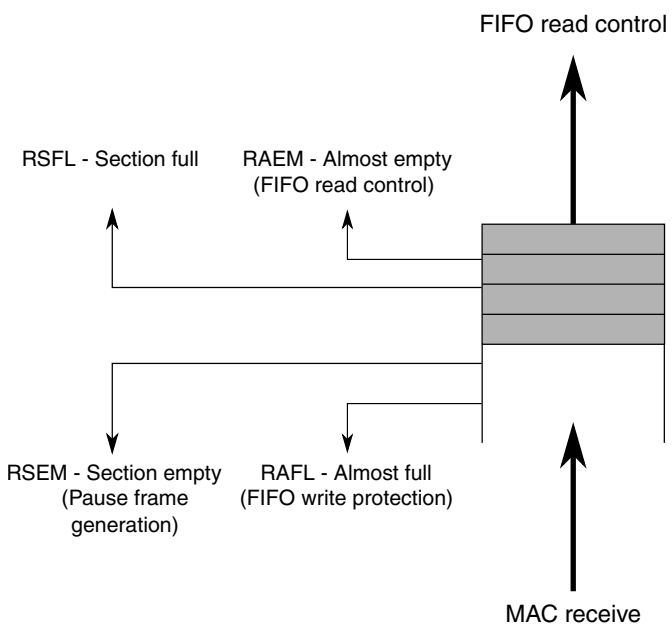

Figure 11-70. Receive FIFO overview

11.6.2.11.2 Transmit FIFO

Four programmable thresholds are available which control the core operation as described below.

Table 11-73. Transmit FIFO thresholds definition

Register	Description
ENET*n*_TAEM [TX_ALMOST _EMPTY]	When the FIFO level reaches the ENET*n*_TAEM value and no end-of-frame is available for the frame, the MAC transmit logic avoids a FIFO underflow by stopping FIFO reads and transmitting the Ethernet frame with an MII error indication. Set ENET*n*_TAEM to a minimum of 4.
ENET*n*_TAFL [TX_ALMOST _FULL]	When the FIFO level approaches the maximum, so that there is no more space for at least ENET*n*_TAFL number of words, the MAC deasserts its control signal to the application. If the application does not react on this signal, the FIFO write control logic avoids FIFO overflow by truncating the current frame and setting the error status. As a result, the frame is transmitted with an GMII/MII error indication. Set ENET*n*_TAFL to a minimum of 4. Larger values allow more latency for the application to react on the MAC control signal deassertion, before the frame is truncated. A typical setting is 8, which offers 3–4 clock cycles of latency to the application to react on the MAC control signal deassertion.
ENET*n*_TSEM [TX_SECTION _EMPTY]	When the FIFO level reaches the ENET*n*_TSEM value, a MAC status signal is deasserted to indicate that the transmit FIFO is getting full. This gives the ENET module an indication to slow or stop its write transaction to avoid a buffer overflow. This is a pure indication function to the application. It has no effect within the MAC. When ENET*n*_TSEM is 0, the signal is never deasserted.
ENET*n*_TFWR	When the FIFO level reaches the ENET*n*_TFWR value and when STRFWD is cleared, the MAC transmit control logic starts frame transmission before the end-of-frame is available in the FIFO (cut-through operation). If a complete frame has a size smaller than the ENET*n*_TFWR threshold, the MAC also transmits the frame to the line. To enable store and forward on the transmit path, set STRFWD. In this case, the MAC starts to transmit data only when a complete frame is stored in the transmit FIFO.

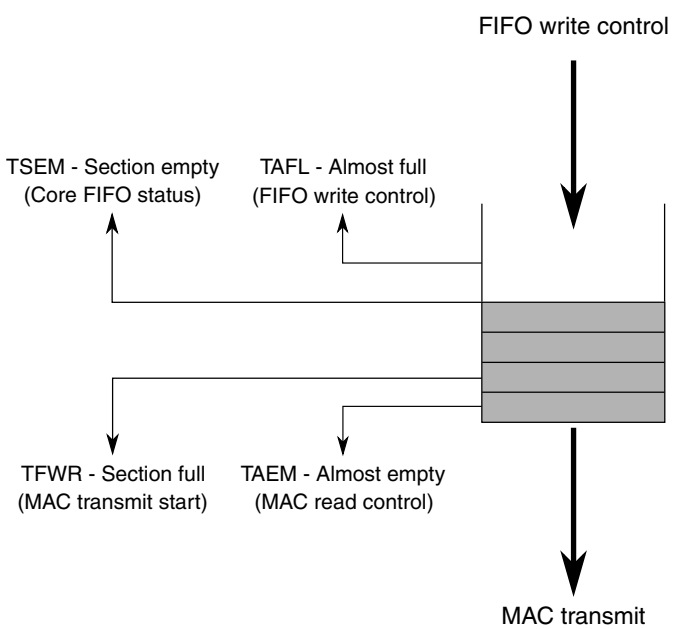

Figure 11-71. Transmit FIFO overview

11.6.2.12 Loopback options

The core implements internal loopback options, which are controlled by the following ENET*n*_RCR register fields:

Table 11-74. Loopback options

Register field	Description
LOOP	Internal MII loopback. The MAC transmit is returned to the MAC receive. No data is transmitted to the external interfaces.

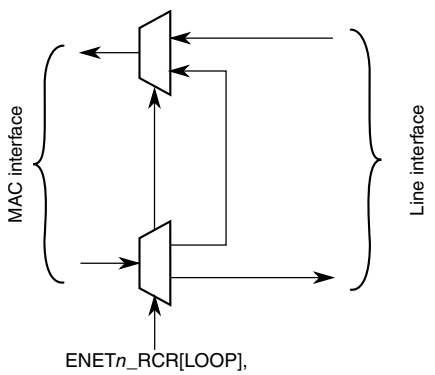

Figure 11-72. Loopback options

11.6.2.13 Legacy buffer descriptors

To support the Ethernet controller on previous chips, legacy FEC buffer descriptors are available. To enable legacy support, write 0 to ENET*n*_ECR[1588EN].

NOTE

- Legacy buffer descriptors are used in single-ring mode, that is, when DMA*n*CFG[DMA_CLASS_EN] are zero. In multi-ring mode, legacy TxBDs are used only with the round-robin scheme.
- The legacy buffer descriptor tables show the byte order for big-endian chips. ECR[DBSWP] must be set to 0 after reset to enable big-endian mode.

11.6.2.13.1 Legacy receive buffer descriptor

The following table shows the legacy FEC receive buffer descriptor. Table 11-78 contains the descriptions for each field.

Table 11-75. Legacy FEC receive buffer descriptor (RxBD)

	Byte 0								Byte 1							
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Offset + 0	E	RO1	W	RO2	L	—	—	M	BC	MC	LG	NO	—	CR	OV	TR
Offset + 2	Data length															
Offset + 4	Rx data buffer pointer — high halfword															
Offset + 6	Rx data buffer pointer — low halfword															

11.6.2.13.2 Legacy transmit buffer descriptor

The following table shows the legacy FEC transmit buffer descriptor. Table 11-80 contains the descriptions for each field.

Table 11-76. Legacy FEC transmit buffer descriptor (TxBD)

	Byte 0								Byte 1							
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Offset + 2	Data Length															
Offset + 4	Tx Data Buffer Pointer — high halfword															
Offset + 6	Tx Data Buffer Pointer — low halfword															

1. This field is not supported by the uDMA.

11.6.2.14 Enhanced buffer descriptors

This section provides a description of the enhanced operation of the driver/uDMA via the buffer descriptors.

It is followed by a detailed description of the receive and transmit descriptor fields. To enable the enhanced features, set ENET*n*_ECR[1588EN].

NOTE

The enhanced buffer descriptor tables show the byte order for big-endian chips. ECR[DBSWP] must be set to 0 after reset to enable big-endian mode.

11.6.2.14.1 Enhanced receive buffer descriptor

The following table shows the enhanced uDMA receive buffer descriptor. Table 11-78 contains the descriptions for each field.

Table 11-77. Enhanced uDMA receive buffer descriptor (RxBD)

	Byte 0								Byte 1							
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 11-78. Receive buffer descriptor field definitions

Word	Field	Description
Offset + 0	15 E	Empty. Written by the MAC (= 0) and user (= 1). 0 The data buffer associated with this BD is filled with received data, or data reception has aborted due to an error condition. The status and length fields have been updated as required. 1 The data buffer associated with this BD is empty, or reception is currently in progress.
Offset + 0	14 RO1	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 0	13 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location. 1 The next buffer descriptor is found at the location defined in ENET*n*_RDSR.
Offset + 0	12 RO2	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 0	11 L	Last in frame. Written by the uDMA. 0 The buffer is not the last in a frame.

Table continues on the next page...

Table 11-78. Receive buffer descriptor field definitions (continued)

Word	Field	Description
		1 The buffer is the last in a frame.
Offset + 0	10–9	Reserved, must be cleared.
Offset + 0	8 M	Miss. Written by the MAC. This field is set by the MAC for frames accepted in promiscuous mode, but flagged as a miss by the internal address recognition. Therefore, while in promiscuous mode, you can use this field to quickly determine whether the frame was destined to this station. This field is valid only if the L and PROM fields are set to 1. 0 The frame was received because of an address recognition hit. 1 The frame was received because of promiscuous mode. The information needed for this field comes from the promiscuous_miss(ff_rx_err_stat[26]) sideband signal.
Offset + 0	7 BC	Set if the DA is broadcast (FFFF_FFFF_FFFF).
Offset + 0	6 MC	Set if the DA is multicast and not BC.
Offset + 0	5 LG	Receive frame length violation. Written by the MAC. A frame length greater than RCR[MAX_FL] was recognized. This field is valid only if the L field is set. The receive data is not altered in any way unless the length exceeds TRUNC_FL bytes.
Offset + 0	4 NO	Receive non-octet aligned frame. Written by the MAC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error or a PHY error occurred. This field is valid only if the L field is set. If this field is set, the CR field is not set.
Offset + 0	3	Reserved, must be cleared.
Offset + 0	2 CR	Receive CRC or frame error. Written by the MAC. This frame contains a PHY or CRC error and is an integral number of octets in length. This field is valid only if the L field is set.
Offset + 0	1 OV	Overrun. Written by the MAC. A receive FIFO overrun occurred during frame reception. If this field is set, the other status fields, M, LG, NO, and CR, lose their normal meaning and are zero. This field is valid only if the L field is set.
Offset + 0	0 TR	Set if the receive frame is truncated (frame length >TRUNC_FL). If the TR field is set, the frame must be discarded and the other error fields must be ignored because they may be incorrect.
Offset + 2	15–0 Data Length	Data length. Written by the MAC. Data length is the number of octets written by the MAC into this BD's data buffer if L is cleared (the value is equal to EMRBR), or the length of the frame including CRC if L is set. It is written by the MAC once as the BD is closed.
0ffset + 4	15–0 Data buffer pointer high	Receive data buffer pointer, high halfword[1]
Offset + 6	15–0 Data buffer pointer low	Receive data buffer pointer, low halfword
Offset + 8	15 ME	MAC error. This field is written by the uDMA. This field means that the frame stored in the system memory was received with an error (typically, a receive FIFO overflow). This field is only valid when the L field is set.
Offset + 8	14–11	Reserved, must be cleared.

Table continues on the next page...

Table 11-78. Receive buffer descriptor field definitions (continued)

Word	Field	Description
Offset + 8	10 PE	PHY Error. This field is written by the uDMA. Set to "1"when the frame was received with an Error character on the PHY interface. The frame is invalid. This field is valid only when the L field is set.
Offset + 8	9 CE	Collision. This field is written by the uDMA. Set when the frame was received with a collision detected during reception. The frame is invalid and sent to the user application. This field is valid only when the L field is set.
Offset + 8	8 UC	Unicast. This field is written by the uDMA, and means that the frame is unicast. This field is valid regardless of whether the L field is set.
Offset + 8	7 INT	Generate RXB/RXF interrupt. This field is set by the user to indicate that the uDMA is to generate an interrupt on the *dma_int_rxb* / *dma_int_rxfevent*.
Offset + 8	6–0	Reserved, must be cleared.
Offset + A	15–13 VPCP	VLAN priority code point. This field is written by the uDMA to indicate the frame priority level. Valid values are from 0 (best effort) to 7 (highest). This value can be used to prioritize different classes of traffic (e.g., voice, video, data). This field is only valid if the L field is set.
Offset + A	12–6	Reserved, must be cleared.
Offset + A	5 ICE	IP header checksum error. This is an accelerator option. This field is written by the uDMA. Set when either a non-IP frame is received or the IP header checksum was invalid. An IP frame with less than 3 bytes of payload is considered to be an invalid IP frame. This field is only valid if the L field is set.
Offset + A	4 PCR	Protocol checksum error. This is an accelerator option. This field is written by the uDMA. Set when the checksum of the protocol is invalid or an unknown protocol is found and checksumming could not be performed. This field is only valid if the L field is set.
Offset + A	3	Reserved, must be cleared.
Offset + A	2 VLAN	VLAN. This is an accelerator option. This field is written by the uDMA. It means that the frame has a VLAN tag. This field is valid only if the L field is set.
Offset + A	1 IPV6	IPV6 Frame. This field is written by the uDMA. This field indicates that the frame has an IPv6 frame type. If this field is not set it means that an IPv4 or other protocol frame was received. This field is valid only if the L field is set.
Offset + A	0 FRAG	IPv4 Fragment.This is an accelerator option.This field is written by the uDMA. It indicates that the frame is an IPv4 fragment frame. This field is only valid when the L field is set.
Offset + C	15–11 Header length	Header length. This is an accelerator option. This field is written by the uDMA. This field is the sum of 32-bit words found within the IP and its following protocol headers. If an IP datagram with an unknown protocol is found, then the value is the length of the IP header. If no IP frame or an erroneous IP header is found, the value is 0. The following values are minimum values if no header options exist in the respective headers: • ICMP/IP: 6 (5 IP header, 1 ICMP header) • UDP/IP: 7 (5 IP header, 2 UDP header) • TCP/IP: 10 (5 IP header, 5 TCP header) This field is only valid if the L field is set.
Offset + C	10–8	Reserved, must be cleared.
Offset + C	7–0 Protocol type	Protocol type. This is an accelerator option. The 8-bit protocol field found within the IP header of the frame. It is valid only when ICE is cleared. This field is valid only when the L field is set.

Table continues on the next page...

Table 11-78. Receive buffer descriptor field definitions (continued)

Word	Field	Description
Offset + E	15–0 Payload checksum	Internet payload checksum. This is an accelerator option. It is the one's complement sum of the payload section of the IP frame. The sum is calculated over all data following the IP header until the end of the IP payload. This field is valid only when the L field is set.
Offset + 10	15 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).
Offset + 10	14–0	Reserved, must be cleared.
Offset + 12	15–0	Reserved, must be cleared.
Offset + 14	15–0 1588 timestamp	This value is written by the uDMA. It is only valid if the L field is set.
Offset + 16		
Offset + 18 – Offset + 1E	15–0	Reserved, must be cleared.

1. The receive buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 64. The buffer must reside in memory external to the MAC. The Ethernet controller never modifies this value.

11.6.2.14.2 Enhanced transmit buffer descriptor

Table 11-79. Enhanced transmit buffer descriptor (TxBD)

	Byte 0								Byte 1							
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Offset + E	TLT – low halfword															
Offset + 10	BDU	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Offset + 12	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Offset + 14	1588 timestamp – high halfword															
Offset + 16	1588 timestamp – low halfword															
Offset + 18	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Offset + 1A	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Offset + 1C	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Offset + 1E	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 11-80. Enhanced transmit buffer descriptor field definitions

Word	Field	Description
Offset + 0	15 R	Ready. Written by the MAC and user. 0 The data buffer associated with this BD is not ready for transmission. You are free to manipulate this BD or its associated data buffer. The MAC clears this field after the buffer has been transmitted or after an error condition is encountered. 1 The data buffer, prepared for transmission by you, has not been transmitted or currently transmits. You may write no fields of this BD after this field is set.
Offset + 0	14 TO1	Transmit software ownership. This field is reserved for software use. This read/write field is not modified by hardware and its value does not affect hardware.
Offset + 0	13 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location 1 The next buffer descriptor is found at the location defined in ETDSR.
Offset + 0	12 TO2	Transmit software ownership. This field is reserved for use by software. This read/write field is not modified by hardware and its value does not affect hardware.
Offset + 0	11 L	Last in frame. Written by user. 0 The buffer is not the last in the transmit frame 1 The buffer is the last in the transmit frame
Offset + 0	10 TC	Transmit CRC. Written by user, and valid only when L is set. 0 End transmission immediately after the last data byte 1 Transmit the CRC sequence after the last data byte This field is valid only when the L field is set.
Offset + 0	9 ABC	Append bad CRC. **Note:** This field is not supported by the uDMA and is ignored.
Offset + 0	8–0	Reserved, must be cleared.
Offset + 2	15–0 Data Length	Data length, written by user. Data length is the number of octets the MAC should transmit from this BD's data buffer. It is never modified by the MAC.
Offset + 4	15–0 Data buffer pointer high	Tx data buffer pointer, high halfword. The buffer must reside in memory external to the MAC. This value is never modified by the Ethernet controller. **NOTE:** For optimal performance, make the transmit buffer pointer evenly divisible by 64.
Offset + 6	15–0 Data buffer pointer low	Tx data buffer pointer, low halfword
Offset + 8	15	Reserved, must be cleared.
Offset + 8	14 INT	Generate interrupt flags. This field is written by the user. This field is valid regardless of the L field and must be the same for all EBD for a given frame. The uDMA does not update this value.
Offset + 8	13 TS	Timestamp. This field is written by the user. This indicates that the uDMA is to generate a timestamp frame to the MAC. This field is valid regardless of the L field and must be the same for all EBD for the given frame. The uDMA does not update this value.

Table continues on the next page...

Table 11-80. Enhanced transmit buffer descriptor field definitions (continued)

Word	Field	Description
Offset + 8	12 PINS	Insert protocol specific checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the protocol checksum and overwrites the corresponding checksum field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + 8	11 IINS	Insert IP header checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the IP header checksum and overwrites the corresponding header field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + 8	10-9	Reserved, must be cleared.
Offset + 8	8 UTLT	Use transmit launch time. If set to 1, TLT high and low values are used to determine if the frame can be transmitted. This field must only be set in the *first* BD of a frame. TLT is always used in combination with either the round-robin scheme or the credit-based shaper. TLT can be used with single a BD queue. However, at least one DMA class, DMA*n*CFG[DMA_CLASS_ EN] must be enabled. For example, to use TLT with only queue 0, enable one of the DMA*n*CFG[DMA_CLASS_EN] fields and clear both TDAR1 and TDAR2. Although this enables multi-queue, only the single queue 0 is used.
Offset + 8	7–4 FTYPE	Type of frame to be transmitted. If a credit-based scheme is used, this field must match the BD ring queue. 0x0 – Non-AVB. Corresponds to ENET_TDSR. 0x1 – AVB Class A. Corresponds to ENET_TDSR1. 0x2 – AVB Class B. Corresponds to ENET_TDSR2. All other values are reserved.
Offset + 8	3–0	Reserved, must be cleared.
Offset + A	15 TXE	Transmit error occurred. This field is written by the uDMA. This field indicates that there was a transmit error of some sort reported with the frame. Effectively this field is an OR of the other error fields including UE, EE, FE, LCE, OE, and TSE. This field is valid only when the L field is set.
Offset + A	14	Reserved, must be cleared.
Offset + A	13 UE	Underflow error. This field is written by the uDMA. This field indicates that the MAC reported an underflow error on transmit. This field is valid only when the L field is set.
Offset + A	12 EE	Excess Collision error. This field is written by the uDMA. This field indicates that the MAC reported an excess collision error on transmit. This field is valid only when the L field is set.
Offset + A	11 FE	Frame with error. This field is written by the uDMA. This field indicates that the MAC reported that the uDMA reported an error when providing the packet. This field is valid only when the L field is set.
Offset + A	10 LCE	Late collision error. This field is written by the uDMA. This field indicates that the MAC reported that there was a Late Collision on transmit. This field is valid only when the L field is set.

Table continues on the next page...

Table 11-80. Enhanced transmit buffer descriptor field definitions (continued)

Word	Field	Description
Offset + A	9 OE	Overflow error. This field is written by the uDMA. This field indicates that the MAC reported that there was a FIFO overflow condition on transmit. This field is only valid when the L field is set.
Offset + A	8 TSE	Timestamp error. This field is written by the uDMA. This field indicates that the MAC reported a different frame type then a timestamp frame. This field is valid only when the L field is set.
Offset + A	7–0	Reserved, must be cleared.
Offset + C	15–0 TLT high	Transmit launch time high. Specifies when frame can by transmitted.
Offset + E	15–0 TLT low	Transmit launch time low. Specifies when frame can by transmitted.
Offset + 10	15 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).
Offset + 10	14–0	Reserved, must be cleared.
Offset + 12	15–0	Reserved, must be cleared.
Offset + 14	15–0 1588 timestamp	This value is written by the uDMA . It is valid only when the L field is set.
Offset + 16		
Offset + 18–Offset + 1E	15–0	Reserved, must be cleared.

11.6.2.15 Client FIFO application interface

The FIFO interface is completely asynchronous from the Ethernet line, and the transmit and receive interface can operate at a different clock rate.

All transfers to/from the user application are handled independently of the core operation, and the core provides a simple interface to user applications based on a two-signal handshake.

11.6.2.15.1 Data structure description

The data structure defined in the following tables for the FIFO interface must be respected to ensure proper data transmission on the Ethernet line. Byte 0 is sent to and received from the line first.

Table 11-81. FIFO interface data structure

	63 56	55 48	47 40	39 32	31 24	23 16	15 8	7 0
Word 0	Byte 7	Byte 6	Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0
Word 1	Byte 15	Byte 14	Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8
...	...							

The size of a frame on the FIFO interface may not be a modulo of 64-bit.

The user application may not care about the Ethernet frame formats in full detail. It needs to provide and receive an Ethernet frame with the following structure:

- Ethernet MAC destination address
- Ethernet MAC source address
- Optional 802.1q VLAN tag (VLAN type and info field)
- Ethernet length/type field
- Payload

Frames on the FIFO interface do not contain preamble and SFD fields, which are inserted and discarded by the MAC on transmit and receive, respectively.

- On receive, CRC and frame padding can be stripped or passed through transparently.
- On transmit, padding and CRC can be provided by the user application, or appended automatically by the MAC independently for each frame. No size restrictions apply.

Note

On transmit, if ENET*n*_TCR[ADDINS] is set, bytes 6–11 of each frame can be set to any value, since the MAC overwrites the bytes with the MAC address programmed in the ENET*n*_PAUR and ENET*n*_PALR registers.

Table 11-82. FIFO interface frame format

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address
12–13	Length/type field
14–N	Payload data

VLAN-tagged frames are supported on both transmit and receive, and implement additional information (VLAN type and info).

Table 11-83. FIFO interface VLAN frame format

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address

Table continues on the next page...

Table 11-83. FIFO interface VLAN frame format (continued)

Byte number	Field
12–15	VLAN tag and info
16–17	Length/type field
18–N	Payload data

Note

The standard defines that the LSB of the MAC address is sent/received first, while for all the other header fields — in other words, length/type, VLAN tag, VLAN info, and pause quanta — the MSB is sent/received first.

11.6.2.15.2 Data structure examples

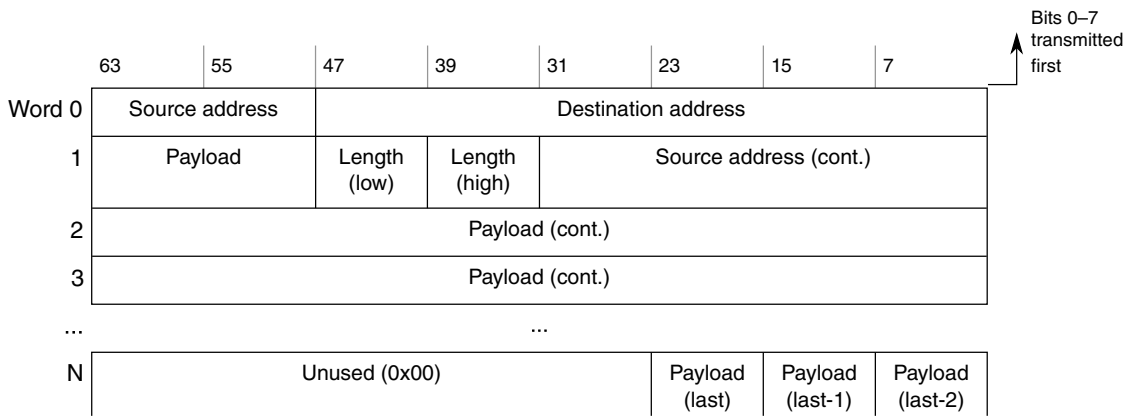

Figure 11-73. Normal Ethernet frame 64-bit mapping example

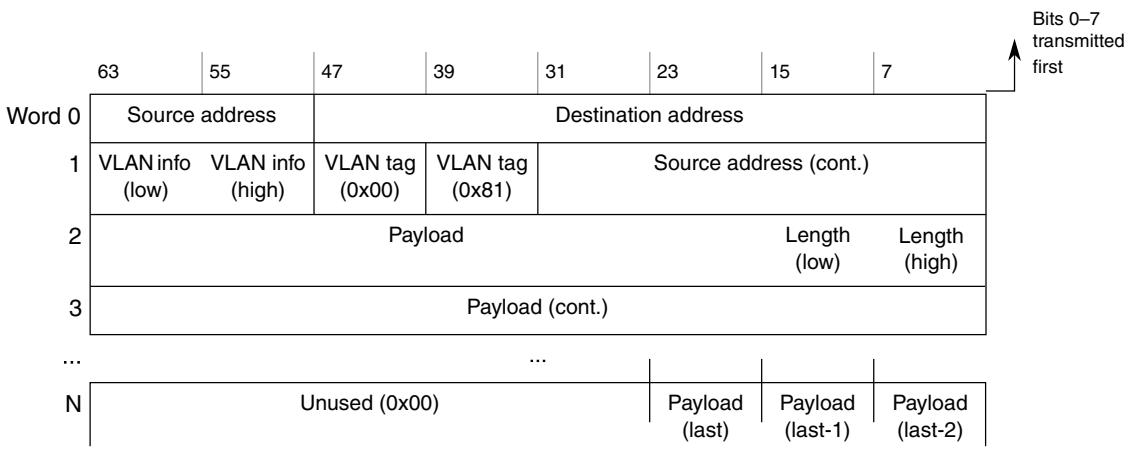

Figure 11-74. VLAN-tagged frame 64-bit mapping example

If CRC forwarding is enabled (CRCFWD = 0), the last four valid octets of the frame contain the FCS field. The non-significant bytes of the last word can have any value.

11.6.2.15.3 Frame status

A MAC layer status word and an accelerator status word is available in the receive buffer descriptor.

See Enhanced buffer descriptors for details.

The status is available with each frame with the last data of the frame.

If the frame status contains a MAC layer error (for example, CRC or length error), RxBD[ME] is also set with the last data of the frame.

11.6.2.16 FIFO protection

The following sections describe the FIFO protection mechanisms.

11.6.2.16.1 Transmit FIFO underflow

During a frame transfer, when the transmit FIFO reaches the almost empty threshold with no end-of-frame indication stored in the FIFO, the MAC logic:

- Stops reading data from the FIFO
- Asserts the MII error signal (MII_TXER) (1 in Figure 11-75) to indicate that the fragment already transferred is not valid
- Deasserts the MII transmit enable signal (MII_TXEN) to terminate the frame transfer (2)

After an underflow, when the application completes the frame transfer (3), the MAC transmit logic discards any new data available in the FIFO until the end of packet is reached (4) and sets the enhanced TxBD[UE] field.

The MAC starts to transfer data on the MII interface when the application sends a new frame with a start of frame indication (5).

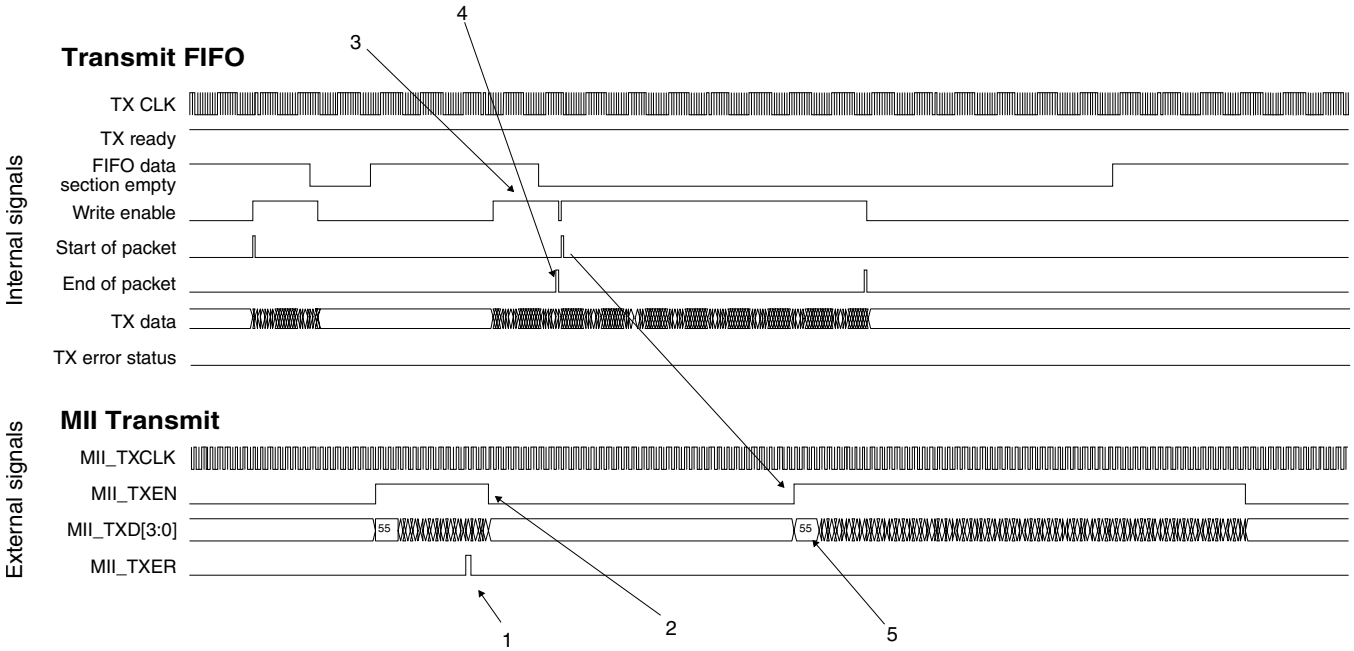

Figure 11-75. Transmit FIFO underflow protection

11.6.2.16.2 Transmit FIFO overflow

On the transmit path, when the FIFO reaches the programmable almost full threshold, the internal MAC ready signal is deasserted. The application should stop sending new data.

However, if the application keeps sending data, the transmit FIFO overflows, corrupting contents that were previously stored. The core logic sets the enhanced TxBD[OE] field for the next frame transmitted to indicate this overflow occurence.

Note

Overflow is a fatal error and must be addressed by resetting the core or clearing ENET*n*_ECR[ETHER_EN], to clear the FIFOs and prepare for normal operation again.

11.6.2.16.3 Receive FIFO overflow

During a frame reception, if the client application is not able to receive data (1), the MAC receive control truncates the incoming frame when the FIFO reaches the programmable almost-full threshold to avoid an overflow.

The frame is subsequently received on the FIFO interface with an error indication (enhanced RxBD[ME] field set together with receive end-of-packet) (2) with the truncation error status field set (3).

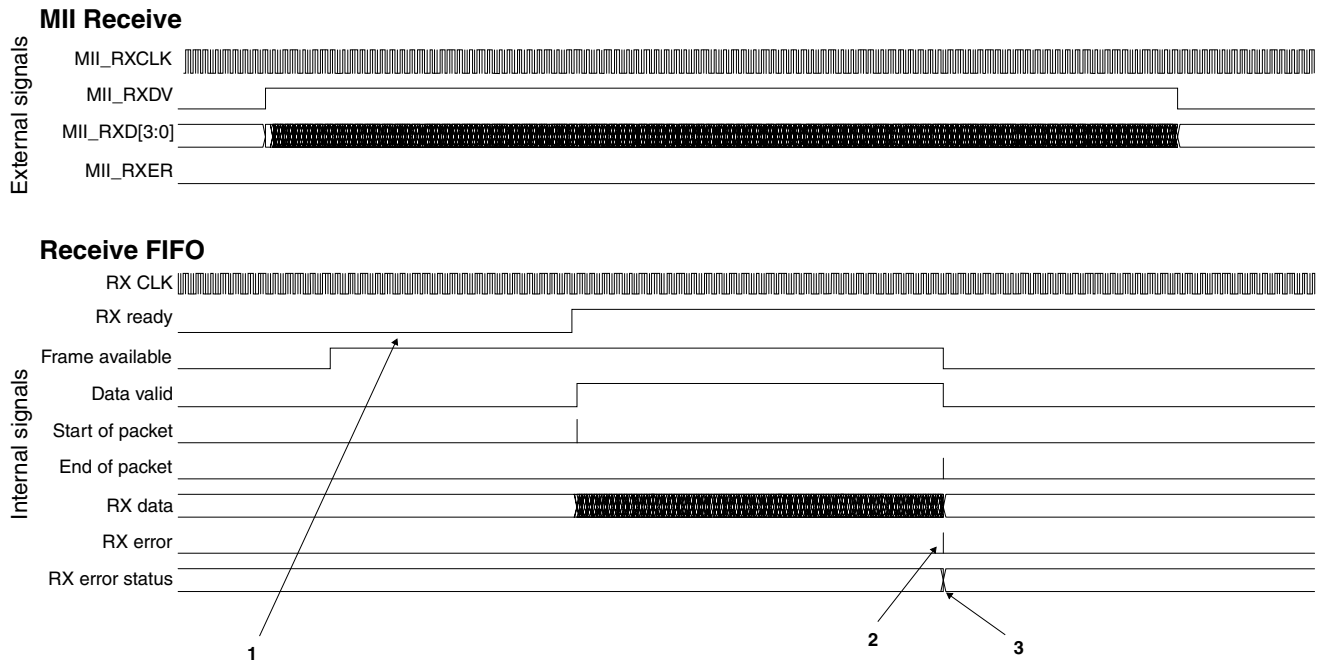

Figure 11-76. Receive FIFO overflow protection

11.6.2.17 PHY management interface

The MDIO interface is a two-wire management interface. The MDIO management interface implements a standardized method to access the PHY device management registers.

The core implements a master MDIO interface, which can be connected to up to 32 PHY devices.

11.6.2.17.1 MDIO clause 22 frame format

The core MDIO master controller communicates with the slave (PHY device) using frames that are defined in the following table.

A complete frame has a length of 64 bits made up of an optional 32-bit preamble, 14-bit command, 2-bit bus direction change, and 16-bit data. Each bit is transferred on the rising edge of the MDIO clock (MDC signal). The MDIO data signal is tri-stated between frames.

The core PHY management interface supports the standard MDIO specification (IEEE 802.3 Clause 22).

Table 11-84. MDIO clause 22 frame structure

ST	OP	PHYADR	REGADR	TA	DATA

Table 11-85. MDIO frame field descriptions

Field	Description
ST (2 bits)	Start indication field, programmed with ENET*n*_MMFR[ST] and equal to 01 for Standard MDIO (Clause 22).
OP (2 bits)	Opcode defines type of operation. Programmed with ENET*n*_MMFR[OP]. 01 Write operation 10 Read operation
PHYADR (5 bits)	Five-bit PHY device address, programmed with ENET*n*_MMFR[PA]. Up to 32 devices can be addressed.
REGADR (5 bits)	Five-bit register address, programmed with ENET*n*_MMFR[RA]. Each PHY can implement up to 32 registers.
TA (2 bits)	Turnaround time, programmed with ENET*n*_MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.
Data (16 bits)	Data, set by ENET*n*_MMFR[DATA]. Written to or read from the PHY

11.6.2.17.2 MDIO clause 45 frame format

The extended MDIO frame structure defined in IEEE 802.3 Clause 45 introduces indirect addressing. First, a write transaction to an address register is done, followed by a write or read transaction which will put the 16-bit data in the register or retrieve the register contents respectively. A preamble of 32 bits of logical ones is sent prior to every transaction. The MDIO data signal is tri-stated between frames.

The extended MDIO defines four transactions, which are determined by the two-bit opcode field.

Table 11-86. MDIO clause 45 frame structure

ST	OP	PRTAD	DEVAD	TA	ADDR/DATA

All bits are transmitted from left to right (Preamble bits first) and all fields have their Most-Significant bit sent first (leftmost in above table). The complete frame has a length of 64 bits (32-bit preamble, 14-bit command, 2-bit bus direction change, 16-bit data). Each bit is transferred with the rising edge of the MDIO clock (MDC).

The fields and transactions are summarized in the following tables.

Table 11-87. MDIO clause 45 frame field descriptions

Field	Description
ST	Start indication. Indicates the end of the preamble and start of the frame. This value is 00 for extended MDIO (Clause 45) frames.
OP	Opcode defines if a read or write operation is performed and is programmed with ENET*n*_MMFR[OP]. See Table 11-88 for more information. 00 Address write 01 Write operation 10 Read inc. operation 11 Read operation
PRTAD	The port address specifies a MDIO port. Each Port can have up to 32 devices which each can have a separate set of registers.
DEVAD	Device address. Up to 32 devices can be addressed (within a port).
TA	Turnaround time, programmed with ENET*n*_MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.
ADDR/DATA	16-bit address (for address write) or data, set by ENET*n*_MMFR[DATA], written to or read from the PHY.

Table 11-88. MDIO Clause 45 Transactions

Transaction Type	Description
Address	A write transaction to the internal address register of the device/port. The data section of the frame contains the value to be stored in the device's internal address "pointer" register for further transactions.
Write	Data write to a register. The 16 bit data will be written to the register identified by the device-internal address.
Read	Data is read from the register identified by the device-internal address.
Read inc.	Read with address postincrement. The register identified by the device-internal address is read. After this, the device-internal address is incremented. If the address register is all '1' (0xFFFF) no increment is done (i.e. increment does not wrap around).

11.6.2.17.3 MDIO clock generation

The MDC clock is generated from the internal bus clock (i.e., IPS bus clock) divided by the value programmed in ENET*n*_MSCR[MII_SPEED].

11.6.2.17.4 MDIO operation

To perform an MDIO access, set the MDIO command register (ENET*n*_MMFR) according to the description provided in MII Management Frame Register (ENETn_MMFR).

To check when the programmed access completes, read the ENET*n*_EIR[MII] field.

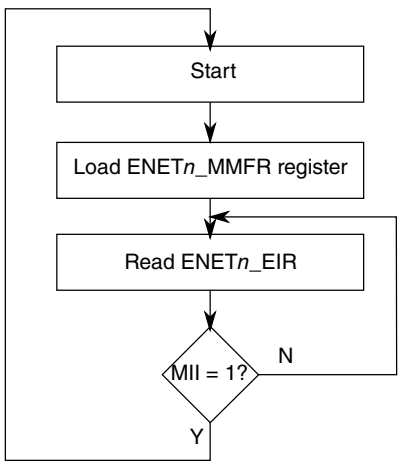

Figure 11-77. MDIO access overview

11.6.2.18 Ethernet interfaces

RMII 10/100 is implemented using interface converters/gaskets.

The following table shows how to configure ENET registers to select each interface.

Mode	ECR[SPEED]	RCR[RMII_10T]	RCR[RMII_MODE]	RCR[RGMII_EN]
RMII - 10 Mbit/s	0	1	1	0
RMII - 100 Mbit/s	0	0	1	0
RGMII - 10 Mbit/s	0	1	0	1
RGMII - 100 Mbit/s	0	0	0	1
RGMII - 1000 Mbit/s	1	—	0	1

11.6.2.18.1 RMII interface

In RMII receive mode, for normal reception following assertion of CRS_DV, RXD[1:0] is 00 until the receiver determines that the receive event has a proper start-of-stream delimiter (SSD).

The preamble appears (RXD[1:0]=01) and the MACs begin capturing data following detection of SFD.

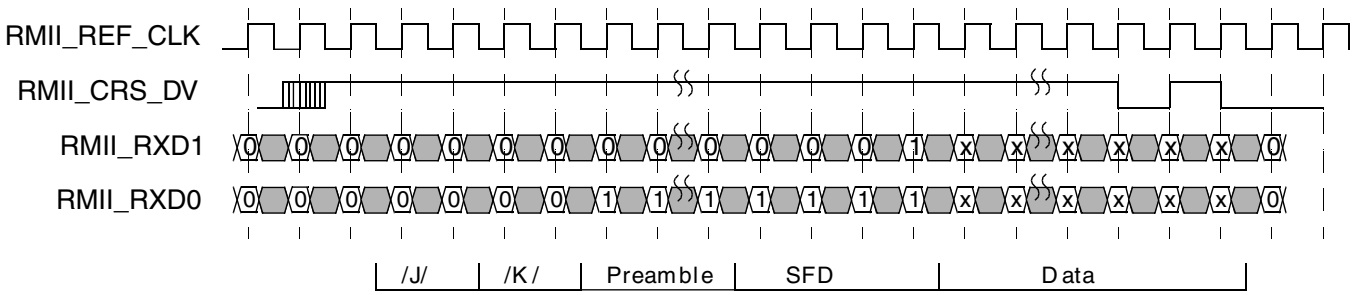

Figure 11-78. RMII receive operation

If a false carrier is detected (bad SSD), then RXD[1:0] is 10 until the end of the receive event. This is a unique pattern since a false carrier can only occur at the beginning of a packet where the preamble is decoded (RXD[1:0] = 01).

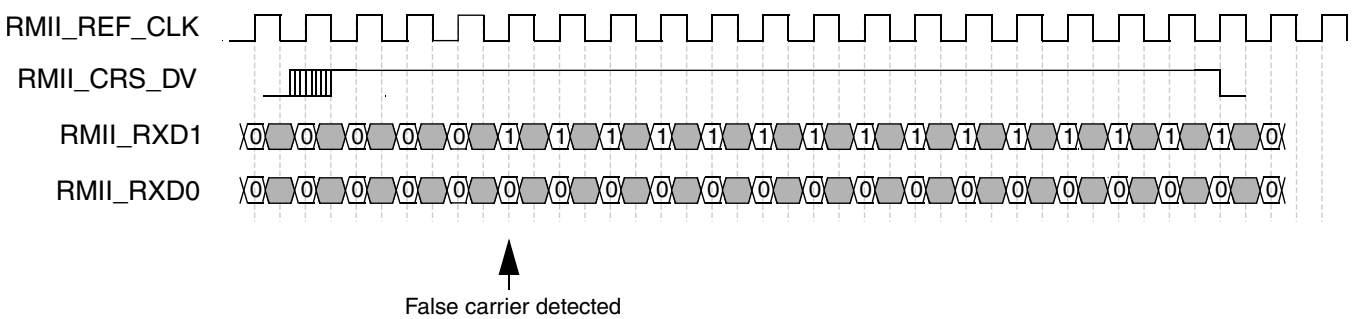

Figure 11-79. RMII receive operation with false carrier

In RMII transmit mode, TXD[1:0] provides valid data for each REF_CLK period while TXEN is asserted.

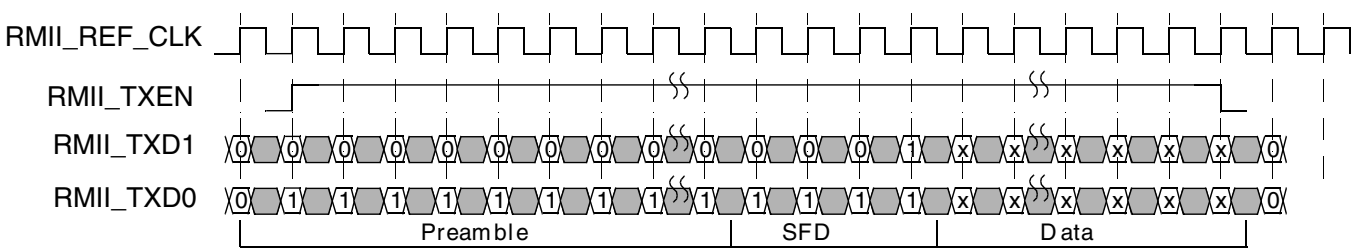

Figure 11-80. RMII transmit operation

11.6.2.18.2 RGMII interface

In RGMII modes, the data and control information is multiplexed by taking advantage of both edges of the reference clocks.

The data signals contain the lower four data bits on the rising edge and the upper four bits on the falling edge. The control signals are multiplexed into a single clock cycle using the same technique.

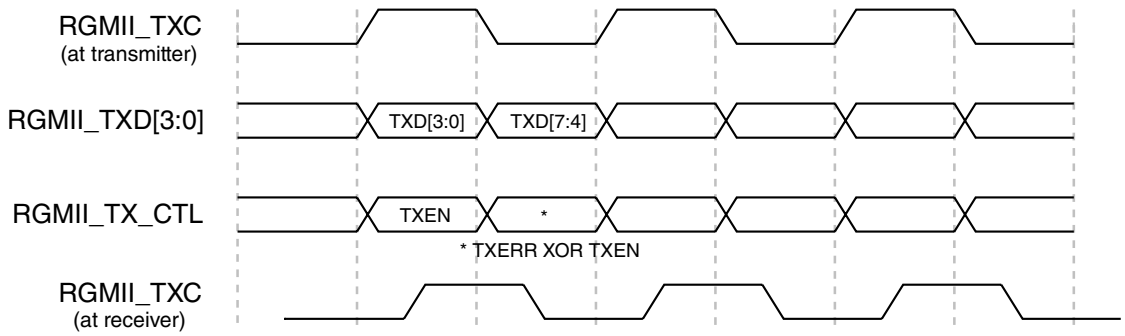

Figure 11-81. RGMII transmit operation

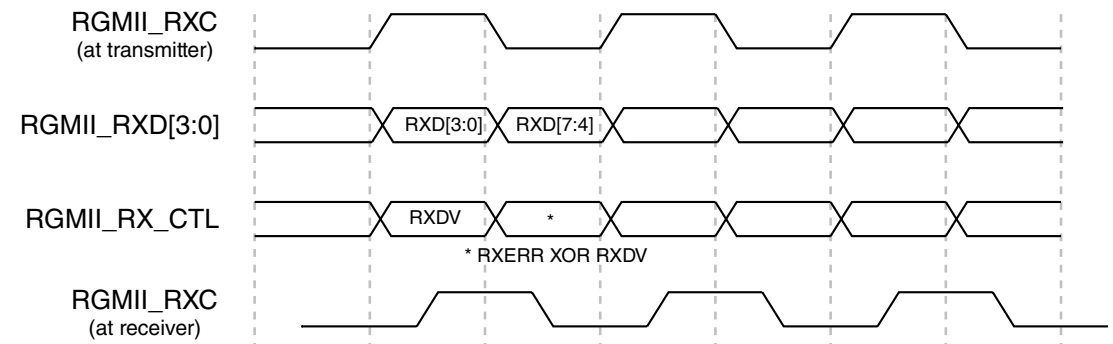

Figure 11-82. RGMII receive operation

11.6.2.19 AVB configuration

The following steps give an example of how to initialize the ENET module for AVB.

1. Set up ENET_QOS:
   - Set TX_SCHEME to 000b, credit-based scheme.
   - Set RX_FLUSH0 to 1, enable RX flush for ring 0.
2. Set up TX BD ring and RX BD ring for each queue, 0-2.
   - Program ENET_MRBR, ENET_TDSR, and ENET_RDSR.
   - Program ENET_MRBR1, ENET_TDSR1, and ENET_RDSR1.
   - Program ENET_MRBR2, ENET_TDSR2, and ENET_RDSR2.
   - Program each TX and RX BD ring queue for all classes used in memory.

NOTE

If using credit-based scheme, ensure that enhanced transmit buffer descriptor FTYPE field matches BD ring queue, for example:

- FTYPE = 0h corresponds to ENET_TDSR

- FTYPE = 1h corresponds to ENET_TDSR1
- FTYPE = 2h corresponds to ENET_TDSR2

3. Program ENET_DMA1CFG and ENET_DMA2CFG for class 1 and class 2 corresponding to BD ring queue 1 and 2. DMA_CLASS_EN must be set to one for that class to be enabled. See DMACFG register for information on how to program IDLE_SLOPE.
4. Program ENET_RCMR1 and ENET_RCMR2 for class 1 and class 2 matching for receive.

NOTE

Even if a match occurs, if ENET_DMA*n*CFG[DMA_CLASS_EN] is zero for the corresponding class, the RX frame will be automatically forwarded to BD ring queue 0.

5. Program the other ENET registers according to application requirements.
6. Program ENET_RDAR, ENET_RDAR1, ENET_RDAR2, ENET_TDAR, ENET_TDAR1, and ENET_TDAR2 to 0100_0000h according to the classes used.
7. Set ENET_ECR[ETHEREN] to one.

11.6.2.20 Interrupt coalescence

The purpose of the interrupt coalescing is to reduce the number of interrupts generated by the MAC so as to reduce the CPU loading.

To facilitate this interrupt coalescing for each queue, these registers are available with the same control and configuration fields.

- Transmit Interrupt Coalescing Register (TXICn) where n=0,1,2 for queue/class 0,1,2.
- Receive Interrupt Coalescing Register (RXICn) where n=0,1,2 for queue/class 0,1,2.

When coalescing is enabled by asserting the corresponding ICEN field and such interrupt is also enabled by the corresponding interrupt mask of the EIMR register, the MAC generates an interrupt when the threshold number of frames is reached (defined by ICFT) or when the threshold timer expires (defined by ICTT).

When coalescing is disabled by de-asserting ICEN, but interrupt is enabled by the corresponding interrupt mask of the EIMR register, the MAC generates an interrupt as they are received without using coalescing. Interrupt coalescing is done for each transmit and receive queue/class independently.

11.6.2.20.1 Interrupt coalescence setup

Interrupt coalescence supports both legacy and enhanced BDs. The following guidelines are recommended when setting up interrupt coalescence.

- When the MAC is configured for enhanced (IEEE 1588) mode, that is, enhanced BDs:
  - Set the INT bit in the enhanced received buffer descriptor to one.
  - Set the INT bit in the enhanced transmit buffer descriptor(s) to one.
- Clear the RXB, RXB1, and RXB2 fields in the EIMR register.
- Clear the TXB, TXB1, and TXB2 fields in the EIMR register.

11.6.2.20.2 Updating the frame count threshold on-the-fly

To update the ICFT field in the RXIC*n* and TXIC*n* registers:

1. Disable interrupt coalescence by clearing the appropriate ICEN field. This will allow the internal interrupt coalescence counter to reset to zero.

NOTE

When disabling interrupt coalescence, if an interrupt event is pending, that is, the interrupt counter is not zero, then an interrupt will occur.

2. Write the new threshold value to the ICFT field.
3. Set ICEN to one.

NOTE

The ICFT field can be updated on-the-fly without disabling the ICEN field. The hardware interrupt will continue and there is a possibility that an interrupt will occur depending on the state of the hardware counter and the previous ICFT value.

11.6.2.20.3 Updating the timer threshold on-the-fly

To update the ICTT field in the RXIC*n* and TXIC*n* registers:

1. Disable interrupt coalescence by clearing the appropriate ICEN field. This will allow the internal interrupt coalescence counter to reset to zero.

NOTE

When disabling interrupt coalescence, if an interrupt event is pending, that is, the interrupt counter is not zero, then an interrupt will occur.

2. Write the new timer value to the ICTT field.
3. Set ICEN to one.

11.6.2.21 Clocks

The table found here describes the clock sources for ENET. Please see the chip-specific clocking section for clock setting, configuration and gating information.

Table 11-89. Clocks

Clock name	Description
ipg_clk	Module clock
ipg_clk_rmii	Module clock for RMII
ipg_clk_s	Peripheral access clock
ipg_clk_time (ts_clk)	Peripheral clock
txc_sampling_clk	Transmit sampling clock

11.6.3 External Signals

The table found here describes the external signals of ENET.

Table 11-90. ENET External Signals

Signal	Description	Mode	Direction
1588_EVENT_IN	Capture/compare block input/ output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set.	RMII	I
1588_EVENT_OUT	Capture/compare block input/ output event bus signal. When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCRn	RMII	O

Table continues on the next page...

Table 11-90. ENET External Signals (continued)

Signal	Description	Mode	Direction
	register for inspection by software. When configured for compare, the corresponding signal 1588_EVENT is asserted for one cycle when the timer reaches the compare value programmed in register ENET_TCCRn. An interrupt or DMA request can be triggered if the corresponding bit in ENET_TCSRn[TIE] or ENET_TCSRn[TDRE] is set. NOTE: ENET_1588_EVENT0_OUT has a programmable output width, see IOMUXC_GPR[CLK_STRETCH], delayed one clock cycle in relation to all other EVENTx_OUT signals.		
MDC	Output clock provides a timing reference to the PHY for data transfers on the MDIO signal.	RMII	O
MDIO	Transfers control information between the external PHY and the media access controller. Data is synchronous to MDC. This signal is an input after reset.	RMII	IO
RX_ER	When asserted with RXDV, indicates the PHY detects an error in the current frame.	RMII	I
RX_EN	Asserting this input indicates the PHY has valid nibbles present on the MII. RX_EN must remain asserted from the first recovered nibble of the frame through to the last nibble. Asserting RX_EN must start no later than the SFD and exclude any EOF. In RMII mode, this pin also generates the CRS signal.	RMII	I
TX_ER	When asserted for one or more clock cycles while TXEN is also asserted, PHY sends one or more illegal symbols.	RMII	O
TX_EN	Indicates when valid nibbles are present on the MII. This signal is asserted with the first nibble of a preamble and is deasserted before the first	RMII	I

Table continues on the next page...

Table 11-90. ENET External Signals (continued)

Signal	Description	Mode	Direction
	TX_CLK following the final nibble of the frame.		
RDATA	Contains the Ethernet input data transferred from the PHY to the media-access controller when RX_EN is asserted.	RMII	I
TDATA	Serial output Ethernet data. Only valid during TX_EN assertion.	RMII	O
RGMII_RD0	Receive data bit 0 (received first)	RGMII	I
RGMII_RD1	Receive data bit 1	RGMII	I
RGMII_RD2	Receive data bit 2	RGMII	I
RGMII_RD3	Receive data bit 3	RGMII	I
RGMII_RX_CTL	Asserting this input indicates the PHY has valid nibbles present on the MII. RXDV must remain asserted from the first recovered nibble of the frame through to the last nibble. Asserting RXDV must start no later than the SFD and exclude any EOF.In RGMII mode, contains RXDV on the rising edge of RGMII_RXC, and a logical derivative of RXDV and RXERR (RXDV XOR RXERR) on the falling edge of RGMII_RXC.	RGMII	I
RGMII_RXC	Timing reference for RGMII_RXD[3:0] and RGMII_RX_CTL	RGMII	I
RGMII_TD0	Transmit data bit 0 (transmitted first)	RGMII	O
RGMII_TD1	Transmit data bit 1	RGMII	O
RGMII_TD2	Transmit data bit 2	RGMII	O
RGMII_TD3	Transmit data bit 3	RGMII	O
RGMII_TX_CTL	Indicates when valid nibbles are present on the MII. This signal is asserted with the first nibble of a preamble and is deasserted before the first TXCLK following the final nibble of the frame. In RGMII mode, contains TXEN on the rising edge of RGMII_TXC, and a logical derivative of TXEN and TXERR (TXEN	RGMII	O

Table continues on the next page...

Table 11-90. ENET External Signals (continued)

Signal	Description	Mode	Direction
	XOR TXERR) on the falling edge of RGMII_TXC.		
RGMII_TXC	Timing reference for RGMII_TXD[3:0] and RGMII_TX_CTL.	RGMII	O
REF_CLK1	In RMII mode, this signal is the reference clock for receive, transmit, and the control interface.	RMII	IO

11.6.4 Memory map/register definition

ENET registers must be read or written with 32-bit accesses. Non-32 bit accesses will terminate with an error.

Reserved bits should be written with 0 and ignored on read. Unused registers read zero and a write has no effect.

This table shows Ethernet registers organization.

Table 11-91. Register map summary

Offset Address	Section	Description
0x0000 – 0x01FF	Configuration	Core control and status registers
0x0200 – 0x03FF	Statistics counters	MIB and Remote Network Monitoring (RFC 2819) registers
0x0400 – 0x0430	1588 control	1588 adjustable timer (TSM) and 1588 frame control
0x0600 – 0x07FC	Capture/Compare block	Registers for the Capture/Compare block

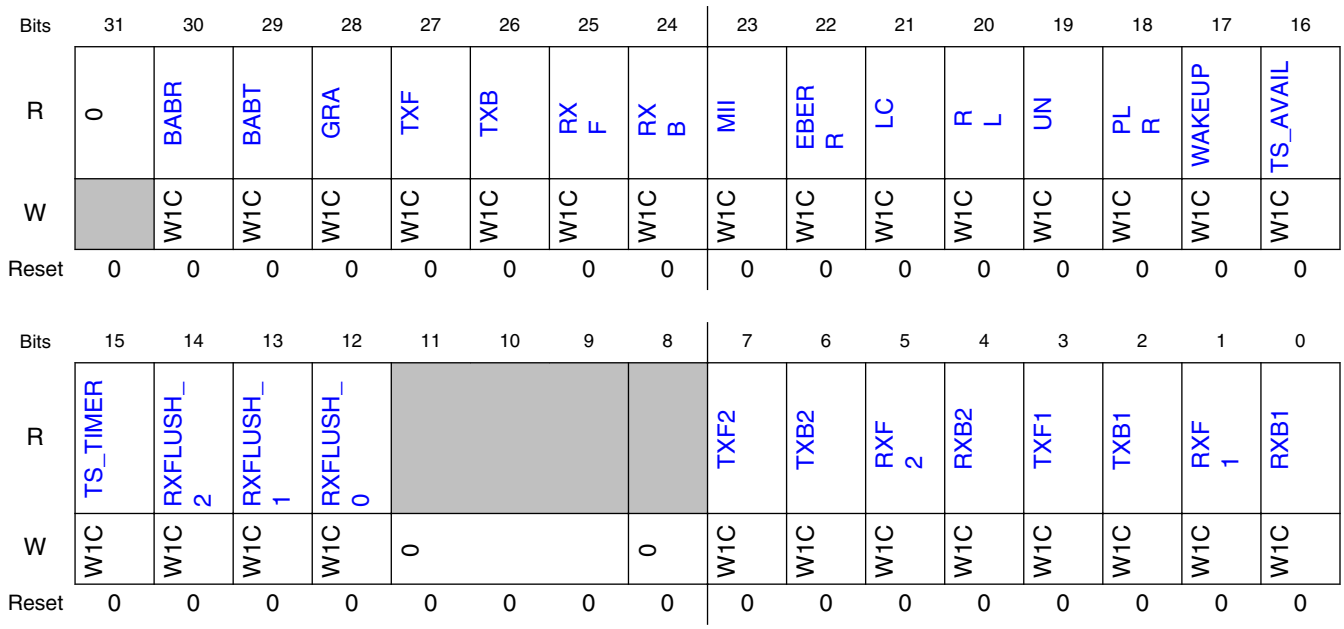
11.6.4.1.2 Interrupt Event Register (EIR)

When an event occurs that sets a bit in EIR, an interrupt occurs if the corresponding bit in the interrupt mask register (EIMR) is also set. Writing a 1 to an EIR bit clears it; writing 0 has no effect. This register is cleared upon hardware reset.



NOTE

TxBD[INT] and RxBD[INT] must be set to 1 to allow setting the corresponding EIR register flags in enhanced mode, ENET_ECR[EN1588] = 1. Legacy mode does not require these flags to be enabled.

11.6.4.1.2.1 Offset

Register	Offset
EIR	4h

11.6.4.1.2.2 Diagram

11.6.4.1.2.3 Fields

Field	Description
31 —	Reserved
30 BABR	Babbling Receive Error Indicates a frame was received with length in excess of RCR[MAX_FL] bytes.
29 BABT	Babbling Transmit Error Indicates the transmitted frame length exceeds RCR[MAX_FL] bytes. Usually this condition is caused when a frame that is too long is placed into the transmit data buffer(s). Truncation does not occur.
28 GRA	Graceful Stop Complete This interrupt is asserted after the transmitter is put into a pause state after completion of the frame currently being transmitted. See Graceful Transmit Stop (GTS) for conditions that lead to graceful stop. **NOTE:** The GRA interrupt is asserted only when the TX transitions into the stopped state. If this bit is cleared by writing 1 and the TX is still stopped, the bit is not set again.
27 TXF	Transmit Frame Interrupt Indicates a frame has been transmitted and the last corresponding buffer descriptor has been updated.
26 TXB	Transmit Buffer Interrupt Indicates a transmit buffer descriptor has been updated.
25 RXF	Receive Frame Interrupt Indicates a frame has been received and the last corresponding buffer descriptor has been updated.
24	Receive Buffer Interrupt

Table continues on the next page...

Field	Description
RXB	Indicates a receive buffer descriptor is not the last in the frame has been updated.
23 MII	MII Interrupt. Indicates that the MII has completed the data transfer requested.
22 EBERR	Ethernet Bus Error Indicates a system bus error occurred when a uDMA transaction is underway. When this bit is set, ECR[ETHEREN] is cleared, halting frame processing by the MAC. When this occurs, software must ensure proper actions, possibly resetting the system, to resume normal operation.
21 LC	Late Collision Indicates a collision occurred beyond the collision window (slot time) in half-duplex mode. The frame truncates with a bad CRC and the remainder of the frame is discarded.
20 RL	Collision Retry Limit Indicates a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. This error can only occur in half-duplex mode.
19 UN	Transmit FIFO Underrun Indicates the transmit FIFO became empty before the complete frame was transmitted. **NOTE:** In situations where the device has various masters generating high traffic, a FIFO underrun can occur on the transmit FIFO. To avoid transmit FIFO underrun, store and forward can be enabled in ENET_TFWR[STRFWD]. See Transmit FIFO Watermark Register (TFWR). Also, a higher priority can be set for ENET traffic using available means on the central bus fabric connecting the ENET module.
18 PLR	Payload Receive Error Indicates a frame was received with a payload length error. See Frame Length/Type Verification: Payload Length Check for more information.
17 WAKEUP	Node Wakeup Request Indication Read-only status bit to indicate that a magic packet has been detected. Will act only if ECR[MAGICEN] is set.
16 TS_AVAIL	Transmit Timestamp Available Indicates that the timestamp of the last transmitted timing frame is available in the ATSTMP register.
15 TS_TIMER	Timestamp Timer The adjustable timer reached the period event. A period event interrupt can be generated if ATCR[PEREN] is set and the timer wraps according to the periodic setting in the ATPER register. Set the timer period value before setting ATCR[PEREN].
14 RXFLUSH_2	RX DMA Ring 2 flush indication. This ring's RX frame has been flushed due to either RDAR2[RDAR] or RxBD[E] being clear and only if QOS[RXFLUSH_2] is enabled. **NOTE:** This field is not supported in every instance. The following table includes only supported registers. **Instance** / **Field supported in** / **Field not supported in** ENET / — / EIR ENET1G / EIR / —
13 RXFLUSH_1	RX DMA Ring 1 flush indication. This ring's RX frame has been flushed due to either RDAR1[RDAR] or RxBD[E] being clear and only if QOS[RXFLUSH_1] is enabled.

11.6.4.1.3 Interrupt Mask Register (EIMR)

EIMR controls which interrupt events are allowed to generate actual interrupts. A hardware reset clears this register. If the corresponding bits in the EIR and EIMR registers are set, an interrupt is generated. The interrupt signal remains asserted until a 1 is written to the EIR field (write 1 to clear) or a 0 is written to the EIMR field.

11.6.4.1.3.1 Offset

Register	Offset
EIMR	8h

11.6.4.1.3.2 Diagram

11.6.4.1.3.3 Fields

Field	Description
31 —	This write-only field is reserved. It must always be written with the value 0.
30 BABR	BABR Interrupt Mask Corresponds to interrupt source EIR[BABR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR BABR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 - The corresponding interrupt source is masked. 1 - The corresponding interrupt source is not masked.
29 BABT	BABT Interrupt Mask Corresponds to interrupt source EIR[BABT] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR BABT field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 - The corresponding interrupt source is masked. 1 - The corresponding interrupt source is not masked.
28 GRA	GRA Interrupt Mask Corresponds to interrupt source EIR[GRA] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR GRA field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 - The corresponding interrupt source is masked. 1 - The corresponding interrupt source is not masked.
27 TXF	TXF Interrupt Mask Corresponds to interrupt source EIR[TXF] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The

Table continues on the next page...

Field	Description
	corresponding EIR TXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 - The corresponding interrupt source is masked. 1 - The corresponding interrupt source is not masked.
26 TXB	TXB Interrupt Mask Corresponds to interrupt source EIR[TXB] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 - The corresponding interrupt source is masked. 1 - The corresponding interrupt source is not masked.
25 RXF	RXF Interrupt Mask Corresponds to interrupt source EIR[RXF] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 - The corresponding interrupt source is masked. 1 - The corresponding interrupt source is not masked.
24 RXB	RXB Interrupt Mask Corresponds to interrupt source EIR[RXB] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RXB field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 - The corresponding interrupt source is masked. 1 - The corresponding interrupt source is not masked.
23 MII	MII Interrupt Mask Corresponds to interrupt source EIR[MII] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR MII field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 - The corresponding interrupt source is masked. 1 - The corresponding interrupt source is not masked.
22 EBERR	EBERR Interrupt Mask Corresponds to interrupt source EIR[EBERR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR EBERR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 - The corresponding interrupt source is masked. 1 - The corresponding interrupt source is not masked.
21 LC	LC Interrupt Mask Corresponds to interrupt source EIR[LC] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR LC field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 - The corresponding interrupt source is masked.

Table continues on the next page...

Field	Description
	1 - The corresponding interrupt source is not masked.
20 RL	RL Interrupt Mask Corresponds to interrupt source EIR[RL] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 - The corresponding interrupt source is masked. 1 - The corresponding interrupt source is not masked.
19 UN	UN Interrupt Mask Corresponds to interrupt source EIR[UN] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR UN field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 - The corresponding interrupt source is masked. 1 - The corresponding interrupt source is not masked.
18 PLR	PLR Interrupt Mask Corresponds to interrupt source EIR[PLR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR PLR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 - The corresponding interrupt source is masked. 1 - The corresponding interrupt source is not masked.
17 WAKEUP	WAKEUP Interrupt Mask Corresponds to interrupt source EIR[WAKEUP] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR WAKEUP field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 - The corresponding interrupt source is masked. 1 - The corresponding interrupt source is not masked.
16 TS_AVAIL	TS_AVAIL Interrupt Mask Corresponds to interrupt source EIR[TS_AVAIL] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TS_AVAIL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 - The corresponding interrupt source is masked. 1 - The corresponding interrupt source is not masked.
15 TS_TIMER	TS_TIMER Interrupt Mask Corresponds to interrupt source EIR[TS_TIMER] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TS_TIMER field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 - The corresponding interrupt source is masked. 1 - The corresponding interrupt source is not masked.
14 RXFLUSH_2	Corresponds to interrupt source EIR[RXFLUSH_2] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting

11.6.4.1.4 Receive Descriptor Active Register - Ring 0 (RDAR)

RDAR is a command register, written by the user, to indicate that the receive descriptor ring 0 has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

11.6.4.1.4.1 Offset

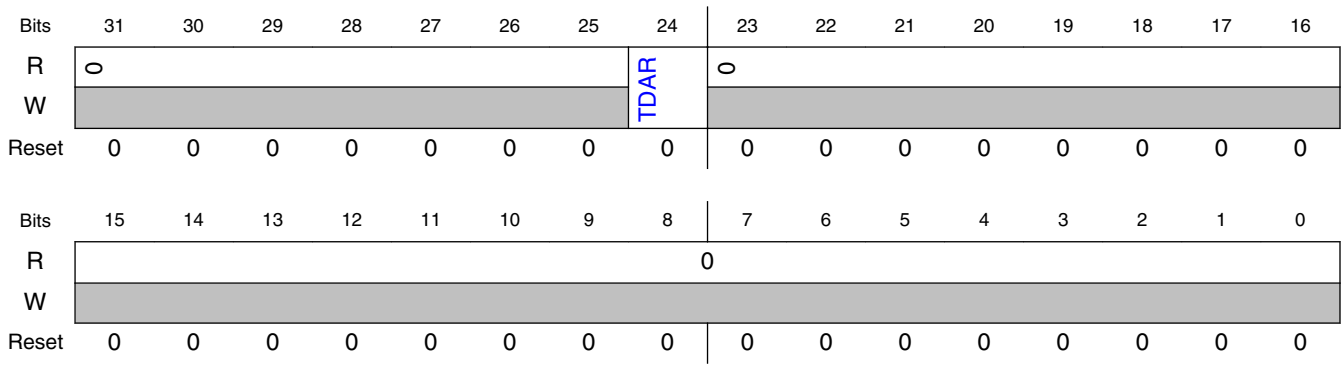
Register	Offset
RDAR	10h

11.6.4.1.4.2 Diagram

11.6.4.1.4.3 Fields

Field	Description
31-25 —	Reserved
24 RDAR	Receive Descriptor Active Always set to 1 when this register is written, regardless of the value written. This field is cleared by the MAC device when no additional empty descriptors remain in the receive ring. It is also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
23-0 —	Reserved

11.6.4.1.5 Transmit Descriptor Active Register - Ring 0 (TDAR)



The TDAR is a command register that the user writes to indicate that the transmit descriptor ring 0 has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

The TDAR register is cleared at reset, when ECR[ETHEREN] transitions from set to cleared, or when ECR[RESET] is set.

11.6.4.1.5.1 Offset

Register	Offset
TDAR	14h

11.6.4.1.5.2 Diagram

11.6.4.1.5.3 Fields

Field	Description
31-25 —	Reserved
24 TDAR	Transmit Descriptor Active Always set to 1 when this register is written, regardless of the value written. This bit is cleared by the MAC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
23-0 —	Reserved

11.6.4.1.6 Ethernet Control Register (ECR)

ECR is a read/write user register, though hardware may also alter fields in this register. It controls many of the high level features of the Ethernet MAC, including legacy FEC support through the EN1588 field.

11.6.4.1.6.1 Offset

Register	Offset

11.6.4.1.6.3 Fields

Field	Description
31-18 —	Always write 01110000000000b to this field.
17 —	Always write 0 to this field.
16 —	Always write 0 to this field.
15-12 —	Always write 0 to this field.
11 SVLANDBL	S-VLAN double tag If enabled, S-VLAN detection requires a double-tagged frame to define a frame as being a VLAN frame. The following rules apply: • If the first tag is the S-VLAN type, it must be followed by a second tag with the C-VLAN type to declare the frame as VLAN frame. • If the first tag is the S-VLAN type but no 2nd tag follows, it is not considered a VLAN frame but instead treated as an untagged frame. • If the first tag is the C-VLAN type, it is considered a VLAN frame as normal. **NOTE:** VLANUSE2ND can be used to determine from which tag the data should be extracted. This applies only if SVLAN_EN = 1, ignored otherwise. **NOTE:** This field is not supported in every instance. The following table includes only supported registers.

Instance	Field supported in	Field not supported in
ENET	—	ECR
ENET1G	ECR	—

Table continues on the next page...

<table>
<tr><th>Field</th><th>Description</th></tr>
<tr><td></td><td>0 - Disable S-VLAN double tag
1 - Enable S-VLAN double tag</td></tr>
<tr><td>10
VLANUSE2ND</td><td>VLAN use second tag
NOTE: This field is not supported in every instance. The following table includes only supported registers.
<table>
<tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr>
<tr><td>ENET</td><td>—</td><td>ECR</td></tr>
<tr><td>ENET1G</td><td>ECR</td><td>—</td></tr>
</table>
0 - Always extract data from the first VLAN tag if it exists.
1 - When a double-tagged frame is detected, the data of the second tag is extracted for further processing. A double-tagged frame is defined as: The first tag can be a C-VLAN or a S-VLAN (if SVLAN_ENA = 1) The second tag must be a C-VLAN</td></tr>
<tr><td>9
SVLANEN</td><td>S-VLAN enable
Enable additional detection of S-VLAN tag according to IEEE802.1Q.
NOTE: This field is not supported in every instance. The following table includes only supported registers.
<table>
<tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr>
<tr><td>ENET</td><td>—</td><td>ECR</td></tr>
<tr><td>ENET1G</td><td>ECR</td><td>—</td></tr>
</table>
0 - Only the EtherType 0x8100 will be considered for VLAN detection.
1 - The EtherType 0x88a8 will be considered in addition to 0x8100 (C-VLAN) to identify a VLAN frame in receive. When a VLAN frame is identified, the two bytes following the VLAN type are extracted and used by the classification match comparators, RCMRn.</td></tr>
<tr><td>8
DBSWP</td><td>Descriptor Byte Swapping Enable
Swaps the byte locations of the buffer descriptors.
NOTE: This field resets to 0 and must not be changed.
0 - The buffer descriptor bytes are not swapped to support big-endian devices.
1 - The buffer descriptor bytes are swapped to support little-endian devices.</td></tr>
<tr><td>7
—</td><td>Always write 0 to this field.</td></tr>
<tr><td>6
DBGEN</td><td>Debug Enable
Enables the MAC to enter hardware freeze mode when the device enters debug mode.
0 - MAC continues operation in debug mode.
1 - MAC enters hardware freeze mode when the processor is in debug mode.</td></tr>
<tr><td>5
SPEED</td><td>Selects between 10/100-Mbit/s and 1000-Mbit/s modes of operation.
NOTE: This field is not supported in every instance. The following table includes only supported registers.</td></tr>
</table>

Table continues on the next page...

Field	Description
	<table><tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr><tr><td>ENET</td><td>—</td><td>ECR</td></tr><tr><td>ENET1G</td><td>ECR</td><td>—</td></tr></table> 0 - 10/100-Mbit/s mode 1 - 1000-Mbit/s mode
4 EN1588	EN1588 Enable Enables enhanced functionality of the MAC. 0 - Legacy FEC buffer descriptors and functions enabled. 1 - Enhanced frame time-stamping functions enabled. Has no effect within the MAC besides controlling the DMA control bit ena_1588.
3 SLEEP	Sleep Mode Enable 0 - Normal operating mode. 1 - Sleep mode.
2 MAGICEN	Magic Packet Detection Enable Enables/disables magic packet detection. **NOTE:** MAGICEN is relevant only if the SLEEP field is set. If MAGICEN is set, changing the SLEEP field enables/disables sleep mode and magic packet detection. **NOTE:** EIMR[WAKEUP] must be written to one if Magic packet wakeup is programed to wake up the chip from low power mode. 0 - Magic detection logic disabled. 1 - The MAC core detects magic packets and asserts EIR[WAKEUP] when a frame is detected.
1 ETHEREN	Ethernet Enable Enables/disables the Ethernet MAC. When the MAC is disabled, the buffer descriptors for an aborted transmit frame are not updated. The uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers. Hardware clears this field under the following conditions: • RESET is set by software • An error condition causes the EBERR field to set. **NOTE:** • ETHEREN must be set at the very last step during ENET configuration/setup/initialization, only *after* all other ENET-related registers have been configured. • If ETHEREN is cleared to 0 by software then next time ETHEREN is set, the EIR interrupts must cleared to 0 due to previous pending interrupts. 0 - Reception immediately stops and transmission stops after a bad CRC is appended to any currently transmitted frame. 1 - MAC is enabled, and reception and transmission are possible.
0 RESET	Ethernet MAC Reset When this field is set, it clears the ETHEREN field.

11.6.4.1.7 MII Management Frame Register (MMFR)

Writing to MMFR triggers a management frame transaction to the PHY device unless MSCR is programmed to zero.

If MSCR is changed from zero to non-zero during a write to MMFR, an MII frame is generated with the data previously written to the MMFR. This allows MMFR and MSCR to be programmed in either order if MSCR is currently zero.

If the MMFR register is written while frame generation is in progress, the frame contents are altered. Software must use the EIR[MII] interrupt indication to avoid writing to the MMFR register while frame generation is in progress.

Field	Description
31-30 ST	Start Of Frame Delimiter See Table 11-84 (Clause 22) or Table 11-86 (Clause 45) for correct value.
29-28 OP	Operation Code See Table 11-84 (Clause 22) or Table 11-86 (Clause 45) for correct value.
27-23 PA	PHY Address See Table 11-84 (Clause 22) or Table 11-86 (Clause 45) for correct value.

Table continues on the next page...

Field	Description
22-18 RA	Register Address See Table 11-84 (Clause 22) or Table 11-86 (Clause 45) for correct value.
17-16 TA	Turn Around This field must be programmed to 10 to generate a valid MII management frame.
15-0 DATA	Management Frame Data This is the field for data to be written to or read from the PHY register.

11.6.4.1.8 MII Speed Control Register (MSCR)

MSCR provides control of the MII clock (MDC pin) frequency and allows a preamble drop on the MII management frame.

The MII_SPEED field must be programmed with a value to provide an MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII_SPEED must be set to a non-zero value to source a read or write management frame. After the management frame is complete, the MSCR register may optionally be cleared to turn off MDC. The MDC signal generated has a 50% duty cycle except when MII_SPEED changes during operation. This change takes effect following a rising or falling edge of MDC.

For example, if the internal module clock (that is, peripheral bus clock) is 25 MHz, programming MII_SPEED to 0x4 results in an MDC as given in the following equation:

MII clock frequency = 25 MHz / ((4 + 1) x 2) = 2.5 MHz

The following table shows the optimum values for MII_SPEED as a function of IPS bus clock frequency.

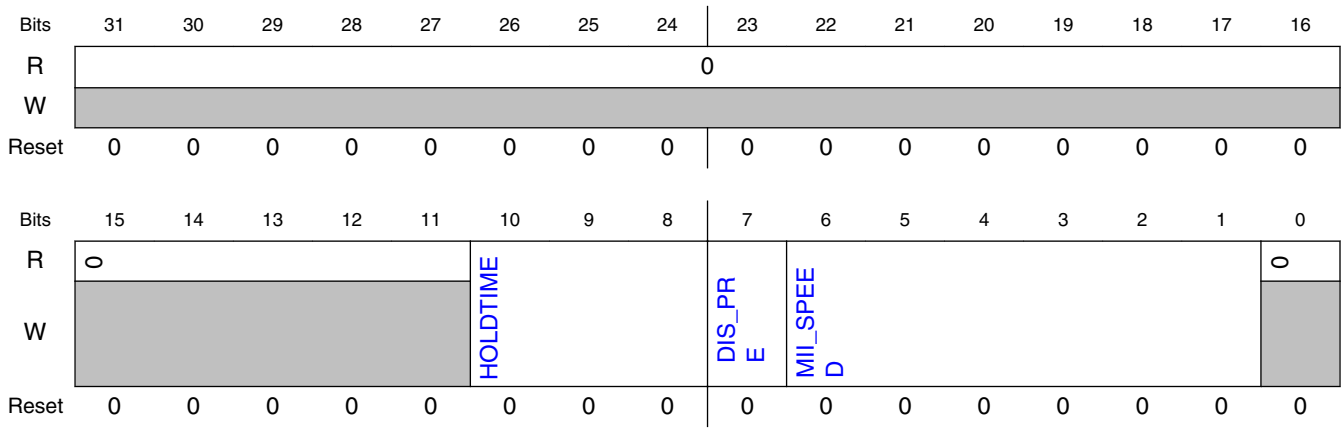

Table 11-92. Programming Examples for MSCR

Internal module clock frequency	MSCR [MII_SPEED]	MDC frequency
25 MHz	0x4	2.50 MHz
33 MHz	0x6	2.36 MHz
40 MHz	0x7	2.50 MHz
50 MHz	0x9	2.50 MHz
66 MHz	0xD	2.36 MHz

Register	Offset
MSCR	44h

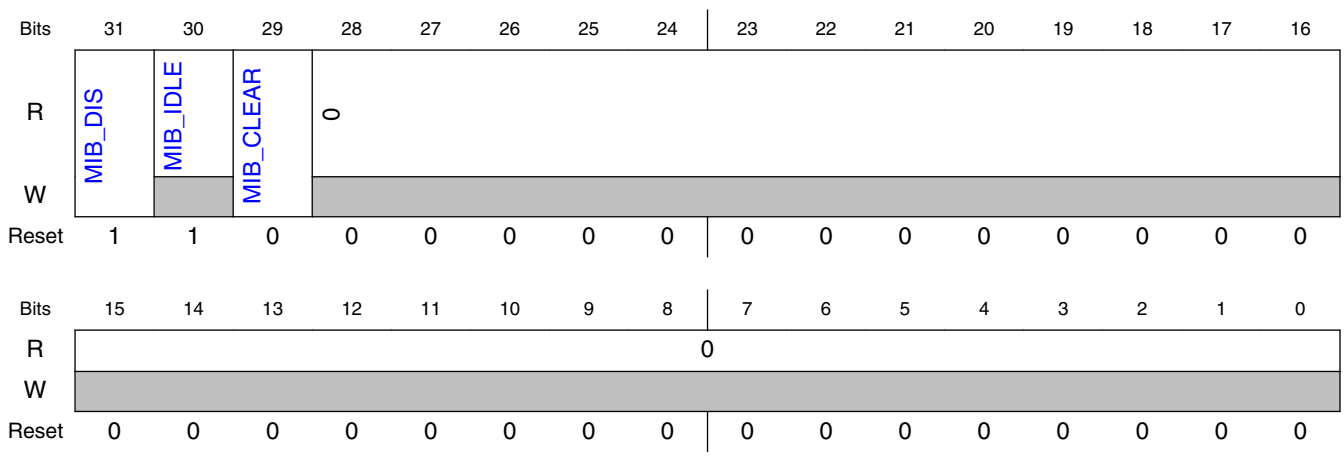
11.6.4.1.8.2 Diagram

11.6.4.1.8.3 Fields

Field	Description
31-11 —	Reserved
10-8 HOLDTIME	Hold time On MDIO Output IEEE802.3 clause 22 defines a minimum of 10 ns for the hold time on the MDIO output. Depending on the host bus frequency, the setting may need to be increased. 000 - 1 internal module clock cycle 001 - 2 internal module clock cycles 010 - 3 internal module clock cycles 111 - 8 internal module clock cycles
7 DIS_PRE	Disable Preamble Enables/disables prepending a preamble to the MII management frame. The MII standard allows the preamble to be dropped if the attached PHY devices do not require it. 0 - Preamble enabled. 1 - Preamble (32 ones) is not prepended to the MII management frame.
6-1 MII_SPEED	MII Speed Controls the frequency of the MII management interface clock (MDC) relative to the internal module clock. A value of 0 in this field turns off MDC and leaves it in low voltage state. Any non-zero value results in the MDC frequency of: 1/((MII_SPEED + 1) x 2) of the internal module clock frequency

Table continues on the next page...

Field	Description
0 —	Reserved



11.6.4.1.9 MIB Control Register (MIBC)

MIBC is a read/write register controlling and observing the state of the MIB block. Access this register to disable the MIB block operation or clear the MIB counters. The MIB_DIS field resets to 1.

11.6.4.1.10.3 Fields

Field	Description
31 GRS	Graceful Receive Stopped Read-only status indicating that the MAC receive datapath is stopped.

Table continues on the next page...

Field	Description
	0 - Receive not stopped 1 - Receive stopped
30 NLC	Payload Length Check Disable Enables/disables a payload length check. 0 - The payload length check is disabled. 1 - The core checks the frame's payload length with the frame length/type field. Errors are indicated in the EIR[PLR] field.
29-16 MAX_FL	Maximum Frame Length Resets to decimal 1518. Length is measured starting at DA and includes the CRC at the end of the frame. Transmit frames longer than MAX_FL cause the BABT interrupt to occur. Receive frames longer than MAX_FL cause the BABR interrupt to occur and set the LG field in the end of frame receive buffer descriptor. The recommended default value to be programmed is 1518 or 1522 if VLAN tags are supported.
15 CFEN	MAC Control Frame Enable Enables/disables the MAC control frame. 0 - MAC control frames with any opcode other than 0x0001 (pause frame) are accepted and forwarded to the client interface. 1 - MAC control frames with any opcode other than 0x0001 (pause frame) are silently discarded.
14 CRCFWD	Terminate/Forward Received CRC Specifies whether the CRC field of received frames is transmitted or stripped. **NOTE:** If padding function is enabled (PADEN = 1), CRCFWD is ignored and the CRC field is checked and always terminated and removed. 0 - The CRC field of received frames is transmitted to the user application. 1 - The CRC field is stripped from the frame.
13 PAUFWD	Terminate/Forward Pause Frames Specifies whether pause frames are terminated or forwarded. 0 - Pause frames are terminated and discarded in the MAC. 1 - Pause frames are forwarded to the user application.
12 PADEN	Enable Frame Padding Remove On Receive Specifies whether the MAC removes padding from received frames. 0 - No padding is removed on receive by the MAC. 1 - Padding is removed from received frames.
11-10 —	This write-only field is reserved. It must always be written with the value 0.
9 RMII_10T	Enables 10-Mbit/s mode of the RMII or RGMII . **NOTE:** The descriptions of the field settings vary by module instance.

Instance	Field value and description
ENET	0 - 100-Mbit/s operation. 1 - 10-Mbit/s operation.
ENET1G	0 - 100-Mbit/s or 1-Gbit/s operation.

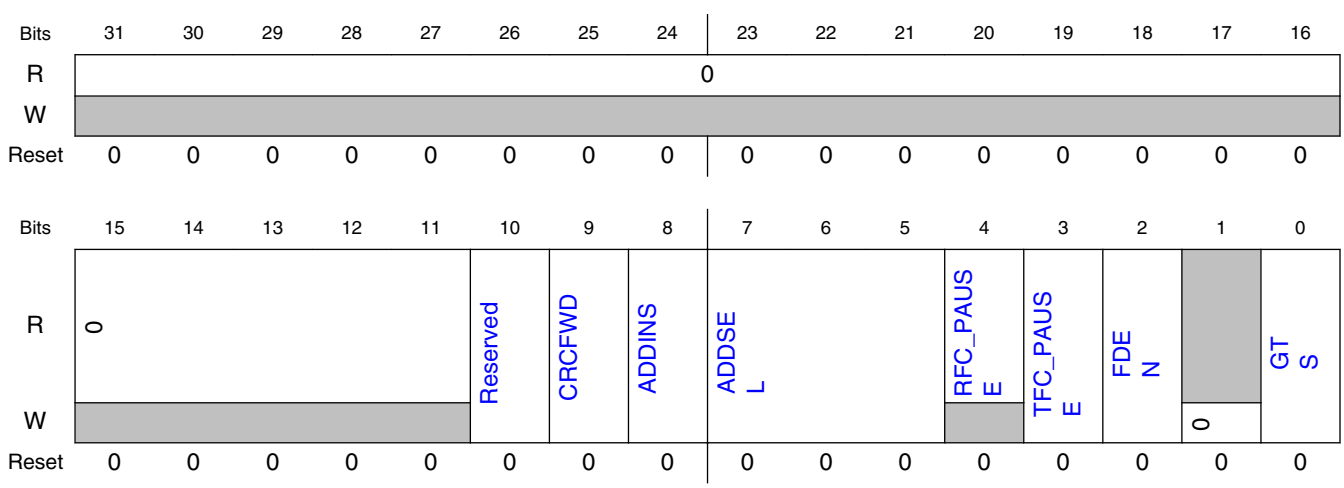
BC_REJ</td><td>Broadcast Frame Reject
If set, frames with destination address (DA) equal to 0xFFFF_FFFF_FFFF are rejected unless the PROM field is set. If BC_REJ and PROM are set, frames with broadcast DA are accepted and the MISS (M) is set in the receive buffer descriptor.
0 - Will not reject frames as described above
1 - Will reject frames as described above</td></tr>
<tr><td>3
PROM</td><td>Promiscuous Mode
All frames are accepted regardless of address matching.
0 - Disabled.
1 - Enabled.</td></tr>
<tr><td>2
MII_MODE</td><td>Media Independent Interface Mode
This field must always be set.
0 - Reserved.
1 - MII or RMII mode, as indicated by the RMII_MODE field.</td></tr>
</table>

Table continues on the next page...

Field	Description
1 DRT	Disable Receive On Transmit 0 - Receive path operates independently of transmit (i.e., full-duplex mode). Can also be used to monitor transmit activity in half-duplex mode. 1 - Disable reception of frames while transmitting. (Normally used for half-duplex mode.)
0 LOOP	Internal Loopback This is an MII internal loopback, therefore MII_MODE must be written to 1 and RMII_MODE must be written to 0. 0 - Loopback disabled. 1 - Transmitted frames are looped back internal to the device and transmit MII output signals are not asserted. DRT must be cleared.



11.6.4.1.11 Transmit Control Register (TCR)

TCR is read/write and configures the transmit block. This register is cleared at system reset. FDEN can only be modified when ECR[ETHEREN] is cleared.

11.6.4.1.11.1 Offset

Register	Offset
TCR	C4h

11.6.4.1.11.2 Diagram

11.6.4.1.11.3 Fields

Field	Description
31-11 —	Reserved
10 —	This field is read/write and must be set to 0.
9 CRCFWD	Forward Frame From Application With CRC 0 - TxBD[TC] controls whether the frame has a CRC from the application. 1 - The transmitter does not append any CRC to transmitted frames, as it is expecting a frame with CRC from the application.
8 ADDINS	Set MAC Address On Transmit 0 - The source MAC address is not modified by the MAC. 1 - The MAC overwrites the source MAC address with the programmed MAC address according to ADDSEL.
7-5 ADDSEL	Source MAC Address Select On Transmit If ADDINS is set, indicates the MAC address that overwrites the source MAC address. 000 - Node MAC address programmed on PADDR1/2 registers. 100 - Reserved. 101 - Reserved. 110 - Reserved.
4 RFC_PAUSE	Receive Frame Control Pause This status field is set when a full-duplex flow control pause frame is received and the transmitter pauses for the duration defined in this pause frame. This field automatically clears when the pause duration is complete.
3 TFC_PAUSE	Transmit Frame Control Pause Pauses frame transmission. When this field is set, EIR[GRA] is set. With transmission of data frames stopped, the MAC transmits a MAC control PAUSE frame. Next, the MAC clears TFC_PAUSE and resumes transmitting data frames. If the transmitter pauses due to user assertion of GTS or reception of a PAUSE frame, the MAC may continue transmitting a MAC control PAUSE frame. 0 - No PAUSE frame transmitted. 1 - The MAC stops transmission of data frames after the current transmission is complete.
2 FDEN	Full-Duplex Enable If this field is set, frames transmit independent of carrier sense and collision inputs. Only modify this bit when ECR[ETHEREN] is cleared. 0 - Disable full-duplex 1 - Enable full-duplex
1 —	This write-only field is reserved. It must always be written with the value 0.
0 GTS	Graceful Transmit Stop When this field is set, MAC stops transmission after any frame currently transmitted is complete and EIR[GRA] is set. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission finishes, clear GTS to restart. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS is set, transmission stops after the

Field	Description
	collision. The frame is transmitted again after GTS is cleared. There may be old frames in the transmit FIFO that transmit when GTS is reasserted. To avoid this, clear ECR[ETHEREN] following the GRA interrupt. 0 - Disable graceful transmit stop 1 - Enable graceful transmit stop

11.6.4.1.12 Physical Address Lower Register (PALR)

PALR contains the lower 32 bits (bytes 0, 1, 2, 3) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 0 through 3 of the six-byte source address field when transmitting PAUSE frames.

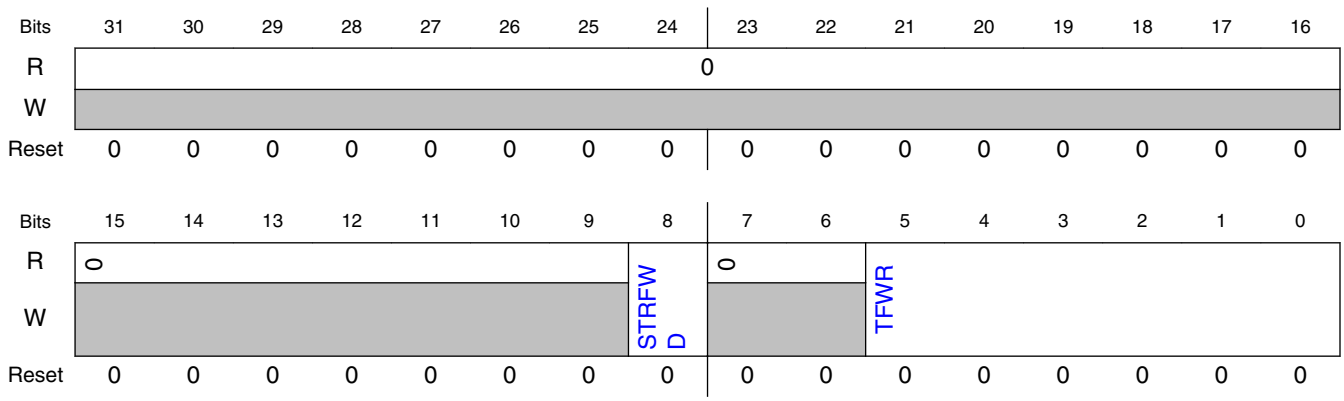
11.6.4.1.20.3 Fields

Field	Description
31-0 GADDR2	Contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0.

11.6.4.1.21 Transmit FIFO Watermark Register (TFWR)

If TFWR[STRFWD] is cleared, TFWR[TFWR] controls the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows you to minimize transmit latency (TFWR = 00 or 01) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement, for example, worst-case bus access latency by the transmit data uDMA channel.

When the FIFO level reaches the value the TFWR field and when the STR_FWD is set to ‘0’, the MAC transmit control logic starts frame transmission even before the end-of-frame is available in the FIFO (cut-through operation).



If a complete frame has a size smaller than the threshold programmed with TFWR, the MAC also transmits the Frame to the line.

To enable store and forward on the Transmit path, set STR_FWD to ‘1’. In this case, the MAC starts to transmit data only when a complete frame is stored in the Transmit FIFO.

11.6.4.1.21.1 Offset

Register	Offset
TFWR	144h

11.6.4.1.21.2 Diagram

11.6.4.1.21.3 Fields

Field	Description
31-9 —	Reserved
8 STRFWD	Store And Forward Enable 0 - Reset. The transmission start threshold is programmed in TFWR[TFWR]. 1 - Enabled.
7-6 —	Reserved
5-0 TFWR	Transmit FIFO Write If TFWR[STRFWD] is cleared, this field indicates the number of bytes, in steps of 64 bytes, written to the transmit FIFO before transmission of a frame begins. **NOTE:** If a frame with less than the threshold is written, it is still sent independently of this threshold setting. The threshold is relevant only if the frame is larger than the threshold given. 000000 - 64 bytes written. 000001 - 64 bytes written. 000010 - 128 bytes written. 000011 - 192 bytes written. 011111 - 1984 bytes written. 111111 - 4032 bytes written.

11.6.4.1.22 Receive Descriptor Ring 1 Start Register (RDSR1)

RDSR1 points to the beginning of circular receive buffer descriptor queue 1 in external memory. This pointer must be 64-bit aligned (bits 2–0 must be zero); however, for optimal performance the pointer should be 512-bit aligned, that is, evenly divisible by 64.

NOTE

This register must be initialized prior to operation.

11.6.4.1.24 Maximum Receive Buffer Size Register - Ring 1 (MRBR1)

MRBR1 is a user-programmable register that dictates the maximum size of all ring-1 receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer.

- To allow one maximum size frame per buffer, MRBR1 must be set to RCR[MAX_FL] or larger.
- R_BUF_SIZE is concatentated with the four least-significant bits of this register and are used as the maximum receive buffer size.
- To properly align the buffer, MRBR1 must be evenly divisible by 64. To ensure this, set the lower two bits of R_BUF_ZIZE to zero. The lower four bits are already set to zero by the device.
- To minimize bus usage (descriptor fetches), set MRBR1 greater than or equal to 256 bytes.

NOTE

This register must be initialized before operation.

Register	Offset
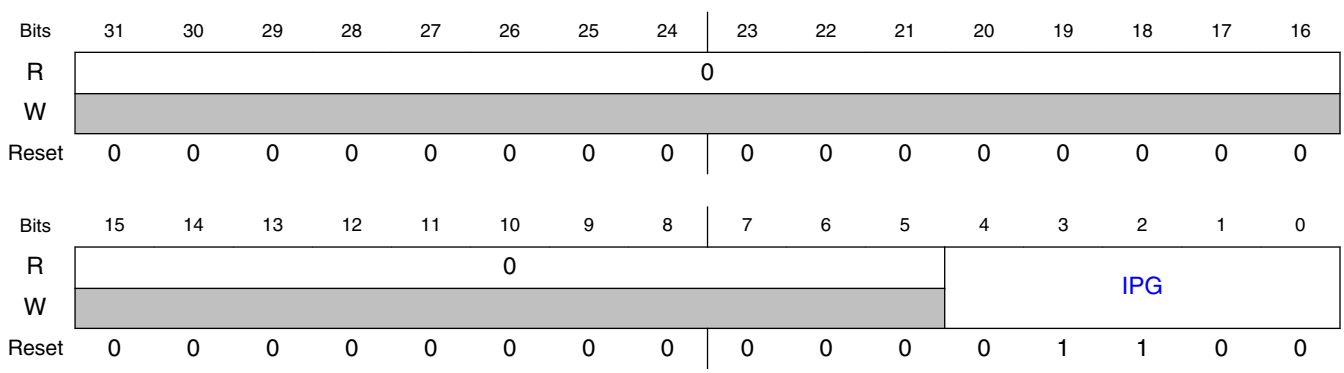
TAFL	1A8h

11.6.4.1.37.2 Diagram

11.6.4.1.37.3 Fields

Field	Description
31-10 —	Reserved
9-0 TX_ALMOST_FULL	Value Of The Transmit FIFO Almost Full Threshold Value, in 64-bit words, of the transmit FIFO almost full threshold. A minimum value of six is required . A recommended value of at least 8 should be set allowing a latency of two clock cycles to the application. If more latency is required the value can be increased as necessary (latency = TAFL - 5). When the FIFO level comes close to the maximum, so that there is no more space for at least TX_ALMOST_FULL number of words, the pin ff_tx_rdy is deasserted. If the application does not react on this signal, the FIFO write control logic, to avoid FIFO overflow, truncates the current frame and sets the error status. As a result, the frame will be transmitted with an GMII/MII error indication. See Transmit FIFO for more information. **NOTE:** A FIFO overflow is a fatal error and requires a global reset on the transmit datapath or at least deassertion of ETHEREN. **NOTE:** This field is not supported in every instance. The following table includes only supported registers.



Field	Description		
	Instance	**Field supported in**	**Field not supported in**
	ENET	TAFL[7–0]	TAFL[9–8]
	ENET1G	TAFL	—

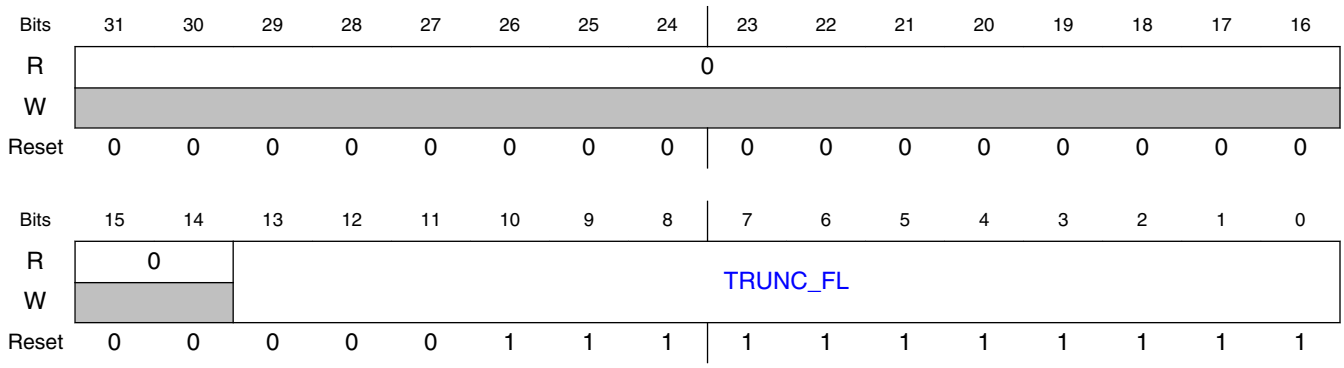
11.6.4.1.38 Transmit Inter-Packet Gap (TIPG)

11.6.4.1.38.1 Offset

Register	Offset
TIPG	1ACh

11.6.4.1.38.2 Diagram

11.6.4.1.38.3 Fields



Field	Description
31-5 —	Reserved
4-0 IPG	Transmit Inter-Packet Gap Indicates the IPG, in bytes, between transmitted frames. Valid values range from 8 to 26. If the written value is less than 8 or greater than 26, the internal (effective) IPG is 12. **NOTE:** The IPG value read will be the value that was written, even if it is out of range.

11.6.4.1.39 Frame Truncation Length (FTRL)

11.6.4.1.39.1 Offset

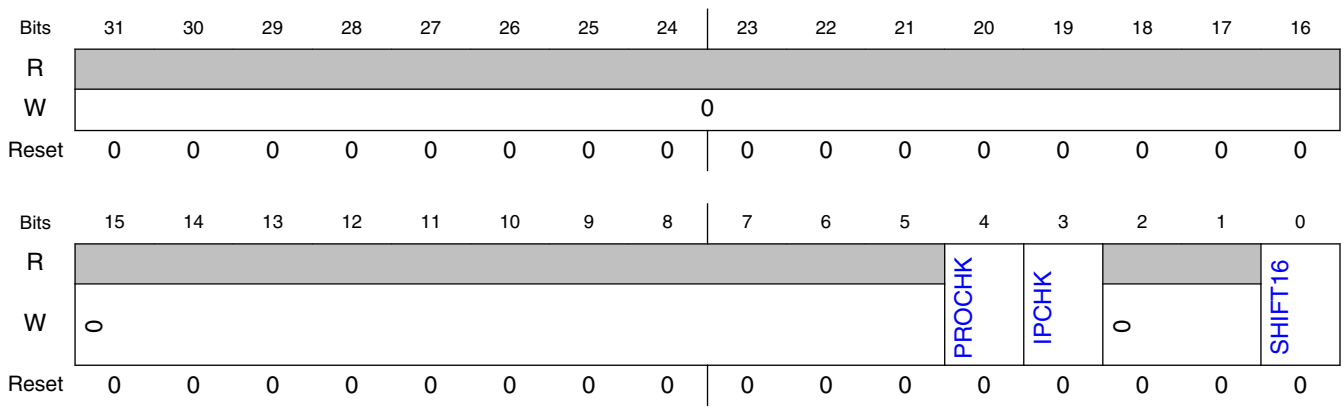
Register	Offset
FTRL	1B0h

11.6.4.1.39.2 Diagram

11.6.4.1.39.3 Fields

Field	Description
31-14 —	Reserved
13-0 TRUNC_FL	Frame Truncation Length Indicates the value a receive frame is truncated, if it is greater than this value. Must be greater than or equal to RCR[MAX_FL]. **NOTE:** Truncation happens at TRUNC_FL. However, when truncation occurs, the application (FIFO) may receive less data, guaranteeing that it never receives more than the set limit.

11.6.4.1.40 Transmit Accelerator Function Configuration (TACC)



TACC controls accelerator actions when sending frames. The register can be changed before or after each frame, but it must remain unmodified during frame writes into the transmit FIFO.

The TFWR[STRFWD] field must be set to use the checksum feature.

11.6.4.1.40.1 Offset

Register	Offset
TACC	1C0h

11.6.4.1.40.2 Diagram

11.6.4.1.40.3 Fields

Field	Description
31-5 —	This write-only field is reserved. It must always be written with the value 0.
4 PROCHK	Enables insertion of protocol checksum. 0 - Checksum not inserted. 1 - If an IP frame with a known protocol is transmitted, the checksum is inserted automatically into the frame. The checksum field must be cleared. The other frames are not modified.
3 IPCHK	Enables insertion of IP header checksum. 0 - Checksum is not inserted. 1 - If an IP frame is transmitted, the checksum is inserted automatically. The IP header checksum field must be cleared. If a non-IP frame is transmitted the frame is not modified.
2-1 —	This write-only field is reserved. It must always be written with the value 0.
0 SHIFT16	TX FIFO Shift-16 0 - Disabled. 1 - Indicates to the transmit data FIFO that the written frames contain two additional octets before the frame data. This means the actual frame begins at bit 16 of the first word written into the FIFO. This function allows putting the frame payload on a 32-bit boundary in memory, as the 14-byte Ethernet header is extended to a 16-byte header.

11.6.4.1.41 Receive Accelerator Function Configuration (RACC)

11.6.4.1.41.1 Offset

Register	Offset
RACC	1C4h

11.6.4.1.41.3 Fields

Field	Description
31-8 —	This write-only field is reserved. It must always be written with the value 0.
7 SHIFT16	RX FIFO Shift-16 When this field is set, the actual frame data starts at bit 16 of the first word read from the RX FIFO aligning the Ethernet payload on a 32-bit boundary. **NOTE:** This function only affects the FIFO storage and has no influence on the statistics, which use the actual length of the frame received. 0 - Disabled. 1 - Instructs the MAC to write two additional bytes in front of each frame received into the RX FIFO.
6 LINEDIS	Enable Discard Of Frames With MAC Layer Errors 0 - Frames with errors are not discarded. 1 - Any frame received with a CRC, length, or PHY error is automatically discarded and not forwarded to the user application interface.

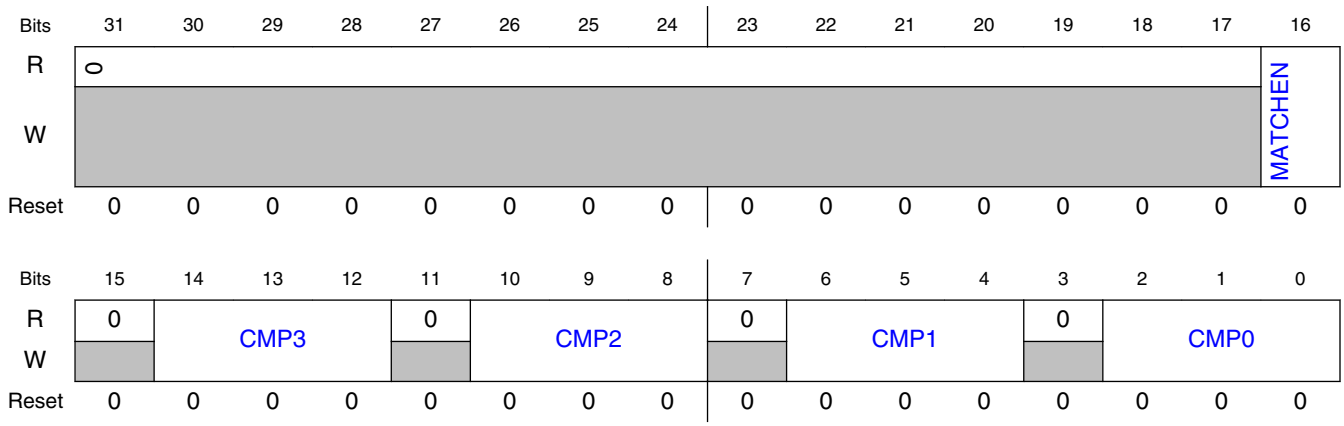
Table continues on the next page...

Field	Description
5-3 —	This write-only field is reserved. It must always be written with the value 0.
2 PRODIS	Enable Discard Of Frames With Wrong Protocol Checksum 0 - Frames with wrong checksum are not discarded. 1 - If a TCP/IP, UDP/IP, or ICMP/IP frame is received that has a wrong TCP, UDP, or ICMP checksum, the frame is discarded. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).
1 IPDIS	Enable Discard Of Frames With Wrong IPv4 Header Checksum 0 - Frames with wrong IPv4 header checksum are not discarded. 1 - If an IPv4 frame is received with a mismatching header checksum, the frame is discarded. IPv6 has no header checksum and is not affected by this setting. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).
0 PADREM	Enable Padding Removal For Short IP Frames 0 - Padding not removed. 1 - Any bytes following the IP payload section of the frame are removed from the frame.

11.6.4.1.42 Receive Classification Match Register for Class n (RCMR1 - RCMR2)

This match register allows specifying up to four priorities, which are tested (OR'ed) simultaneously. The match detection uses the extracted VLAN field according to the rules for VLAN detection configured through the ECR register. If both match registers, RCMR1 and RCMR2, report a match at the same time, only the class 1 match is indicated as the final result.

11.6.4.1.42.1 Offset



Register	Offset
RCMR1	1C8h
RCMR2	1CCh

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ENET	—	RCMR1–RCMR2
ENET1G	RCMR1–RCMR2	—

11.6.4.1.42.2 Diagram

11.6.4.1.42.3 Fields

Field	Description
31-17 —	This write-only field is reserved. It must always be written with the value 0.
16 MATCHEN	Match Enable **NOTE:** A comparison is done only on incoming VLAN frames. If no VLAN frame is received no match will occur. If both match registers have overlapping compare values and hence can match both on the same frame, only class 1 will be indicated and the class 2 match is ignored. 0 - Disabled (default): no compares will occur and the classification indicator for this class will never assert. 1 - The register contents are valid and a comparison with all compare values is done when a VLAN frame is received.
15 —	This write-only field is reserved. It must always be written with the value 0.
14-12 CMP3	Compare 3 Fourth value to compare against. If unused it must be set to the same value as CMP0.
11 —	This write-only field is reserved. It must always be written with the value 0.
10-8 CMP2	Compare 2 Third value to compare against. If unused it must be set to the same value as CMP0.
7 —	This write-only field is reserved. It must always be written with the value 0.
6-4 CMP1	Compare 1 Second value to compare against. If unused it must be set to the same value as CMP0.
3	This write-only field is reserved. It must always be written with the value 0.

Table continues on the next page...

Field	Description
—	
2-0 CMP0	Compare 0 A three-bit value that will be compared with the frame's VLAN priority field (if a VLAN frame is received). All four compare values, CMP0..3, will be used in parallel. If any of the values match, a match for the class is reported (if MATCHEN is 1). **NOTE:** To implement a single priority match, all four compare values must be set to the same value.

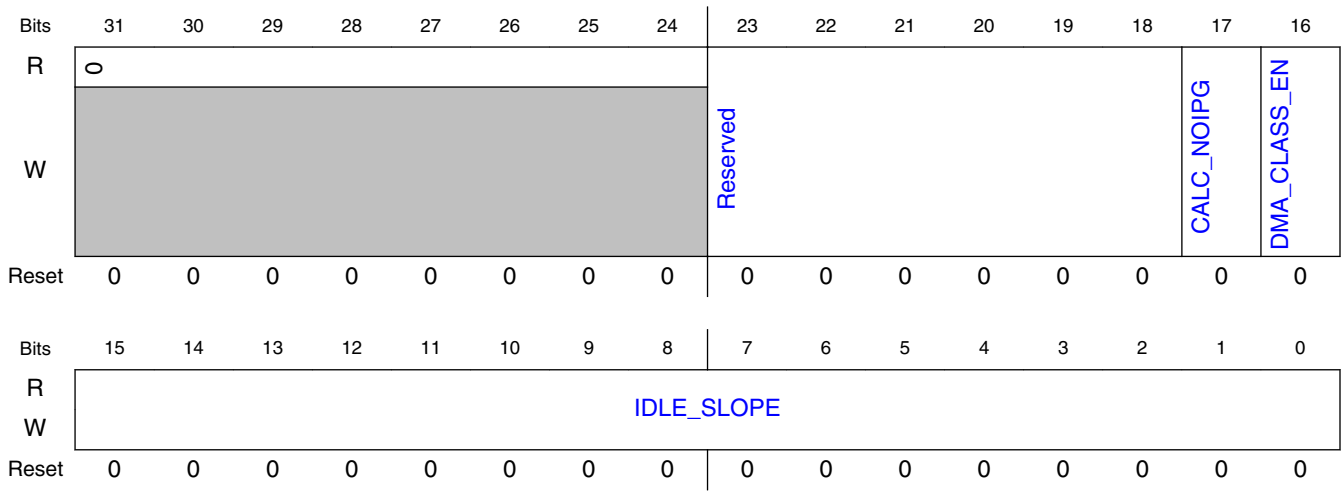
11.6.4.1.43 DMA Class Based Configuration (DMA1CFG - DMA2CFG)

The DMA class based configuration registers are used to configure the DMA controller interface to support the additional class 1 (buffer descriptor ring 1) and class 2 (buffer descriptor ring 2) traffic and define configuration options such as bandwidth allocation as needed.

NOTE

The registers are cleared when ECR[ETHEREN] becomes 0.

11.6.4.1.43.1 Offset



Register	Offset
DMA1CFG	1D8h
DMA2CFG	1DCh

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ENET	—	DMA1CFG–DMA2CFG
ENET1G	DMA1CFG–DMA2CFG	—

11.6.4.1.43.2 Diagram

11.6.4.1.43.3 Fields

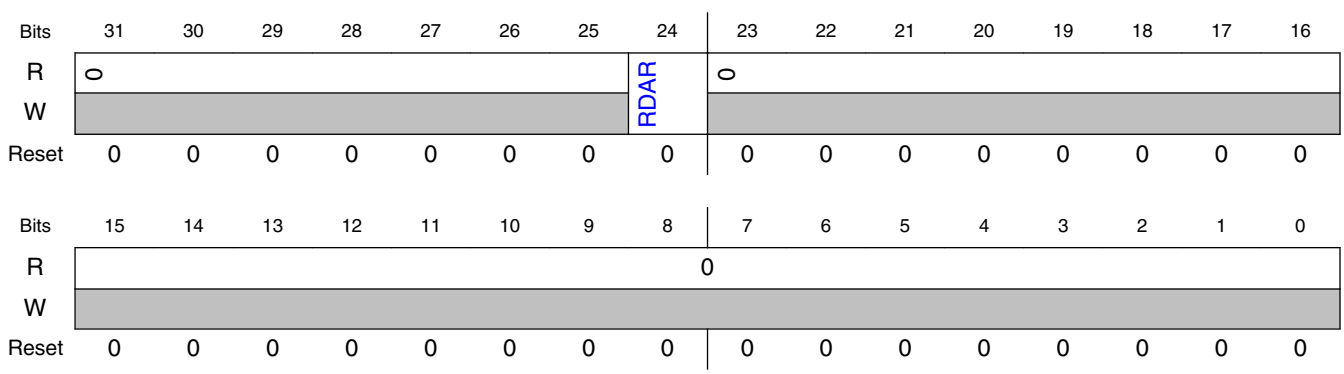
Field	Description
31-24 —	Reserved
23-18 —	Write only zeroes to this field **NOTE:** Write only zeroes to this field.
17 CALC_NOIPG	Calculate no IPG Disable inclusion of IPG bytes for bandwidth calculations. 0 - The traffic shaper function should consider 12 octets of IPG in addition to the frame data transferred for a frame when doing bandwidth calculations. This is the default. 1 - Addition of 12 bytes for the IPG should be omitted when calculating the bandwidth (for traffic shaping, when writing a frame into the transmit FIFO, the shaper will usually consider 12 bytes of IPG for every frame as part of the bandwidth allocated by the frame. This addition can be suppressed, meaning short frames will become more bandwidth than large frames due to the relation of data to IPG overhead).
16 DMA_CLASS_EN	DMA class enable 0 - The DMA controller's channel for the class is not used. Disabling the DMA controller of a class also requires disabling the class match comparator for the class (see registers RCMRn). When class 1 and class 2 queues are disabled then their frames will be placed in queue 0. 1 - Enable the DMA controller to support the corresponding descriptor ring for this class of traffic.
15-0 IDLE_SLOPE	Idle slope 16-bit value to define the per class idle slope setting used by the credit based shaper defining allocated bandwidth for the class. This value is used to calculate the BW (bandwidth) fraction, given by the equation, BW fraction = 1/(1+512/IDLE_SLOPE). Idle slope is restricted to certain values. For values less than 128, idle slope = 2^n, where n = 0, 1, 2, ...6. For values equal to or greater than 128, idle slope = 128×m, where m = 1, 2, 3, ...12. Example 1. BW fraction = 0.20 = 1/(1+(512/128)); therefore idleslope = 128. Example 2. BW fraction = 0.33 = 1/(1+(512/256)); therefore idleslope = 256.

Field	Description
	Example 3. BW fraction = 0.75 = 1/(1+(512/1536)); therefore idleslope = 1536. **NOTE:** For AVB applications, the BW fraction of class 1 and class 2 combined must not exceed .75.

11.6.4.1.44 Receive Descriptor Active Register - Ring 1 (RDAR1)

RDAR1 is a command register, written by the user, to indicate that the receive descriptor ring 1 has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

11.6.4.1.44.1 Offset



Register	Offset
RDAR1	1E0h

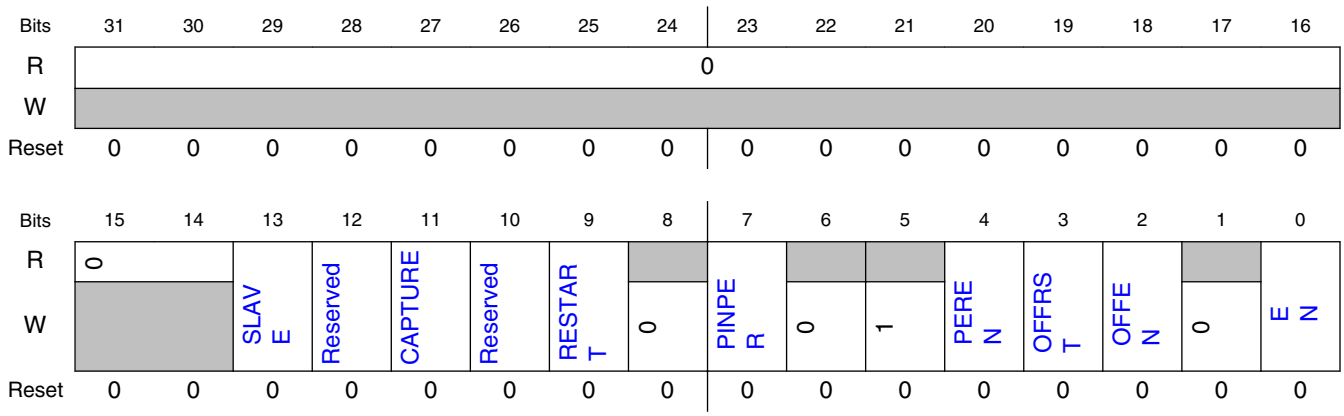
11.6.4.1.99.3 Fields

Field	Description
31-0 COUNT	Number of octets for frames received without error **NOTE:** Counts total octets (includes header and FCS fields). Does not increment for the broadcast frames when broadcast reject is enabled and promiscuous mode is disabled within the receive control register (RCR).

11.6.4.1.100 Adjustable Timer Control Register (ATCR)

ATCR command fields can trigger the corresponding events directly. It is not necessary to preserve any of the configuration fields when a command field is set in the register, that is, no read-modify-write is required.



NOTE

The CAPTURE and RESTART fields and bits 12 and 10 must be 0 in order to write to the other fields in this register.

11.6.4.1.100.1 Offset

Register	Offset
ATCR	400h

11.6.4.1.100.2 Diagram

11.6.4.1.100.3 Fields

Field	Description
31-14 —	Reserved
13 SLAVE	Enable Timer Slave Mode 0 - The timer is active and all configuration fields in this register are relevant. 1 - The internal timer is disabled and the externally provided timer value is used. All other fields, except CAPTURE, in this register have no effect. CAPTURE can still be used to capture the current timer value.
12 —	Always write 0 to this field Always write 0 to this field.
11 CAPTURE	Capture Timer Value When this field is set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes. **NOTE:** **WARNING:** To ensure that the correct time value is read from the ATVR register, a minimum amount of time must elapse from issuing this command to reading the ATVR register. This minimum time is defined by the greater of either six register clock cycles or six 1588/timestamp clock cycles. 0 - No effect. 1 - The current time is captured and can be read from the ATVR register.
10 —	Always write 0 to this field Always write 0 to this field.
9 RESTART	Reset Timer Resets the timer to zero. This has no effect on the counter enable. If the counter is enabled when this field is set, the timer is reset to zero and starts counting from there. When set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes. RESTART should be used when the timer is enabled. **NOTE:** **WARNING:** The Reset Timer command requires at least 6 clock cycles of either the register clock or the 1588/timestamp clock, whichever is greater, to complete.
8	Reserved

Table continues on the next page...

Field	Description
—	
7 PINPER	Enables event signal output external pin frc_evt_period assertion on period event Enables event signal output assertion on period event. **NOTE:** Not all devices contain the event signal output. See the chip configuration details. 0 - Disable. 1 - Enable.
6 —	Reserved
5 —	This field must be written always with one **NOTE:** This field must be written always with one.
4 PEREN	Enable Periodical Event 0 - Disable. 1 - A period event interrupt can be generated (EIR[TS_TIMER]) and the event signal output is asserted when the timer wraps around according to the periodic setting ATPER. The timer period value must be set before setting this bit. Not all devices contain the event signal output. See the chip configuration details.
3 OFFRST	Reset Timer On Offset Event 0 - The timer is not affected and no action occurs, besides clearing OFFEN, when the offset is reached. 1 - If OFFEN is set, the timer resets to zero when the offset setting is reached. The offset event does not cause a timer interrupt.
2 OFFEN	Enable One-Shot Offset Event 0 - Disable. 1 - The timer can be reset to zero when the given offset time is reached (offset event). The field is cleared when the offset event is reached, so no further event occurs until the field is set again. The timer offset value must be set before setting this field.
1 —	Reserved
0 EN	Enable Timer 0 - The timer stops at the current value. 1 - The timer starts incrementing.

11.6.4.1.101 Timer Value Register (ATVR)

R W	PERIOD															
Reset	1	1	0	0	1	0	1	0	0	0	0	0	0	0	0	0

11.6.4.1.103.3 Fields

Field	Description
31-0 PERIOD	Value for generating periodic events Value for generating periodic events. Each instance the timer reaches this value, the period event occurs and the timer restarts. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds. The value should be initialized to 1,000,000,000 (1×10^9) to represent a timer wrap around of one second. The increment value set in ATINC should be set to the true nanoseconds of the period of clock ts_clk, hence implementing a true 1 second counter. **NOTE:** The value of PERIOD has the following constraint: 2^{32} – ENET_ATINC[INC_COR] – 3×ENET_ATINC[INC] ≥ PERIOD > 0.

11.6.4.1.104 Timer Correction Register (ATCOR)

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

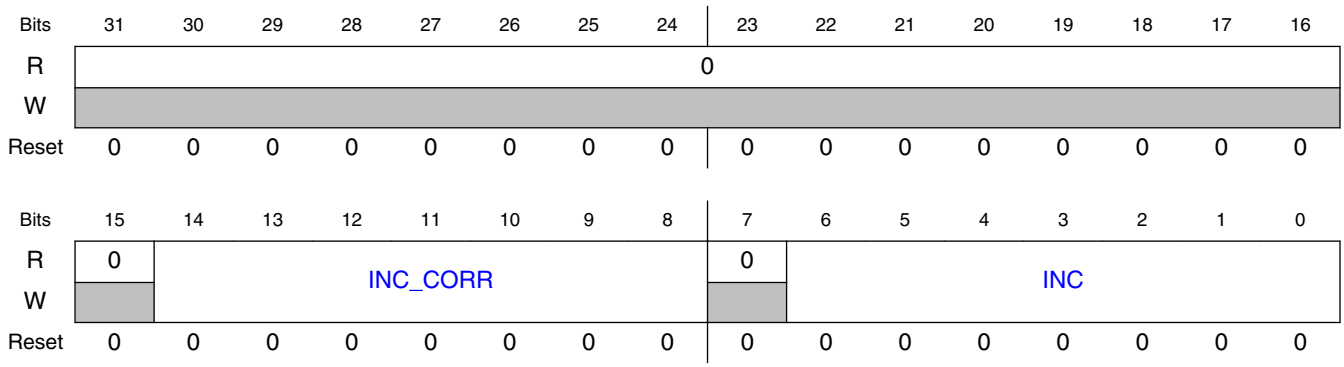
11.6.4.1.104.3 Fields



Field	Description
31 —	Reserved
30-0 COR	Correction Counter Wrap-Around Value Defines after how many timer clock cycles (ts_clk) the correction counter should be reset and trigger a correction increment on the timer. The amount of correction is defined in ATINC[INC_CORR]. A value of 0 disables the correction counter and no corrections occur. **NOTE:** This value is given in clock cycles, not in nanoseconds as all other values.

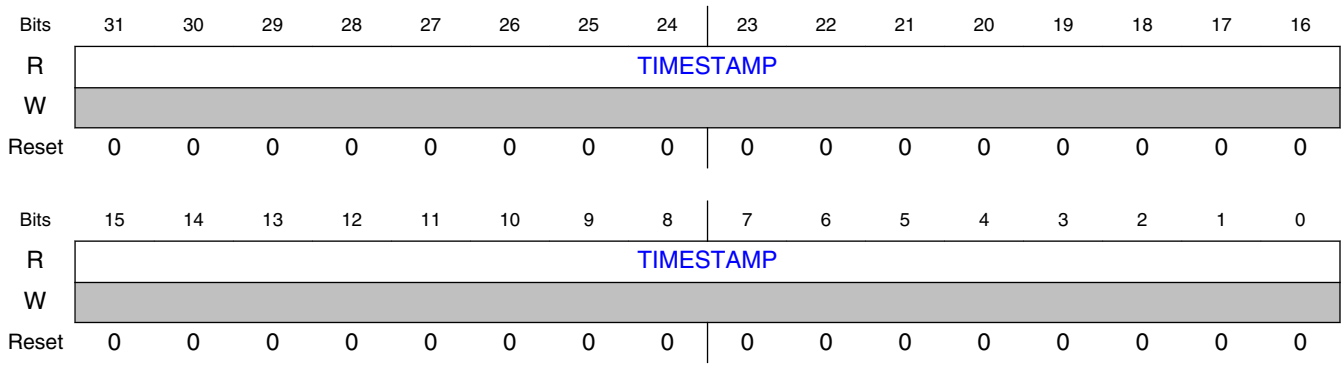
11.6.4.1.105 Time-Stamping Clock Period Register (ATINC)

11.6.4.1.105.1 Offset

Register	Offset
ATINC	414h

11.6.4.1.105.2 Diagram

11.6.4.1.105.3 Fields



Field	Description
31-15 —	Reserved
14-8 INC_CORR	Correction Increment Value This value is added every time the correction timer expires (every clock cycle given in ATCOR). A value less than INC slows down the timer. A value greater than INC speeds up the timer.
7 —	Reserved
6-0 INC	Clock Period Of The Timestamping Clock (ts_clk) In Nanoseconds The timer increments by this amount each clock cycle. For example, set to 10 for 100 MHz, 8 for 125 MHz, 5 for 200 MHz. **NOTE:** For highest precision, use a value that is an integer fraction of the period set in ATPER.

11.6.4.1.106 Timestamp of Last Transmitted Frame (ATSTMP)

11.6.4.1.106.1 Offset

Register	Offset
ATSTMP	418h

11.6.4.1.106.2 Diagram

11.6.4.1.106.3 Fields

Field	Description
31-0 TIMESTAMP	Timestamp of the last frame transmitted by the core that had TxBD[TS] set the ff_tx_ts_frm signal asserted from the user application Timestamp of the last frame transmitted by the core that had TxBD[TS] set . This register is only valid when EIR[TS_AVAIL] is set.

11.6.4.1.108.3 Fields

Field	Description
31-16 —	Reserved
15-11 TPWC	Timer PulseWidth Control Specifies the pulse width associated with TMODE values of 1110 or 11X1. Updating this field takes a few cycles to register because it is synchronized to the 1588 clock. When changing this field: 1. Always disable the channel and read the TMODE field to verify that the channel is disabled. 2. Set TPWC to the desired value. 3. Reenable the channel. **NOTE:** This field is not supported in every instance. The following table includes only supported registers. 00000 - Pulse width is one 1588-clock cycle. 00001 - Pulse width is two 1588-clock cycles. 00010 - Pulse width is three 1588-clock cycles. 00011 - Pulse width is four 1588-clock cycles. 11111 - Pulse width is 32 1588-clock cycles.

11.6.4.1.109.3 Fields

Field	Description
31-0 TCC	Timer Capture Compare This register is double buffered between the module clock and 1588 clock domains. When configured for compare, the 1588 clock domain updates with the value in the module clock domain whenever the Timer Channel is first enabled and on each subsequent compare. Write to this register with the first compare value before enabling the Timer Channel. When the Timer Channel is enabled, write the second compare value either immediately, or at least before the first compare occurs. After each compare, write the next compare value before the previous compare occurs and before clearing the Timer Flag. The compare occurs one 1588 clock cycle after the IEEE 1588 Counter increments past the compare value in the 1588 clock domain. If the compare value is less than the value of the 1588 Counter when the Timer Channel is first enabled, then the compare does not occur until following the next overflow of the 1588 Counter. If the compare value is greater than the IEEE 1588 Counter when the 1588 Counter overflows, or the compare value is less than the value of the IEEE 1588 Counter after the overflow, then the compare occurs one 1588 clock cycle following the overflow. When configured for capture, the value of the IEEE 1588 Counter is captured into the 1588 clock domain and then updated into the module clock domain, provided the Timer Flag is clear. Always read the capture value before clearing the Timer Flag.

11.7 Ethernet Quality Of Service (ENET_QOS)

11.7.1 Overview

NOTE

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

The Ethernet Quality Of Service module supports the 10/100/1000Mbps applications in compliance with IEEE802.3-2015 specifications. It can support advanced applications such as Time-Sensitive Networking (TSN) and Audio Video Bridge (AVB). Other prominent features of the MAC core include a flexible receive parser, media clock recovery and generation, and safety.

11.7.1.1 Block diagram

The following figure shows the block diagram of this module. The module has four main blocks to perform all functions. The AHB interface is connected to all DMA channels. The DMA arbiter helps in arbitration of all paths (transmit and receive) in channels. Each channel has a separate set of control and status registers (CSR) for managing the transmit and receive functions, descriptor handling, and interrupt handling.

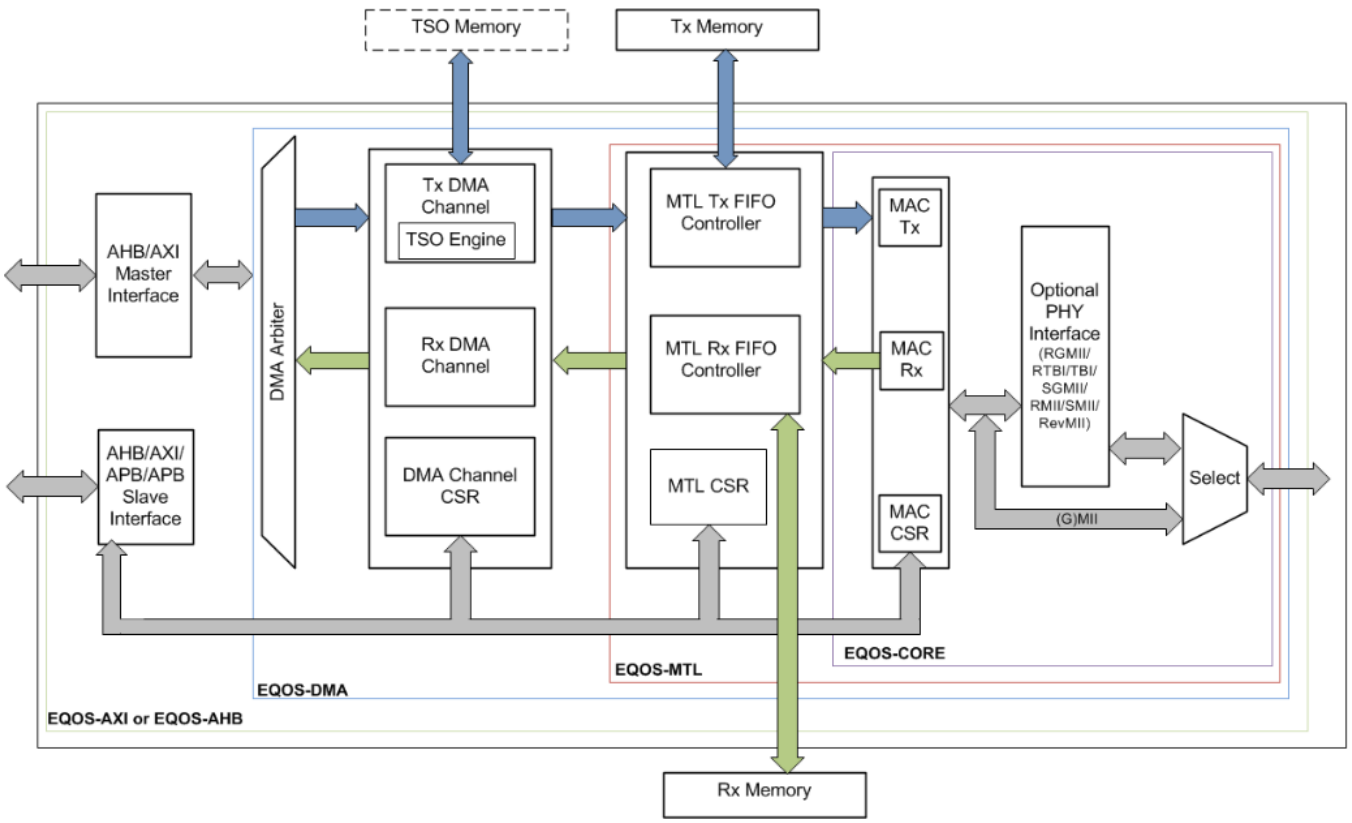

Figure 11-83. System-Level Block Diagram

11.7.1.2 Features

This module supports the following features in addition to the default features defined in IEEE802.3 specification

- RMII (10/100Mbps), RGMII (10/100/1000Mbps)
- Time aware shaper (IEEE802.1Qbv), Time synchronization (IEEE1588-2008), and Frame pre-emption (IEEE802.1Qbu) for Time-Sensitive Networking (TSN)
- Media clock recovery and generation for AVB
- RMII specification version 1.2 from RMII consortium
- Separate interface for Transmit, Receive and Control path
- Broadcast/Multicast Packet duplication
- Full duplex flow control operations (IEEE 802.3x pause packet and priority flow control)
- Network statistics with MAC management (RMON) counters
- Flexibility to control the Pulse per second (PPS) output signal
- MDIO (clause 22 and Clause 45) interface for configuration and management of PHY device
- Preamble and start of packet data (SFD) insertion/deletion
- Automatic CRC and pad generation/stripping option, option to disable CRC checking
- Programmable inter-packet gap
- Source address insertion/replacement
- VLAN insertion, replacement and deletion in transmitted packets with per-packet or static-global control
- Insertion, replacement and deletion of up to two VLAN tags
- Insertion, replacement and deletion of queue/channel based VLAN tags
- IEEE802.1Q VLAN tag detection and option to delete from received packets
- Programmable safety watchdog timeout limits
- Flexible address filtering modes:
    - Up to 2 additional 48-bit perfect (DA) address filters with masks for each byte
    - Up to 2 48-bit SA address comparison check with masks for each byte
    - 64-bit Hash filter for multicast and unicast (DA) addresses
    - Option to pass all multi-cast addressed packets
    - Promiscuous mode to pass all packets without any filtering for network monitoring
    - Pass all incoming packets (as per filter) with a status report
- Additional packet filtering:
    - VLAN tag-based: Perfect match and Hash-based filtering. Filtering based on either outer or inner VLAN tag is possible
    - Layer 3 and Layer 4-based: TCP or UDP over IPv4 or IPv6
    - Extended VLAN tag based filtering 4 filter selections

11.7.2 Functional Description

11.7.2.1 Architecture

This section describes the interfaces, protocols, and functionality. Following are the main blocks of the ENET QOS block.

- DMA Controller
- MAC Transaction Layer (MTL)
- MAC
- Interrupts

11.7.2.1.1 DMA controller

The DMA has independent Transmit (Tx) and Receive (Rx) engines, and a control and status register (CSR) space. The Tx engine transfers data from the system memory to the MTL interface, whereas the Rx engine transfers data from the MTL interface to the system memory. The DMA engine uses descriptors to efficiently move data from source to destination with minimal Host intervention. The DMA is designed for packet-oriented data transfers such as packets in Ethernet. The DMA controller can be programmed to interrupt the Host for situations such as Packet Transmit and Receive Transfer completion, and other normal or error conditions.

The DMA and Host communicate through the following two data structures:

- Control and Status registers (CSR)
- Descriptor lists and data buffers

The DMA supports up to 5 Tx and 5 Rx Descriptor lists (or DMA channels). The base address of each list is written to the respective Tx Descriptor List Address register and Rx Descriptor List Address register. The descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one. The offset is controlled by the DSL field of DMA_Ch[n]_Control register. The number of descriptors in the list is programmed in the respective Tx (or Rx) Descriptor Ring Length register. Once the DMA processes the last descriptor in the list, it automatically jumps back to the descriptor in the List Address register to create a descriptor ring.

The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers in the system memory. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet but cannot exceed a single packet. Buffers contain only data. Buffer status is maintained in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of next packet when end of packet (EOP) is detected.

This module supports the ring structure for the DMA descriptor. For more information on Descriptor, see the Descriptors.

Following sections describes the operation of DMA Controller.

11.7.2.1.1.1 DMA Controller Bus Burst Access

The DMA engines attempt to transfer data in a burst of maximum size as programmed in the PBL bit fields of Transmit Control and Receive Control registers of the respective DMA. The Rx and Tx descriptors are always accessed in the maximum possible (limited by PBL or 16 * 8/bus width) burst length for 16 bytes to be read. The burst transfers initiated by the DMA can be split into multiple burst transfers as per the AHB requirements and the settings of DMA_SysBus_Mode register.

The Tx DMA initiates a data transfer only when sufficient space is available in the MTL Tx Queue to accommodate either of the following:

- Bytes corresponding to the configured burst (PBL * bus_width/8)
- Remaining bytes in Tx Buffer without EOP
- Number of bytes till EOP

The Rx DMA initiates a data transfer in the following conditions:

- Sufficient data is available in MTL Rx Queue to accommodate the configured burst
- EOP (when it is less than the configured burst length) is detected in the Rx Queue

11.7.2.1.1.2 DMA application data buffer alignment

The Tx and Rx data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for buffers can be aligned to any of the four bytes. However, the DMA always initiates write transfers with address aligned to the bus width and dummy data (old data) in the invalid byte lanes. This typically happens during the transfer of the beginning or end of an Ethernet packet. For the receiver, the software driver should discard the dummy bytes based on the start address of the buffer and size of the packet.

Table 11-93. Data buffer alignment examples

Examples	
Buffer Read	If the Tx buffer address is 32'h00000FF2 (for 32-bit data bus), and 15 bytes need to be transferred, the DMA reads five full words from address 32'h00000FF0, but when transferring data to the MTL Tx queue, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last

Table continues on the next page...

Table 11-93. Data buffer alignment examples (continued)

	transfer are also ignored. The DMA always ensures that it transfers a full 32-bit data to the MTL Tx queue, unless it is the end of packet.
Buffer Write	If the Rx buffer address is 32'h0000FF2 (for 64-bit data bus) and 16 bytes of a received packet need to be transferred, the DMA writes 3 full words from address 32'h00000FF0. However, the first 2 bytes of the first transfer and the last 6 bytes of the third transfer have dummy data. The DMA considers the offset address only if it is the first Rx buffer of the packet. The DMA ignores the offset address and performs full word writes for the middle and the last Rx buffer of the packet.

11.7.2.1.1.3 DMA buffer size calculations

The DMA does not update the size fields in the Tx and Rx descriptors. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver has to perform the size calculations.

The Tx DMA transfers the exact number of bytes (indicated by buffer size field of TDES2) towards the MAC. If a descriptor is marked as first (FD bit of TDES3 is set), the DMA marks the first transfer from the buffer as SOP. If a descriptor is marked as last (LD bit of TDES3), the DMA marks the last transfer from that data buffer as EOP to the MTL.

The Rx DMA transfers data to a buffer until the buffer is full or the end of packet is received from the MTL. When the FD bit of a descriptor is set, the amount of valid data in a buffer is accurately indicated by the buffer size field (programmed in DMA Channel Receive Control register) minus the data buffer pointer offset. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, the buffer may not be full (as indicated by the buffer size in Bits [14:1] of Receive Control register). To compute the amount of valid data in this final buffer, the driver must read the packet length (PL bits of RDES3[14:0]) and subtract the sum of the buffer sizes of the preceding buffers in this packet. The Rx DMA always transfers the start of next packet with a new descriptor.

11.7.2.1.2 MAC transaction layer

The MAC Transaction Layer (MTL) provides the FIFO memory Interface to buffer and regulate the packets between system memory and the MAC. It also enables the data to be transferred between the system clock and MAC clock domains. The MTL layer has two

data paths: Transmit path and Receive Path. The size of the FIFO is 8 Kb for Tx and Rx. The MTL communicates with the host through Application Transmit Interface (ATI) on the Transmit path and Application Receive Interface (ARI) on the receive path.

11.7.2.1.2.1 Transmit path

Internal DMA handles all transactions for the transmit path through ATI. Internal DMA pushes the Ethernet packets read from system memory into the corresponding queue. The packet is then popped out and transferred to the MAC when the queue threshold is reached (threshold mode) or complete packet is in the queue (store-and-forward mode). When EOP is transferred, the status of the transmission is taken from the MAC and transferred back to the internal DMA.

11.7.2.1.2.1.1 Transmit control word

The following control information related to packet transmission is provided as a part of the Control Word through ATI interface:

- Packet Length (if DCB is enabled with WFQ scheduling algorithm)
- CRC Pad Control
- Source Address Insertion Control
- VLAN Insertion and Replacement Control and VLAN Tag for Outer and Inner VLAN Tags
- TCP/IP Checksum Insertion Control
- One-step Timestamping Control Correction
- Transmit Timestamp Enable

11.7.2.1.2.1.2 Transmit operation

The following two modes of operation triggers reading of the data towards the MAC:

- Threshold mode: In Threshold (or cut-through) mode, as soon as the number of bytes in the Queue cross the configured threshold level (or when the end of packet is written before the threshold is crossed), the data is ready to be popped out and forwarded to the MAC. The threshold level is configured by using the TTC bits of MTL_TxQ0_Operation_Mode register corresponding to an MTL queue.
- Store-and-forward mode:

In store-and-forward mode, the MTL pops out the packet towards the MAC only when one or more of the following conditions are true:

- A complete packet is stored in the Queue
- The Tx FIFO becomes almost full
- The ATI watermark becomes low

The watermark becomes low when the requested queue does not have space to accommodate the requested burst length on the ATI. Therefore, the MTL when operating in the store-and-forward mode allows packet transmission even if the packet length is bigger than the Tx queue size.

The application can flush complete content of the Tx queue by setting Bit 0 (FTQ) of Transmit Operation Mode register corresponding to an MTL queue. This bit is self-clearing and initializes the Queue pointers to the default state. If the FTQ bit is set during a packet transfer from the MTL to the MAC, the MTL stops further transfer because the queue is considered to be empty. Therefore, an underflow event occurs at the MAC transmitter.

11.7.2.1.2.1.3 Initialization flow

Upon reset, the MTL is ready to manage the flow of data to and from the DMA, and MAC. For configurations with a single Transmit Queue, there are no initialization requirements for enabling the MTL. For configurations with multiple Transmit Queues, initialize the queue size for each of the queues by programming the TQS bits of MTL_TxQ0_Operation_Mode register corresponding to a Transmit queue. Also, initialize the MAC block. Internal DMA controllers must be individually enabled through their respective CSRs.

11.7.2.1.2.2 Receive path

The MTL Rx module receives the packets from the MAC and pushes them into the Rx Queue. The status (fill level) of the queue is indicated to DMA when it crosses the configured Receive threshold (RTC bits[1:0] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue), or the complete packet is received. The MTL also indicates the fill level of the queue so that the DMA can initiate preconfigured burst transfers towards the AHB interface.

For more information on queues, see Multiple Channels and Queues Support.

11.7.2.1.2.2.1 Receive Operation

During a Receive operation, the MTL is a slave for the MAC. The general sequence of events is as follows:

1. When the MAC receives a packet, it indicates the availability of receive data.
2. The MAC indicates the SOP and EOP delimiters.
3. The MTL accepts the data and pushes it into corresponding Rx queue.
4. After the EOP is transferred, the MAC drives the status word which is also pushed into the corresponding Rx queue by the MTL.

5. If IEEE 1588 timestamp feature is enabled and the 64-bit timestamp is available along with the packet status, it is pushed into the Rx queue as a part of the status word. Therefore, two additional locations are taken per packet to store the timestamp in the Rx queue.
6. The MTL takes the data out of the queue and sends it to the DMA depending on the following modes:

11.7.2.1.2.2.1.1 Threshold mode

In the (default) Threshold mode, the MTL reads the data and indicates its availability to the application or DMA when one of the following occurs:

- Data bytes equal to the threshold amount are written to the Rx queue (RTC bits[1:0] of MTL_RxQ0_Op-eration_Moderegister of corresponding MTL queue)
- A full packet of data is received into the queue

11.7.2.1.2.2.1.2 Store and forward mode

In the store-and-forward mode (when Bit 5 of MTL_RxQ0_Operation_Mode register of a queue is set to 1), the initial Rx queue locations are reserved for the status words before writing the SOP. A packet is read out only after it is completely written into the Rx queue. In this mode, all error packets are dropped (if configured through Bit 4 of MTL_RxQ0_Operation_Mode register of a queue) such that only valid packets are read and forwarded to the application.

11.7.2.1.2.2.2 Multi packet receive operation

In Threshold mode, the packet status is available immediately after the packet data. In store-and-forward mode, the packet data is available after the packet status. The MTL is capable of storing any number of packets into the queue as long as it is not full.

If the MAC receives a packet when the corresponding Rx queue is full, the MTL ignores that packet and overflow pulse is generated on the corresponding Rx queue. In addition, the MTL increments the overflow counter in the MTL_RxQ0_Missed_Packet_Overflow_Cnt of corresponding queue.

11.7.2.1.2.2.3 Error handling in receive operation

Following things would happen, If the MTL Rx queue is full before it receives the EOP data from the MAC.

1. An overflow is declared
2. The whole packet (including the status word) is dropped

3. The overflow counter in the DMA (Overflow Counter register of corresponding MTL queue) is incremented.

This is true even if Bit 4 (FEP) of MTL_RxQ0_Operation_Mode register of corresponding MTL queue is set.

If the start address of such a packet has already been transferred to the Read Controller, the rest of the packet is dropped and a dummy EOP is written to the queue along with the status word with overflow status. The status indicates a partial packet because of overflow. In such packets, the Packet Length field is invalid. If the MTL Receive Queue is configured to operate in the store-and-forward mode and the length of the received packet is more than the queue size, overflow occurs and all such packets are dropped.

The MTL Rx Control logic can filter error and undersized packets, if enabled by using the FEP and FUP bits of MTL_RxQ0_Operation_Mode register of corresponding MTL queue. If the start address of such a packet has already been transferred to the Rx Queue Read Controller, that packet is not filtered. The start address of the packet is transferred to the Read Controller after the packet crosses the receive threshold set by Bits[1:0] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue.

If the MTL Receive Queue is configured to operate in the store-and-forward mode, all error packets can be filtered and dropped. For the application or DMA to flush the error packet being read from the queue, it must assert the flush signal. The MTL then stops transferring data to the application (DMA). It internally reads the rest of the packet and drops it. The MTL then starts the transfer of next packet (if available).

11.7.2.1.3 MAC

MAC can support RMII or RGMII Phy interface. MAC consists of Mac Transmit interface (MTI), MAC Receive Interface (MRI) and MAC Control Interface (MCI).

11.7.2.1.3.1 MAC transmission

The MAC transmission process is as follows:

1. Transmission is initiated when the MAC Transaction Layer (MTL) pushes in data with the SOP signal asserted.
2. When the SOP signal is detected, the MAC accepts the data and begins transmitting to the RMII or RGMII.
3. After the EOP is transferred to the MAC, the MAC does one of the following:
    - The MAC completes the normal transmission and gives the transmission status to the MTL.

- If a normal collision (in half-duplex mode) occurs during transmission, the MAC gives the Transmit Status with retry bit set to the MTL. The MAC gives the Retry request till one of the following is true:
  - Packet is successfully transmitted
  - Maximum retry requests expire
  - When maximum retry requests expire, the MAC aborts the packet transmission with Excessive Collision Transmit Status. The MAC accepts and drops all further data until the next SOP is received. The MTL block should retransmit the same packet from SOP on observing a Retry request (in the Status) from the MAC.
- If any one of the following happens, the MAC aborts the packet transmission:
  - No carrier (half-duplex mode)
  - Loss of carrier (half-duplex mode)
  - Excessive deferral (half-duplex mode)
  - Late collisions (half-duplex mode)
  - Jabber
  - The MAC accepts and drops all further data until the next SOP is received

4. The MAC issues an underflow status if the MTL is not able to provide the data continuously during the transmission. The MAC accepts and drops all further data until the next SOP is received.
5. During the normal transfer of a packet from MTL, if the MAC receives a SOP without getting an EOP for the previous packet, it ignores the SOP and considers the new packet as continuation of the previous packet.

11.7.2.1.3.2 MAC reception

A receive operation is initiated when the MAC detects an SFD on RMII, RGMII, or MII. The MAC strips the preamble and SFD before proceeding to process the packet. The header fields are checked for filtering and the FCS field used to verify the CRC for the packet. The received packet is stored in a shallow buffer until the address filtering is performed. The packet is dropped in the MAC if it fails the address filter.

11.7.2.1.4 Interrupts

This module supports interrupt coalescing which reduces the number of interrupts generated by IP and reduces the CPU load. Various interrupt event gets captured in status register. If interrupt enable bit of an interrupt is set then corresponding interrupt will be generated based on event status in status registers. INTM (interrupt mode) bit decides that interrupt signal is a level signal or pulse signal.

Interrupt output signals are shown below which are synchronous to control and Status register (CSR) clock.

- Sbd_intr_o – common interrupt
- Sbd_perch_tx_intr_o[max_dma_ch] – Interrupt per Tx channel
- Sbd_perch_rx_intr_o [max_dma_ch] – Interrupt per Rx channel

NOTE

max_dma_ch is equal to number of Tx/Rx queues which is 2.

The sbd_intr_o common interrupt is level signal. When sbd_intr_o interrupt is asserted, then corresponding interrupt event source can be found in DMA_Interrupt status register. DMA_Interrupt status register is read only register which contains the interrupt event source bits corresponding to each DMA channel (Tx and Rx queue pair), MAC transaction layer and MAC blocks. Software must then read the following registers corresponding to the bits that are set.

- MAC_Interrupt_Status register
- MTL_Interrupt_Status register
- DMA_CH(n)_Status register

sbd_intr_o interrupt gets de-asserted only when all the enabled interrupt events are cleared in their respective status registers and correspondingly all the bits in the DMA_Interrupt_Status register are cleared.

The DMA_CH[n]_Status register captures all the interrupt events of that Tx DMA and Rx DMA channel pair. The DMA_CH[n]_Interrupt_Enable register contains the corresponding enable bits for each of the interrupt event. There are two groups of interrupts in the DMA channel namely Normal and Abnormal interrupts. They are indicated by bits[15:14] of DMA_CH[n]_Status register respectively. The normal group is for events that happen during the normal transfer of packets (TI, RI, TBU) while the abnormal interrupt events are for error events

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts are generated.

The common sbd_intr_o output signal is asserted for the transfer complete interrupts only when the corresponding interrupts are enabled in DMA_CH[n]_Interrupt_Enable register.

This module also supports the following per Channel Transfer Complete interrupt signals.

- sbd_perch_tx_intr_o[max_dma_ch] (Transmit Per Channel Interrupts)
- sbd_perch_rx_intr_o[max_dma_ch] (Receive Per Channel Interrupts)

The behavior of the RI/TI/ sbd_perch_tx_intr_o[]/sbd_perch_rx_intr_o[] changes depending on the settings of INTM field bit[17:16] in DMA_Mode. Following table explains the Transfer Complete Interrupt behavior.

Table 11-94. Transfer Complete Interrupt Behavior

Interrupt Mode	Behavior of the sbd_perch_tx_intr_o[] and sbd_perch_rx_intr_o[]	Behavior of TI/RI and sbd_intr_o
INTM=1	These signals reflect the value of corresponding TI/RI bits in DMA_CH[n]_Status register when the corresponding interrupt enable is set. Hence they are level signals and are cleared by the application by writing 1'b1 to the RI/TI status bits. This signal will not be asserted when the corresponding interrupt enable bit is not set.	The TI/RI is set as explained above. However, the sbd_intr_o signal and NIS status bit are not asserted for any RI/TI events.
INTM=2	In this mode, RI/TI interrupts are queued. These signals reflect the value of corresponding TI/RI bits inDMA_CH[n]_Status register when the corresponding interrupt enable is set. They are level signals and cleared by software by writing 1'b1 to the RI/TI status bits. However, it is set again if another TI/RI event(s) is detected before the TI/RI bits are cleared for the previous event.	The RI/TI status bits are set whenever the Transfer Complete event is detected and gets reset whenever software driver clears those bits by writing 1. However, if another Transfer Complete event is detected before it is cleared (serviced) by the software, then the module automatically set these status bits again. However, the sbd_intr_o signal is not generated based on TI/RI

11.7.2.2 Using PHY interfaces

This module support the following modes:

- RMII 10/100 Mbps interface
- RGMII 10/100/1000 Mbps interface

The internal Phy_intf_sel input signal decides which mode has been selected. Phy_intf_sel signal gets sampled at reset. PS and FES bit of MAC configuration register selects the speed of mode.

The module supports the IEEE802.3-2015 specification for RMII and RGMII specification version 1.2 from RMII consortium.

NOTE

RMII reference clock (50 MHz) can be fed to IP from an external source or internally from PLL on SoC.

The module supports can access the phy registers through Station Management Agent (SMA) which is a two wire Station management interface (MIM). One wire is management data clock (MDC) and other wire is management data input/output (MDIO). As per IEEE 802.3 specification, maximum operating frequency of MDC is 2.5 Mhz which can be derived from system clock using a divider. The CR bit of MAC_MDIO_Address register can be programmed to generate different MDC clock frequency.

SMA supports both MDIO clause 45 and clause 22 frame structure as per IEEE802.3 specification. The C45E bit of MAC_MDIO_Address register can be set to enable the clause 45 frame structure.

11.7.2.3 VLAN and double VLAN insertion, deletion, replacement and tagging

These sections describes the VLAN and Double VLAN features.

11.7.2.3.1 Double VLAN processing

The module can support processing of two VLAN tags in double VLAN tagging processing. These two VLAN tags can also be named as inner (C-VLAN) and outer (S-VLAN) VLAN tag. If packet is having only one tag then it would be considered as outer tag.

It supports the following function in Double VLAN processing feature using the MAC_VLAN_Incl, MAC_Inner_VLAN_Incl and MAC_VLAN_Tag registers.

- Insertion, replacement, or deletion of up to two VLAN tags in the Transmit path.
- Packet filtering and stripping based on any one of the two VLAN Tags in the Receive path. Stripping and providing up to two VLAN Tags in the Receive path as a part of the Receive status.

11.7.2.3.1.1 Transmit path

Following table describes the features supported by the MAC on the Transmit side.

Table 11-95. Double VLAN Processing Features in Transmit Path

Feature	Description
Support for C-VLAN and S-VLAN Tag types	The inner or outer VLAN tag can be of C-VLAN and S-VLAN type. The VLAN type is specified through the CSVL bit of MAC_VLAN_INCL and MAC_INNER_VLAN_INCL registers.

Table continues on the next page...

Table 11-95. Double VLAN Processing Features in Transmit Path (continued)

	The module supports processing of any sequence of outer and inner VLAN tags. **NOTE:** The module does not support the C-VLAN S-VLAN sequence. The MAC does not check whether the packet provided by the application has a valid sequence of the VLAN Tag types or the insertion or replacement operation results in invalid sequence of VLAN Tag type. Therefore, the application must provide correct sequence of VLAN Tag types and program the MAC in such a way that it results in correct sequence of VLAN Tag types in the transmitted packet. The application must ensure the following: • The inner tag should not be S-VLAN when outer C-VLAN Tag insertion is enabled. • The outer tag should not be C-VLAN when inner S-VLAN Tag insertion is enabled. • The inner tag should not be S-VLAN when outer tag should be replaced with C-VLAN. • The outer tag should not be C-VLAN when inner tag should be replaced with S-VLAN.
VLAN Tag deletion	VLAN tag deletion for outer or inner tag can be enabled through VLC field in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register, respectively. When VLAN deletion is enabled, the MAC deletes the tag present at the corresponding position. When a packet has only one tag, it is considered as the outer tag. If inner tag deletion is enabled and the packet has only one tag, the MAC does not delete the inner tag.
VLAN Tag Insertion or Replacement	VLAN tag insertion or replacement for outer or inner tag can be enabled through VLC field in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register, respectively. When VLAN tag insertion or replacement is enabled, the VLTI bit in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register is used to determine whether the VLAN tag should be taken from the register or the Control Word.

11.7.2.3.1.2 Receive path

Following table describes the features supported by the MAC on the receive side and the corresponding bits in the MAC_VLAN_Tag register.

Table 11-96. Double VLAN Processing in Receive Path

Feature	Description
Outer or inner VLAN tag-based filtering	The MAC can filter packets based on the outer or inner VLAN tag through the ERIVLT bit.

Table continues on the next page...

Table 11-96. Double VLAN Processing in Receive Path (continued)

C-VLAN or S-VLAN tag-based filtering	The MAC can filter packets based on the C-VLAN or S-VLAN type based on the ERSVLM bit.
Outer and Inner VLAN Tag stripping	The MAC can strip the outer and inner VLAN Tags from received frame based on the EVLS and EIVLS bits.
16-bit outer and inner VLAN Tag and Type in Rx status	The MAC can provide the 16-bit outer and inner VLAN Tag and Type in the Rx status based on the EVLRXS and EIVLRXS bits, respectively.
Disabling or skipping checking of outer VLAN Tag type	The MAC can disable or skip checking of outer VLAN Tag type to match C-VLAN or SVLAN based on the DOVLTC bit.

11.7.2.3.1.3 Source address and VLAN insertion, replacement, or deletion

The module supports the SA and VLAN insertion, replacement and deletion. The source address (SA) and VLAN fields are Tx packet-related control information that are provided as part of the control word through interfaces. IP supports the feature to insert or replace the source address based on the information in the MAC Address Registers, and also the feature to insert, replace or delete the VLAN fields (VLAN Type and VLAN Tag) based on the setting of the VLTI bit in the MAC_VLAN_Incl register. SA insertion or replacement feature can be enabled for all Transmit packets or selective packets. Similarly, VLAN insertion, replacement, or deletion feature can be enabled for all Tx packets or selective packets.

11.7.2.3.1.4 Programming source address insertion or replacement

The software can use the SA insertion or replacement feature to instruct the MAC to do the following for Tx packets:

- Insert the content of the MAC Address Registers in the SA field
- Replace the content of the SA field with the content of the MAC Address Registers

When SA insertion is enabled, the application must ensure that the packets sent to the MAC do not have the SA field. The MAC does not check whether the SA field is present in the Transmit packet and it inserts the content of MAC Address Registers in the SA field. Similarly, when SA replacement is enabled, the application must ensure that the SA field is present in the packets sent to the MAC.

The MAC replaces the six bytes following the Destination Address field in the Transmit packet with the content of the MAC Address Registers.

- SARC bit of MAC_Configuration register can be program to enable the SA insertion or replacement for all Tx packets.
- SA insertion for selective packet can be enabled by programming the SA Insertion Control field (bits [25:23] of TDES3) in the first Transmit descriptor of the packet. When Bit 25 of TDES3 is set, the SA Insertion Control field indicates insertion or replacement by MAC Address1 registers. When Bit 25 of TDES3 is reset, it indicates insertion or replacement by MAC Address 0 registers.

If MAC Address1 Registers are not enabled, the MAC Address0 registers are used for insertion or replacement irrespective of the value of the most-significant bit of the SA Insertion Control field.

11.7.2.3.1.5 Programming VLAN insertion, replacement, or deletion

The software can use the VLAN insertion, replacement, or deletion feature to instruct the MAC to do the following for Tx packets:

- Delete the VLAN Type and VLAN Tag fields
- Insert or replace the VLAN Type and VLAN Tag fields

Insertion or replacement is done based on the setting of VLTI bit in the MAC_VLAN_Incl register as described in the following table:

Table 11-97. VLAN Insertion or Replacement Based on VLTI Bit

Condition	Description
VLTI bit is set	The MAC inserts or replaces the following: • VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of MAC_VLAN_Incl register) • VLAN Tag field depending on the Content of the VT field of Transmit context descriptor of the packet
VLTI bit is reset	The MAC inserts or replaces the following: • VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of MAC_VLAN_Incl register) • VLAN Tag field with the VLT field of MAC_VLAN_Incl register

When VLAN replacement or deletion is enabled, the MAC checks if the VLAN Type field (0x8100 or 0x88a8) is present after the DA and SA fields in the Transmit packet. The replace or delete operation does not occur if the VLAN Type field is not detected in two bytes following the DA and SA fields. However, when VLAN insertion is enabled, the MAC does not check the presence of VLAN Type field in the Transmit packet and just inserts the VLAN Type and VLAN Tag fields.

VLAN insertion, replacement, or deletion feature can be enabled for all Tx packets by programming the VLC and VLP fields of MAC_VLAN_Incl register.

VLAN insertion, replacement, or deletion for selective packets can be enabled by programming the VTIR field of TDES2 Normal Descriptor.

In addition, the VLP (VLAN Priority control) bit must be reset in MAC_VLAN_Incl register (for outer VLAN) and MAC_Inner_VLAN_Incl register (in inner VLAN) for the MAC to take the control inputs from the host, depending on the configuration.

11.7.2.4 Packet Filtering

There are various packets filtering scheme available in MAC receiver. Filtering sequence in their precedence order of received packet is shown in the following figure.

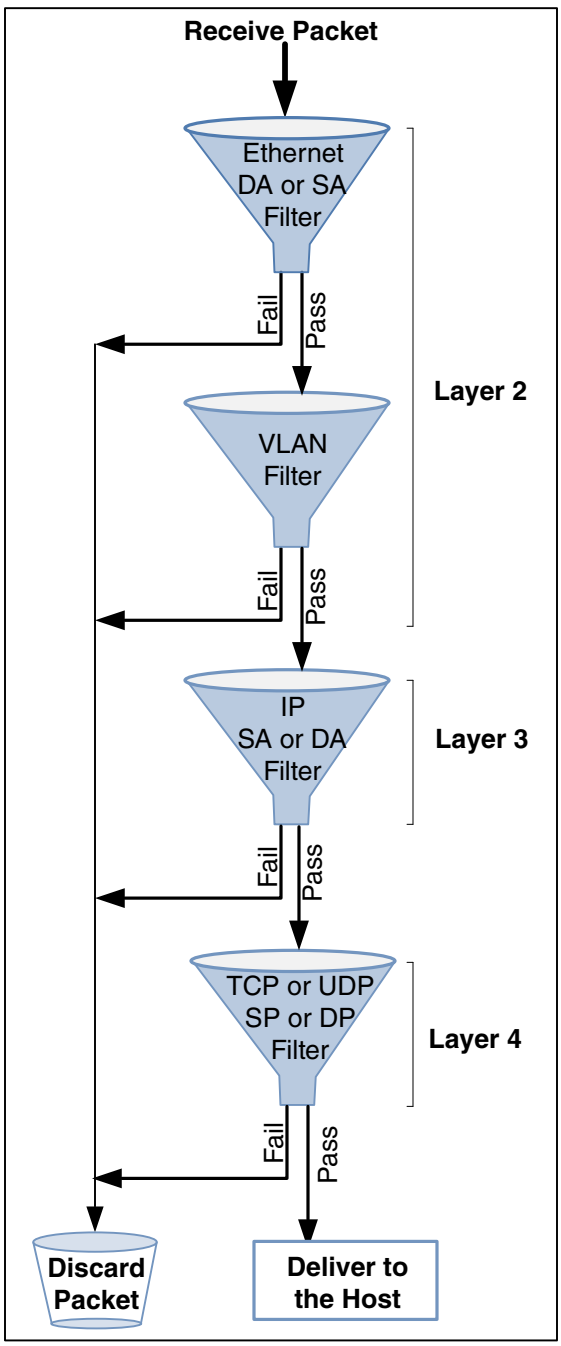

Figure 11-84. Packet Filtering Sequence

If any of the Layer filters are not enabled, that filter is bypassed and the subsequent filter is applied. A packet that fails any of the filters, is discarded. However, the discarded packet can be forwarded to the host based on the register control.

11.7.2.4.1 Source address or destination address filtering

The Address Filtering Module of the MAC checks the source address (SA) and destination address (DA) fields of each incoming packet. Programming of different type of address filtering is described in the following sections.

11.7.2.4.1.1 Unicast destination address filtering

MAC supports up to 3 MAC addresses for unicast perfect filtering. If perfect filtering is selected (HUC bit of MAC_Packet_Filter register is reset), the MAC compares all 48 bits of received unicast address with the programmed MAC address for any match. Default MacAddr0 is always enabled. The MacAddr1 to MacAddr2 addresses are selected with an individual enable bit. Each byte of MacAddr1 to MacAddr2 can be masked during comparison with corresponding received DA byte by setting the corresponding Mask Byte Control bit in the register. This enables group address filtering for the DA.

In hash filtering mode (when HUC bit is set), the MAC performs imperfect filtering for unicast addresses using a 64-bit Hash table. For hash filtering, the MAC uses the upper 6 bits CRC of the received destination address to index the content of the Hash table. A value of 000000 selects Bit 0 of selected register, and a value of 111111 selects Bit 63 of Hash Table register. If the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast packet is considered to have passed the Hash filter; otherwise, the packet is considered to have failed the Hash filter.

11.7.2.4.1.2 Multicast destination address filtering

PM bit of MAC_Packet_Filter register can be enabled to pass all multicast packets or disabled to do multicast addresses filtering based on HMC bit of MAC_Packet_Filter register. The multicast address is compared with the programmed MAC Destination Address registers (1–2). Also, Group address filtering is supported.

In Hash filtering mode, the MAC performs imperfect filtering using a 64-bit Hash table. The MAC uses the upper 6-bits CRC of received multicast address to index the content of the Hash table. A value of 000000 selects Bit 0 of selected register and a value of 111111 selects Bit 63 of the Hash Table register. If the corresponding bit is set to 1, the multicast packet is considered to have passed the Hash filter. Otherwise, the packet is considered to have failed the Hash filter.

11.7.2.4.1.3 Hash or perfect address filtering

HPF bit of MAC_Packet_Filter register must be configured for enabling or disabling the destination address filtering by either Hash filter or Perfect filter. HUC and HMC bit of MAC_Packet_Filter register must be configured to select the Hash filtering or Perfect filtering for Unicast/Multicast packet.

11.7.2.4.1.4 Broadcast address filtering

The MAC does not filter any broadcast packets by default. DBF bit of MAC_Packet_filter register must be set to reject the broadcast packets.

11.7.2.4.1.5 Unicast source address filtering

By default, MAC compares the source address field with the value programmed in the source address registers. Bit 30 of MAC address register [1-2] can be configure to use it for source address instead of destination address comparison. The MAC also supports group filtering with source address(SA) . You can filter a group of addresses by masking one or more bytes of the address. The MAC drops the packets that fail the SA filter if the SAF bit is set in MAC_Packet_Filter register. Otherwise, the result of the SA filter is given as a status bit in the Receive Status word. When the SAF bit is set, the SA filter and DA filter result is AND'ed to decide whether the packet needs to be forwarded. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in-order.

11.7.2.4.1.6 Inverse filtering

For DA and SA filtering, you can invert the filter-match result at the final output by setting the DAIF and SAIF bits of MAC_Packet_Filter register. The DAIF bit is applicable for both Unicast and Multicast DA packets. The result of the unicast or multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of unicast SA filter is reversed.

Following two tables summarize the DA and SA filtering based on the type of packets received.

Table 11-98. Destination Address Filtering

Packet Type	PR	HPF	HUC	DAIF	HMC	PM	DBF	DA Filter Operation
Broadcast	1	X	X	X	X	X	X	Pass

Table continues on the next page...

Table 11-98. Destination Address Filtering (continued)

	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	Pass all packets
	0	X	0	0	X	X	X	Pass on Perfect/ Group filter match
	0	X	0	1	X	X	X	Fail on Perfect/ Group filter match
	0	0	1	0	X	X	X	Pass on Hash filter match
	0	0	1	1	X	X	X	Fail on Hash filter match
	0	1	1	0	X	X	X	Pass on Hash or Perfect/ Group filter match
	0	1	1	1	X	X	X	Fail on Hash or Perfect/ Group filter match
Multicast	1	X	X	X	X	X	X	Pass all packets
	X	X	X	X	X	1	X	Pass all packets
	0	X	X	0	0	0	X	Pass on Perfect/ Group filter match and drop Pause packets if PCF = 0x
	0	0	X	0	1	0	X	Pass on Hash filter match and drop Pause packets if PCF = 0x
	0	1	X	0	1	0	X	Pass on Hash or Perfect/ Group filter match and drop Pause packets if PCF = 0x

Table continues on the next page...

Table 11-98. Destination Address Filtering (continued)

	0	X	X	1	0	0	X	Fail on Perfect/ Group filter match and drop Pause packets if PCF = 0x
	0	0	X	1	1	0	X	Fail on Hash filter match and drop Pause packets if PCF = 0x
	0	1	X	1	1	0	X	Fail on Hash or Perfect/ Group filter match and drop Pause packets if PCF = 0x

Table 11-99. Source Address Filtering

Packet Type	PR	SAIF	SAF	SA Filter Operation
Unicast	1	X	X	Pass all packets.
	0	0	0	Pass status on Perfect or Group filter match but do not drop packets that fail
	0	1	0	Fail status on Perfect or Group filter match but do not drop packet
	0	0	1	Pass on Perfect or Group filter match and drop packets that fail
	0	1	1	Fail on Perfect or Group filter match and drop packets that fail

NOTE

When the RA bit of MAC_Packet_Filter register is set, all packets are forwarded to the system along with the correct result of the address filtering in the Rx Status.

11.7.2.4.2 VLAN Filtering

VLAN tag filter can be done by either perfect match or hash table. Depending upon the configuration, MAC can compare either lower 12 bits or all 16 bits of received VLAN tag for perfect match. MAC forwarded the VLAN tagged packet with match status while it drops all the packets which don't matches.

MAC uses 16-bit VLAN hash table for group address filtering based on the VLAN tag. If hash filtering is enabled then most significant 4-bit of CRC-32 of VLAN tag are used to index the content of the VLAN Hash Table Register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the VLAN tag of the packet matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged packet should be dropped.

The MAC also supports the inverse matching for VLAN packets. In the inverse matching mode, when the VLAN tag of a packet matches the perfect or hash filter, the packet should be dropped. If the VLAN perfect and VLAN hash match are enabled, a packet is considered as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and hash filters indicate mismatch.

Table below shows the different possibilities for VLAN matching and the final VLAN match status. When the RA bit of MAC_Packet_Filter register is set, all packets are received and the VLAN match status is indicated in the VF bit of RDES2 Normal Descriptor (Write-Back Format). When the RA bit is not set and the VTFE bit is set in MAC_Packet_Filter register, the packet is dropped if the final VLAN match status is Fail.

When VLAN VID is programmed to 0 in the VL field of MAC_VLAN_Tag register, all VLAN-tagged packets are considered as perfect matched but the status of the VLAN hash match depends on the VTHM and VTIM bits in MAC_VLAN_Tag register.

Table 11-100. VLAN Match Status

VID	VLAN Perfect Filter Match Result	VTHM Bit	VLAN Hash Filter Match Result	VTIM Bit	Final VLAN Match Status
VID = 0	Pass	0	X	X	Pass
	Pass	1	X	0	Pass
	Pass	1	Fail	1	Pass
	Pass	1	Pass	1	Fail
VID!= 0	Pass	X	X	0	Pass
	Fail	0	X	0	Fail
	Fail	1	Fail	0	Fail
	Fail	1	Pass	0	Pass

Table continues on the next page...

Table 11-100. VLAN Match Status (continued)

VID	VLAN Perfect Filter Match Result	VTHM Bit	VLAN Hash Filter Match Result	VTIM Bit	Final VLAN Match Status
	Fail	0	X	1	Pass
	Pass	X	X	1	Fail
	Fail	1	Pass	1	Fail
	Fail	1	Fail	1	Pass

In this table, X represents any value.

11.7.2.4.3 VLAN Filter Fail Packets Queue

When VLAN filtering is enabled, the VLAN Filter Fail Packets can be routed to a programmable Queue (VFFQ) when Bit RA = 1 or VTFE = 0 of MAC_Packet_Filter register and the enable bit (VFFQE of MAC_RXQ_CTRL4) for the queue is set.

The packets that passes the VLAN filtering, are routed to Rx queues based on the VLAN TAG priority field by programming the PSRQ in the corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers. The packets that fail the VLAN filter are discarded if RA=0 or VTFE=1. However, when RA=1 or VTFE=0, the VLAN filter fail packets are still forwarded to the application. In such a scenario, when the VLAN Filter Fail Queue Enable (VFFQE) bit is set, the VLAN filter fail packets are forwarded to the Rx queue number programmed in the VFFQ bit. If VFFQE=0, the Rx queue number is determined by the VLAN priority mapping as per the PSRQ fields.

Table below shows the Rx Queue routing table for Unicast tagged packets, with DA/SA Filter enabled.

Table 11-101. Rx Queue Routing table for Unicast Tagged Packets

RA	VFTE	SA/DA Filter Result	VLAN Filter Result	VFFQE	Queue Routing
X	X	PASS	PASS	X	PSRQ
0	0	PASS	FAIL	0	PSRQ
0	0	PASS	FAIL	1	VFFQ
0	X	FAIL	X	X	DROPPED
0	1	PASS	FAIL	X	DROPPED
1	X	FAIL	X	0	UFFQ*/PSRQ
1	X	FAIL	X	1	UFFQ*/VFFQ
1	X	PASS	FAIL	0	PSRQ
1	X	PASS	FAIL	1	VFFQ

X : Don't care condition * : When UFFQE is enabled else PSRQ

11.7.2.4.4 Extended Receive VLAN Filtering and Routing

When Extended Rx VLAN filtering and routing is enabled then both perfect filtering and Hash filtering can be enabled. The overall VLAN filter result is based on the Perfect filter result and Hash filter result (if enabled). Filter result is passed to application/software as part of the status bit. Extended Routing will happen only if VLAN filter has passed. Routing is only based on Perfect filter result. Each Perfect filter has a DMA channel enable and DMA channel number filed which should be programmed for routing.

For more details about routing, see details on 'Extended VLAN Based DMA Selection' in Dynamic (Per Packet) Mapping.

11.7.2.4.4.1 Comparison mode

Software/Application has following comparison option for each VLAN tag filter

- It can program the MAC to compare the inner or outer VLAN tag with either 12 bits or 16 bits programmed VID.
- It can choose that VID comparison is for SVLAN or CVLAN type frames, if type check is enabled for a filter.

11.7.2.4.4.2 Filtering

Perfect Filtering is done based on the MAC_VLAN_Tag_Filter registers. For each VLAN Tag Filter, the MAC will compare the relevant VLAN Tag ID and gives a result. If any one of the VLAN Tag Filters gives a match then the frame is considered to have passed the VLAN Tag Filters. If the frame mismatches all the filters, then the frame is considered to have failed the VLAN filter. This behavior is applicable only when the Inverse Filtering is not enabled in MAC_VLAN_Tag_Ctrl Register.

If inverse Filtering is enabled and the frame has mis-matched all the relevant filters then it is considered to have passed the VLAN filter. If the frame matches any one of the relevant filters then it is considered as a fail. If none of the enabled filters can perform a comparison or if none of the filters are enabled, then the frame is bypassed to the application.

The overall filter result and the programming on the VTFE and RA bits of the MAC Filter Register determine if the frame will be dropped or forwarded to the application. If RA = 1 or VTFE = 0, it does not matter if the filter result is a pass or fail. The frame is

always forwarded. If RA = 0 and VTFE = 1, only then, if the VLAN Tag Filter result is a pass does the MAC forward the frame. If the frame is forwarded to the application, then the relevant filter result is indicated through the Status bits.

11.7.2.4.4.3 Filter Status

The Extended Receive VLAN Filtering and Routing feature provides two status bits to indicate the comparison result of the VLAN tags.

By default, the MAC indicates the VLAN Filter Status through one bit in the status – VF field in RDES2. When Extended RX VLAN Filtering and Routing is enabled, two status bits are used to indicate the comparison result of VLAN tags. The Outer VLAN Tag Filter Pass and Inner VLAN Tag Filter Pass bits are defined in the following positions. The status indicated through these bits is highly dependent on the programming as explained below.

In RDES2:

- Bit 15 – Outer VLAN Tag Filter Status
- Bit 14 – Inner VLAN Tag Filter Status

In ARI status: MAC Filter Status:

- Bit 15 – Outer VLAN Tag Filter Status
- Bit 14 – Inner VLAN Tag Filter Status

In MRI Status:

- Bit 47 – Outer VLAN Tag Filter Status
- Bit 46 – Inner VLAN Tag Filter Status

Outer VLAN Tag Filter Status (OTS)

- In perfect Filtering, without inverse filtering enabled, if this bit is set, it indicates that the frame's Outer VLAN Tag has matched one of the VLAN Tag Filters.
- If this bit is reset, it indicates that the frame's Outer VLAN Tag has either failed the relevant Outer VLAN Tag Filters or bypassed them.
- If none of the filters are enabled for Outer VLAN Tag Comparison, then this bit is reset.

- If Inverse Filtering is enabled and this bit is set, then the frame's VLAN Tag has passed all the relevant VLAN Tag Filters. If it is reset, then it has failed at least one of or bypassed all the Filters programmed for Outer VLAN Tag Comparison.
- This bit is valid for both Single and Double VLAN Tagged frames.

Inner VLAN Tag Filter Status (ITS)

- In perfect Filtering, without inverse filtering enabled, if this bit is set, it indicates that the frame's Inner VLAN Tag has matched one of the VLAN Tag Filters.
- If this bit is reset, it indicates that the frame's Inner VLAN Tag has either failed the relevant Inner VLAN Tag Filters or bypassed them.
- If none of the filters are enabled for Inner VLAN Tag Comparison, then this bit is reset.
- If Inverse Filtering is enabled and this bit is set, then the frame's VLAN Tag has passed all the relevant VLAN Tag Filters. If it is reset, then it has failed at least one of or bypassed all the Filters programmed for Inner VLAN Tag Comparison.
- This bit is valid for only Double VLAN Tagged frames, when Double VLAN Processing is enabled.

The application must look at the status bits and the programming to determine if the Frame has passed or failed the VLAN Filter.

Following two tables 'OTS and ITS Bit Values with At Least 1 Perfect Filter Enabled' and 'OTS and ITS Bit Values with Only VLAN Hash Filter Enabled' show the possible Filter combinations and the corresponding filter results. These tables explain the scenarios when Double VLAN Processing and Hash VLAN filter are enabled in the design.

Legend for the table 'OTS and ITS Bit Values with At Least 1 Perfect Filter Enabled'

- VTIM: VLAN Tag Inverse Match Enable – bit 17 in VLAN_Tag_Ctrl Register.
- HFO: Hash Filter enabled for Outer VLAN Tag Comparison - bit 25 and bit 27 in VLAN_Tag_Ctrl Register.
- HFI: Hash Filter enabled for Inner VLAN Tag Comparison – bit 25 and bit 27 in VLAN_Tag_Ctrl Register.
- PFO – Perfect Filter comparison enabled for Outer VLAN Tag - Any of the MAC_VLAN_Tag_Filter Registers is enabled (bit 16 is set) and programmed for Outer VLAN Tag comparison (bit 20 is set to 0).

- PFI – Perfect Filter comparison enabled for Inner VLAN Tag - Any of the MAC_VLAN_Tag_Filter Registers is enabled (bit 16 is set) and programmed for Inner VLAN Tag comparison (bit 20 is set to 1).
- OTS – Outer VLAN Tag Filter Status
- ITS – Inner VLAN Tag Filter Status

Following table shows the possible values of status bits (OTS and ITS) when at least one Perfect filter is enabled.

Table 11-102. OTS and ITS Bit Values with At Least 1 Perfect Filter Enabled

VTIM	HFO	HFI	PFO	PFI	OTS	ITS
0	0	0	0	1	0	1/0
0	0	0	1	0	1/0	0
0	0	0	1	1	1/0	1/0
0	1	0	1	1	1/0	1/0
0	1	0	1	0	1/0	0
0	1	0	0	1	1/0	1/0
0	0	1	1	1	1/0	1/0
0	0	1	1	0	1/0	1/0
0	0	1	0	1	0	1/0
1	0	0	0	1	0	1/0
1	0	0	1	0	1/0	0
1	0	0	1	1	1/0	1/0
1	1	0	1	1	1/0	1/0
1	1	0	1	0	1/0	0
1	1	0	0	1	1/0	1/0
1	0	1	1	1	1/0	1/0
1	0	1	1	0	1/0	1/0
1	0	1	0	1	0	1/0

Following table shows the possible values of status bits (OTS and ITS) when none of the perfect filters are enabled and only the VLAN Hash Filter is enabled.

Table 11-103. OTS and ITS Bit Values with Only VLAN Hash Filter Enabled

VTIM	HFO	HFI	OTS	ITS
0	0	0	0	0
0	1	0	1/0	0
0	0	1	1/0	1/0
1	0	0	1/0	0
1	1	0	1/0	0

Table continues on the next page...

Table 11-103. OTS and ITS Bit Values with Only VLAN Hash Filter Enabled (continued)

VTIM	HFO	HFI	OTS	ITS
1	0	1	1/0	1/0

With no perfect filters enabled, any VLAN packet is considered to have bypassed the perfect filter. If Hash Filter is enabled for one of the Tags, then the respective Status bit depends on the Filter's result. The Status bits are set to 0 if VLAN Hash Filter is also not enabled.

If the value of ITS/OTS is shown as 1/0; then it indicates that the final result is dependent on the enabled relevant filter's result.

Example 1: The second row of table 'OTS and ITS Bit Values with Only VLAN Hash Filter Enabled' indicates that at least one Perfect Filter is enabled for Outer VLAN tag comparison and none of the filters are enabled for Inner VLAN tag comparison. Inverse VLAN Filtering is not enabled. The bit OTS is given as 1/0. If the received frame passes at least one of the enabled Outer VLAN Tag filters then the bit is set to 1. If the frame doesn't pass any of the enabled Outer VLAN Tag filters, then the bit is set to 0.

Example 2: Last Row of table 'OTS and ITS Bit Values with Only VLAN Hash Filter Enabled' indicates that Inverse Filtering is enabled, Hash Filter and at least one perfect filter is enabled for Inner VLAN Tag comparison, then if the received frame's Inner VLAN tag mismatches with both the Hash Filter and all the enabled Perfect filters, then the frame will have the ITS bit set to 1 else it is set to 0. OTS will be set to 0 as no comparison is performed.

11.7.2.4.4.4 Stripping

Each of the VLAN Tags has individual control over stripping. The programming options of always strip, never strip, strip on pass and strip on fail are available. Inner or Outer VLAN Tag Stripping is based on the pass or fail results of the individual tag. If a tag is bypassed by all the relevant filters, stripping is not applicable for the tag.

- If strip on Pass is enabled for the outer VLAN Tag, then the stripping occurs only if the Outer VLAN tag has passed the relevant filters. The Outer VLAN Tag Filter Result bit will be set.
- If strip on Fail is enabled for the outer VLAN Tag, then stripping occurs only if the Outer VLAN Tag has failed relevant filters. The Outer VLAN Tag Filter Result Bit will be reset.

- If the Outer VLAN tag of the received frame is bypassed by the entire filter (no comparison has been made), then the tag is not stripped, though the Status Bit is still 0.
- As multiple filters are enabled, it is possible that the received VLAN frame could have matched any one or more of the filters. The VLAN Tag's value is not always deterministic from the filter status bits.

If the software/application strips the VLAN Tag based on the filter result, it might lose the VID. So the suggested use is, if stripping is enabled for any of the tags, the tag can be put in the status. For this the software/application will have to enable the respective "VLAN Tag in Status" bit - 24 or 31 in the MAC VLAN Tag Control Register.

See section Programming Guidelines for Extended VLAN Filtering and Routing on Receive

11.7.2.4.5 Layer 3 and Layer 4 Filtering

IP supports the Layer 3 based packet filtering which is IP Source or Destination Address filtering in the IPv4 or IPv6 packets, and Layer 4 based packet filtering which is Source or Destination Port number filtering in TCP or UDP. When layer 3 and layer 4 packet filtering is enabled then packets are filtered in the following manner.

- Matched Packets: The MAC forwards the packets that match all enabled fields to the application along with the status. The MAC gives the matched field status only if the IPC bit of MAC_Configuration register is set and one of the following conditions is true:
  - All enabled Layer 3 and Layer 4 fields match
  - At least one of the enabled field matches and other fields are bypassed or disabled

When multiple Layer 3 and Layer 4 filters are enabled, any filter match is considered as a match. If more than one filter matches, the MAC provides the status of the lowest filter where Filter 0 is the lowest filter and Filter 3 is the highest filter.

- Unmatched Packets: The MAC drops the packets that do not match any of the enabled fields. You can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets.

- Non-TCP or UDP IP Packets: By default, all non-TCP or UDP IP packets are bypassed from the Layer 3 and Layer 4 filters. MAC can optionally be programmed to drop all non-TCP or UDP over IP packets.
- IP has a control register “MAC_L3_L4_Control” to control the Layer L3 and L4 packet filtering along with address registers to program the Layer L3 and L4 fields to be matched.

11.7.2.4.6 Flexible Receive Parser

When this function is enabled, all incoming packets are parsed as per the programmable instruction stored in memory. It does the following function

- Packet Filter (Accept or Reject)
- DMA Channel Selection

Flexible receive parser block operates over the first 128 bytes data of receive packet based on 64 bytes of instruction on each packet. Following figure shows the functional block diagram of Flexible Receive Parser.

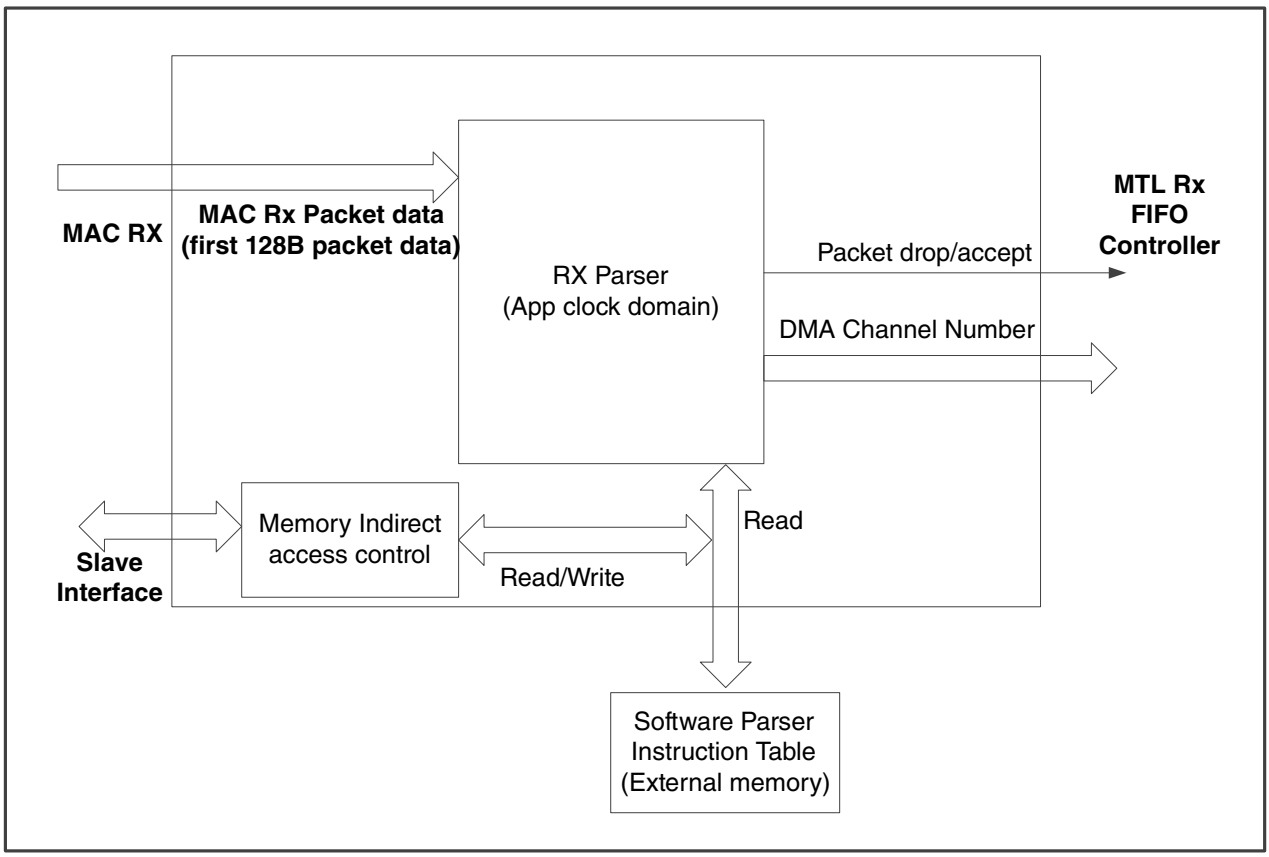

Figure 11-85. Functional block diagram of flexible recieve parser

11.7.2.4.6.1 Instruction Table Format of the Flexible Receive Parser

Software must build the 96-bit wide instruction before enabling the receive parser feature. Each instruction is programmed as an entry in the instruction memory.

The format of each entry in the Instruction table is shown in the following table.

Table 11-104. Rx Parser Instruction Entry Format

Field	Field Name	Description
31:0	MATCH_DATA	The 4-byte data. This data is used for comparing with incoming packet data starts at the frame offset as defined in [79:72] of the entry. The comparison is done only on those bits whose corresponding mask bits are set to 1 (MATCH_EN bits of [63:32]). See the Notes (below this table) on the byte

Table continues on the next page...

Table 11-104. Rx Parser Instruction Entry Format (continued)

Field	Field Name	Description
		order relative to Ethernet arrival data and endianness supported by QoS IP on the slave interface. The programming of this instruction table should adhere to the same.
62:32	MATCH_EN	When the MATCH_EN is set to 1, the corresponding Packet data bit is used for comparing. Otherwise, corresponding data bit is don't care.
64	AF	Accept frame
65	RF	Reject frame
66	IM	Inverse match
67	NIC	Next instruction control
71:68	Reserved	-
79:72	Frame Offset	[77:72] indicates the frame offset in terms of 4 bytes. (Here [79:78] always 0)Frame offset in the packet data to be compared for Match.This is in terms of 4 bytes. Value Actual Frame offset in bytes 0 01 42 8… ..63 252 The max value programmed in this Instruction Table is 128 B. The 'Actual Frame Offset' should not cross this limit.
87:80	OK Index	If (NIC==0) Memory Index to be used next when ENTRY_MATCH==1 and neither AF or RF is set to 1. If (NIC==1) Memory Index to be used next when ENTRY_MATCH==0 Note: ENTRY_MATCH is a calculated value based on MATCH_DATA, MATCH EN, and IM. It is not a field.
92:88	DMA CH NO	Indicates the DMA Channel Number (1-bit for each). This will be used when ENTRY_MATCH==1 and AF==1 (Accept frame). The encoding is as follows: • bit[0]- DMA Channel Number 0 • bit[1]- DMA Channel Number 1 • bit[2]- DMA Channel Number 2 • bit[3]- DMA Channel Number 3 • bit[4]- DMA Channel Number 4. Note: The DMA Channel number is encoded using bit wise as QoS IP support multicasting/broadcast across DMA Channels. See section 3.3.12 for more details and proper usage.
128:93	Reserved	0 (This field is only for software view and reserved for future enhancements. The memory width remains as 93-bits for now)

The parser begins parsing from the 0th entry, for each received packet. The subsequent parsing entry location (next entry or OK_INDEX[]) depends on the parser result of the current entry. Following figure shows the detailed flow.

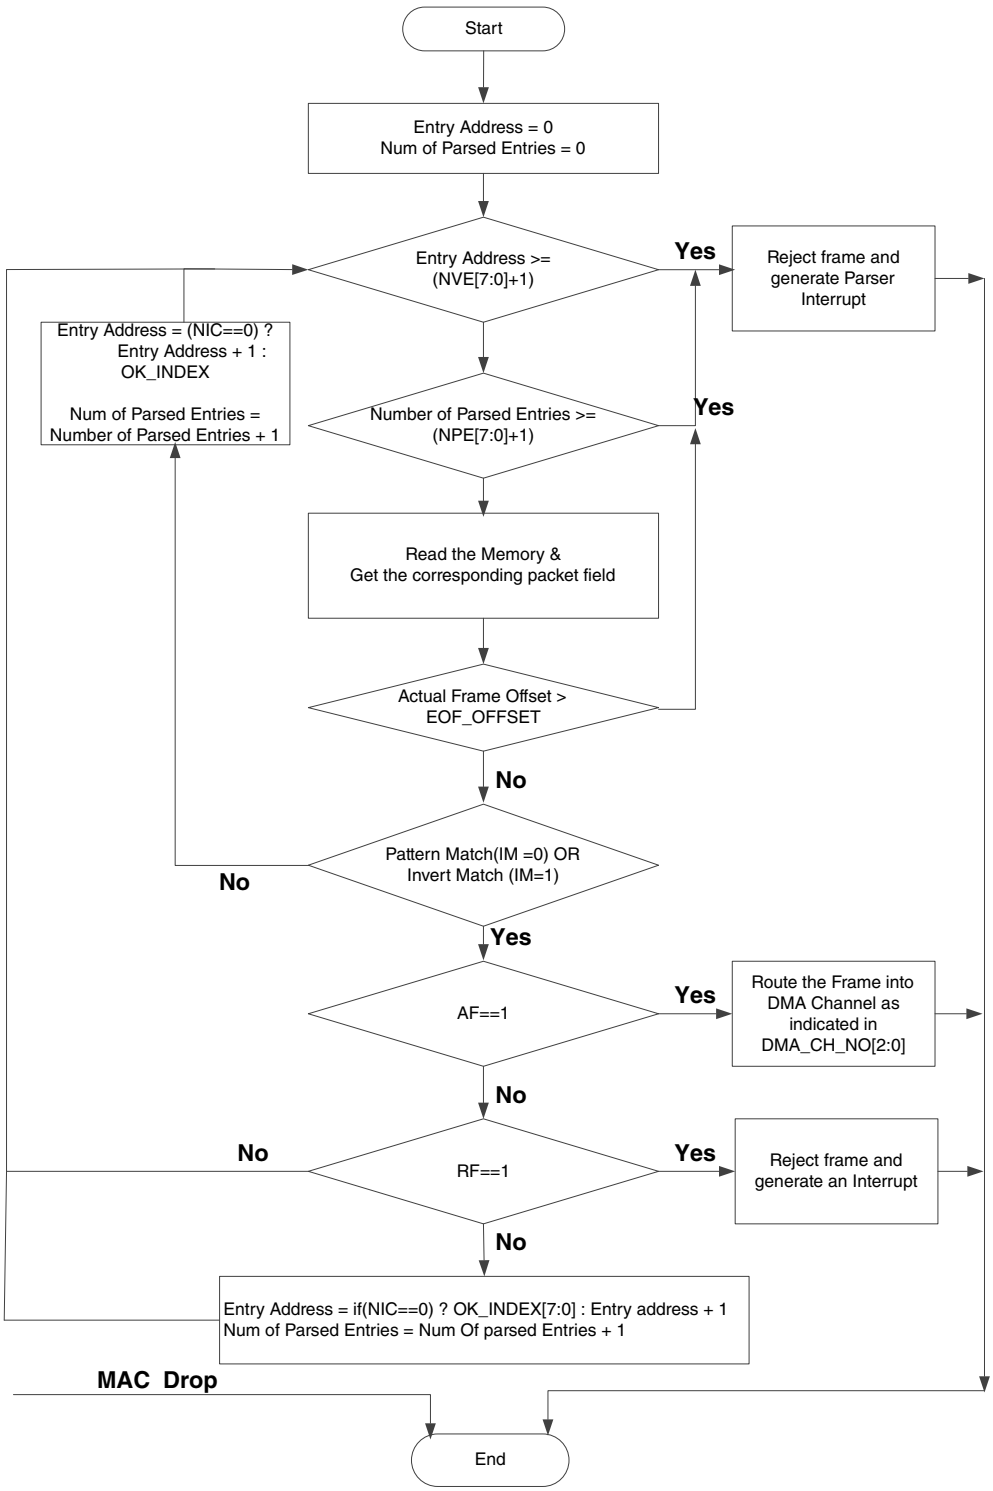

Figure 11-86. Flexible recieve parser flow chart

In the above figure, MAC Drop means the packet is dropped by the MAC due to another filter condition (for example, DA filter) and will not reach the Flexible Receive Parser.

The EOF_OFFSET shown in the figure is equal to the least among the following:

- Actual Packet size
- 128 Byte when frame pre-emption feature is not enabled/configured
- 128 Byte when frame pre-emption feature is enabled and packet is pre-emptible.
- 64 Byte when frame pre-emption feature is enabled and packet is Express Packet

11.7.2.4.6.2 Number of Valid Entries (NVE)

NVE indicates the number of valid entries in the instruction table. The default value is 64. Software can change this value by writing into MTL_RXP_Control_Status registers field NVE[7:0].

While parsing, if the Entry address is found to be is greater than NVE[7:0]+1, an error is flagged in the MTL_RXP_Interrupt_Control_Status register bit[0], NVEOVIS (Number of Valid Entries overflow status). IP generates an interrupt status (MTL_Interrupt_Status, bit[23], MTLPIS (MTL Parser Interrupt Status)).

11.7.2.4.6.3 Number of Parsable Entries (NPE)

NPE indicates the number of entries that can be parsed on an incoming packet. The default value is 64. Software can change this value by writing into MTL_RXP_Control_Status registers field NPE[7:0] (Number of Parsable Entries) bits [21:16].

While parsing, if the number of parsed entries is more than NPE[7:0]+1, an error is flagged in the MTL_RXP_Interrupt_Control_Status register bit[1], NPEOVIS (Number of Parsable Entries overflow status). IP generates an interrupt status (MTL_Interrupt_Status, bit[23], MTLPIS (MTL Parser Interrupt Status).

While NVE[] indicates is the number of valid entries in the Rx parser memory built by software, NPE[] indicates the worstcase parsable entries considering the various possible paths that the parser can take. (NVE[] >= NPE[]).

11.7.2.4.6.4 Frame Offset

It indicates the frame offset, in terms of 4 bytes which is used while comparing against the current table entry.

In an entry, an error is flagged in the TL_RXP_Interrupt_Control_Status register bit[2], FOOVIS (Frame Offset Overflow Interrupt Status) in any of the following cases:

When Frame Offset is more than

- Packet size
- 128B if pre-emption is disabled
- 128B if pre-emption is enabled and packet is pre-empitble
- 64B if pre-emption is enabled and packet is an Express packet

IP generates an interrupt status (MTL_Interrupt_Status bit[23]) and MTLPIS (MTL Parser Interrupt Status).

NOTE

If the frame ends after the (frame_offset *4) bytes but before ((frame_offset *4)+4) bytes, the Receive parser declares Frame Offset Error if comparison is enabled (via MASK bits) for the non-received bytes; from (frame_offset *4) to ((frame_offset *4)+4).

11.7.2.4.6.5 Frame Reject

In cases where an Entry matches (considering the Inverse match, IM bit in the instruction table) and Frame Accept bit is not set, and Frame Reject bit (RF) is set, the frame is dropped.

When a frame is dropped due to RF = 1, IP generates an interrupt status (MTL_Interrupt_Status, bit[23], MTLPIS (MTL Parser Interrupt Status).

11.7.2.4.6.6 Out of Order Processing

The Rx parser flow can be out of order. The decision tree need not be based on the order in which packet arrives. That is, the decision tree can be out of order; the decision tree need not be based on the same order as the packet data arrival (data within one packet). This implies that the next entry and next frame offset (OK_INDEX[]/ FRAME_OFFSET[]) can be less than the current entry address and current Frame Offset.

11.7.2.4.6.7 DMA Channel Selection

When the Rx parser is enabled (FRPE bit[16] is set to 1 in MTL_Operation_Mode register) the Rx parser overrides the DMA selection criteria of the MAC.

When the Rx parser is disabled (FRPE bit[16] is set to 0 in MTL_Operation_Mode register) the MAC/MTL determines the DMA channel number.

11.7.2.4.6.8 Receive Queue Selection

The Rx Queue is determined by the existing MAC functionality, irrespective of the enabling/disabling of the Rx Parser. This is because the Rx parser is mainly designed for selecting the DMA channel and Rx queuing is decided by the MAC to enable the proper functioning of the Pause/PFC feature.

NOTE

When there are multiple queues and multiple DMA Channels are enabled, a particular DMA channel might receive out of order packets. This is because queue selection is based on MAC criteria (VLAN Priority and other criteria) and Rx DMA channel selection is based on Rx parser.

11.7.2.4.6.9 MAC Packet Filtering/Drop/Error Handling

The MAC does the packet filtering based on the received packet fields. Disable the Packet Filtering features inside the MAC when the Rx parser is enabled. To disable the Packet Filtering features inside the MAC,

1. Set Promiscuous Mode (PR, bit[0] of MAC_Packet_Filter register)
2. Set all other bits in the MAC_Packet_Filter register to its default values

When MAC decides to drop the packet (due to Rx MAC dependent Error such as GMII Error, Receive Watch Dog Error, CRC Error and Giant Frame Error) the packet is dropped irrespective of the Rx parser decision.

11.7.2.4.6.10 PAD Strip/CRC Strip Handling

The pad strip and CRC strip are controlled by the software and applicable to all the received packets. When these features are enabled, software must build the Rx parser instructions accordingly.

NOTE

Enable PAD and CRC stripping in real use case.

11.7.2.4.6.11 VLAN Strip Handling

The MAC supports stripping the VLANs, outer as well as inner VLAN. When MAC is programmed to strip the VLAN, the Rx parser considers those VLAN tags to be part of the incoming packet.

11.7.2.4.6.12 Multicast and Broadcast Support

IP supports multicast and broadcast packet and the packet is routed to the highest queue number.

When Rx Parser is enabled, the packet routing is decided by the DMA Channel Numbers (DMA CH NO, Bits [95:88]) in the Instruction Table.

When Rx Parser is disabled, the packet routing is determined by DCS (DMA Channel Select) field of the MAC_AddressX_High register. For more details, see Broadcast/ Multicast Packet Duplication.

NOTE

DCS/DMA CH NO field is per DMA Channel control and therefore, multiple DMA channels can be selected for routing the packet.

11.7.2.4.6.13 Pre-emption Support

The MAC supports the frame pre-emption feature when the Flexible Rx parser feature is enabled. The minimum packet size for Frame Preemption is 64 Bytes. This means that:

- The Rx parser can operate on 64 bytes of Express traffic.
- The Rx parser can operate on 128 bytes of pre-emptible traffic, as a 64-bit packet of pre-emptible traffic might be interrupted by Express traffic before that packet is fully received, so the parser needs to have 64 bits on either side of the express traffic in order to capture the full 64-bits of a pre-empted packet.

11.7.2.4.6.14 Software Access to the Flexible Receive Parser Memory

Software can read/write into the Rx parser memory, using the following registers via indirect addressing.

- MTL_RXP_Indirect_Acc_Control_Status
- MTL_RXP_Indirect_Acc_data

For more details, see ENET_QOS register descriptions.

11.7.2.4.6.15 Statistical Counters

IP supports the following statistics counters for flexible receive parser.

1. MTL_RXP_Drop_Cnt
2. DMA_RXP_Error_Cnt

DMA_CH(#i)_Rxp_Accept_cnt (i=0; i<2)

For more details, see ENET_QOS register descriptions.

11.7.2.4.6.16 Changing the Instruction Table by Software

Software can update the instruction table in the memory in the following ways

- Disable the MAC Receiver and Receive Parser by setting the RE field of the MAC_Configuration register to 0 and FRPE bit of MTL_Operation_mode register to 0. Wait for Rx Parser to become inactive (RXPIA, MTL_RXP_Control_Status register bit[31]).
- (Optional) Program in the Entry address 0 to unconditionally (all MATCH_EN bit 0) skip to OK_INDEX[] (to certain location in the memory) where it is programmed to reject or accept all packets.

11.7.2.4.6.17 Receive Cut-Through Functionality

In the case of cut-through mode, the Rx controller attempts to transfer the received packets to DMA just after the cut-through threshold amount of packet data is received (RTC field in the MTL_RxQx_Operation_Mode register).

However due to Rx parser's result worst case arrival time can be more than the programmed cut-through threshold. So, the Rx controller delays the packet transfer to DMA accordingly. So, the cut-through functionality is re-defined as follows

The Rx controller attempts to transfer packet to DMA after at least RTC number of bytes have been received and Rx parser results are available.

11.7.2.4.6.18 Receive Packet Drop Indication

In most cases, the packet drops internally in the Rx Queue. However, back-to-back packets can arrive for the same queue and first packet's Rx parser result is not available when the second packet arrives. In such cases, the packet cannot be flushed internally and forwarded to DMA or the Application Interface and status is indicated accordingly. For more details, see RDES2, bit 16(RXPD) in Receive Normal Descriptor (Write-Back Format).

11.7.2.4.6.19 Runt Packet Handling

The Rx parser can perform the operation with 64B minimum size packet. If the runt packet is received (should be indicated by MAC), the Rx parser assumes that it gets dropped in the MAC. This is because, back-to-back runt packets (< 64B) cannot be handled in the Rx parser.

11.7.2.4.6.20 Uncorrectable ECC Error Handling

When the parser detects an uncorrectable ECC error while parsing the parser memory, the packet is not dropped. Instead, the packet is sent to the application with an Error Indication. The RXPI (RX Parser Incomplete) is set in the packet status along with Error Summary (ES) bit.

For more details, see Receive Normal Descriptor (Write-Back Format).

11.7.2.5 IEEE 1588 Timestamp Support

The MAC supports the IEEE 1588 Precision Time Protocol (PTP). The MAC is able to do precise time stamping and capturing of incoming and outgoing frame to enable support of PTP with its associated software. The MAC supports the all clock types defined in IEEE 1588-2008. Typical frequency of PTP timestamp clock is 125 MHz. The MAC supports:

- Taking a timestamp snapshot of all packets or only PTP type packets.
- Taking a timestamp snapshot of only event messages.
- Identifying the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sending the PTP message type status given by the MAC. The PTP status is finally written back to the Receive Descriptor: RDES1 Normal Descriptor (Write-Back Format).
- Measuring sub-second time in decimal or binary format.

11.7.2.5.1 Delay Request-Response Mechanism

The system or network is classified into the master and slave nodes for distributing the timing and clock information. Following figure shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

Figure 11-87. Networked Time Synchronization

As shown in the figure, PTP uses the following process:

1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the reference time information of the master. This message leaves the system of the master at t1. This time must be captured for Ethernet ports at the internal GMII interface.
2. The slave receives the Sync message and also captures the exact time, t2, using its timing reference.
3. The master sends a Follow_up message to the slave, which contains t1 information for later use.
4. The slave sends a Delay_Req message to the master and notes the exact time, t3, at which this packet leaves the internal GMII interface.
5. The master receives the message, capturing the exact time t4, at which the message enters its system.
6. The master sends the t4 information to the slave in the Delay_Resp message.
7. The slave uses the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the timing reference of the master.

Most of the PTP implementation is done in the software above the Ethernet layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the internal GMII interface. This timing information must be captured and returned to the software for proper implementation of PTP with high accuracy.

11.7.2.5.2 Peer-to-Peer PTP Transparent Clock (P2P TC) Message Support

The IEEE 1588-2008 supports peer-to-peer PTP (Pdelay) message in addition to the SYNC, Delay Request, Follow-up, and Delay Response messages. Following figure shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

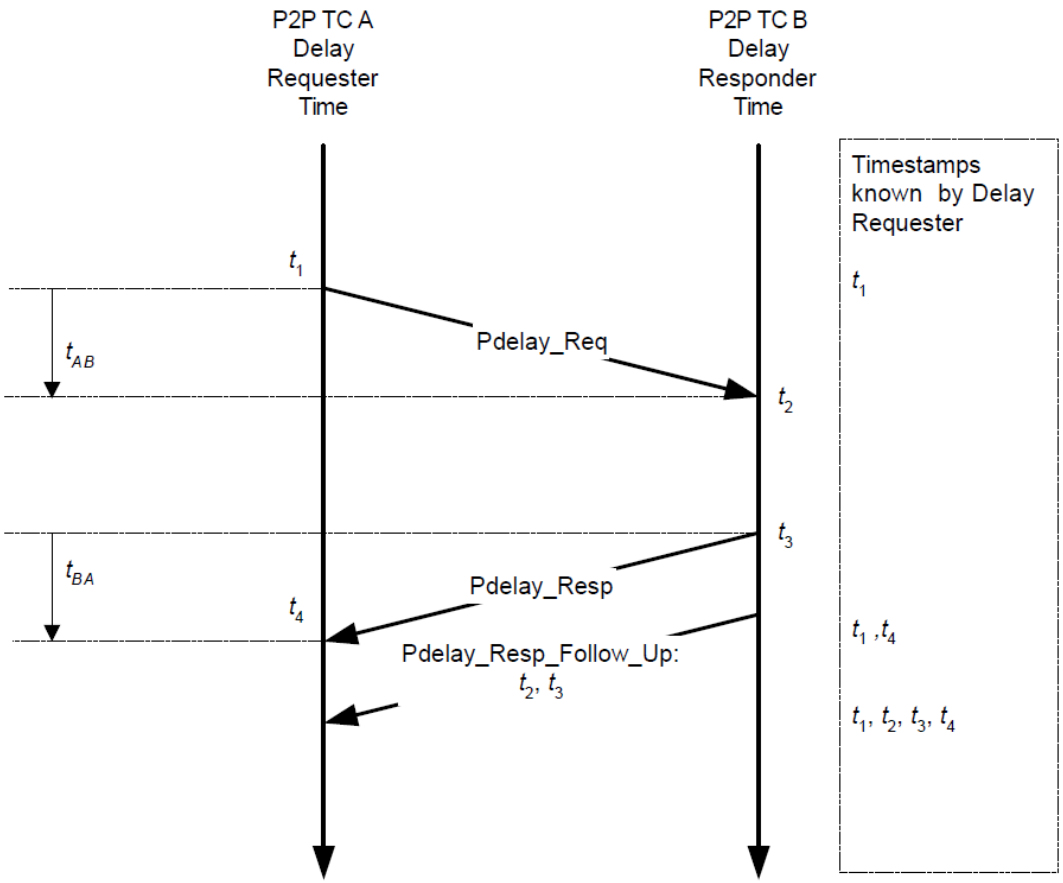

Figure 11-88. Propagation Delay Calculation in Clocks Supporting Peer-to-Peer Path Correction

As shown in the above figure, the propagation delay is calculated in the following way:

1. Port 1 issues a Pdelay_Req message and generates a timestamp (t1) for the Pdelay_Req message.
2. Port 2 receives the Pdelay_Req message and generates a timestamp (t2) for this message.
3. Port 2 returns a Pdelay_Resp message and generates a timestamp (t3) for this message. To minimize errors because of any frequency offset between the two ports, Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message. Port 2 returns any one of the following:

- Difference between the timestamps t2 and t3 in the Pdelay_Resp message
- Difference between the timestamps t2 and t3 in the Pdelay_Resp_Follow_Up message
- Timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages, respectively

4. Port 1 generates a timestamp (t4) on receiving the Pdelay_Resp message.
5. Port 1 uses all four timestamps to compute the mean link delay.

11.7.2.5.3 Timestamp Correction

According to the IEEE 1588 specification, a timestamp must be captured when the PTP message timestamp point (leading edge of the first bit of the octet immediately following the Start Frame Delimiter octet) crosses the boundary between the node and the network. As the MAC takes the timestamp at an internal point far from the actual boundary of the node and network, this captured timestamp is corrected/updated for the ingress/egress path latency (including the delay in the PHY layers). Further correction is done for the inaccuracies/errors introduced due to the clock (internal GMII Tx, Rx clock) being different at the capture point as compared to the PTP clock (clk_ptp_ref_i) that is used to generate the time. The resultant CDC (Clock Domain Crossing) circuits add error depending on the clock period of the internal GMII or MII and PTP clocks.

11.7.2.5.3.1 Ingress Correction

In the Receive side the timestamp captured at the internal snapshot point is delayed (later in time) as compared to the time at which that packet's SFD bit is received at the port's boundary. Therefore, the captured timestamp must be reduced by the ingress latency and the errors in CDC sampling. This correction value must be determined/calculated by the software and written into the MAC_Timestamp_Ingress_Corr_* registers.

The correction value consists of the following 3 components:

1. External latency in the PHY layer between boundary point and the input of the core.

   If the PHY is compliant to the IEEE 802.3 Clause 45 MMD registers, it has a register indicating the maximum and minimum ingress latency. The software can read these registers and determine the average ingress latency in the PHY. Alternatively (if the PHY does not support these registers), the ingress latency must be determined from its datasheet or timing characteristics.

2. Internal latency from the input of the core to the internal capture point.

The internal ingress latency can be read from the MAC_Ingress_Timestamp_Latency register. This is a read-only register and gives the latency in scaled Nanoseconds format defined in IEEE 1588 Clause 5.3.2. The latency differs based on the active PHY interface (for example, RMII) and the operating speed. Therefore, the software must read this register after any speed change in the MAC to determine the current internal latency.

3. CDC Synchronization

   The CDC synchronization error is almost equal to 2 times the clock-period of the PTP clock (clk_ptp_ref_i).

The values determined from these 3 components should be added by the software and must be written into the TSIC and TSICSNS fields of the MAC_Timestamp_Ingress_Corr_* registers.

NOTE

The value written to the register must be negative (two's complement as explained below), because it has to be subtracted from the captured timestamp. The MAC Receiver adds the value in this register to the captured timestamp and then gives the resultant value as the timestamp of the received packet.

When TSCTRLSSR bit in MAC_Timestamp_Control register is set, the nanoseconds field of the captured timestamp is in decimal format with a granularity of 1ns. So the Bit31 of TSIC must be set to 1 (for negative value) and bits[30:0] must be written with "10^9 - total ingress_correction_value[nanosecond part]" represented in binary. For example, if the required correction value is -5 ns, then the value is 0xBB9A_C9FB.

When TSCTRLSSR bit in MAC_Timestamp_Control register is reset, the nanoseconds field of the captured timestamp is in binary format with a granularity of ~0.466ns. Therefore, bits[30:0] must be written with "2^31 - total ingress_correction_value" represented in binary with bit[31] = 1.

11.7.2.5.3.2 Egress Correction

In the Transmit side the timestamp captured at the internal snapshot point is earlier (advanced in time) as compared to the time at which that packet's SFD bit is output at the port's boundary. Therefore, the captured timestamp must be compensated by the egress latency and the errors in CDC sampling. This correction value must be determined/ calculated by the software and written into the MAC_Timestamp_Egress_Corr_* registers.

The correction value consists of the following 3 components:

1. External latency in the PHY layer between the output of the core and the boundary of the port and the network

   If the PHY is compliant to the IEEE 802.3 Clause 45 MMD registers, it has a register indicating the maximum and minimum egress latency. The software can read these registers and determine the average egress latency in the PHY. Alternatively (if the PHY does not support these registers), the egress latency must be determined from its datasheet or timing characteristics.

2. Internal latency from the internal capture point and the output of the core

   This internal egress latency can be read from the MAC_Egress_Timestamp_Latency register. This is a read-only register and gives the latency in scaledNanoseconds format defined in IEEE 1588 Clause 5.3.2. The latency will differ based on the active PHY interface (for example, RMII) and the operating speed. Hence the software must read this register after any speed change in the MAC to determine the current internal latency.

3. CDC synchronization error

   The CDC synchronization error value for one-step timestamping would be = (1 * period of clk_ptp_ref_i + 4 * period of clk_tx_i). Otherwise (Two-step timestamping mode), the value = -(2 * period of clk_ptp_ref_i).

11.7.2.5.3.3 Frequency Range of Reference Timing Clock

The timestamp information is transferred across asynchronous clock domains, from the MAC clock domain to the application/system clock domain. Therefore, a minimum delay is required between two consecutive timestamp captures. This delay is 4 clock cycles of RMII and 3 clock cycles of PTP clocks. If the delay between two timestamp captures is less than this delay, the MAC does not take a timestamp snapshot for the second packet.

11.7.2.5.3.4 PTP Processing and Control

Following table shows the common message header for the PTP messages. This format is taken from the IEEE 1588-2008.

Table 11-105. Message Format Defined in IEEE 1588-2008

Bits								Octet	Offset
7	6	5	4	3	2	1	0		
transportSpecific				messageType				1	0
Reserved				versionPTP				1	1
messageLength								2	2
domainNumber								1	4
Reserved								1	5
flagField								2	6
correctionField								8	8
Reserved								4	16
sourcePortIdentity								10	20
sequenceId								2	30
controlField (*)								1	32
logMessageInterval								1	33

(*) – control Field is used in version 1. In version 2, message Type field is used for detecting different message types.

There are some fields in the Ethernet payload that are being use to detect the PTP packet type and control the snapshot to be taken. These fields are given below in table for PTP packets over Ethernet.

Following table provides information about the fields that are matched to control the snapshots for the PTP packets sent over Ethernet for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, Annex D and the message format.

Table 11-106. Ethernet PTP Packet Fields Required for Control And Status

Field Matched	Octet Position	Matched Value	Description
MAC Destination Multicast Address[1]	0–5	01-1B-19-00-00-00 01-80-C2-00-00-0E	All PTP messages can use any of the following multicast addresses[2]: • 01-1B-19-00-00-00 • 01-80-C2-00-00-0E[3]
MAC Packet Type	12, 13	0x88F7	PTP Ethernet packet
PTP Control Field (IEEE 1588 version 1)	46	0x00, 0x01, 0x02, 0x03, or 0x04	• 0x00: SYNC • 0x01: Delay_Req • 0x02: Follow_Up • 0x03: Delay_Resp • 0x04: Management

Table continues on the next page...

Table 11-106. Ethernet PTP Packet Fields Required for Control And Status (continued)

Field Matched	Octet Position	Matched Value	Description
PTP Message Type Field (IEEE 1588 version 2)	14 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	• 0x0: SYNC • 0x1: Delay_Req • 0x2: Pdelay_Req • 0x3: Pdelay_Resp • 0x8: Follow_Up • 0x9: Delay_Resp • 0xA: Pdelay_Resp_Follow_Up • 0xB: Announce • 0xC: Signaling • 0xD: Management
PTP Version	15 (nibble)	0x1 or 0x2	• 0x1: Supports PTP version 1 • 0x2: Supports PTP version 2

1. The unicast address match of destination addresses (DA), programmed in MAC address 0 to 31, is used if the TSENMACADDR bit of MAC_Timestamp_Control register is set.
2. IEEE 1588-2008, Annex F
3. The MAC does not consider the PTP version 1 messages with Peer delay multicast address (01-80-C2-00-00-0E) as valid PTP messages.

11.7.2.5.4 Transmit Path Functions

The MAC captures a timestamp when the Start Packet Delimiter (SFD) of a packet is sent on the internal GMII interface. The packets, for which the timestamps has to be captured can be controlled on per-packet basis. Each Transmit packet can be marked to indicate whether a timestamp should be captured for it. The MAC does not process the transmitted packets to identify the PTP packets. You can specify the packets by using the control bits in the Transmit descriptor. The MAC returns the timestamp to the software inside the corresponding Transmit descriptor, thus connecting the time-stamp automatically to the specific PTP packet. The 64-bit timestamp information is written to the TDES0 and TDES1 fields. The TDES0 field holds the 32 least significant bits of the timestamp.

11.7.2.5.5 Receive Path Functions

The MAC can be programmed to capture the timestamp of all packets received on the internal GMII interface or to process packets to identify the valid PTP messages. Use the following options of the MAC_Timestamp_Control register to control the snapshot of the time to be sent to the application:

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp
- Enable snapshot for PTP packets transmitted directly over Ethernet
- Enable timestamp snapshot for the received packet for IPv4 or IPv6
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP)
- Enable the node to be a master or slave and select the snapshot type

Table 11-107. Timestamp Snapshot Dependency on Register Bits

SNAPTYPSEL	TSMSTRENA	TSEVNTENA	PTP Messages
00	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp
00	0	1	SYNC
00	1	1	Delay_Req
01	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp,Pdelay_Req, Pdelay_Resp,Pdelay_Resp_Follow_Up
01	0	1	SYNC, Pdelay_Req, Pdelay_Resp
01	1	1	Delay_Req, Pdelay_Req, Pdelay_Resp
10	x	x	SYNC, Delay_Req
11	x	x	Pdelay_Req, Pdelay_Resp

The DMA returns the timestamp to the software inside the corresponding Receive Descriptor. The extended status, containing the timestamp message status and the IPC status, is written in normal descriptor RDES1 and the snapshot of the timestamp is written in RDES0 and RDES1 fields of context descriptor. The RDES0 field holds the 32 least significant bits of the timestamp.

NOTE

For Programming Guidelines for IEEE 1588 Timestamping (System Time Correction), see System Time Correction

11.7.2.5.6 IEEE 1588 System Time Source

The ENET QOS block supports both external and internal time source for reference timestamping.

- External Time source uses the 64-bit external time reference and clock as input in IP. The clock input is used to synchronize the external timing reference into MAC clock domain. Upper 32-bit indicates the time in seconds while lower 32-bit indicates the time in nanoseconds.
- Internal time source uses the only clock input to generate timing reference internally for snapshot and capture timestamps. Internal time reference has two field.
  - UInteger48 seconds Field: The seconds field is the integer portion of the timestamp in units of seconds. It is 48-bits wide.

    For example, 2.000000001 seconds are represented as seconds Field = 0x0000_0000_0002.

  - UInteger32 nano secondsField The nanoseconds field is the fractional portion of the timestamp in units of nanoseconds.

    For example, 2.000000001 seconds are represented as nanoSeconds = 0x0000_0001. The nanoseconds field supports the following two modes:

    - Digital rollover mode: In this mode, the maximum value in the nanoseconds field is 0x3B9A_C9FF, that is, (10e9-1) nanoseconds.
    - Binary rollover mode: In this mode, the nanoseconds field rolls over and increments the seconds field after value 0x7FFF_FFFF. Accuracy is ~0.466 ns per bit.

There is a system time register module which is being used when internal time reference is being used. The 80-bit time is maintained in this module and updated using the input reference clock (clk_ptp_ref_i). This time is the source for taking snapshots (timestamps) of Ethernet packets being transmitted or received at the internal GMII interface.

The system time counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the Timestamp Update register. For initialization, the system time counter is written with the value in the Timestamp Update register. For system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, the frequency offset and/or frequency drift of a slave clock (clk_ptp_ref_i) with respect to the master clock (as defined in IEEE 1588-2002) is corrected over a period of time instead of in one clock, as in coarse correction. This helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals.

NOTE

For Programming Guidelines for IEEE 1588 Timestamping (For Internal Time-stamp Source Configuration). see Initialization Guidelines for System Time Generation

11.7.2.5.7 IEEE 1588 Higher Word Register

If system time source is internal, then higher word register can be invoked. MAC timestamp is 64-bit wide. The values of the upper 16-bits of the seconds field can be read from the CSR register.

11.7.2.5.8 Flexible Pulse-Per-Second Output

The ENET QOS block supports the flexibility of programming the start or stop time, width and interval of pulse generated on pulse per second (PPS) output. IP supports 4 such output signals. By default, the block is in fixed pulse per second output mode with an interval of 1 second.

Initially. the start time should be programmed in target time registers "MAC_PPSx_Target_Time_Seconds and MAC_PPSx_Target_Time_Nanoseconds" for all desired/enabled PPS output. Reprogramming the start or stop time must be done after the synchronization of the earlier programmed value. Bit 31 of the MAC_PPS#_Target_Time_Nanoseconds register indicates that the synchronization is complete. If the application programs a start or stop time that has already elapsed, the MAC sets an error status bit indicating the programming error. If enabled, the MAC also sets the Target Time Reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

The PPS width and interval are programmed in terms of granularity of system time, that is, number of the units of sub-second increment value.

NOTE

See Programming Guidelines for Flexible Pulse-Per-Second Output

11.7.2.5.9 Media Clock Generation and Recovery

Media clock recovery and generation needs a dedicated hardware and software to complete the operation. IP generates a reference clock with the help of dedicated hardware which is then multiplied to get the desired media clock. Software extracts the presentation time from the incoming PTP 1722 frames and programs these value into CSR registers so IP can read them for media clock recovery.

As shown in the following figure, the timestamp array and the DMA module are external to IP. IP supports a 32-bit presentation time counter in nanoseconds that wraps at the full32 bit value to match up with 1722 presentation time format and an handshake mechanism with external application(such as DMA) to program the presentation time into CSR register.

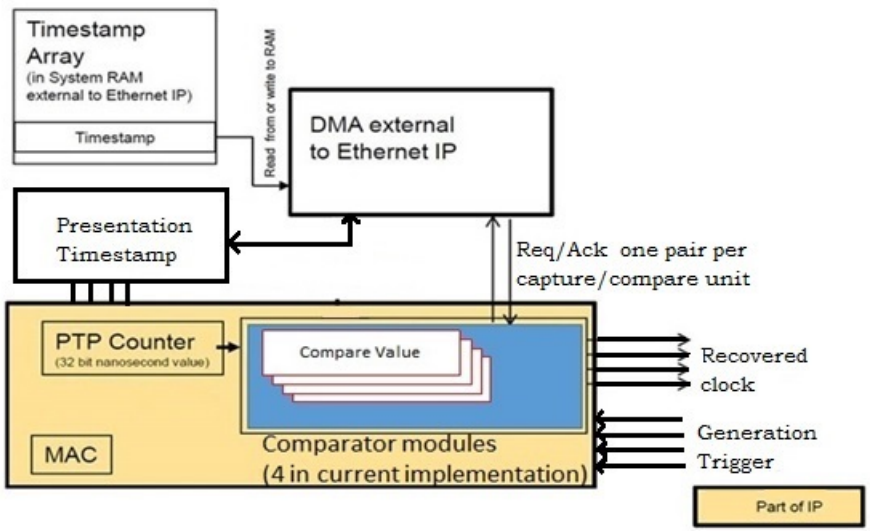

Figure 11-89. Block Diagram of Media Clock Generation and Recovery

11.7.2.5.9.1 Presentation Time Counter

Presentation time counter is another view of the PTP System time (1588 timer). For a given PTP System time (PTP[63:32] represents time in seconds and PTP[31:0] represents time in nanoseconds), there exists a corresponding Presentation Time (32-bit value in nanosecond). The Presentation time computed is referred to as Current Presentation Time (CPT).

The Current Presentation Time (CPT) can be viewed as derived from 64bit PTP System Time. PTPNS[63:0] = (PTP[63:32] * 32'd1,000,000,000) + PTP[31:0] where, PTPNS is the PTP system time converted into a 64bit nanosecond value.

Current Presentation Time[31:0] = PTPNS[31:0]

Media Clock Recovery is possible when the System Time is internally generated in IP and CPT is computed in the same way as the Internal PTP System Time generation. Because CPT and System Time values are in nanoseconds, and must be synchronous, the increment cycle of both the timers are same. The timer is updated at the same instance, but the updated value could be different. The software must compute a separate 32-bit

update value in nanoseconds for the CPT update. CPT sampled at different edges of a triggering input results in the generation of Media Clock timestamps which are inserted in 1722 based AVBTP packets, to recover the clock at the destination.

11.7.2.5.9.2 Comparator Modules

As shown in the figure 'Block Diagram of Media Clock Generation and Recovery' the module supports four comparator modules to handle multiple media clocks that might be required. The Comparator modules hand shake with the application to

Program the timestamps into the MAC_PPS(#i)_Target_Time_Seconds register when PTGE field of MAC_Timestamp_Control register is set.

Set the Presentation Time Control bits of the particular instance for recovery mode.

The timestamps received from the application are referred as Target Presentation Time (TPT).

When MCGREN#i field of MAC_PPS_Control register is set to 1, the IP operates in MCGR mode. The comparator module sends up to two requests to the application for TPT write, when PTGE field of MAC_Timestamp_Control register is set and the Presentation time control bits of the particular instance is set for MCGR mode. Subsequent requests are generated each time a Presentation Time match occurs. (CPT transitions from a value less than TPT, to a value greater than or equal to CPT). The first request is asserted when a specific comparator instance is set to MCGR mode with a non-zero Presentation Time Control and an additional request is made when the first data is received into the Comparator. This allows the application to write the next TPT value while IP processes the previous TPT value for a match.

The TPT read from the MAC_PPS(#i)_Target_Time_Second is considered as a future time. A toggle/pulse is generated in the next cycle when a match is detected. When a match is detected, the mcgr_dma_req_o#i request for that comparator is asserted (to obtain next TPT) until the corresponding application acknowledgment is set.

The presentation control bits (PPSCMD#i field of MAC_PPS_Control register) determine the shape of the generated waveform. Also, these bits can be programmed to either toggle or generate a high/low pulse for one PTP clock cycle, upon match.

Media Clock Recovery: A match is when the free-running CPT value matches the received TPT value. A output signal EMAC_TMR signal as shown in the IO mux sheet is asserted (toggle, low pulse, or high pulse) based on the presentation control value programmed.

Media Clock Generation: Based on the presentation control value programmed in MAC_PPS_Control register, the particular comparator captures the presentation time and programs it into MAC_PPS(#i)_Target_Time_Second register. A request is raised to the application to read the captured timestamp. Until the acknowledgment is received from the application, acknowledging that the read operation is complete, no new timestamps are captured.

11.7.2.5.9.3 Media Clock Generation and Recovery Flow

Following figure shows the media clock generation and recovery flow. For both media clock generation and recovery, set the PTGE field of MAC_Timestamp register for CPT generation and set the MCGREN#i field of MAC_PPS_Control Register for the corresponding instance to be enabled in the MCGR mode.

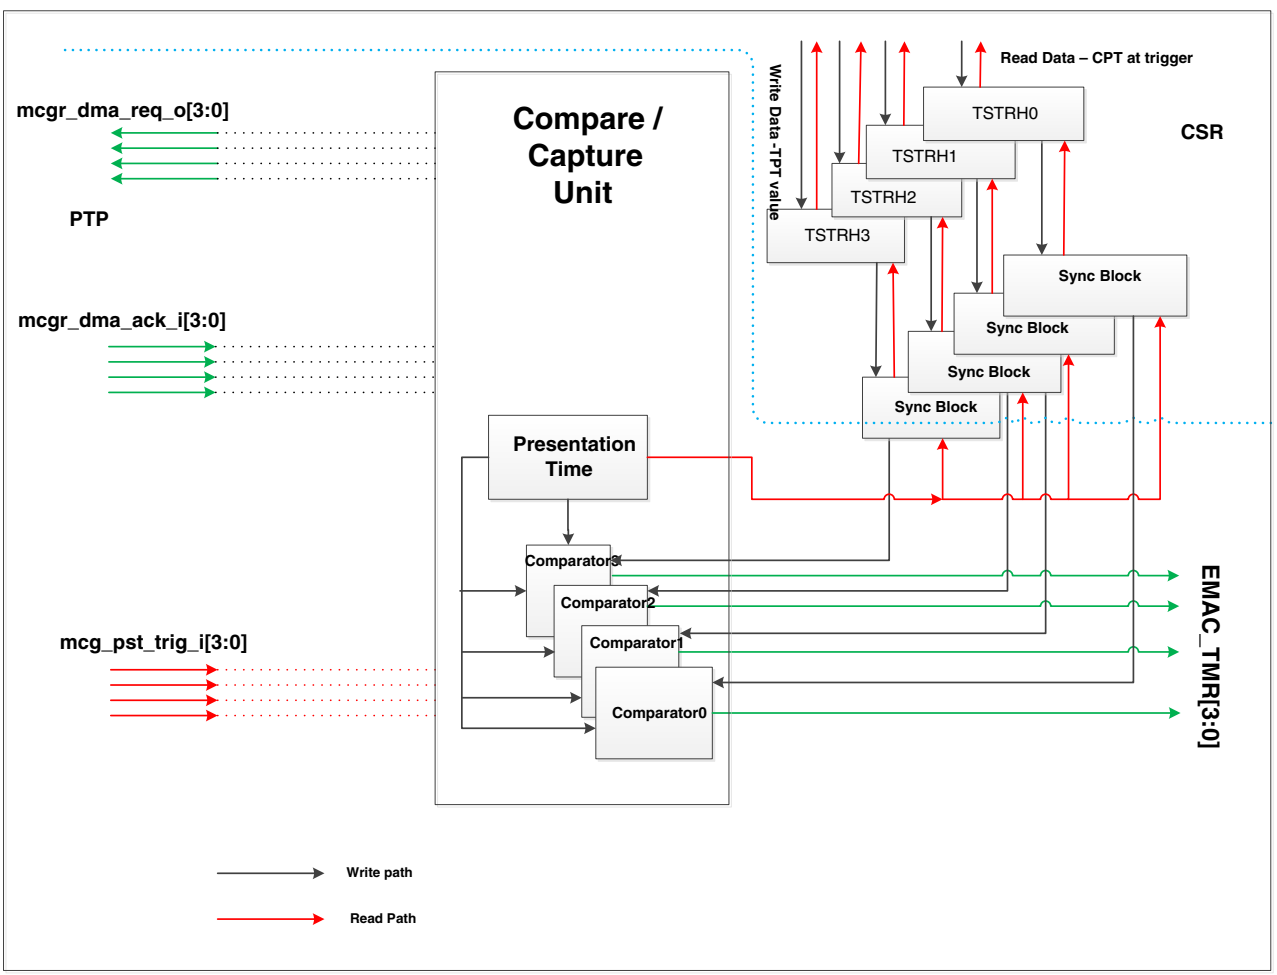

Figure 11-90. Media Clock Generation and Recovery Flow

NOTE

1. The consecutive triggers to sample the presentation time should always be asserted after a few PTP clock cycles to allow for synchronization delays. (This is not an issue when the input trigger maximum frequency is 8KHz and the PTP clock is running at least at 1MHz)
2. DMA acknowledgment can be both posted as well as non-posted, in the Media Clock Recovery Mode.
3. See "Programming Guidelines for Media Clock Generation and Recovery"

11.7.2.5.10 One step timestamp

IP supports the one step time stamp feature. It can be enabled for a packet by setting the Bit 20 (OSTC) in the control word.

NOTE

See Programming Guidelines for IEEE 1588 Timestamping.

11.7.2.5.11 IEEE 1588 Sub Nanoseconds Timestamp

The ENET QOS block supports the ingress and egress correction accuracy in sub-nanoseconds. It is programmed in the TSICSNS and TSECSNS fields of the MAC Timestamp Ingress Correction Subnanosecond and MAC Timestamp Egress Correction Subnanosecond registers, respectively. In this case, the correction has an unit of nanosecond, multiplied by 2^8. The least significant 8 bits of the value should be programmed in the sub-nanoseconds register.

For example, if the required egress correction is 3.6 nS and TSCTRLSSR bit is set, then TSEC must be 0x3 and TSECSNS must be 0x99 (0.6 * 256). Similarly, if the required ingress correction is -3.6 ns and TSCTRLSSR bit is set, then TSIC must be 0xBB9A_C9FC and TSICSNS must be 0x66 (fractional part of (10^9 - 3.6) * 256).

11.7.2.6 Multiple Channels and Queues Support

IP supports the five queues and channel on Tx and Rx paths.

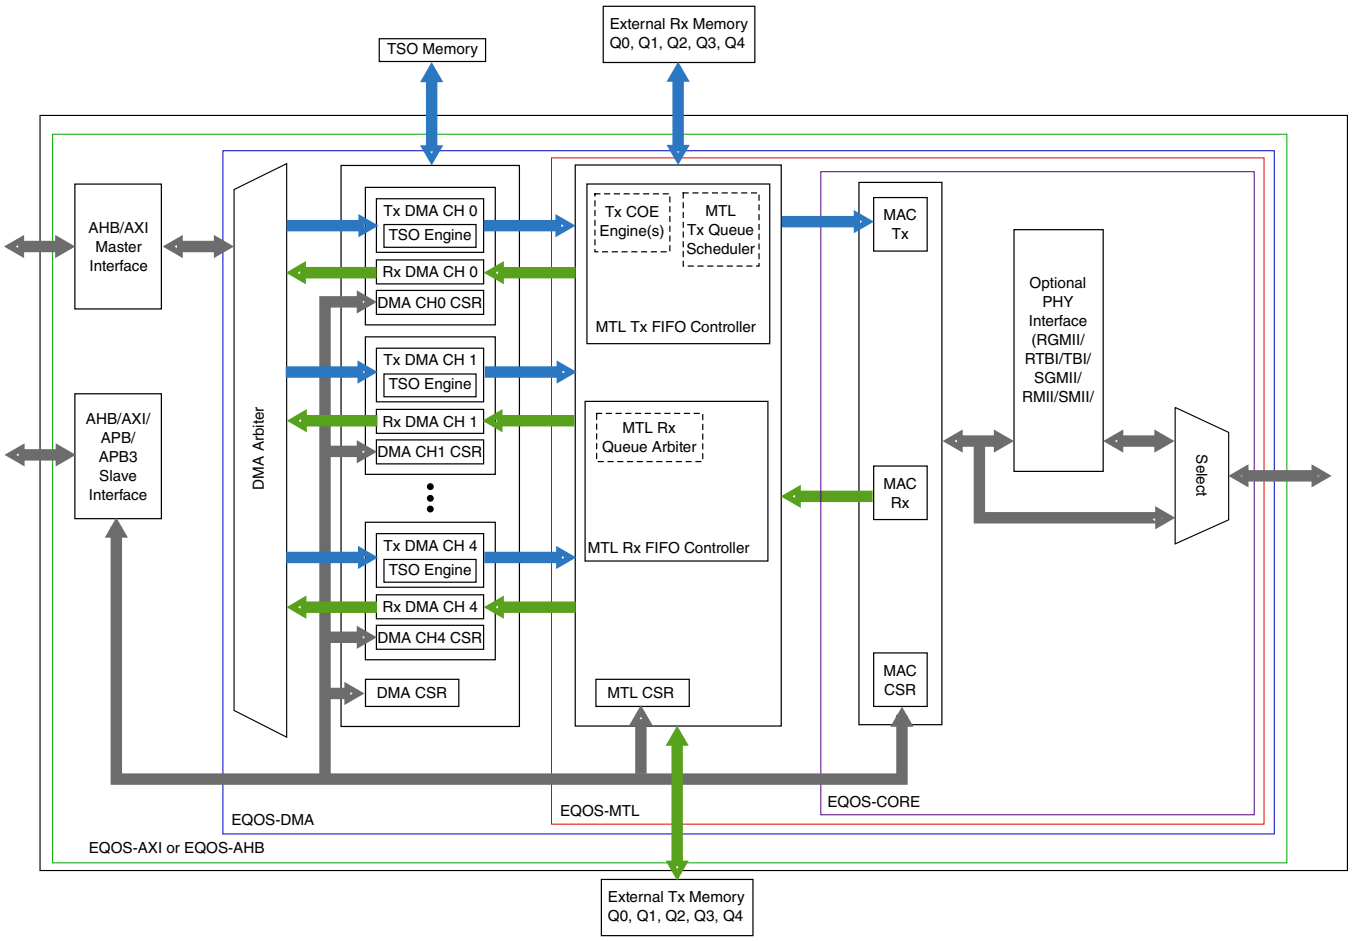

Figure 11-91. Module with Multiple Channels and Queues Block Diagram

DMA arbiter of IP supports two types of arbitration scheme, fixed priority and weighted round-robin. The DMA arbiter performs the arbitration between the Tx and Rx paths of DMA channels for accessing descriptors and data buffers. The DA bit of the DMA_Mode register specifies the arbitration scheme (fixed or weighted round-robin) between the Tx and Rx DMA of a channel.

Priority between the corresponding Tx DMA and Rx DMA can be set by using TXPR field of the DMA_Mode register. PR field of the DMA_Mode register can be set to specify the weighted priority between the Tx DMA and Rx DMA in round robin arbitration scheme.

Following table provides information about the priority scheme between Tx DMA and Rx DMA.

Table 11-108. Priority Scheme for Tx DMA and Rx DMA

Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Priority Schemes
x	x	x	0	1	Rx always has priority over Tx

Table continues on the next page...

Table 11-108. Priority Scheme for Tx DMA and Rx DMA (continued)

Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Priority Schemes
0	0	0	0	0	Tx and Rx have equal priority. Rx gets the access first on simultaneous requests
0	0	1	0	0	Rx has priority over Tx in ratio 2:1
0	1	0	0	0	Rx has priority over Tx in ratio 3:1
0	1	1	0	0	Rx has priority over Tx in ratio 4:1
1	0	0	0	0	Rx has priority over Tx in ratio 5:1
1	0	1	0	0	Rx has priority over Tx in ratio 6:1
1	1	0	0	0	Rx has priority over Tx in ratio 7:1
1	1	1	0	0	Rx has priority over Tx in ratio 8:1
x	x	x	1	1	Tx always has priority over Rx
0	0	0	1	0	Tx and Rx have equal priority. Tx gets the access first on simultaneous requests
0	0	1	1	0	Tx has priority over Rx in ratio 2:1
0	1	0	1	0	Tx has priority over Rx in ratio 3:1
0	1	1	1	0	Tx has priority over Rx in ratio 4:1
1	0	0	1	0	Tx has priority over Rx in ratio 5:1
1	0	1	1	0	Tx has priority over Rx in ratio 6:1
1	1	0	1	0	Tx has priority over Rx in ratio 7:1
1	1	1	1	0	Tx has priority over Rx in ratio 8:1

11.7.2.6.1 Multiple Queues and Channels Support in the Transmit Path

IP supports the five transmit queues and five channels.

NOTE

See Programming Guidelines for Multi-Channel Multi-Queuing

11.7.2.6.2 Multiple Queues and Channels Support in the Receive Path

IP supports five receive channels and five queues.

In the Receive direction, the MTL Rx Controller selects the Rx DMA for which it is transferring or reading the data from the Rx FIFO memory. This scheduling is based on the programming done in the respective MTL_RxQ[x]_Control register.

Each Rx DMA indicates when it is ready to transfer data and the size of the burst-length (number of beats) that it has to transfer. The scheduler checks whether sufficient data (of requested burst length) is available to be transferred to these DMAs and then selects the Rx DMA that gets serviced using the programmed priorities.

NOTE

See Programming Guidelines for Multi-Channel Multi-Queuing.

11.7.2.6.3 Rx Queue to DMA Mapping

The packets in the MTL Rx Queues can be routed to any one of the multiple DMA channels by programming the register MTL_RxQ_DMA_Map0 Register for queues 0 through 3, and MTL_RxQ_DMA_Map1 for queue 4.

The following types of Rx Queue to DMA mapping are possible through programming.

11.7.2.6.3.1 Static Mapping

In this mode, all of the packets of an Rx Queue are connected to a specific DMA channel. For example, all the packets from Rx Queue 0 can be routed to a DMA channel by programming Q0MDMACH (bit[3:0]) and Q0DDMACH (bit[7] = 0) of the MTL_RxQ_DMA_Map0 Register.

Similarly, packets from other Rx Queues can be routed to any DMA channel by programming register fields corresponding to each Queue.

11.7.2.6.3.2 Dynamic (Per Packet) Mapping

In this mode, the destination DMA channel of a packet being read from a Rx Queue is not constant but decided independently for each packet. For example, if you set the Q1DDMACH bit of the MTL_RxQ_DMA_Map0 register, the static mapping is disabled

for Rx Queue 1 and the value in Q1MDMACH is ignored. The destination DMA channel is decided by the MAC receiver for each packet, depending on the following in decreasing order of priority:

1. L3-L4 filter Based DMA Selection: The TCP/UDP and IP header fields of the received packet are matched against the corresponding values programmed and enabled for comparison in the MAC_L3_L4_Address_Control register. If the match is successful, the DMA channel number programmed in the DMCHN field of the MAC_L3_L4_Ad-dress_Control register is selected as the destination DMA channel number provided DMCHEN bit of the same register is set. If none of the L3-L4 Registers give a comparison match, then the module proceeds to the next step below.
2. Extended VLAN Based DMA Selection: Extended routing is applicable only if the VLAN Filter has passed. Routing is only based on Perfect Filter Result. Each perfect filter has a DMA Channel Enable and a DMA Channel Number field which can be programmed. Routing is applicable for a filter, only if the DMA Channel Enable bit is set. The frame is routed to the smallest Matching Filter's DMA Channel provided it is enabled. If that filter's DMA Channel number is not enabled, the frame gets routed to Channel 0. For example, if a frame's VLAN tag matches filters 7, 3, and 1. Then the MAC checks if Filter 1's DMA Channel Number is enabled through programming. If yes, the frame gets routed to the programmed value; otherwise it gets routed to DMA. When the inverse filter is enabled; is routed to the least mismatched filter's DMA channel number provided it is enabled. If the DMA Channel enable bit is not set, then the frame is routed based on DA based addressing or to Channel 0.

   If Hash Filter is also enabled, it is used to determine the Filter result only. Routing will still depend on the Perfect Filters enabled. If none of the perfect filters are enabled or if all of them are bypassed, then the VLAN Filter based routing will not take place. The frame will be routed via DA Based addressing or to Channel 0. If all the perfect filters give a fail result and the Hash Filter has passed, then the VLAN Filter result is a pass but routing will be based on DA Based Addressing or to Channel 0. Similar behavior is seen when inverse Filtering is enabled as well.
3. Ethernet DA-Based DMA Selection: The DA address of the received packet is compared against the programmed DA values in MAC Address Registers. If the address matches any of the programmed values, the corresponding DCS field (when enabled) determines the destination DMA channel number.

If none of the previous operations is able to make a successful match/decision, then the packet is routed to DMA Channel 0 by default.

11.7.2.6.3.2.1 Broadcast/Multicast Packet Duplication

Broadcast/Multicast Packet Duplication feature provides a mechanism to send the received Broadcast/Multicast packets to multiple DMA channels.

The DCS field of the of MAC_Address0_High and other optional MAC_Address(#i)_High (i=1 to 2) registers determines the DMA channel number to which the received packet (that matches the MAC Address present in that register) must be routed.

Packet duplication is not supported in other DMA channel routing mechanisms such as Extended VLAN, or L3-L4 based routing.

The Packet Duplication feature is supported only on the highest MTL Queue configured. Therefore, packet duplication for Broadcast/Multicast packets requires that the MCBCQ field of MAC_RxQ_Ctrl1 register is programmed to the highest RxQ present in the configuration.

11.7.2.6.4 Selection of Tag Priorities Assigned to Rx Queues

The VLAN Tag priorities can be assigned to Rx Queues by programming the PSRQ field in the corresponding MAC_RxQ_Ctrl2 registers. The bit corresponding to the VLAN Tag priority can be set in the PSRQ field for assigning that priority to the Rx Queue. For example, if you want to assign VLAN Tag priority of 3 to Rx Queue 0, set bit [3] in PSRQ field of MAC_RxQ_Ctrl2 register. The VLAN Tag priority assigned to particular Rx Queue must be unique, that is, more than one Rx Queue cannot be assigned the same VLAN Tag priority. However, more than one VLAN Tag priorities can be assigned to same Rx Queue.

The settings in the PSRQ field is used for VLAN Tagged Rx packet routing to Rx Queues as well as for PFC based Tx flow control. The received VLAN Tagged Rx packet is routed to Rx Queue that has the VLAN Tag priority match. In PFC based Tx flow control, PSRQ field corresponding to a particular Rx Queue is used for enabling VLAN Tag priorities in the PFC packet transmitted when corresponding Rx Queue threshold levels are reached.

11.7.2.6.5 Rx Side Routing from MAC to Queues

IP supports Rx Side Routing from the MAC to Queues. The MAC routes the Rx packets to the Rx Queues based on following packet types in that order

- Unicast/Multicast destination address packets that fail the destination address filter
- Multicast/Broadcast destination address packets that pass the destination address filter
- VLAN Tag Priority field in VLAN Tagged AV data packets

- AV Control packets
- VLAN Tagged IEEE 1588 PTP over Ethernet packets
- Untagged IEEE1588 PTP over Ethernet packets
- VLAN Tag Priority field in VLAN Tagged packets
- Untagged packets

The outer C-VLAN Tagged AV data Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers and the corresponding Rx Queue is enabled for AV through RXQ#EN field in MAC_RxQ_Ctrl0 register. These packets may be single VLAN Tagged with C-VLAN type or Double VLAN Tagged with outer VLAN Tag of C-VLAN type when Double VLAN feature is enabled (EDVLP bit in MAC_VLAN_Tag register is set) with inner C-VLAN Tagged or inner S-VLAN Tagged when SVLAN processing is enabled (ESVL bit in MAC_VLAN_Tag register is set). This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The AV Control Rx packets can be routed based on the Rx Queue number specified in the AVCPQ field in MAC_RxQ_Ctrl1 register and corresponding Rx Queue is enabled for AV through RXQ#EN field in MAC_RxQ_Ctrl0 register. These packets may be single VLAN Tagged with C-VLAN type or Double VLAN Tagged with outer VLAN Tag of C-VLAN type when Double VLAN feature is enabled (EDVLP bit in MAC_VLAN_Tag register is set) with inner C-VLAN Tagged or inner S-VLAN Tagged when SVLAN processing is enabled (ESVL bit in MAC_VLAN_Tag register is set). This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The VLAN Tagged Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers and the corresponding Rx Queue is enabled for DCB/generic through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The untagged IEEE 1588 PTP over Ethernet Rx packets can be routed based on the Rx Queue number specified in the PTPQ field in MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. The VLAN tagged IEEE 1588 PTP over Ethernet Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers or the Rx Queue number specified in the PTPQ field in MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This is determined by programming in TPQC field of MAC_RxQ_Ctrl1 register. This type of Rx packet routing is available when IEEE 1588 Timestamp feature support and Multiple Rx Queues are selected in the configuration. The VLAN Tagged IEEE 1588 PTP over Ethernet Rx packets are detected only when

802.1AS mode is disabled (AV8021ASMEN bit in MAC_Timestamp_Control register is set to 0), otherwise this type of Rx packets are routed as generic VLAN Tagged Rx packets.

The multicast/broadcast destination address Rx packets that pass the destination address filter can be routed based on the Rx Queue number specified in the MCBCQ field of MAC_RxQ_Ctrl1 register when enabled through MCBCQEN bit of MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The untagged Rx packets can be routed based on the Rx Queue number specified in the UPQ field of MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The unicast destination address Rx packets that fail the destination address filter can be routed based on the Rx Queue number specified in the UFFQ field of MAC_RxQ_Routing_Ctrl register when enabled through UFFQE bit of MAC_RxQ_Routing_Ctrl register, RA bit of MAC_Packet_Filter register is set to 1 and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The multicast destination address Rx packets that fail the destination address filter can be routed based on the Rx Queue number specified in the MFFQ field of MAC_RxQ_Routing_Ctrl register when enabled through MFFQE bit of MAC_RxQ_Routing_Ctrl register, RA bit of MAC_Packet_Filter register is set to 1 and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

If the Rx packet cannot be classified in any of the defined packet type for routing, it will be routed through Rx Queue 0.

11.7.2.6.6 Rx Side Arbitration Between DMA and MTL

IP controller supports Rx side arbitration between the DMA and the MTL.

After completing the current packet processing, the DMA Channel Controller fetches the next descriptor. After the descriptor fetching is complete, the DMA Channel Controller evaluates the amount of data to be to be transferred to the Rx Buffer based on the programmed PBL and Rx Buffer Length. Accordingly, it requests the MTL to transfer the data.

After servicing the current request, the MTL Rx Queue arbitration scheme selects Rx Queue based on the arbitration scheme (RAA field of the MTL_Operation_Mode register) and the weights programmed in the Queue <n> Receive Control Register. The arbitration is done among Queues for which DMA is ready to service. After the Rx Queue is selected, PBL (Programmable Burst Length) amount of data is read out from that Queue and is routed to the Rx DMA Channel based on the Rx Channel selection criteria.

The arbitration takes place when every PBL data transfer is completed and descriptors are ready for the processing from at least one DMA Channel.

11.7.2.6.7 Tx Side Arbitration between DMA and MTL

IP support Tx side arbitration between the DMA and the MTL. Since the number of Tx DMA channels is always equal to the number of Tx Queues in the MTL, they are always mapped directly. For instance, each Tx DMA pushes data into its respective Tx Queue assigned to it.

The data inside each Tx Queue is stored in packets. Hence, if two DMAs are allowed to transfer data into the same queue, when a Tx DMA starts a packet transfer, the other DMA cannot transfer data unless the previous packet is completely pushed-in. This means that the second DMA remains idle until the first packet is transferred. Hence, each DMA is always connected directly to its corresponding Tx Queue.

11.7.2.6.8 Time-Sensitive Networking (TSN)

The ENET QOS block supports TSN in 100 Mbps or 1000 Mbps mode, which enables the transfer of time-sensitive traffic over a network. The block implements the IEEE 802.1Qbv-2015 (Enhancements to Scheduling Traffic), IEEE 802.3br (Interspersing Traffic) and IEEE 802.1Qbu (Frame Preemption) TSN protocol.

The Transmit path of Queue 0 supports the strict priority algorithm and is used for best-effort traffic while transmit paths of additional queues support traffic management by using the credit-based shaper algorithm. For a queue, the credit-based shaper algorithm determines that a queue is available for transmission if the following conditions are true:

- The queue contains one or more packets.
- The credit for the queue is positive as per the algorithm.
- AV traffic can be received on all queues. The block can also receive untagged PTP packets in addition to AV traffic on any queue.

11.7.2.6.9 Queue Modes

Both Tx and Rx queues can handle AV traffic.

Queueing is based on WRR (Weighted Round Robin) or WSP (Weighted Strict Priority) algorithm for generic traffic while it is based on CBS (Credit Base Shaper) and SP (Strict Priority) algorithm for AV traffic.

Whether an Rx Queue is configured for generic or AV-based routing depends on the RXQ#EN field of corresponding queue. Queueing is done based on VLAN tag priority. The VLAN tag priority should match the PSRQ field of the MAC_RXQ_CTRL2 registers. The Rx packets can also be routed to a particular DMA channel based on the DCS field of perfectly-matched MAC Address register.

By default, untagged packets in generic traffic are routed to Receive queue specified in UPQ field of MAC_RXQ_CTRL1 register. Queue 0 is the default value of UPQ field. You can override the default value with any other value, for the UPQ field.

AV control packets (tagged or untagged) are routed based on the AVCPQ field of the MAC_RXQ_CTRL1 register. The PTP over Ethernet packets are routed based on the AVPTPQ field of MAC_RXQ_CTRL1 register.

11.7.2.6.10 Queue Priorities

Priority of an Rx queue can be programmed in corresponding field of MAC_RxQ_Ctrl2 registers. AV queue (high priority) should be programmed as higher priority than the Best-effort queue (low priority).

11.7.2.6.11 Enhancements to Scheduled Traffic (EST)

The IEEE 802.1Qbv-2015 defines the schedule for each of the queues on every egress port which makes the implementation aware of traffic arrival schedule. This information can be used to block the lower priority traffic from transmission in this time window/slot. This ensures that scheduled traffic is forwarded from sender to receiver through all the network nodes with a deterministic delay.

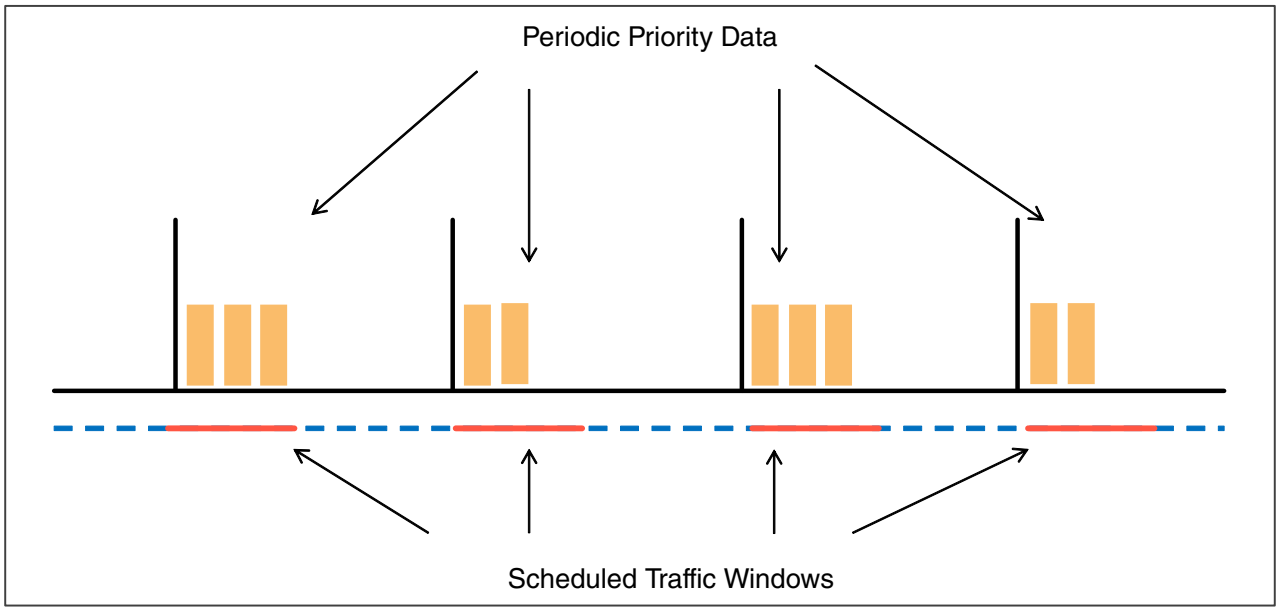

Figure 11-92. Time Aware Shaper Implementation for Traffic Scheduling

One of the important requirements to achieve a low latency is to ensure there are no interfering frames during the scheduled windows that are reserved for high priority traffic. The use of scheduled traffic imposes limitations while starting a transmission.

As shown in the following figure, if an interfering frame begins transmission just before the start of a reserved time period, it can extend transmission into the reserved window, and potentially interfere with higher priority traffic. Therefore, a guard band whose size is equal to the largest possible interfering frame is required before the window starts.

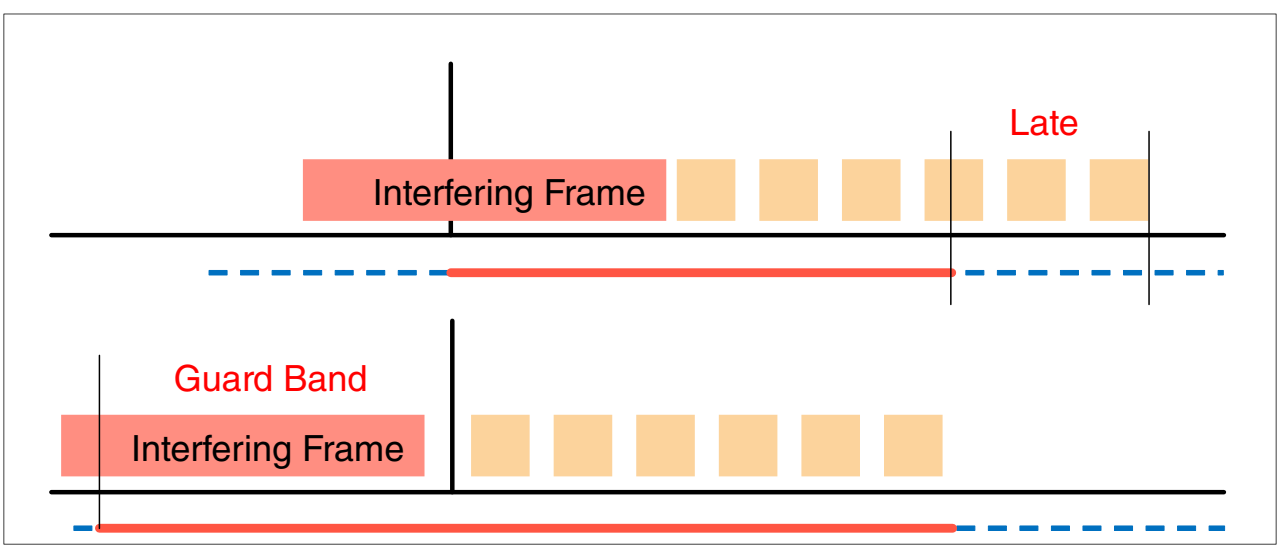

Figure 11-93. Implementing a Guard Band to Avoid Delays Due to Interfering Frames

A larger guard band equates to a less efficient use of network bandwidth. However, with the implementation of IEEE802.1Qbu (frame preemption), this issue is addressed. Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band needs to be only as large as the largest possible interfering fragment instead of the largest possible interfering frame.

During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

11.7.2.6.11.1 Frequently Used Terms in EST

- Gate Control List: The list in the hardware memory that holds the gate controls and the associated time intervals.
- Gate Controls: For a given schedule (row in gate control list) there is a Gate Open (O) and Gate Close (C) state associated with each traffic class. The set of O or C values, whose width is same as configured TCs is called the Gate Controls. Example: CCOCO means TC4=C, TC3=C, TC2=O and so on.
- Time Interval: Time interval (in nanoseconds) is a 16, 20, or 24-bit configurable field in the Gate Control list that indicates the time for which the associated gate controls are valid.
- Base Time Register: Each Gate Control List is associated with a 64-bit Base Time Register that holds the start time (in PTP format) for the list.

11.7.2.6.11.2 Updates to the Transmit Scheduling to Support EST

To support EST, following updates are required to the transmit scheduling:

- Implementation of Gate Control List (GCL)
- Enforcing gate controls in the scheduler
- Accounting for Gate Open (O) duty cycle in the computation of idleSlope (CBS)

11.7.2.6.11.2.1 Implementation of Gate Control List (GCL)

Following figure shows block diagram from the IEEE 802.1Qbv spec that illustrates how the gate control list governs the gate close(C) and open(O) events based on the schedule provided for each event. GCL has the following two parts:

- Time Interval: Defines the time in nano seconds for which the gate controls are valid and should be applied before reading the next gate controls from the list. Configurable width of 16, 20 or 24 to represent a maximum of 64us, 1ms, or 16ms schedule interval respectively. Supports left shift of the time interval upto 7 bits to be

able to apply a multiplication factor from 1 to 128ns (in steps of 2(power)n). The maximum value (post shifting) of this field must be 999,999,999 ns.
- Gate Control: Defines the Open (O) represented by logic 1 or Close (C) represented by logic 0 state for the gate of each TC.

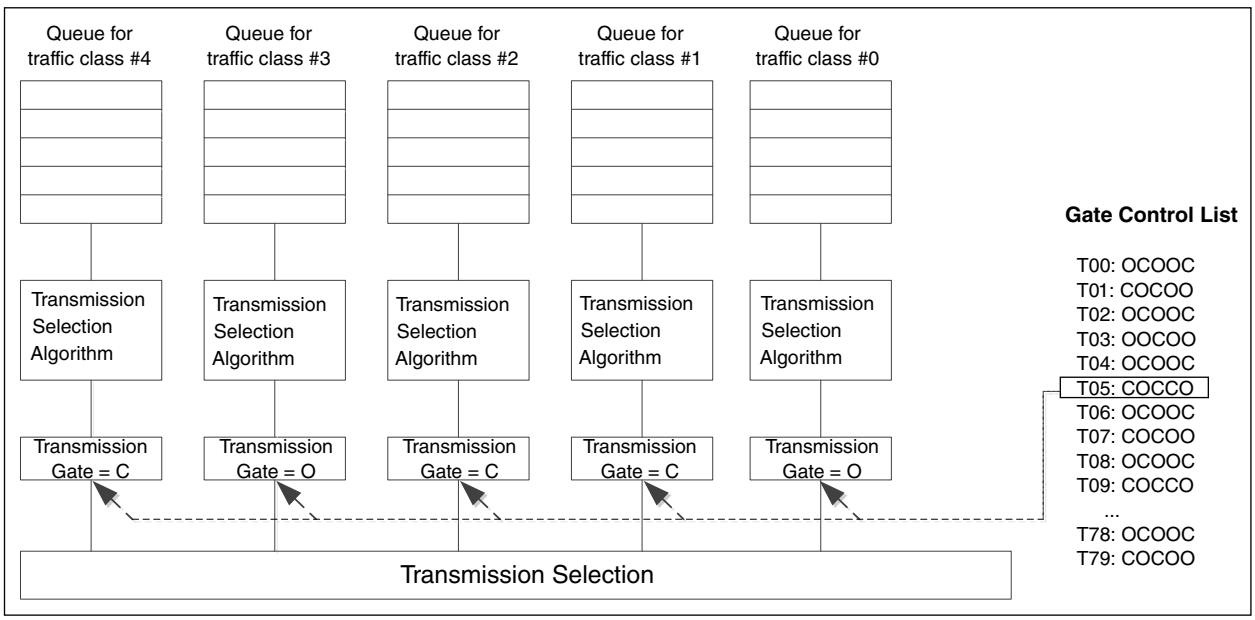

Figure 11-94. Block Diagram from IEEE 802.1 Qbv Specification - GCL Governing Gate Close and Open Events

The implementation of GCL consists of the following two Gate Control Lists:

- HWOL - Hardware Owned List which is a list for hardware access.
- SWOL - Software Owned List which is a list for software access.

The access to these lists is mutually exclusive. The ownership to the list is set by hardware in the SWOL field of MTL_EST_Status register. Following table provides the implementation details of GCL.

Table 11-109. External Memory Used for Holding the Two Gate-Control Lists

Gate Control (up to 5 bits)	Time Interval (ns) 16, 20, or 24 bits	
OOCCC	T0	HWOL or SWOL
OOOOC	T1	
CCCCO	T2	
CCCCC	T3

11.7.2.6.11.2.2 Registers Related to Gate Control List

Following are the set of 4 registers (one for each GCL) related to GCL. These registers are implemented through Indirect Addressing using the GCL_Control and GCL_Data registers.

1. 64-bit Base Time Register (BTR)

2. 40-bit Cycle Time (CTR)

3. m-bit Time Extension (TER)

4. n-bit [Gate Control] List Length (LLR) (n depends of the configured GCL depth)

11.7.2.6.11.2.2.1 Base Time Register (BTR)

Base Time Registers is a 64-bit register that holds the start time to execute the GCL. The format of the BTR is same as the PTP format (upper 32-bits holds time in seconds and lower 32 bits hold time in nano seconds). Once the execution of a given list begins, the implementation can update the value in BTR to indicate the next list execution begin time.

11.7.2.6.11.2.2.2 Cycle Time Register (CTR)

Cycle Time Register is a 40-bit register that holds the time at which the execution of the GCL should be repeated. The Cycle Time Register consists of an 8-bit value in seconds, and a 32-bit value in nano seconds (similar to the PTP time format with truncated seconds register). For a given Gate Control List the start time is "Base Time" + N *

"Cycle Time" where N is an integer value representing the iteration number starting with 0 for first iteration. If the Gate Control List execution takes longer than the Cycle time, then the list is truncated at the Cycle Time and the subsequent loop begins at Cycle Time.

11.7.2.6.11.2.2.3 Time Extension Register (TER)

Time Extension Register (TER) is a m-bit (where m = Configured Time Interval width + 7) register that holds the amount of time (in nano seconds) the current Gate Control List can be extended before switching to the new Gate Control List. This will be useful in avoiding small fragments of the current list being executed before switching to a new list.

11.7.2.6.11.2.2.4 List Length Register (LLR)

List Length Register (LLR) is an n-bit register (when n is 7, 8, 9, 10, or 11 for a GCL configured depth of 64, 128, 256, 512, or 1024 respectively) that holds the integer value of the length of the GCL (that is the number of valid rows in each GCL). The processing of the GCL stops after the number of rows read equals to the LLR value.

11.7.2.6.11.2.3 Transmission Gating Implementation

A Bridge or an end station can be enhanced to allow transmission from each TC that is yet to be scheduled relative to a known timescale. To achieve this, a transmission gate is associated with each TC; the state of the transmission gate determines if the queued frames can be selected for transmission.

For a TC, the transmission gate can be in one of the following two states:

1. OPEN:Queued frames are selected for transmission, in accordance with the definition of the transmission selection algorithm associated with the TC.
2. CLOSED: Queued frames are not selected for transmission.

A frame on a traffic class queue is not available for transmission if the transmission gate is in the closed state or if there is insufficient time available to transmit the entirety of that frame before the next gate-close event associated with that queue.

The implementation has visibility to the current schedule of gate controls and the immediate next schedule of the gate controls. So the maximum Gate Open period does not exceed the sum of the two Time Intervals. This is because, a frame is selected for transmission only if the gate is currently Open and the duration of gate open interval is greater than the time taken to transfer the entire frame.

The implementation must know the frame size before the transmission, so that the transmission overruns can be avoided and only the frames that can complete are scheduled at all times.

The implementation adequately compensates for the implementation delays in the data transfer from the buffer to the line by offsetting the current time with all the relevant delays (provided by the CTOV field of MTL_EST_Control register). This ensures that the schedule provided is always accurately implemented at the line.

11.7.2.6.11.3 Idle Slope Computation Updates

When EST is enabled, credit is accumulated only when the gate is open; therefore, the effective data rate of the idleSlope must be increased to reflect the duty cycle for the transmission gate associated with the queue.

The idleSlope is computed based on the GateOpenTime and OperCycleTime values. Program the idleSlope registers (implemented one per CBS enabled TC) based on the following equation. The existing MTL register has sufficient bit width to accommodate the new values for idleSlope.

idleSlope = (operIdleSlope(N) * OperCycle/GateOpenTime)

11.7.2.6.11.3.1 Operational Details of GCL

Set the switch to software List, the SSWL field of the MTL_EST_Control Register, so that hardware can access the programmed gate control list. The first set of gate controls are applied when the current time is equal to the value in the Base Time Register (BTR) and is held until the programmed "Time Interval" value.

To avoid transmission overruns, one additional gate control event is always read ahead from the list. This enables the GCL to determine the next gate close events (if any) for the TCs that are open.

The scheduling based on the Gate Open state and Time Interval of only the current and subsequent schedule. An internal accumulator is used to add the time intervals when gate controls are applied. BTR + Accumulator holds the time at which the next set of gate controls are to be applied.

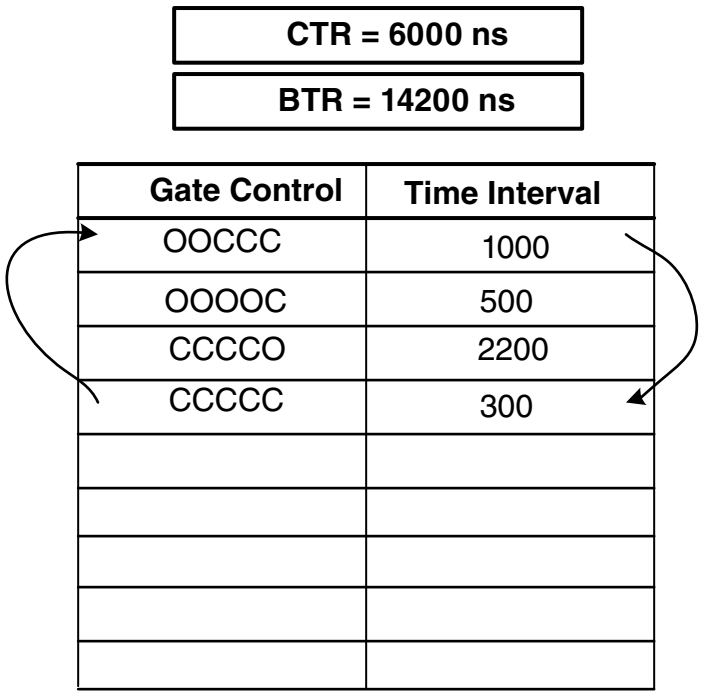

Figure 11-95. GCL and Associated Registers - BaseTime and CycleTime

The GCL is read progressively from the first row adhering to the schedule. The read operations continue until the List Length (from LLR Register) is reached and the execution of the list restarts at BTR + CTR time. At this point the BTR is incremented by value in CTR to mark the beginning of a new cycle. In the absence of any gate controls, all the gates are deemed to be in Open state, during the execution of the list.

In cases where the execution time of the list is greater than the CycleTime, the list is truncated and the next iteration starts when the current time equals BTR + CTR.

Table 11-110. GCL and Associated Registers - BTR and CTR

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
14200	OOCCC	1000	14200
15200	OOOOC	1500	14200
15700	CCCCO	3700	14200
17900	CCCCC	4000	14200
18200	OOOOO	0	20200
20200	OOCCC	1000	20200
21200	OOOOC	1500	20200

In the example in table, the execution starts at 14200 and the first set of Gate Controls "OOCCC" are applied immediately. As the time interval is 1000ns the next set of gate controls are applied at 14200 (BTR) + 1000 (Accumulator) = 15200 ns . As there are no gate controls available after the execution of the last gate control and before the next iteration of the loop, the gates are deemed to be in open state during that time period as depicted at time 18200 in the table.

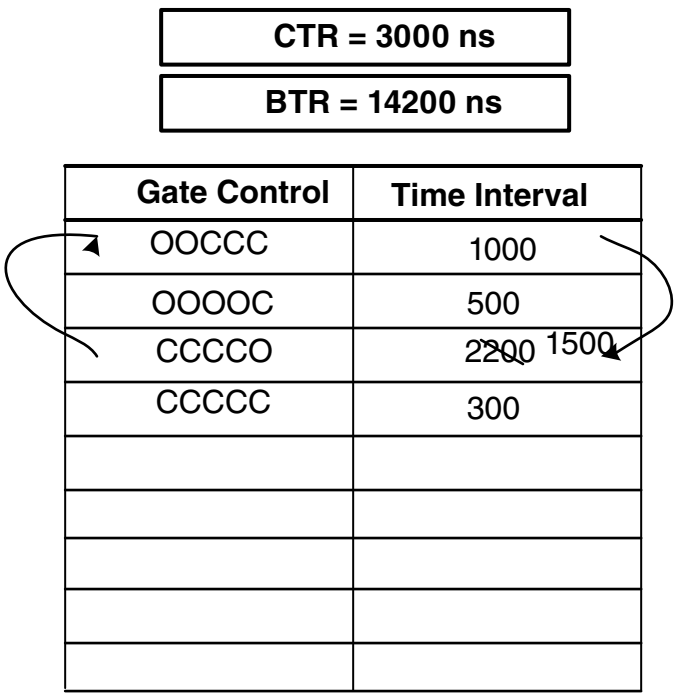

Figure 11-96. GCL and Associated Registers - BaseTime and CycleTime List Execution Time > CycleTime

As the list execution takes longer than the allocated CycleTime, the list is truncated and the list is started from the BTR+CTR as shown in the following table.

Table 11-111. GCL and Associated Registers - BTR and CTR, Execution Time > Cycle Time

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
14200	OOCCC	1000	14200
15200	OOOOC	1500	14200
15700	CCCCO	3700	14200
17200	OOCCC	1000	17200
18200	OOOOC	1500	17200
18700	CCCCO	3700	17200

While applying the third set of gate controls, the BTR + CycleTime (17200) < BTR + Accumulator (17900), so the list is truncated and execution switches to a new iteration at 17200.

11.7.2.6.11.3.2 Installing a New GCL

When a new software programmed GCL is available and must be executed at the new BTR value, the switch to the new GCL can happen in one of the following ways.

- New Base Time aligned with current schedule
- New Base Time unaligned with current schedule

11.7.2.6.11.3.2.1 New Base Time Aligned with Current Schedule

If the choice of cycle time for the new gating cycle is unchanged from the cycle time for the current gating cycle, and if the BTR chosen for the new gating cycle (new BTR) is an integer multiple of the current cycle time (+ current BTR), then the new gating cycle exactly lines up with the old gating cycle, that is, the cycle start times for the new gating cycle is same as they would have been for the old configuration. This could be considered to be the ideal case and allows the new gating cycle to be installed and executed with no timing issues. The implementation completes the execution of an iteration of the current list and switches to the new list at the beginning of the BaseTime listed in the new list.

If (New BaseTime > = Current Time)

ConfigChangeTime = New BaseTime

Else If (New BaseTime < Current Time)

1. Set the BTRError

2. ConfigChangeTime = (New BaseTime + N* New CycleTime)

where N is the smallest integer for which the relation ConfigChangeTime >= CurrentTime and (N =< 8) is TRUE.

When N > 8 the hardware cannot auto recover and the loop count value in BTRError reporting is set to 1111 requiring the software to reprogram the New Base Time.

Following figure illustrates the installation of the new GCL along with the timelines.

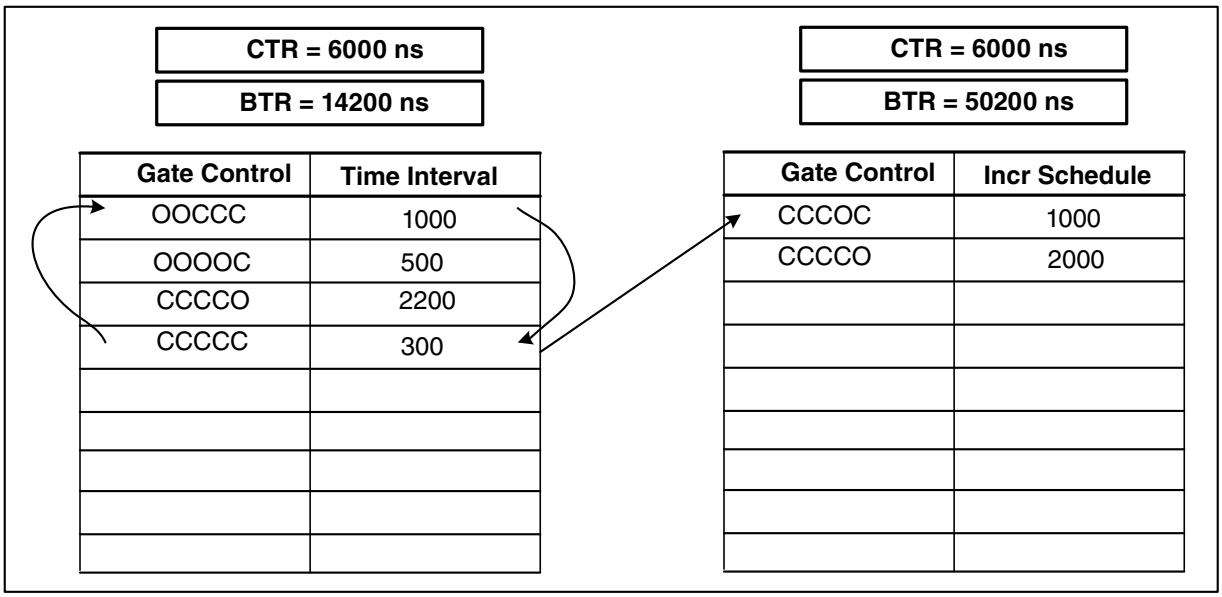

Figure 11-97. Switching to a New Configuration that is Aligned with the Existing Configuration

In the above example, after the sixth iteration of the first GCL, the BTR values of the old and new GCL are equal. At that point the new GCL is processed as a natural extension to the existing GCL.

Table 11-112. GCL and Associated Registers - BTR and CTR

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
44200	OOCCC	1000	44200
45200	OOOOC	1500	44200
45700	CCCCO	3700	44200
47900	CCCCC	4000	44200
48200	OOOOO	0	50200
50200	CCCOC	1000	50200
51200	CCCCO	3000	50200
53200	OOOOO	0	56200

11.7.2.6.11.3.2.2 New Base Time Unaligned with Current Schedule

If new CycleTime differs from current CycleTime or New BaseTime is in the future and is not an integer multiple of current CycleTime, then the old and new cycles do not line up; when new BaseTime is reached (when the new configuration is installed and starts to execute), the last old cycle is normally truncated to start the first new cycle. This could be undesirable if it results in a very short last old cycle; arguably it would be better to simply extend the penultimate old cycle by that small amount, rather than starting a very short

cycle. The Cycle Time Extension Register (related to the current config list) allows this extension of the last old cycle to be done in a defined way; if the last complete old cycle ends normally in less than current Cycle Time Extension (TER) ns before the new base time, then the last complete cycle before new BaseTime is reached is extended so that it ends at new BaseTime.

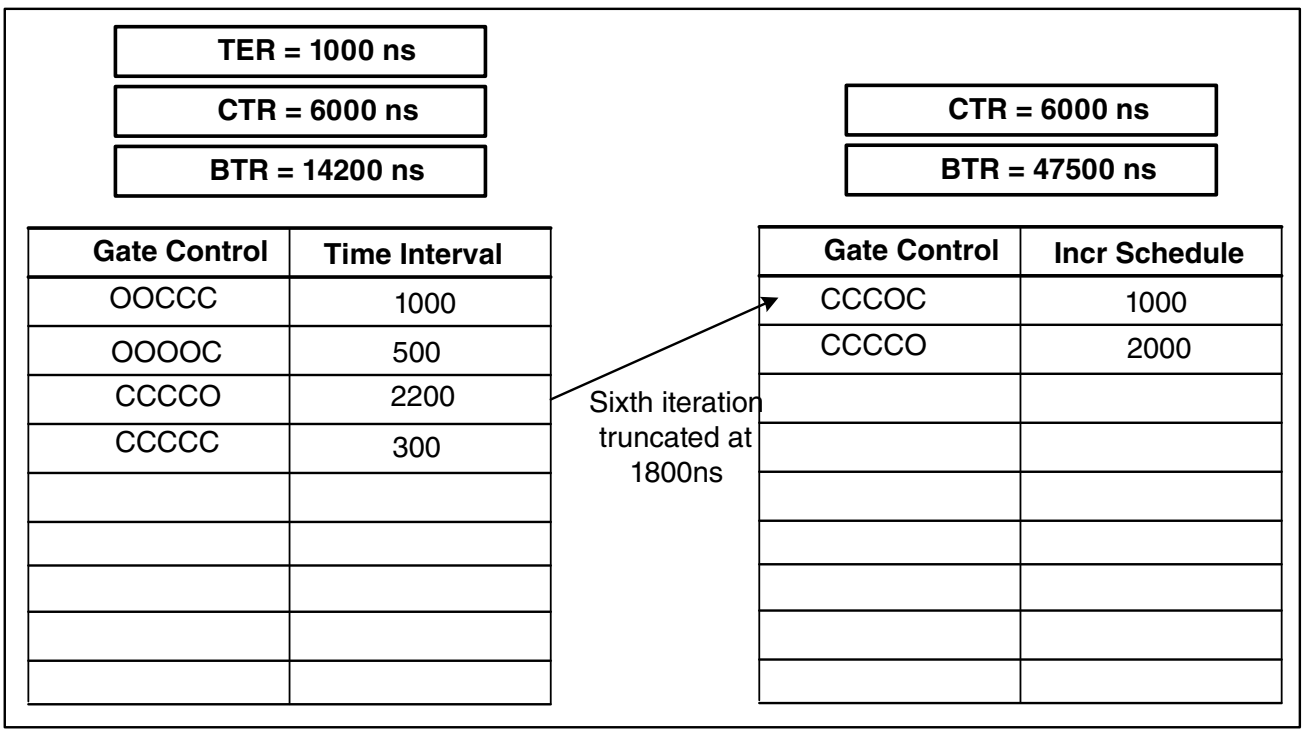

Figure 11-98. Switching to New List Truncating the Current List

At the end of the fifth iteration the Current time + Cycle time extension (TER) < New BTR so the sixth iteration of current configuration is started. During the sixth iteration of the current list when the new BTR value is smaller than the next schedule in the current list, it switches to the new list.

Table 11-113. Extending to New List By Truncating the Current List

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
44200	OOCCC	1000	44200
45200	OOOOC	1500	44200
45700	CCCCO	3700	44200
47500	CCCOC	4000	44200
48500	CCCCO	0	50200
50500	OOOOO	1000	50200

Below is an example where the current config list is extended instead of starting a new iteration as the extension time of 800ns is less than the allowed cycle extension time (TER) of 1000ns.

Figure 11-99. Switching to New List By Extending the Current List

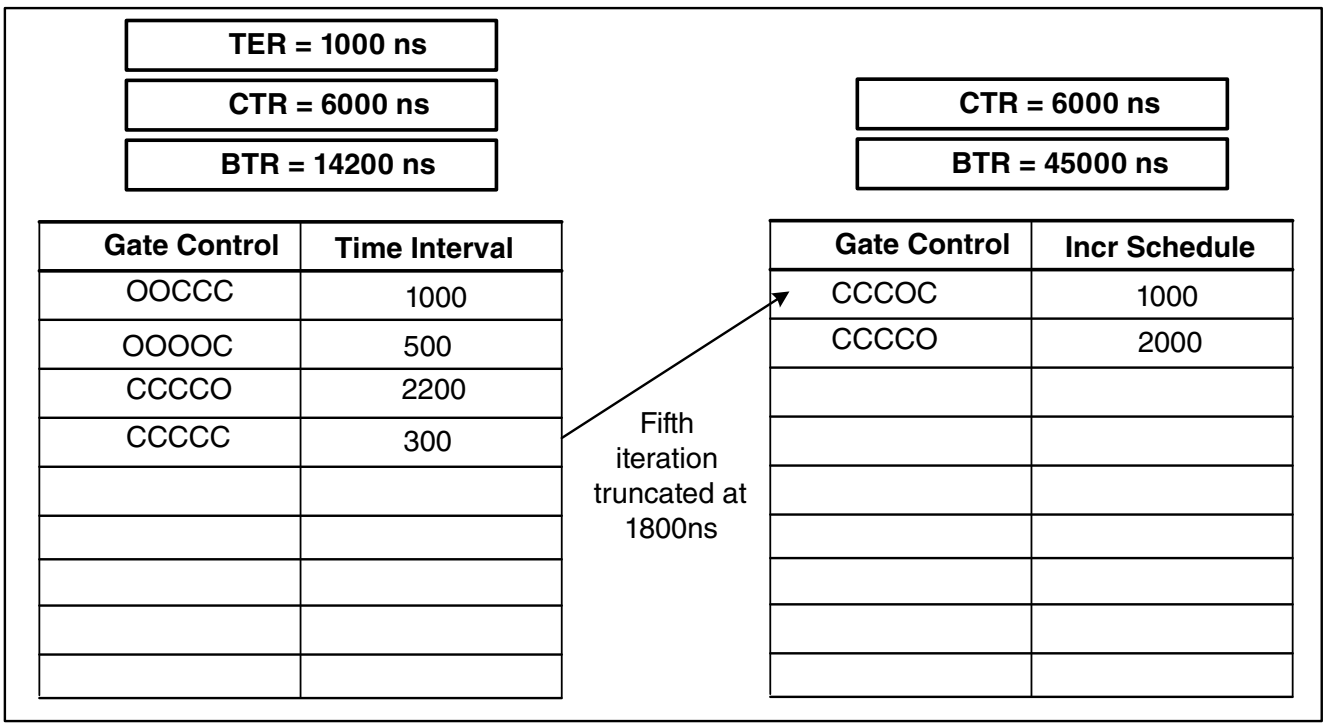

Table 11-114. Switching to New List By Extending the Current List

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
38200	OOCCC	1000	38200
39200	OOOOC	1500	38200
39700	CCCCO	3700	38200
41900	CCCCC	4000	38200
42200	OOOOO	0	44200
45000	CCCOC	1000	45000
46000	CCCCO	3000	45000
48000	OOOOO	0	51000

11.7.2.6.11.4 Impact of Transmit Scheduling Algorithms on EST

When EST is used in isolation, the Gate Control List manages the final open/close state of the Queues along with the checks carried out by the Transmission Selection Algorithm in MTL. As the Gate Controls operate on a predefined repetitive schedule, it is recommended to use Strict Priority or Credit Based Shaper (CBS) scheduling algorithms.

Other algorithms such as the Weighted Round Robin (WRR), Deficit Weighted Round Robin (DWRR) and Weighted Fair Queuing (WFQ) implement masking of the queues based on the current winning queue. The algorithm is applied only among the group of queues that open simultaneously. To ensure Queues whose gates are "Open" get priority, these algorithms are modified to treat "gate open" queues and "gate closed" queues as separate groups giving priority to gate open queues.

For example, consider 4 queues (Q3, Q2, Q1, Q0) with weights 4:3:2:1; Q3 and Q2 are in Open state in slot one slot, while Q1 and Q0 are in Open state in another slot. In this case, the scheduler works as follows:

1. In the first slot, the Q3 and Q2 are serviced in the ratio of 4:3 for the duration the slot is open.
2. In the second slot, the queues Q1 and Q0 are serviced in the ratio of 2:1.
3. Fresh arbitration is started every time a slot is opened.

In other words, the traffic does not get distributed in the intended ratio of 4:3:2:1; but as two groups with different ratios and only for the duration of the slot when the gates are open continuously

NOTE

See Programming Guidelines for EST

11.7.2.6.12 Frame Preemption (FPE)

Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band needs to be only as large as the largest possible interfering fragment instead of the largest possible interfering frame. During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

Preemption allows one or more higher priority (express) frames to interrupt the transmission of a lower priority (preemptable) frame; the preemptable frame transmission is resumed and completed after the express frame transmission is complete. To support frame preemption, the following two abstractions of the MAC are used:

- A preemptable MAC, called pMAC, which carries the preemptable traffic.
- An express MAC, called eMAC, which carries the express traffic.

In the implementation, only the parts of the MAC that hold the state during preemption are replicated and represented as pMAC and eMAC. The MAC uses the following two ways to put the transmission of the preemtable traffic on hold, in the presence of express traffic:

- The MTL scheduler interrupts the preemptable traffic that is currently being transmitted. When the preemption capability is active, the MAC interrupts the transmission and reception of preemptable frames. A preempted fragment can be followed by zero or more express frames, before the continuation fragments. The preemptable frame can be fragmented any number of times, however, the minimum final and non-final fragment length criterion must be met. However, interleaving of more than 1 preemptable packet is not permitted. This implies that if a preemptable packet is fragmented by an express packet, another preemptable packet cannot be transferred until all the remaining fragments of the first preempted packet are transferred.
- The MTL scheduler prevents starting the transmission of preemptable traffic. When the preemption capability is inactive, the pMAC entity is disabled and only express traffic is transmitted or received. Frame preemption feature can be enabled by setting EFPE field of the MAC_FPE_CTRL_STS register.

11.7.2.6.12.1 GCL Modification to Support FPE

In the EST-only configuration, the GCL entry has up to 24 bits of Time Interval and up to 8 high order bits representing the Gate Open/Close state requirements as shown in the following figure.

Gate Control (up to 5 bits)	Time Interval(ns) 16, 20 , or 24 bits
OOCCC	T0
OOOOC	T1
CCCCO	T2
CCCCC	T3
|	|
|	|
OCOCO	T126
OOOOC	T127

Figure 11-100. Gate Control List When FPE is Disabled

EST only supports SetGate operation, which implies that the gates are set to either open or close at a given time interval. However, when both Frame Preemption (FPE) and EST are enabled, the GCL also supports Set-and-Hold-MAC and Set-and-Release-MAC operations, in addition to the SetGate operation. To enable the support of hold and release operations, the format of the GCL is slightly changed while configuring and enabling the FPE. The first Queue (Q0) is always programmed to carry preemption traffic and therefore it is always Open. The bit corresponding to Q0 is renamed as Release/Hold MAC control. The TX Queues whose packets are preemptable are indicated by setting the PEC field of the MTL_FPE_CTRL_STS register. The GCL bit of the corresponding Queue are ignored and considered as always "Open". So, even if the software writes a "0" ("C"), it is ignored for such queues.

Gate Control (up to 4 bits)	Release/Hold Indication	Time Interval(ns) 16, 20, or 24 bits
CCCO	0	T0
CCCC	0	T1
OCCC	1	T2
COCC	1	T3
CCOC	1	T4
CCCO	0	T5
CCCC	0	T6

Figure 11-101. Gate Control List When FPE is Enabled

When the Release/Hold bit transitions from a '0' to '1', a Set-and-Hold-MAC operation is performed. This marks the cease of the preemptable traffic. This is achieved by sending a Hold request to MTL "ha" ns in advance (where ha is the time interval mentioned in the Hold Advance (HADV) field of the MTL_FPE_Advance register). When the Release/ Hold bit transitions from a '1' to '0' a Set-and-Release-MAC operation is performed. This marks the resuming of the preemptable traffic. This is achieved by sending a Release request to MTL "ra" ns in advance (where ra is the time interval mentioned in the Release Advance (RADV) field of the MTL_FPE_Advance register). The preemptable traffic is blocked for the time duration the Release/Hold bit is set to a '1' in the Gate Control List.

11.7.2.6.12.2 Impact of Preemption on CBS

In Credit Based Shaper (CBS), the definition of "Transmit" is:

- TRUE for the duration of frame transmission from the queue.
- FALSE when frame transmission from the queue is complete.
- When CBS algorithm is used with frame preemption, the value of "Transmit" is TRUE only while the frame is being transmitted by the MAC. If the frame transmission is delayed or interrupted (for instance, a preemptable frame transmission is interrupted to allow the transmission of an express frame from a different queue, or the start of an express frame is delayed because a preemptable frame is being transmitted) the value of "Transmit" is FALSE until transmission of the frame commences or is resumed.

Also, the value of "Transmit" is FALSE during the transmission of any overhead that is a consequence of frame preemption, (for example, when additional frame overhead, such as mCRC or Fragment Count, is added to the preemptable frame.

At any given time, if there are no frames in the queue, and the value of Transmit is FALSE, and credit is positive value, the credit value is set to zero if there is no preemptable frame from the queue for which transmission is in progress but has been interrupted.

11.7.2.6.12.3 mPacket Format

When the preemption capability is active, MAC sends mPackets to the PHY. An mPacket can be one of the following:

1. A express packet
2. A preemptable packet
3. An initial fragment of a preemptable packet
4. A continuation fragment of a preemptable packet

Start mPacket Delimiter (SMD)

The value of the SMD indicates whether the mPacket contains an express packet, the start of a preemptable packet (initial fragment or complete packet), or any of continuation fragments of a preemptable packet. Following table shows the valid SMD values.

Table 11-115. Possible SMD Values of mPacket

mPacket Type	Notation	Frame Count	Value
verify packet	SMD-V	-	0x07
respond packet	SMD-R	-	0x19
express packet	SMD-E	-	0xD5
preemptable packet start	SMD-S0	0	0xE6
	SMD-S1	1	0x4C
	SMD-S2	2	0x7F
	SMD-S3	3	0xB3
continuation fragment	SMD-C0	0	0x61
	SMD-C1	1	0x52
	SMD-C2	2	0x9E
	SMD-C3	3	0x2A

frag_count

A frag_count is a modulo-4 counter that increments for each continuation fragment of the preemptable packet. The frag_count protects against mPacket reassembly errors by enabling detection of the loss of up to 3 packet fragments.

The frag_count field is present only in mPackets with SMD-C notation (continuation fragment). The frag_count is zero in the first continuation fragment of each preemptable packet.

Table 11-116. Possible frag_count Values

frag_count	Value
0	0xE6
1	0x4C
2	0x7F
3	0xB3

mData

The contents of the packet from the MAC, starting with the first byte after the SFD to the last byte before the FCS are sent in the mData fields of one or more mPackets for that frame. The minimum size of the mData field is 60 bytes.

CRC The CRC field contains a cyclic redundancy check (CRC) and has an indication of the final mPacket of a frame. In the final mPacket of a frame, the CRC field contains the last 4 octets of the MAC frame (the FCS field).

For other mPackets, the CRC field contains an mCRC value. The mCRC is calculated on the octets of the packet from the first octet of the frame (the octet following the SFD of preemption frames) to the last octet of the packet transmitted in that mPacket by performing an XOR of the calculated 32 bit CRC value of the fragment and a value of 0x0000FFFF.

Summary of Packet Formats

- Express Packet: 7bytes of PREAMBLE, SMD-E, Data, and CRC
- Complete Preemptable Packet: 7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, CRC
- Initial Fragment (non-final) of Preemptable Packet: 7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, mCRC
- Continuation fragments (non-final) of Preemptable packet: 6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, mCRC
- Final fragment of Preemptable packet: 6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, CRC

Table 11-117. Current and Previous SMD Values

Previous Preemptable packet SMD	Current Preemptable packet SMD
SMD-S0	SMD-S1
SMD-S1	SMD-S2
SMD-S2	SMD-S3
SMD-S3	SMD-S0

Table 11-118. Current and Previous SMD Values

Previous Preemptable fragment SMD	Previous Preemptable fragment FC	Current Preemptable continuation fragment SMD	Current Preemptable continuation fragment FC
SMD-S0	NA	SMD-C0	FC0
SMD-S1	NA	SMD-C1	FC0
SMD-S2	NA	SMD-C2	FC0
SMD-S3	NA	SMD-C3	FC0

SMD-C3	FC2	SMD-C3	FC3
SMD-C3	FC3	SMD-C3	FC0

11.7.2.6.12.4 Transmit Preemption

When FPE is enabled (setting EFPE=1 in MAC_FPE_CTRL_STS register), the MTL preempts a preemptable frame, when a "hold" request is asserted (EST/Qbv configured and enabled) express frames are available for transmission, that is, frame is present in MTL FIFO and is qualified for arbitration, after ensuring that the minimum mPacket mData field size is met. Therefore, preemption occurs only if at least 60 bytes of the preemptable frame have been transmitted and at least 64 bytes (including the frame CRC) remain to be transmitted.

The earliest starting position of preemption is controlled by the AFSZ field of the MTL_FPE_CTRL_STS Register. Preemption does not occur until at least 64 * (1+ AFSZ) - 4 bytes of the preemptable frame have been sent.

When preemption occurs, all the preemptable queues are blocked and only the express queues are allowed to arbitrate (if more than one express queue has traffic) and transmit.

Continuation fragment of the preempted frame is the first frame to be transmitted after "release" request is asserted (EST/Qbv configured and enabled) and all the express traffic transmission completes.

NOTE

PTP packets should be transmitted as express packets.

MTL communicates the following frame-type information to the MAC using a 2-bit preemption control signal on the MTI interface qualified by SoF and EoF.

- Express Frame
- Preemption Frame (Full or Fragment)
- Continuation Fragment (non-Final or Final)

Table 11-119. Preemption Control Values on MTI Interface for Various Frame Types

Qualifier	Preemption Control Value	Frame Type
SoF	00	Start Express
SoF	01	Start Preemption
SoF	10	Continuation Fragment
SoF	11	Reserved
EoF	00	End of Frame
EoF	01	End of Fragment

MTL should wait for the previous fragment status to be received before resuming the continuation fragments of a preempted frame. Fragment status is described in detail in the Tx Fragment Status section.

11.7.2.6.12.4.1 MAC Tx Preemption

MAC supports preemption by implementing the functionality needed to generate the mPackets as described in “mPacket Format”.

Based on the Preemption Control value received on the MTI interface (qualified with SoF and EoF), MAC determines the frame type (shown in the above table 'Preemption Control Values on MTI Interface for Various Frame Types') and generates mPackets accordingly.

When the preemption capability is active, MAC replaces the SFD of a preemption packet with an SMD-S value. A 2-bit rolling frame count is encoded in the SMD-S value.

The SMD-E value is the same as the SFD value so the SFD of an express packet does not need to be replaced.

11.7.2.6.12.4.1.1 Tx Fragment Status

MAC sends Tx fragment status to indicate successful transmission of fragmented mPackets.

In case of a transmission error (underflow, jabber, and so on) the frame status is sent (and not a fragment status) with an error indication along with all other relevant status fields. In case of receiving an error status for a transmitted fragment, the MTL drops the remaining fragments and does not send any more continuation fragments.

11.7.2.6.12.5 Receive Preemption

11.7.2.6.12.5.1 MAC Receive Preemption

When FPE is enabled, the MAC Receiver pases the incoming packets and differentiates between Express packets and preemptable packets. An SMD containing an SMD-E indicates express packet, and SMD containing an SMD-S indicates the first mPacket of a preemptable packet.

If an mPacket containing an SMD-S is received when MAC has not completed receiving the previous preempted packet, MAC sets a CRC Error status for the previously received partial packet.

When an SMD-S is detected, MAC records the frame count indicated by the SMD and then begins sending data on the MRI interface.

The MAC checks the last four bytes of the mPacket . If the last four bytes of the mPacket do not match CRC, that indicates the end of the packet with or without a CRC error as per the CRC check result. If the last four octets of the mPacket match, that indicates that the packet was preempted.

An SMD containing an SMD-C indicates an mPacket that continues the data for a preempted packet. Upon receiving an SMD value of SMD-C, MAC checks the following:

1. A preempted packet is in progress
2. The frame count indicated by the SMD matches the frame count of the packet in progress
3. The frag_count value indicates the next fragment count.

If any of the above check fails, the mPacket is discarded and MAC sets a CRC Error status for the partially received packet.

If all the checks pass, the next fragment count is incremented modulo 4.

When a packet is preempted, the MAC saves the state of the partially received packet (filter check status, timestamp, length fields etc.) and will be able to process any received Express packets before the continuation fragment is received.

The MAC Receiver sends a "dummy status" for all the mPacket fragments successfully received and sends the Rx status with the final fragment. If an error is detected during any of the fragments the Rx status is sent and the fragment is marked as final fragment. All subsequent continuation fragments received for this packet are dropped in the MAC.

The MAC communicates the following frame type information to the MTL using a 2-bit preemption control signal.

1. Express Frame
2. Preemption Frame (Full or Fragment)
3. Continuation Fragment (non-Final or Final)

Table 11-120. Preemption Control Values on MRI Interface for Various Frame Types

Qualifier	Preemption Control Value	Frame Type
SoF	00	Start Express
SoF	01	Start Preemption
SoF	10	Continuation Fragment
SoF	11	Reserved
EoF	00	End of Frame
EoF	01	End of Fragment

11.7.2.6.12.5.1.1 Data Alignment

When a received frame cannot be fragmented on any byte boundary, MAC retains the unaligned bytes of data in the previous fragment and resends them with the next fragment as shown in the following figure.

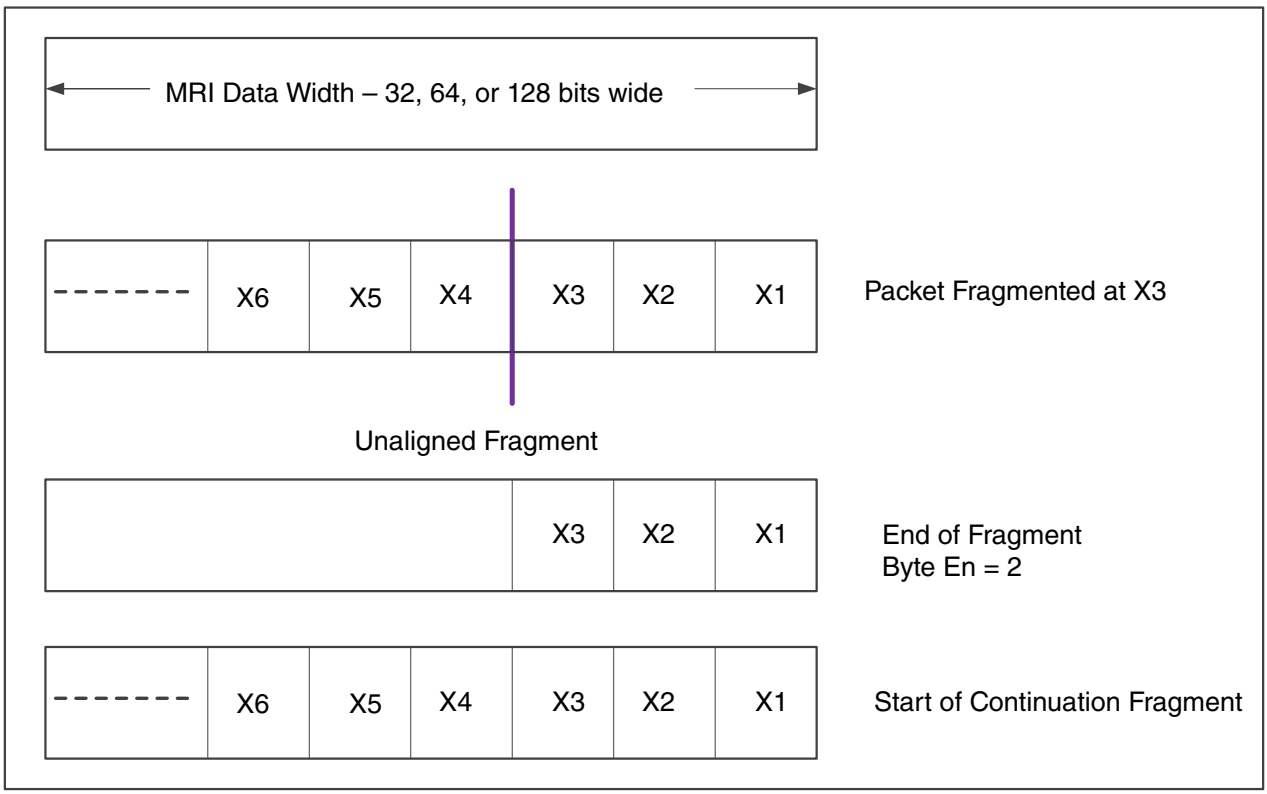

Figure 11-102. Data Alignment Feature of MAC

11.7.2.6.12.5.1.2 MTL Receive Preemption

The MTL Rx must have at least 2 Rx queues to support FPE function as the preemptable packets and the express packets must be routed to separate Rx queues. The destination Rx queue of a received packet is controlled by MAC_RxQ_Ctrl[n] registers. Program these registers such that Preemptable traffic and express traffic are not routed to the same Rx queue. As the queue mapping for tagged packets is based on VLAN user-priority field, this implies that priority of preemptable and express packets are mutually exclusive. In other words, packets of a certain priority (traffic class) are either express or preemptable but cannot be both.

For the preemptable frames, in addition to the PSRQ (Priority Selected in Rx queue) based queue routing, a programmable "Frame Preemption Residue Queue" (FPRQ) is supported to route all other Preemption Packets received (Untagged, SA/ DA or VLAN Filter Fails forwarded due to RA being set or VTFE being reset).

Table 11-121. Preemption Control Values on MRI Interface for Various Frame Types

Preemption Packet Type	Queue Routing
AV Tagged Packets passing the SA/DA and VLAN filters	PSRQ*
DCB/Generic Tagged Packets passing the SA/DA and VLAN filters	PSRQ**
Tagged Packets failing the SA/DA and VLAN filters without setting the Receive All (RA = 0) or setting VTFE = 1	Dropped
All other packets OR when RA = 1	FPRQ

11.7.2.6.12.5.1.3 MTL Receive Arbitration

On the ARI Interface, data is fetched from the MTL Rx FIFO based on the arbitration selected in the MTL_Operation_Mode register. Frame based arbitration can be used only when all the MTL Preemption Queues are operating in Store and Forward mode, else there will be loss of bandwidth on the ARI interface because all the fragments of a preemptable packet is not available. Therefore, any express packets received between the fragments are blocked until all the fragments are received and transferred; this defeats the purpose of express traffic.

When operating in either Threshold (cut through) or Store and forward modes of operation, PBL based arbitration is recommended over Frame based arbitration. In case of PBL based arbitration, the watermark check is always performed and the arbitration/ transfer of data in terms of chunks of "PBL" size of data which is almost similar to the concepts of "fragments". Therefore the express queue packets get blocked for less time as well as the ARI interface transfers the data without loss of efficiency.

11.7.2.6.12.6 Verify and Respond mPackets

When FPE function is present, the MAC can receive and detect the Verify and Respond mPackets, even when FPE is not enabled by software. When MAC detects valid Verify/ Respond mPackets, it notifies the software by setting the RVER and RRSP fields of MAC_FPE_CTRL_STS register respectively. Optionally an interrupt can be generated. As such packets have empty (all-zero) data payload, they are dropped inside the MAC and not forwarded to the MRI.

Software can set the SVER and SRSP fields of MAC_FPE_CTRL_STS register to request MAC to transmit Verify and Respond mPackets respectively. Upon successful transmission of these frames, MAC clears the SVER/SRSP bits and sets the TVER & TRSP fields of MAC_FPE_CTRL_STS register. Optionally an interrupt can be generated when these events occur.

11.7.2.6.12.7 Frame Preemption and MMC Counter and Interrupt Registers

The following MMC counters and associated Interrupt registers are instantiated/present in the MAC when Frame Preemption feature is enabled.

Table 11-122. MMC Counters and Associated Interrupt Registers

Frame Assembly Error Counter	Description	Associated MMC Counter
Frame Assembly Error Counter	A 32-bit counter that provides the number of MAC frames with reassembly errors on the Receiver, due to mismatch in the Fragment Count value.	MMC_Rx_Packet_Assembly_Err_Cntr
Frame SMD Error Counter	A 32-bit counter that provides the number of received MAC frames rejected due to arriving with an SMD-C when there was no preceding preempted frame.	MMC_Rx_Packet_SMD_Err_Cntr
Frame Assembly OK Counter	A 32-bit counter that provides the number of MAC frames that were successfully reassembled.	MMC_Rx_Packet_Assembly_Ok_Cntr
MAC Rx Fragment Counter	A 32-bit counter that provides the number of additional mPackets received due to preemption.	MMC_Rx_FPE_Fragment_Cntr
MAC Tx Fragment Counter	A 32-bit counter that provides the number of additional mPackets transmitted due to preemption.	MMC_Tx_FPE_Fragment_Cntr
Hold Request Counter	A 32-bit counter that maintains the count of number of times a hold request is given to MAC.	MMC_Tx_Hold_Req_Cntr

11.7.2.6.12.7.1 Additional Registers Associated With MMC Interrupts

Following are the additional registers associated with MMC interrupts for the MMC error counters:

- MMC_FPE_Tx_Interrupt
- MMC_FPE_Tx_Interrupt_Mask
- MMC_Rx_Interrupt
- MMC_FPE_Rx_Interrupt_Mask

11.7.2.6.13 Time-Based Scheduling

Time-based scheduling feature is suitable for traffic whose periodicity and rate are predictable. To improve the quality-of-service of such traffic,

- The transmit DMA fetches the packet from the host memory for transmission at designated time. This helps the software to setup the Transmit descriptors in advance

even before packet is ready/available. It reduces the overhead on the software and avoids constant monitoring of the time and preparing descriptors just in time when the packet is targeted to be transmitted.
- The MAC transmits the packet only at the designated/pre-determined time even if the packets are fetched in advance. This helps in maintaining a constant transmission rate that can be consumed by the receiver station; therefore avoiding congestion and excessive buffering in the network.

The time-based scheduling feature supports fetching and launching an Ethernet packet at (or after) a pre-determined time. The time-based scheduling is supported only in the following modes/configurations:

- Full duplex mode
- Link speed is 100Mbps or higher

The following figure shows the time-based scheduling flow.

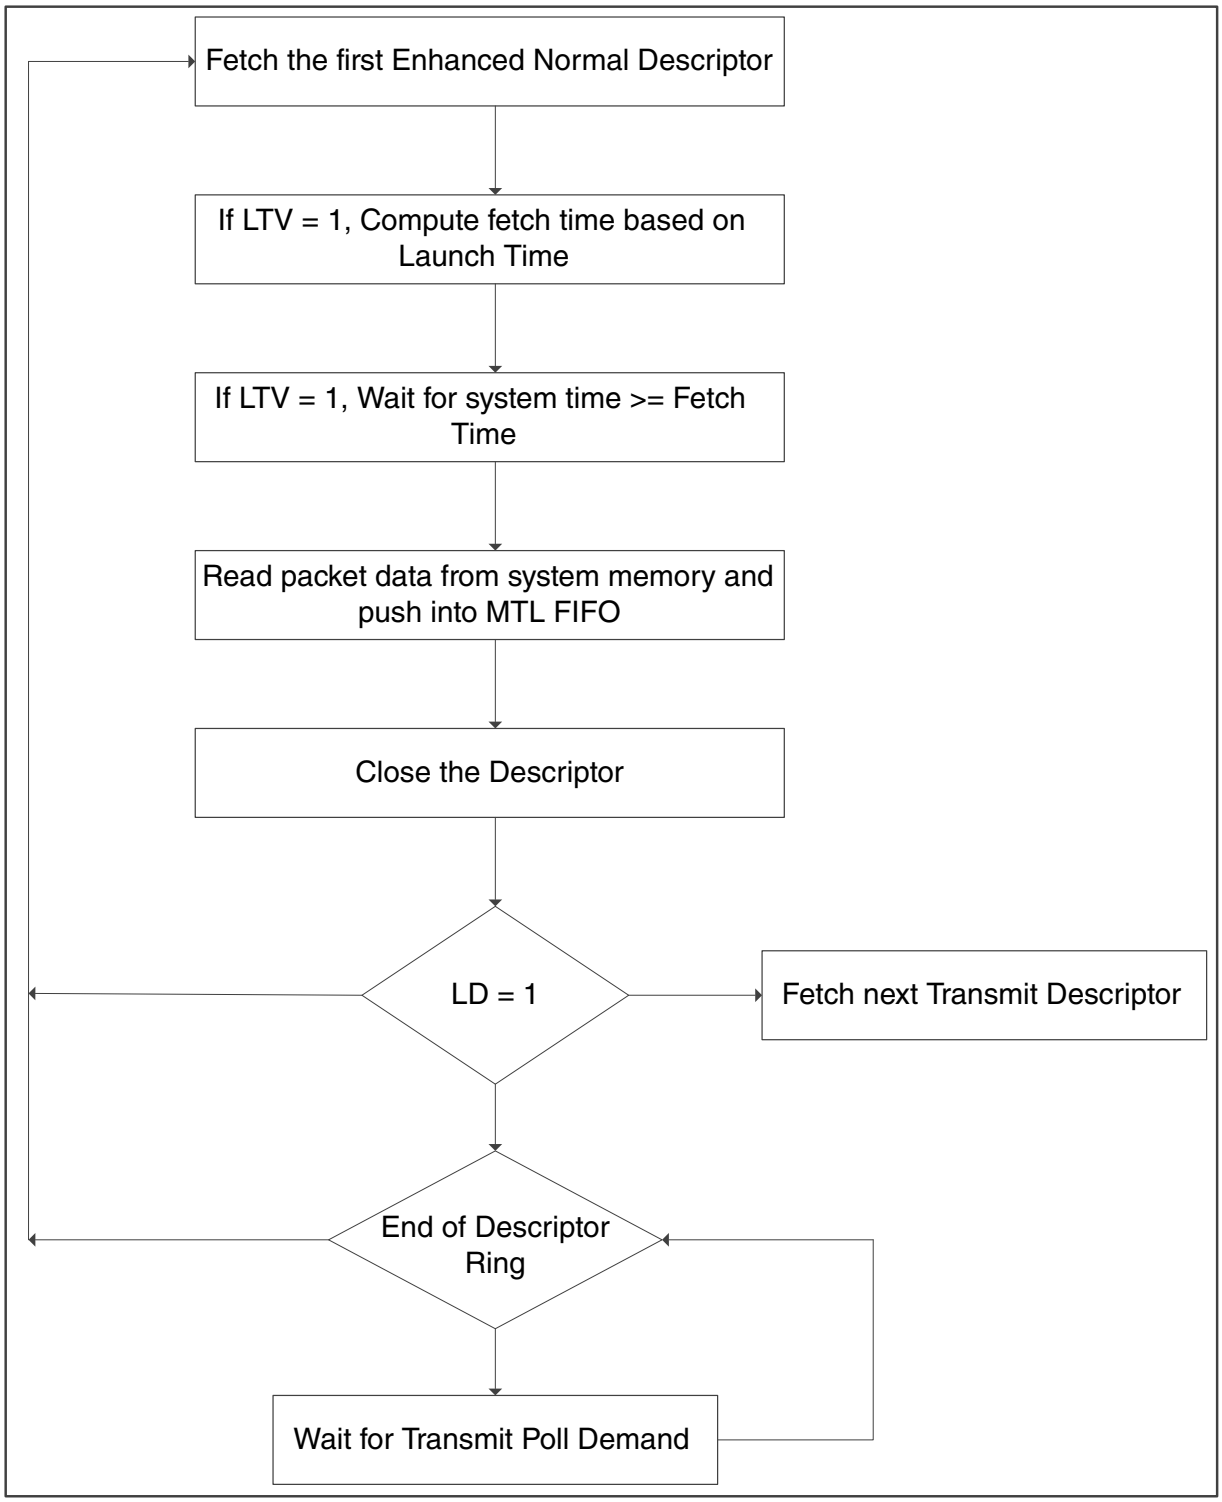

Figure 11-103. Time-Based Scheduling Flow

Following are the definitions specific to the time-based scheduling feature:

11.7.2.6.13.1 Launch Time

Launch time is the time beyond which the MTL can schedule the packet for transmission. The launch time is reset after the transmission of one frame. Following are the two formats of the launch time.

Normal/Absolute Format:

In this format, the launch time is interpreted in the Normal/Absolute format if the ESTM bit of the MTL_TBS_CTRL register is set to 0.

The launch time is a 32-bit value, where most-significant 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns. The launch time is compared against the IEEE 1588 based System/PTP Time (bits[39:8]) and rolls over after 256 seconds.

The maximum value of the lower 32-bits of System Time is 999,999,999 decimal (0x3B9AC9FF) and it wraps to 0 when reaching this value (representing a full second). Therefore, the maximum value of the lower 24 bits of the Launch Time (after multiplying by 256) must be 0x3B9AC9.

As the maximum value of Launch time is 256 seconds,

- Launch Time is greater than current System Time when its value is between System Time[39:8] and System Time[39:8] + 128 sec
- Launch Time is less than current System Time when its value is between "System Time[39:8] + 128sec" and "System Time[39:8] + 256 sec", because this is a modulo 256 computation.

EST/Offset Format

In this format, the Launch time is an offset value relative to the time indicated by the Base Time Register (BTR) of the GCL list provided in the GCL Slot Number (GSN). The value in the BTR is always updated to the start time of the current loop of the GCL.

For each packet, the GSN value and the Launch Time value are specified in the Enhanced Transmit Descriptor in the DMA configurations, or as Control Word in the MTL configurations.

The launch time offset is a 32-bit value; the upper 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns, which is added to the BTR value corresponding to GCL Slot Number. The value of the Launch Time Offset must be smaller than the value of the Cycle Time (specified in the CTR register that is

implemented when EST is enabled). If the CTR is greater than or equal to 1s, the maximum value of the lower-24 bits of Launch Time offset should be 999,999,999 decimal (0x3B9AC9FF).

In this format, the launch time is a 64-bit value, which is interpreted as, Launch Time = Launch GSN BTR[63:0] + (Launch Time Offset[31:0] << 8), which is compared with the System Time [63:0].

GSN BTR is the Base Time value at which the Launch GSN loop started execution.

GCL Slot Number (GSN) A modulo 16 count of the GCL loop count is implemented and known as GSN. The count is incremented for every new GCL loop; installation of new GCL list does not impact the count. The current GCL slot number can be obtained by reading the CGSN field of the MTL_EST_Status register.

The maximum value of GSN is 15. Therefore GSN values between Current GSN (CGSN field of MTL_EST_Status register) and CGSN+8 represent current or future slots; all other GSN values are interpreted as elapsed slots or past slots. So, for the correct interpretation of time, GSN value must be between CGSN and CGSN+8, for correct interpretation of time.

11.7.2.6.13.2 Launch Expiry Time

Normal/Absolute Mode

In the normal mode, when the LEOV (Launch Expiry Offset Valid bit of MTL_TBS_CTRL register) is set, the Launch Expiry Offset (LEOS field of MTL_TBS_CTRL register) determines the maximum amount of time a frame is eligible for launch, starting from the time the frame becomes eligible for launch.

The Launch Expiry Offset is a 24-bit value defined in 256ns units, with a maximum possible value of 999,999,999 ns (0x3B9AC9FF).

Launch Expiry Time = (Launch Time[39:8] + LEOS[32:8]) * 256ns

The packet with a specific Launch time is considered eligible for transmission when the Launch time is less than the System Time and (if LEOV is set) the System Time is less than the Launch Expiry time.

When the System time is greater than the Launch Expiry time the frame is categorized as expired and will be dropped from the MTL FIFO.

NOTE

- For correct interpretation and meaningful operation, the Fetch, Launch, and Launch Expiry time should never be set

to a value larger than Current System Time + 128 sec; such a value is interpreted as time that has already elapsed.
- In full duplex mode, the frames dropped from the MTL FIFO have Error Summary (Bit 15) and Excessive Deferral (bit 3) of TxStatus set.

EST/Offset Mode

In the EST mode of operation, when the LEOV field of the MTL_TBS_CTRL register is set, the launch expiry GSN offset (LEGOS field of the MTL_TBS_CTRL register) and Launch Expiry Offset (LEOS field of MTL_TBS_CTRL register) determine the maximum amount of time a frame remains eligible for launch, starting from the time the frame becomes eligible for launch.

Launch Expiry Offset = (LEGOS: LEOS)

LEGOS holds the GSN offset (multiples of CTR time) and LEOS holds maximum value of CTR (sub CTR values) in ns.

Launch Expiry offset is a 24-bit value defined in the units of 256 ns, with a maximum possible value of the smaller of 999,999,999ns or CTR-1 ns.

The Launch Expiry GSN is computed as follows:

Launch Expiry GSN = (Launch GSN + LEGOS + CCMA) Where, CCMA is the CTR Carry due to Modulo addition. This value is 1 if ((Launch Time Offset + LEOS) << 8) is equal to or greater than CTR.

When CCMA = 1, Launch Expiry Offset = (Launch Time Offset+ LEOS) - CTR

When CCMA = 0,

Launch Expiry Offset = (Launch Time Offset + LEOS).

Launch Expiry Time = Launch Expiry GSN BTR[63:0] + Launch Expiry Time Offset.

When LEOV is not set, Launch Expiry Time is not checked.

When LEOV is set, and

- the system time is greater than the Launch Expiry time, the frame is dropped from MTL FIFO. The frame is considered as expired.
- the launch time is smaller than the System Time and Launch Expiry Time is greater than system time, the frame is considered eligible for launch.

NOTE

- Max value of LEGOS is 7. This implies that when LEOV is set, the frame has a maximum life time of <8 GCL loop iterations after it becomes eligible for Launch.
- The slot number of the First GCL List executed each time after EST is enabled, is zero.

11.7.2.6.13.3 Fetch Time

The fetch time accounts for all possible delays in the DMA fetch operation and ensures that the frame is present in the MTL FIFO before the launch time.

If FTOV field of DMA_TBS_CTRL register is set, then fetch time can be indicated for each packet. If the FTOV filed is not set, the Fetch Time Offset is not valid and the DMA fetches packets without any time constraints.

11.7.2.6.13.3.1 Normal/Absolute Mode

In the Normal mode fetch time derived/calculated by reducing the time specified in the Fetch Time Offset (FTOS) field of DMA_TBS_CTRL register from the given Launch time.

Normal mode of operation, the Fetch Launch Time is computed as:

Fetch Time[39:8] = (Launch Time[39:8] - FTOS[31:8])

The Fetch time is 32-bits and is compared against System Time[39:8] to determine the Eligible for fetching the frame:

- The Fetch time is defined as "greater" than System Time if the Fetch Time is in the range of "System Time[39:8]" and "System Time[39:8] + 128 sec". The frame is considered as not-eligible for fetch.
- The Fetch time is defined as "smaller" than the System Time if the Fetch time is in the range of "System Time[39:8] + 128 sec" and "System Time[39:8] + 256 sec". The frame is considered as eligible for fetch.

This is a modulo 256 computation.

11.7.2.6.13.3.2 EST/Offset Mode

In the EST/Offset mode, the Fetch GSN Offset (FGOS field of MTL_TBS_CTRL register) provides the Slot Number offset to be deducted from the Launch GSN. In this case the FTOS value should be the smaller of 999,999,999ns or CTR-1 ns.

If (Launch Time Offset >= FTOS):

Fetch Time Offset = ((Launch Time Offset - FTOS) * 256ns)

CBFS(CTR Borrow for Fetch Subtraction) = 0

If (Launch Time Offset < FTOS) Fetch Time Offset = CTR + ((Launch Time Offset - FTOS) * 256ns)

CBFS (CTR Borrow for Fetch Subtraction) = 1

The Fetch GSN is computed as follows:

Fetch GSN = Launch GSN - FGOS - CBFS

Fetch Time = Fetch GSN BTR[63:0] + Fetch Time Offset

The frame is marked eligible for DMA fetch when the fetch time is smaller than the System Time.

11.7.2.6.13.3.3 DMA Operations Sequence

Following is the sequence of operation when FTOV = 1:

1. Fetch the first Enhanced Normal Descriptor (FD is set)
2. If LTV is set and Fetch enabled, compute the Fetch Time based on the Launch Time Wait for the System Time to be greater than Fetch Time
3. Read the Frame (Data) from the host memory and transfer to MTL FIFO
4. Close the Normal Descriptor
5. Fetch the next Normal Descriptor (if the previous Descriptor was not the Last)
6. Repeat steps 4 to 6, until the last descriptor of the frame (LD is set)

After the Last Descriptor of a frame, the next enhanced normal descriptor should be programmed with a new Launch Time and with LTV bit set. Otherwise, the subsequent frames will be processed without any time restrictions.

NOTE

See Programming the Launch Time in Time-Based Scheduling

11.7.2.7 TCP/IP Offloading Features

11.7.2.7.1 Transmit Checksum Offload Engine

The MAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, using which, the software can offload the task of checksum insertion to the hardware. In the transmit path MAC calculates the checksum

and inserts it in the Tx packet. This feature helps in reducing the load on the software and can improve the overall throughput of the system. This feature is supported for only Q0 queue.

The checksum offload engine module supports two types of checksum calculation and insertion. The checksum engine can be controlled for each packet by setting the CIC bits (TDES3 Bits[17:16]).

Note: The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement, when this function is enabled, the Tx FIFO automatically operates in the store-and-forward mode even if IP is configured for Threshold (cut-through) mode.

11.7.2.7.1.1 IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Type field of Ethernet packet has the value 0x0800 and the Version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

NOTE

IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (TDES3[0]). This status bit is set whenever the values of the Ethernet Type field and the Version field of IP header are not consistent, or when the Ethernet packet does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
  - The received Ethernet type is 0x0800, but the Version field of IP header is not equal to 0x4.
  - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes).
  - The total packet length is less than the value given in the IPv4 Header Length field.
- For IPv6 datagrams:
  - The Ethernet type is 0x86dd but the IP header Version field is not equal to 0x6.
  - The packet ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received.

11.7.2.7.1.2 TCP/UDP/ICMP Checksum Engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the Checksum field of the input packet. This engine includes the Checksum field in the checksum calculation, and then replaces the Checksum field with the final calculated checksum.
- The engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

NOTE

For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 16'h0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 16’h0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (TDES3[12]). This engine sets the Payload Checksum Error status bit when:

- It detects that the packet has been forwarded to the MAC Transmitter engine in the store-and-forward mode without the end of packet (EOP) being written to the FIFO.
- when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received.

When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field. The following table describes the functions supported by Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as "No" in the table.

NOTE

You should not enable checksum insertion for IPv4 or IPv6 packets that are greater than the frame size constraint specified in Description of Transmit Checksum Offload Engine because

it may result in incorrect checksum insertion or unexpected behavior.

Table 11-123. Transmit Checksum Offload Engine Functions for Different Packet Types

Packet Type	Hardware IP headerchecksum insertion	Hardware TCP/UDPchecksum insertion
Non-IPv4 or IPv6 packet	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers:		
Hop-by-hop options (in IPv6 main header)	Not Applicable	Yes
Hop-by-hop options (in IPv6 extension header)	Not Applicable	No
Destinations options	Not Applicable	Yes
Routing (with segment left 0)	Not Applicable	No
Routing (with segment left > 0)	Not Applicable	No
TCP, UDP, or ICMP	Not Applicable	Yes
Authentication	Not Applicable	No
Any other next header field in main or extension headers	Not Applicable	No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels:	#160;	#160;
IPv4 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 Tunnels:	#160;	#160;
IPv4 packet in an IPv6 tunnel	Not applicable	No
IPv6 packet in an IPv6 tunnel	Not applicable	No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Yes	Yes

Table continues on the next page...

Table 11-123. Transmit Checksum Offload Engine Functions for Different Packet Types (continued)

Packet Type	Hardware IP headerchecksum insertion	Hardware TCP/UDPchecksum insertion
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

11.7.2.7.2 Receive Checksum Offload Engine

IP provides the Checksum Offload Engine that is used to detect any error in an IPv4 or IPv6 packet in the receive path. The MAC verifies the checksum field of the received packet with the internally calculated checksum and provides the status.

The Receive Checksum Offload engine is used to detect errors in IP packets by calculating the header checksum and further matching it with the received header checksum. This engine also identifies a TCP, UDP, or ICMP payload in received IP packets and calculates the checksum of such payloads appropriately.

Here, the IPv4 or IPv6 packets in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the Type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the Enable Double VLAN Processing option is selected and the EDVLP bit of the MAC_VLAN_Tag register is set.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload

Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

Following table describes the functions supported by the Rx COE based on the packet type. When the payload of an IP packet is not processed (indicated as "No" in the table), the information (whether the checksum engine is bypassed or not) is given in the receive status.

NOTE

The MAC does not append any payload checksum bytes to the received Ethernet packets.

Table 11-124. Receive Checksum Offload Engine Functions for Different Packet Types

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
Non-IPv4 or IPv6	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 header's protocol field contains a protocol other than TCP, UDP, or ICMP	Yes	No
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers: • Hop-by-hop options (in IPv6 main header) • Hop-by-hop options (in IPv6 extension header) • Destinations options • Routing (with segment left 0) • Routing (with segment left > 0) • TCP, UDP, or ICMP • Any other next header field in main or extension headers	• Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable	• Yes • No • Yes • Yes • No • Yes • No
IPv4 packet has TCP header with Options fields	Yes	Yes

Table continues on the next page...

Table 11-124. Receive Checksum Offload Engine Functions for Different Packet Types (continued)

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
IPv4 Tunnels: • IPv4 packet in an IPv4 tunnel • IPv6 packet in an IPv4 tunnel	• Yes (IPv4 tunnel header) • Yes (IPv4 tunnel header)	• No • No
IPv4 Tunnels: • IPv4 packet in an IPv6 tunnel • IPv6 packet in an IPv6 tunnel	• Not Applicable • Not Applicable	• No • No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Not Applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not Applicable	No

Set the IPC bit of the MAC_Configuration register for enabling Receive Checksum offload.

11.7.2.8 MAC Management Counters

IP supports storing the statistics about the received and transmitted packets in registers that are accessible through the application/software. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The MMC counters are free running.

For MMC register details, see registers "MMC_Control" to "MMC_Rx_FPE_Fragment_Cntr" in ENET_QOS register descriptions.

11.7.2.9 Flow Control

11.7.2.9.1 Transmit Flow Control

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end.

11.7.2.9.1.1 Flow control in Full duplex mode

IP supports the IEEE802.3x Pause Packets.

Pause packet structure is shown in the following table.

Table 11-125. Pause Packet Fields

Field	Description
DA	Contains the special multicast address
SA	Contains the MAC address 0
Type	Contains 8808
MAC Control opcode	Contains 0001 for IEEE 802.3x Pause Control packets; 0101 for PFC packets
PT	Contains Pause time specified in the PT field of the MAC_Q#_Tx_Flow_Ctrl register

11.7.2.9.1.2 Pause Packet Control

When the FCB bit is set, the MAC generates and transmits a single Pause packet. If the FCB bit is set again after the Pause packet transmission is complete, the MAC sends another Pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously-transmitted Pause packet, the application should program the Pause Time register with appropriate value and then again set the FCB bit.

11.7.2.9.1.3 Flow Control in Half-Duplex Mode

In half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

Following table describes the flow control in the Tx path for Queue 0 based on the setting of the following bits:

- EHFC bit of MTL_RxQ0_Operation_Mode register

- TFE bit of MAC_Q0_Tx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Flow control is similar for all queues.

Table 11-126. Tx MAC Flow Control

EHFC	TFE	DM	Description
x	0	x	The MAC transmitter does not perform the flow control or backpressure operation.
0	1	0	The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1.
1	1	0	The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx performs back-pressure when Rx Queue level crosses the threshold set by Bits[10:8] of MTL_RxQ0_Operation_Mode register.
0	1	1	The MAC transmitter sends the Pause packet when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1.
1	1	1	The MAC transmitter sends the Pause packet when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx sends a Pause packet when Rx Queue level crosses the threshold set by Bits[10:8] of MTL_RxQ0_Operation_Mode register.

11.7.2.9.1.4 Enabling Transmit Flow Control

To independently enable Transmit Flow Control for each Tx queue, set the TFE bit in the MAC_Q#_Tx_Flow_Ctrl register.

11.7.2.9.2 Receive Flow Control

In the Receive path, the Flow Control is functional only in the full-duplex mode. If any Pause packet is received in the half-duplex mode, the packet is considered as a normal control packet.

NOTE

Receive pause packets should have a frame size of 64 bytes.

The Receive Flow Control is implemented by the MAC based on the bit value of the respective register, and the destination address and different fields of the received packet.

Following table describes the flow control in the Rx path based on the setting of the following bits:

- RFE bit of MAC_RX_FLOW_CTRL register
- DM bit of MAC_CONFIGURATION register

Table 11-127. Rx MAC Flow Control

RFE	DM	Description
0	x	The MAC receiver does not detect the received Pause packets.
1	0	The MAC receiver does not detect the received Pause packets but recognizes such packets as Control packets.
1	1	The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter.

11.7.2.9.2.1 Enabling Receive Flow Control

To enable Pause Flow Control, set the RFE bit in the MAC_Rx_Flow_Ctrl register.

11.7.2.10 Loopback Mode

The MAC supports Loopback of transmitted packets to its receiver.

The following are some guidelines for using the loopback mode:

- Enable loopback only with the full-duplex mode. In half-duplex mode, the carrier sense signal (crs) or collision (col) signal inputs get sampled which may result into issues such as packet dropping.

- If the loopback mode is enabled without connecting a PHY chip (for example, in FPGA setup), you should externally generate the Tx and Rx clocks and provide these clocks to the MAC.
- Do not loop back big packets. Big packets (>1522 bytes) may get corrupted in the loopback FIFO.

To enable this feature, program the LM bit of the MAC_Configuration register.

You can enable loopback for all PHY interfaces. The data is always looped back through internal asynchronous FIFO on to the internal Receive GMII interface, irrespective of which PHY interface is selected. The loopback data is also passed through the corresponding transmit PHY interface block, on to the Ethernet line.

11.7.2.11 Descriptors

11.7.2.11.1 Overview

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory. The module supports the following two types of descriptors:

- Normal Descriptor: Normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted.
- Context Descriptor: Context descriptors are used to provide control information applicable to the packet to be transmitted.

Each normal descriptor contains two buffers and two address pointers. These buffers enable the adapter port to be compatible with various types of memory management schemes.

NOTE

There is no limit for the number of descriptors that can be used for a single packet.

11.7.2.11.2 Descriptor Structure

The module supports the ring structure for DMA descriptor as shown in the following figure.

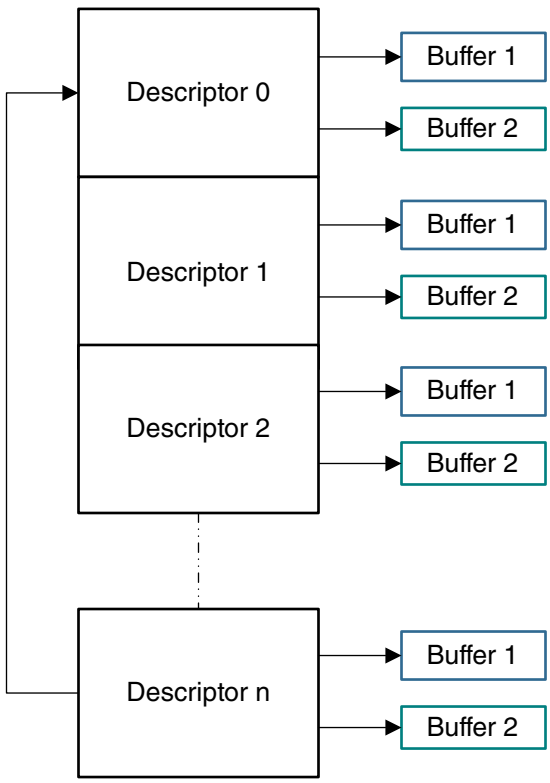

Figure 11-104. Descriptor Ring Structure

In Ring structure, descriptors are separated by the Word, DWord, or LWord number programmed in the DSL field of the DMA_CH#_Control register. The application needs to program the total ring length, that is, the total number of descriptors in ring span in the following registers of a DMA channel:

- Transmit Descriptor Ring Length Register (DMA_CH#_TxDesc_Ring_Length)
- Receive Descriptor Ring Length Register (DMA_CH#_RxDesc_Ring_Length)

The Descriptor Tail Pointer Register contains the pointer to the descriptor address (N). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (N – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

Current Descriptor Pointer == Descriptor Tail Pointer;

The DMA goes into the Suspend mode when this condition occurs. The application must perform a write to the Descriptor Tail pointer register and update the tail pointer so that the following condition is true:

Current Descriptor Pointer < Descriptor Tail Pointer;

The DMA automatically wraps around the base address when the end of ring is reached, as shown in the following figure.

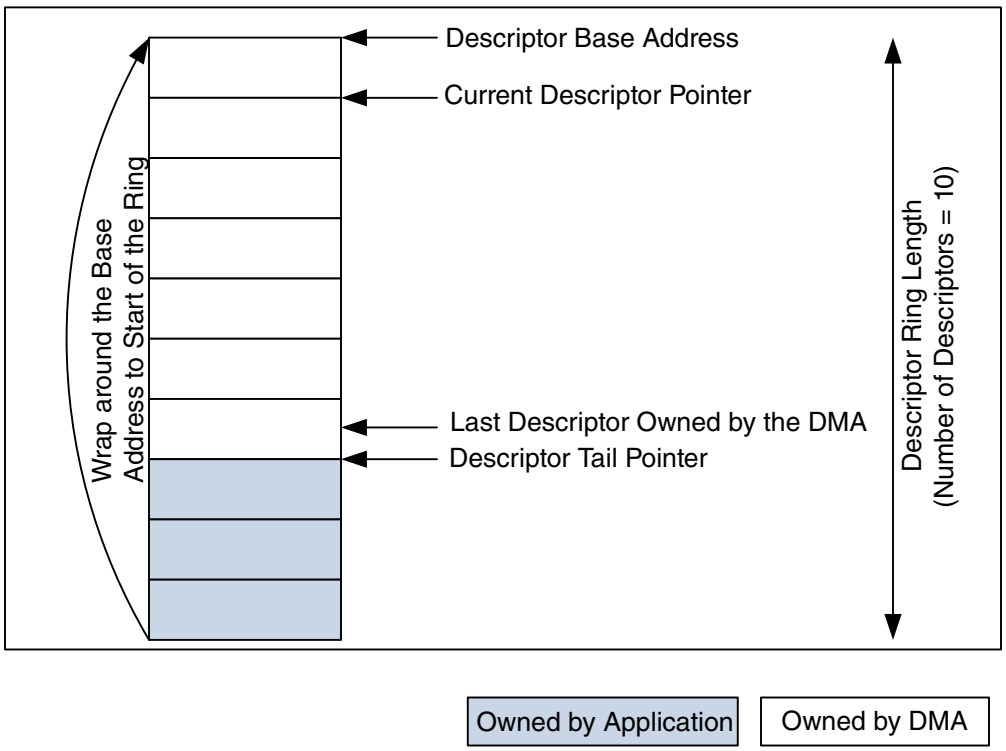

Figure 11-105. DMA Descriptor Ring

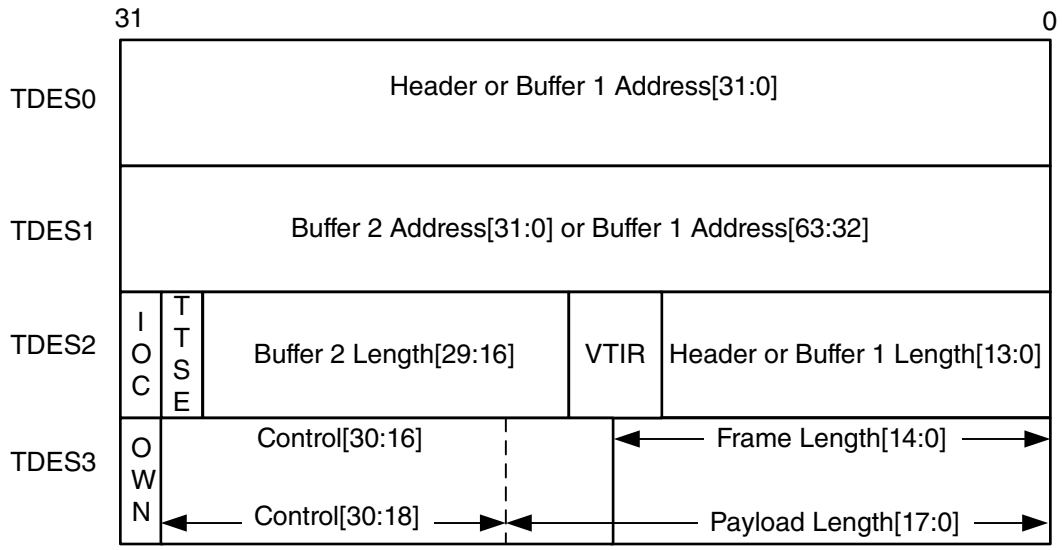
For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only one descriptor in the beginning, the application sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA processes the first descriptor and then waits for the application to advance the tail pointer.

11.7.2.11.3 Transmit Descriptor

The DMA in the module requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields which can be used to control the MAC operation on per-transmit packet basis. The Transmit Normal descriptor has two formats: Read format and Write-Back format



NOTE

TSO Split header is not supported.

11.7.2.11.3.1 Transmit Normal Descriptor (Read Format)

Following figure shows the Read Format for a Transmit normal descriptor. Table: 'TDES0 Normal Descriptor (Read Format)' through Table: 'TDES3 Normal Descriptor (Read Format)' describe the read format for the Transmit Normal Descriptors: TDES0, TDES1, TDES2, and TDES3.

Figure 11-106. Transmit Descriptor Read Format

11.7.2.11.3.1.1 TDES0 Normal Descriptor (Read Format)

Table 11-128. TDES0 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF1AP	Buffer 1 Address Pointer or TSO Header Address Pointer These bits indicate the physical address of Buffer 1. These bits indicate the TSO Header Address pointer when the following bits are set: • TSE bit of TDES3 • FD bit of TDES3

11.7.2.11.3.1.2 TDES1 Normal Descriptor (Read Format)

Table 11-129. TDES1 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 or Buffer 1 Address Pointer

Table 11-129. TDES1 Normal Descriptor (Read Format)

Bit	Name	Description
		This bit indicates the physical address of Buffer 2 when a descriptor ring structure is used. There is no limitation for the buffer address alignment. In 40- or 48-bit addressing mode, these bits indicate the most-significant 8- or 16- bits of the Buffer 1 Address Pointer.

11.7.2.11.3.1.3 TDES2 Normal Descriptor (Read Format)

Table 11-130. TDES2 Normal Descriptor (Read Format)

31	30	29-16	15:14	13:0
IOC	TTSE/ TMWD	B2L	VTIR	HL or B1L

Table 11-131. TDES2 Normal Descriptor (Read Format)

Bits	Name	Description
31	IOC	Interrupt on Completion This bit controls the setting of TI and ETI status bits in the DMA_CH#_Status register. When ETIC = 1 and TDES2[LD] = 0, this bit sets the ETI bit. When TDES3[LD] = 1, this bit sets the TI status bit.
30	TTSE/TMWD	Transmit Timestamp Enable or External TSO Memory Write Enable This bit enables the IEEE1588 time stamping for Transmit packet referenced by the descriptor, if TSE bit is not set. If TSE bit is set and external TSO memory is enabled, setting this bit disables external TSO memory writing for this packet.
29:16	B2L	Buffer 2 Length The driver sets this field. When set, this field indicates Buffer 2 length.
15:14	VTIR	VLAN Tag Insertion or Replacement These bits request the MAC to perform VLAN tagging or untagging before transmitting the packets. The application must set the CRC Pad Control bits appropriately when VLAN Tag Insertion, Replacement, or Deletion is enabled for the packet. The following list describes the values of these bits:

Table continues on the next page...

Table 11-131. TDES2 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
		• 2'b00: Do not add a VLAN tag. • 2'b01: Remove the VLAN tag from the packets before transmission. This option should be used only with the VLAN packets. • 2'b10: Insert a VLAN tag with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. • 2'b11: Replace the VLAN tag in packets with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. This option should be used only with the VLAN packets. These bits are valid when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core.
13:0	HL or B1L	Header Length or Buffer 1 Length For Header length only bits [9:0] are taken. The size 13:0 is applicable only when interpreting buffer 1 length. If the TCP Segmentation Offload feature is enabled through the TSE bit of TDES3, this field is equal to the header length. When the TSE bit is set in TDES3, the header length includes the length in bytes from Ethernet Source address till the end of the TCP header. The maximum header length supported for TSO feature is 1023 bytes. The maximum header length supported for TSO feature is 1023 bytes. If the TCP Segmentation Offload feature is not enabled, this field is equal to Buffer 1 length.

11.7.2.11.3.1.4 TDES3 Normal Descriptor (Read Format)

Table 11-132. TDES2 Normal Descriptor (Read Format)

31	30	29	28	27:26	25:23	22:19	18	17:16	15	14:0
OWN	CTXT	FD	LD	CPC	SAIC	SLOTNUM or THL	TSE	CIC/TPL	TPL	FL/TPL

Table 11-133. TDES3 Normal Descriptor (Read Format)

Bits	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffer(s).
30	CTXT	Context Type This bit should be set to 1'b0 for normal descriptor.
29	FD	First Descriptor When this bit is set, it indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value.
27:26	CPC	CRC Pad Control This field controls the CRC and Pad Insertion for Tx packet. This field is valid only when the first descriptor bit (TDES3[29]) is set. The following list describes the values of Bits[27:26]: • 2'b00: CRC and Pad Insertion The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes. • 2'b01: CRC Insertion (Disable Pad Insertion) The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit Buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes. • 2'b10: Disable CRC Insertion

Table continues on the next page...

Table 11-133. TDES3 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
		The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. • 2'b11: CRC Replacement The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. This field is valid only for the first descriptor. Note: When the TSE bit is set, the MAC ignores this field because the CRC and pad insertion is always done for segmentation.
25:23	SAIC	SA Insertion Control These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 or 1 register. The application must set the CRC Pad Control bits appropriately when SA Insertion Control is enabled for the packet. Bit 25 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement. The following list describes the values of Bits[24:23]: • 2'b00: Do not include the source address • 2'b01: Include the source address. For reliable transmission, the application must provide frames without source addresses. • 2'b10: Replace the source address. For reliable transmission, the application must provide frames with source addresses. • 2'b11: Reserved

Table continues on the next page...

Table 11-133. TDES3 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
		These bits are valid in the EQOS-DMA, EQOS-AXI, and EQOS-AHB configurations when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core and when the First Segment control bit (TDES3 [29]) is set. This field is valid only for the first descriptor.
22:19	SLOTNUMor THL	SLOTNUM: Slot Number Control Bits in AV Mode These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by TDES0 or TDES1. When the Transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot interval maintained in the RSN field DMA_CH#_Slot_Function_Control_Status. It fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels. THL: TCP/UDP Header Length If the TSE bit is set, this field contains the length of the TCP/UDP header. The minimum value of this field must be 5 for TCP header. The value must be equal to 2 for UDP header. This field is valid only for the first descriptor.
18	TSE	TSO Split header is not supported. The value of this bit is always zero.
17:16	CIC/TPL	Checksum Insertion Control or TCP Payload Length These bits control the checksum calculation and insertion. The following list describes the bit encoding: • 2'b00: Checksum Insertion Disabled. • 2'b01: Only IP header checksum calculation and insertion are enabled.

Table continues on the next page...

Table 11-133. TDES3 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
		• 2'b10: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. • 2'b11: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware. This field is valid when the Enable Transmit TCP/IP Checksum Offload option is selected and the TSE bit is reset. When the TSE bit is set, this field contains the upper bits [17:16] of the TCP Payload (or IP Payload for UDP fragmentation). This allows the TCP/UDP packet length field to be spanned across TDES3[17:0] to provide 256 KB packet length support. This field is valid only for the first descriptor.
15	TPL	Reserved or TCP Payload Length When the TSE bit is reset, this bit is reserved. When the TSE bit is set, this is Bit 15 of the TCP payload length [17:0]. This field is valid only when the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected while configuring the core.
14:0	FL/TPL	Frame Length or TCP Payload Length This field is equal to the length of the packet to be transmitted in bytes. When the TSE bit is not set, this field is equal to the total length of the packet to be transmitted: Ethernet Header Length + TCP /IP Header Length – Preamble Length – SFD Length + Ethernet Payload Length When the TSE bit is set, this field is equal to the lower 15 bits of the TCP payload length in case of segmentation and IP payload in case of UDP fragmentation.

Table 11-133. TDES3 Normal Descriptor (Read Format)

Bits	Name	Description
		In case of segmentation, this length does not include Ethernet header or TCP/UDP/IP header length. In case of fragmentation, this length does not include Ethernet header and IP header. When DWRR/WFQ algorithm is NOT enabled, value written into this field is not used when TSE = 0.

11.7.2.11.3.2 Transmit Normal Descriptor (Write-Back Format)

The write-back format of the Transmit Descriptor includes timestamp low, timestamp high, OWN, and Status bits.

The write-back format is applicable only for the last descriptor of the corresponding packet. The LD bit (TDES3[28]) is set in the descriptor where the DMA writes back the status and timestamp information for the corresponding Transmit packet.

Following figure illustrates the write-back format of the Transmit Descriptor.

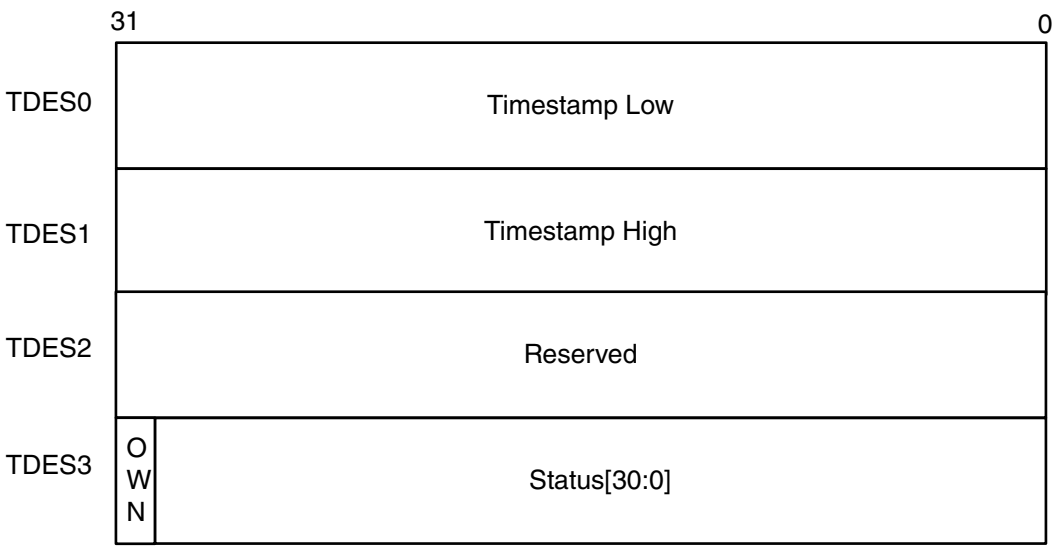


Figure 11-107. Transmit Descriptor Write-Back Format

TDES0 Normal Descriptor (Write-Back Format)

As described in following table, this format is only applicable to the last descriptor of a packet.

Table 11-134. TDES0 Normal Descriptor (Write-Back Format)TDES0 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for the corresponding Transmit packet. The DMA writes the timestamp only if TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Descriptor bit (LD) in the descriptor is set and the Timestamp status (TTSS) bit is set.

TDES1 Normal Descriptor (Write-Back Format)

As mentioned in the following table, this format is only applicable to the last descriptor of a packet.

Table 11-135. TDES1 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High The DMA updates this field with the most significant 32 bits of the timestamp captured for corresponding transmit packet. The DMA writes the timestamp only if the TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Descriptor bit (LD) in the descriptor is set and Timestamp status (TTSS) bit is set.

TDES2 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Table 11-136. TDES2 Normal Descriptor (Write-Back Format)

Bit	Description
31:0	Reserved

TDES3 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Table 11-137. TDES3 Normal Descriptor (Write-Back Format)

31	30	29	28	27:24	23	22:18	17	16	15	14	13	12	11	10	9	8	7:4	3	2	1	0

Table 11-138. TDES3 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the the module DMA owns the descriptor. The DMA clears this bit when it completes the packet transmission. After the write-back is complete, this bit is set to 'b0.
30	CTXT	Context Type This bit should be set to 'b0 for Normal descriptor.
29	FD	First Descriptor This bit indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor This bit is set 'b1 for last descriptor of a packet. The DMA writes the status fields only in the last descriptor of the packet.
27:24	Rsvd	Reserved
23	DE	Descriptor Error When this bit is set, it indicates that the descriptor content is incorrect. The DMA sets this bit during write-back while closing the descriptor. Descriptor Errors can be: • Incorrect sequence from the context descriptor. For example, a location after the first descriptor for a packet. • All 1s • CTXT, LD, and FD bits set to 1. Note 1: When Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA will set the TI bit in the DMA_CH#_Status register

Table continues on the next page...

Table 11-138. TDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		Note 2: Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent.
22:18	Rsvd	Reserved
17	TTSS	Tx Timestamp Status This status bit indicates that a timestamp has been captured for the corresponding transmit packet. When this bit is set, TDES0 and TDES1 have timestamp values that were captured for the Transmit packet. This field is valid only when the Last Segment control bit (TDES3 [28]) in a descriptor is set. This bit is valid only when IEEE1588 timestamping feature is enabled; otherwise, it is reserved.
16	EUE	ECC Uncorrectable Error Status Indicates the ECC uncorrectable error in the TSO memory. Note: Uncorrectable error in Transmit FIFO memory is reported with (Bit 13) FF = 1. This is because, all such packets are flushed by the module.
15	ES	Error Summary This bit indicates the logical OR of the following bits: • TDES3[0]: IP Header Error • TDES3[14]: Jabber Timeout • TDES3[13]: Packet Flush • TDES3[12]: Payload Checksum Error • TDES3[11]: Loss of Carrier • TDES3[10]: No Carrier • TDES3[9]: Late Collision • TDES3[8]: Excessive Collision • TDES3[3]: Excessive Deferral • TDES3[2]: Underflow Error This bit is also set when EUE (bit 16) is set.
14	JT	Jabber Timeout

Table continues on the next page...

Table 11-138. TDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		This bit indicates that the MAC transmitter has experienced a jabber time-out. This bit is set only when the JD bit of the MAC_Configuration register is not set.
13	FF	Packet Flushed This bit indicates that the DMA or MTL flushed the packet because of a software flush command given by the CPU.
12	PCE	Payload Checksum Error This bit indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either because of insufficient bytes, as indicated by the Payload Length field of the IP Header or the MTL starting to forward the packet to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet packet being transmitted to avoid deadlock, the MTL starts forwarding the packet when the FIFO is full, even in the store-and-forward mode. This error can also occur when Bus Error is detected during packet transfer. When the Full Checksum Offload engine is not enabled, this bit is reserved.
11	LoC	Loss of Carrier This bit indicates that Loss of Carrier occurred during packet transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during packet transmission). This is valid only for the packets transmitted without collision and when the MAC operates in the half-duplex mode.
10	NC	No Carrier This bit indicates that the carrier sense signal form the PHY was not asserted during transmission.
9	LC	Late Collision

Table continues on the next page...

Table 11-138. TDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		This bit indicates that packet transmission was aborted because a collision occurred after the collision window (512 byte times including Preamble and Carrier Extension in GMII mode). This bit is not valid if Underflow Error is set.
8	EC	Excessive Collision This bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after first collision and the transmission of the packet is aborted.
7:4	CC	Collision Count This 4-bit counter value indicates the number of collisions occurred before the packet was transmitted. The count is not valid when the EC bit is set.
3	ED	Excessive Deferral This bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbps mode or Jumbo Packet enabled mode) if DC bit is set in the MAC_Configuration register. When TBS is enabled in full duplex mode and this bit is set, it indicates that the frame has been dropped after the expiry time has reached.
2	UF	Underflow Error This bit indicates that the MAC aborted the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions: • The DMA encountered an empty Transmit Buffer while transmitting the packet • The application filled the MTL Tx FIFO slower than the MAC transmit rate The transmission process enters the suspended state and sets the underflow bit corresponding to a queue in the MTL_Interrupt_Status register.
1	DB	Deferred Bit

Table continues on the next page...

Table 11-138. TDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		This bit indicates that the MAC deferred before transmitting because of presence of carrier. This bit is valid only in the half-duplex mode.
0	IHE	IP Header Error When IP Header Error is set, this bit indicates that the Checksum Offload engine detected an IP header error. This bit is valid only when Tx Checksum Offload is enabled. Otherwise, it is reserved. If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload. In full duplex mode, when EST/Qbv is enabled and this bit is set, it indicates the frame drop status due to Frame Size error or Schedule Error.

11.7.2.11.3.3 Transmit Context Descriptor

The context descriptor is used to provide the timestamps for one-step timestamp correction, VLAN Tag ID for VLAN insertion feature.

The Transmit Context descriptor can be provided any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor is used to provide the timestamps for one-step timestamp correction and VLAN Tag ID for VLAN insertion feature. Write back is done on a context descriptor only to reset the OWN bit.

NOTE

The VLAN Tag IDs and MSS values, provided by the application in a context descriptor with their corresponding Valid bits set, are stored internally by the DMA. When the outer or inner VLAN tag is provided with the Valid bit set, the DMA always passes the last valid VLAN tag to the MTL. The application cannot invalidate the valid VLAN tag stored by the DMA. The VLAN tag is inserted or replaced based on the control inputs provided for the packet.

The Inner VLAN Tag Control input is used only for the next packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which the DMA should use the inner VLAN Tag control input.

The following figure shows the format of the Transmit Context descriptor.

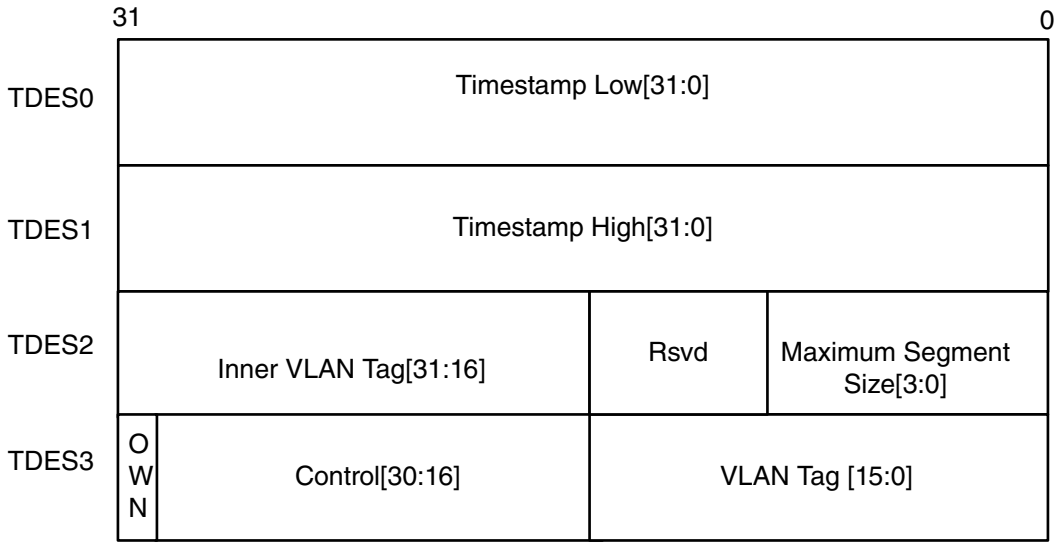

Figure 11-108. Transmit Context Descriptor Format

11.7.2.11.3.3.1 TDES0 Context Descriptor

Following table describes the format of the TDES0 Context descriptor.

Table 11-139. TDES0 Context Descriptor

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low For one-step correction, the driver can provide the lower 32 bits of timestamp in this descriptor word. The DMA uses this value as the low word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

11.7.2.11.3.3.2 TDES1 Context Descriptor

Following table describes the format of the TDES1 Context descriptor.

Table 11-140. TDES1 Context Descriptor

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High For one-step correction, the driver can provide the upper 32 bits of timestamp in this descriptor. The DMA uses this value as the high word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

11.7.2.11.3.3.3 TDES2 Context Descriptor

Following table explains the format of the TDES2 Context descriptor.

Table 11-141. TDES2 Context Descriptor

Bit	Name	Description
31:16	IVT	Inner VLAN Tag When the IVLTV bit of TDES3 context descriptor is set and the TCMSSV and OSTC bits of TDES3 context descriptor are reset, TDES2[31:16] contains the inner VLAN Tag to be inserted in the subsequent Transmit packets.
15:14	Rsvd	Reserved
13:0	MSS	TSO Split header is not supported. The value of this bit is always zero.

11.7.2.11.3.3.4 TDES3 Context Descriptor

Table 11-142. TDES3 Context Descriptor

31	30	29:28	27	26	25:24	23	22:18	17	16	15:0
OWN	CTXT	Rsvd	OSTC	TCMSSV	Rsvd	CDE	Rsvd	IVLTV	VLTV	VT

Follwoing table details the format of the TDES3 Context descriptor.

Table 11-143. TDES3 Context Descriptor

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the module DMA owns the descriptor. When this bit is reset, it indicates that the

Table continues on the next page...

Table 11-143. TDES3 Context Descriptor (continued)

Bit	Name	Description
		application owns the descriptor. The DMA clears this bit immediately after the read.
30	CTXT	Context Type This bit should be set to 1'b1 for Context descriptor.
29:28	Rsvd	Reserved
27	OSTC	One-Step Timestamp Correction Enable When this bit is set, the DMA performs a one-step timestamp correction with reference to the timestamp values provided in TDES0 and TDES1.
26	TCMSSV	One-Step Timestamp Correction Input or MSS Valid When this bit and the OSTC bit are set, it indicates that the Timestamp Correction input provided in TDES0 and TDES1 is valid. When the OSTC bit is reset and this bit and the TSE bit of TDES3 are set in subsequent normal descriptor, it indicates that the MSS input in TDES2 is valid.
25:24	Rsvd	Reserved
23	CDE	Context Descriptor Error When this bit is set, it indicates that the descriptor content is incorrect.The DMA sets this bit during write-back while closing the context descriptor. Descriptor Errors can be: • Incorrect sequence from the context descriptor. For example, a location before the first descriptor for a packet. • All 1s. • CD, LD, and FD bits set to 1. Note 1: When Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA will set the TI bit in the DMA_CH#_Status register Note 2: Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be

Table continues on the next page...

Table 11-143. TDES3 Context Descriptor (continued)

Bit	Name	Description
		considered as the First Descriptor (even if FD bit is not set) and partial packet is sent.
22:20	Rsvd	Reserved
19:18	IVTIR	Inner VLAN Tag Insert or Replace When this bit is set, these bits request the MAC to perform Inner VLAN tagging or un-tagging before transmitting the packets. If the packet is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes. The following list describes the values of these bits: • 2'b00: Do not add the inner VLAN tag. • 2'b01: Remove the inner VLAN tag from the packets before transmission. This option should be used only with the VLAN frames. • 2'b10: Insert an inner VLAN tag with the tag value programmed in the MAC_In-ner_VLAN_Incl register or context descriptor. • 2'b11: Replace the inner VLAN tag in packets with the tag value programmed in the MAC_Inner_VLAN_Incl register or context descriptor. This option should be used only with the VLAN frames. These bits are valid when the Enable SA and VLAN Insertion on Tx and Enable Double VLAN Processing options are selected.
17	IVLTV	Inner VLAN Tag Valid When this bit is set, it indicates that the IVT field of TDES2 is valid.
16	VLTV	VLAN Tag Valid When this bit is set, it indicates that the VT field of TDES3 is valid.
15:0	VT	VLAN Tag This field contains the VLAN Tag to be inserted or replaced in the packet. This field is used as VLAN Tag only when the VLTI bit of the MAC_VLAN_Incl register is reset.

11.7.2.11.4 Receive Descriptor

The DMA in the module attempts to read a descriptor only if the Tail Pointer is different from the Base Pointer or current pointer. It is recommended to have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC. Otherwise, the performance of the DMA is impacted greatly because of the unavailability of the descriptors. In such situations, the RxFIFO in MTL becomes full and starts dropping packets.

The following Receive Descriptors are present:

- Normal descriptors
- Context descriptors

All RX descriptors are prepared by the software and given to the DMA as "Normal" Descriptors with the content as shown in Receive Normal Descriptor (Read Format). The DMA reads this descriptor and after transferring a received packet (or part of) to the buffers indicated by the descriptor, the Rx DMA will close the descriptor with the corresponding packet status. The format of this status is given in the "Receive Normal Descriptor (Write-Back Format)".

For some packets, the normal descriptor bits are not enough to write the complete status. For such packets, the RX DMA writes the extended status to the next descriptor (without processing or using the Buffers/ Pointers embedded in that descriptor). The format and content of the descriptor write back is described in "Receive Context Descriptor".

11.7.2.11.4.1 Receive Normal Descriptor (Read Format)

The read format for a Receive Normal descriptor is made up of a header or Buffer 1 address, reserved field, payload or Buffer 2 or Next Descriptor address, a 30-bit reserved filed, OWN bit, and an interrupt bit.

Following figure shows the Read Format for a Receive Normal Descriptor.

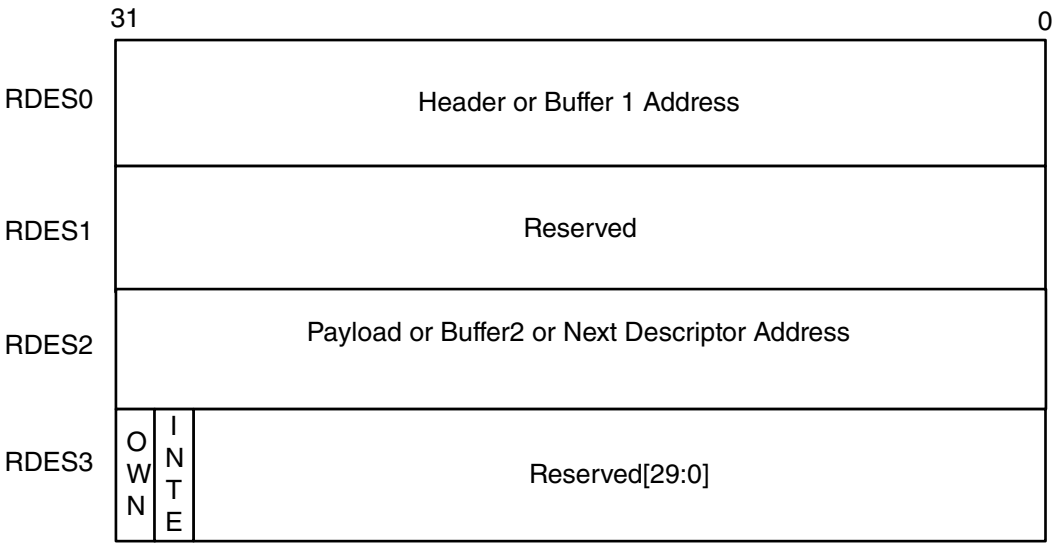

Figure 11-109. Receive Normal Descriptor Read Format

NOTE

In the Receive Descriptor (Read Format), if the Buffer Address field is all 0s, the module does not transfer data to that buffer and skips to the next buffer or next descriptor.

11.7.2.11.4.1.1 RDES0 Normal Descriptor (Read Format)

Following table explains the read format of the RDES0 Normal Descriptor.

Table 11-144. RDES0 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF1AP	Header or Buffer 1 Address Pointer When the SPH bit of Control register of a channel is reset, these bits indicate the physical address of Buffer 1. When the SPH bit is set, these bits indicate the physical address of Header Buffer where the Rx DMA writes the L2/L3/L4 header bytes of the received packet. The application can program a byte-aligned address for this buffer which means that the LS bits of this field can be non-zero. However, while transferring the start of packet, the DMA performs a Write operation with RDES0[1:0] (or RDES0[2:0]/[3:0] in case of 64-/128-bit configuration) as zero. However, the packet data is shifted as per actual offset as given by buffer address pointer.

Table 11-144. RDES0 Normal Descriptor (Read Format)

Bit	Name	Description
		If the address pointer points to a buffer where the middle or last part of the packet is stored, the DMA ignores the offset address and writes to the full location as indicated by the data-width.

11.7.2.11.4.1.2 RDES1 Normal Descriptor (Read Format)

Following table describes the read format of the RDES1 Normal Descriptor.

Table 11-145. RDES1 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	Reserved or BUF1AP	In 64-bit addressing mode, this field contains the most-significant 32 bits of the Buffer 1 Address Pointer. Otherwise, this field is reserved.

11.7.2.11.4.1.3 RDES2 Normal Descriptor (Read Format)

Following table provides the read format of the RDES2 Normal Descriptor.

Table 11-146. RDES2 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 Address Pointer These bits indicate the physical address of Buffer 2. When the SPH bit of the DMA_CH#_Control register is set, the buffer address pointer must be bus width-aligned, that is, RDES2[3:0, 2:0, or 1:0] = 0 corresponding to 128, 64, or 32 bus width. LSBs are ignored internally. When the SPH bit of the DMA_CH#_Control register is reset, there is no limitations on the RDES2 value. However, the RxDMA uses the LS Bits of the pointer address only while transferring the start bytes of a packet. If the BUF2AP is giving the address of a buffer in which the middle or last part of a packet is stored, the DMA ignores BUF2AP[3:0 or 2:0 or 1:0] (corresponding to 128- or 64- or 32-bit data-bus) and writes to the complete location.

11.7.2.11.4.1.4 RDES3 Normal Descriptor (Read Format)

Following table describes the read format of the RDES3 Normal Descriptor.

31	30	19-26	25	24	23:0
OWN	IOC	Rsvd	BUF2V	BUF1V	Rsvd

Table 11-147. RDES3 Normal Descriptor (Read Format)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: • The DMA completes the packet reception • The buffers associated with the descriptor are full
30	IOC	Interrupt Enabled on Completion When this bit is set, an interrupt is issued to the application when the DMA closes this descriptor.
29:26	Rsvd	Reserved
25	BUF2V	Buffer 2 Address Valid When this bit is set, it indicates to the DMA that the buffer 2 address specified in RDES2 is valid. The application must set this bit so that the DMA can use the address, to which the Buffer 2 address in RDES2 is pointing, to write received packet data.
24	BUF1V	Buffer 1 Address Valid When set, this indicates to the DMA that the buffer 1 address specified in RDES1 is valid. The application must set this value if the address pointed to by Buffer 1 address in RDES1 can be used by the DMA to write received packet data.
23:0	Rsvd	Reserved

11.7.2.11.4.2 Receive Normal Descriptor (Write-Back Format)

The following figure illustrates the write-back format for a Receive Normal descriptor.

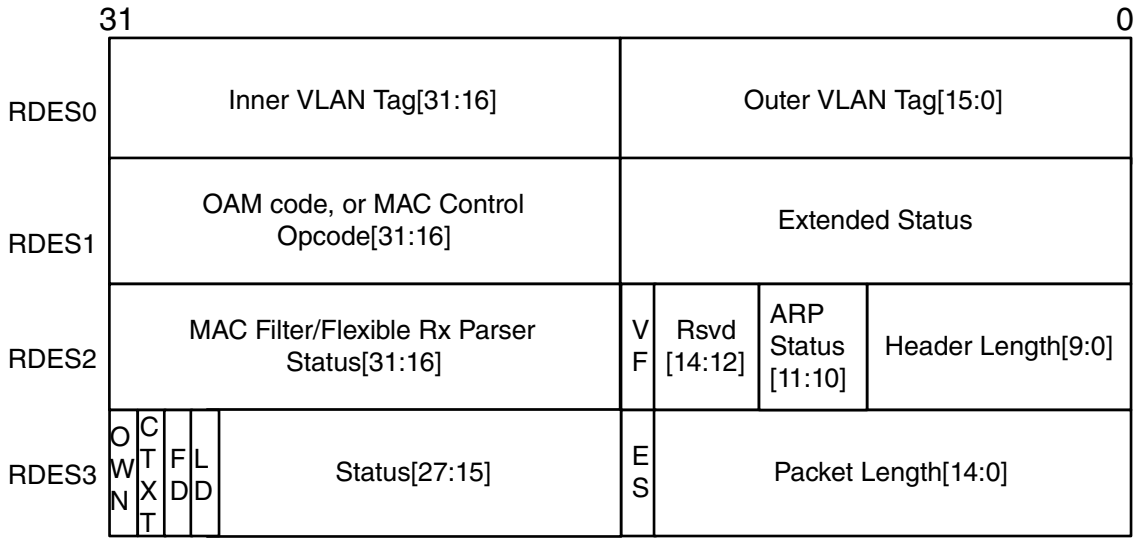

Figure 11-110. Receive Normal Descriptor (Write-Back Format)

NOTE

When Flexible RX Parser is enabled, RDES2[31:16] indicates Parser status, and not the MAC filter status. MAC filter status is not available when Flexible RX parser is enabled.

11.7.2.11.4.2.1 RDES0 Normal Descriptor (Write-Back Format)

Following table describes the write-back format for the RDES0 Normal Descriptor.

Table 11-148. RDES0 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:16	IVT	Inner VLAN Tag This field contains the Inner VLAN tag of the received packet if the RS0V bit of RDES3 is set. This is valid only when Double VLAN tag processing and VLAN tag stripping are enabled.
15:0	OVT	Outer VLAN Tag This field contains the Outer VLAN tag of the received packet if the RS0V bit of RDES3 is set.

11.7.2.11.4.2.2 RDES1 Normal Descriptor (Write-Back Format)

The Status fields in write-back format are valid only for the last descriptor (RDES3[28] is set). Following table provides the details of the write-back format for RDES1 Normal Descriptor.

31:16	15	14	13	12	11:8	7	6	5	4	3	2:0
OPC	TD	TSA	PV	PFT	PMT	IPCE	IPCB	IPV6	IPV4	IPHE	PT

Table 11-149. RDES1 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:16	OPC	OAM Sub-Type Code, or MAC Control Packet opcode OAM Sub-Type Code If Bits[18:16] of RDES3 are set to 3'b111, this field contains the OAM sub-type and code fields. MAC Control Packet opcode The bits[15:8] of RDES3 contains the subtype and bits [7:0] contains the code.
15	TD	Timestamp Dropped This bit indicates that the timestamp was captured for this packet but it got dropped in the MTL Rx FIFO because of overflow. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
14	TSA	Timestamp Available When Timestamp is present, this bit indicates that the timestamp value is available in a context descriptor word 2 (RDES2) and word 1(RDES1). This is valid only when the Last Descriptor bit (RDES3 [28]) is set. The context descriptor is written in the next descriptor just after the last normal descriptor for a packet.
13	PV	PTP Version This bit indicates that the received PTP message has the IEEE 1588 version 2 format. When this bit is reset, it indicates the IEEE 1588 version 1 format. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.

Table continues on the next page...

Table 11-149. RDES1 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
12	PFT	PTP Packet Type This bit indicates that the PTP message is sent directly over Ethernet. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
11:8	PMT	PTP Message Type These bits are encoded to give the type of the message received: • 0000: No PTP message received • 0001: SYNC (all clock types) • 0010: Follow_Up (all clock types) • 0011: Delay_Req (all clock types) • 0100: Delay_Resp (all clock types) • 0101: Pdelay_Req (in peer-to-peer transparent clock) • 0110: Pdelay_Resp (in peer-to-peer transparent clock) • 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) • 1000: Announce • 1001: Management • 1010: Signaling • 1011–1110: Reserved • 1111: PTP packet with Reserved message type These bits are available only when you select the Timestamp feature.
7	IPCE	IP Payload Error When this bit is set, it indicates either of the following: • The 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) calculated by the MAC does not match the corresponding checksum field in the received segment.

Table continues on the next page...

Table 11-149. RDES1 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		• The TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field. • The TCP, UDP, or ICMP segment length is less than minimum allowed segment length for TCP, UDP, or ICMP. Bit 15 (ES) of RDES3 is not set when this bit is set.
6	IPCB	IP Checksum Bypassed This bit indicates that the checksum offload engine is bypassed. This bit is available when you select the Enable Receive TCP/IP Checksum Check feature.
5	IPV6	IPv6 header Present This bit indicates that an IPV6 header is detected. When the Enable Split Header Feature option is selected and the SPH bit of Control Register of a channel is set, the IPV6 header is available in the header buffer area to which RDES0 is pointing.
4	IPV4	IPV4 Header Present This bit indicates that an IPV4 header is detected. When the SPH bit of RDES3 is set, the IPV4 header is available in the header buffer area to which RDES0 is pointing.
3	IPHE	IP Header Error When this bit is set, it indicates either of the following: • The 16-bit IPv4 header checksum calculated by the MAC does not match the received checksum bytes. • The IP datagram version is not consistent with the Ethernet Type value. • Ethernet packet does not have the expected number of IP header bytes. This bit is valid when either Bit 5 or Bit 4 is set. This bit is available when you select the Enable Receive TCP/IP Checksum Check feature.
2:0	PT	Payload Type

Table 11-149. RDES1 Normal Descriptor (Write-Back Format)

Bit	Name	Description
		These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE): • 3'b000: Unknown type or IP/AV payload not processed • 3'b001: UDP • 3'b010: TCP • 3'b011: ICMP • 3'b110: AV Tagged Data Packet • 3'b111: AV Tagged Control Packet • 3'b101: AV Untagged Control Packet • 3'b100: IGMP if IPV4 Header Present bit is set else DCB (LLDP) Control Packet If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these bits to 3'b000.

11.7.2.11.4.2.3 RDES2 Normal Descriptor (Write-Back Format)

31:29	28	27	26:19	18	17	16	15	14	13:11	10	9:0
L3L4FM	L4FM	L3FM	MADRM	HF	DAF	SAF	OTS	ITS	Rsvd	ARPNR	HL

Table 11-150. RDES2 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:29	L3L4FM	Layer 3 and Layer 4 Filter Number Matched These bits indicate the number of the Layer 3 and Layer 4 Filter that matched the received packet: • 000: Filter 0 • 001: Filter 1 • 010: Filter 2 • 011: Filter 3 • 100: Filter 4 • 101: Filter 5

Table continues on the next page...

Table 11-150. RDES2 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		• 110: Filter 6 • 111: Filter 7 This field is valid only when Bit 28 or Bit 27 is set high. When more than one filter matches, these bits give the number of lowest filter. Note: This status is not available when Flexible RX Parser is enabled.
28	L4FM	Layer 4 Filter Match When this bit is set, it indicates that the received packet matches one of the enabled Layer 4 Port Number fields. This status is given only when one of the following conditions is true: • Layer 3 fields are not enabled and all enabled Layer 4 fields match • All enabled Layer 3 and Layer 4 filter fields match When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by Bits[31:29]. Note: This status is not available when Flexible RX Parser is enabled.
27	L3FM	Layer 3 Filter Match When this bit is set, it indicates that the received packet matches one of the enabled Layer 3 IP Address fields. This status is given only when one of the following conditions is true: • All enabled Layer 3 fields match and all enabled Layer 4 fields are bypassed • All enabled filter fields match When more than one filter matches, this bit gives the layer 3 filter status of filter indicated by Bits[31:29]. Note: This status is not available when Flexible RX Parser is enabled.
26:19	MADRM	MAC Address Match or Hash Value When the HF bit is reset, this field contains the MAC address register number that matched the Destination address of the received packet. This field is valid only if the DAF bit is reset.

Table continues on the next page...

Table 11-150. RDES2 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		When the HF bit is set, this field contains the hash value computed by the MAC. A packet passes the hash filter when the bit corresponding to the hash value is set in the hash filter register. Note: This status is not available when Flexible RX Parser is enabled.
18	HF	Hash Filter Status When this bit is set, it indicates that the packet passed the MAC address hash filter. Bits[26:19] indicate the hash value. Note: This status is not available when Flexible RX Parser is enabled.
17	DAF/RXPI	Destination Address Filter Fail When Flexible RX Parser is disabled, and this bit is set, it indicates that the packet failed the DA Filter in the MAC. When Flexible RX Parser is enabled, this bit is set to indicate that the packet parsing is incomplete (RXPI) due to ECC error. Note: When this bit is set, ES bit of RDES3 is also set.
16	SAF/RXPD	SA Address Filter Fail When Flexible RX Parser is disabled, and this bit is set, it indicates that the packet failed the SA Filter in the MAC. When Flexible RX Parser is enabled, this bit is set to indicate that the packet is dropped (RXPD) by the parser. Note: When this bit is set, ES bit of RDES3 is also set.
15	OTS	VLAN Filter Status When set, this bit indicates that the VLAN Tag of the received packed passed the VLAN filter. This bit is redefined as Outer VLAN Tag Filter Status (OTS). This bit is valid for both Single and Double VLAN Tagged frames
14	ITS	Inner VLAN Tag Filter Status (ITS) This bit is valid only for Double VLAN Tagged frames, when Double VLAN Processing is enabled. For more information, see Filter Status.
13:11	Rsvd	Reserved

Table continues on the next page...

Table 11-150. RDES2 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
10	ARPNR	ARP Reply Not Generated When this bit is set, it indicates that the MAC did not generate the ARP Reply for received ARP Request packet. This bit is set when the MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time). This bit is reserved when the Enable IPv4 ARP Offload option is not selected.
9:0	HL	L3/L4 Header Length This field contains the length of the header of the packet split by the MAC at L3 or L4 header boundary as identified by the MAC receiver. This field is valid only when the first descriptor bit is set (FD = 1). The header data is written to the Buffer 1 address of corresponding descriptor. If header length is zero, this field is not valid. It implies that the MAC did not identify and split the header. This field is valid when the Enable Split Header Feature option is selected.

11.7.2.11.4.2.4 RDES3 Normal Descriptor (Write-Back Format)

Following table describes the write-back format for the RDES3 Normal Descriptor.

31	30	29	28	27	26	25	24	23	22	21	20	19	18:16	15	14:0
OWN	CTXT	FD	LD	RS2V	RS1V	RS0V	CE	GP	RWT	OE	RE	DE	LT	ES	PL

Table 11-151. RDES3 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true:

Table continues on the next page...

Table 11-151. RDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		• The DMA completes the packet reception • The buffers associated with the descriptor are full
30	CTXT	Receive Context Descriptor When this bit is set, it indicates that the current descriptor is a context type descriptor. The DMA writes 1'b0 to this bit for normal receive descriptor. When CTXT and FD bits are used together, {CTXT, FD} • 2'b00: Intermediate Descriptor • 2'b01: First Descriptor • 2'b10: Reserved • 2'b11: Descriptor Error (due to all 1s) Note: When Descriptor Error occurs, the Receive DMA closes the receive descriptor indicating Descriptor Error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data Receive DMA will set the CDE bit in DMA_CH#_Status register but not the RI bit even when IOC is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data.
29	FD	First Descriptor When this bit is set, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet. If the size of the second buffer is also 0, the next descriptor contains the beginning of the packet. See the CTXT bit description for details of using the CTXT bit and FD bit together.
28	LD	Last Descriptor When this bit is set, it indicates that the buffers to which this descriptor is pointing are the last buffers of the packet.
27	RS2V	Receive Status RDES2 Valid

Table continues on the next page...

Table 11-151. RDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		When this bit is set, it indicates that the status in RDES2 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
26	RS1V	Receive Status RDES1 Valid When this bit is set, it indicates that the status in RDES1 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
25	RS0V	Receive Status RDES0 Valid When this bit is set, it indicates that the status in RDES0 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
24	CE	CRC Error When this bit is set, it indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received packet. This field is valid only when the LD bit of RDES3 is set.
23	GP	Giant Packet When this bit is set, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable is set). Note: Giant packet indicates only the packet length. It does not cause any packet truncation.
22	RWT	Receive Watchdog Timeout When this bit is set, it indicates that the Receive Watchdog Timer has expired while receiving the current packet. The current packet is truncated after watchdog timeout.
21	OE	Overflow Error When this bit is set, it indicates that the received packet is damaged because of buffer overflow in Rx FIFO. Note: This bit is set only when the DMA transfers a partial packet to the application. This happens only when the Rx FIFO is operating in the threshold mode. In the store-and-forward mode, all partial packets are dropped completely in Rx FIFO.
20	RE	Receive Error

Table continues on the next page...

Table 11-151. RDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		When this bit is set, it indicates that the gmii_rxer_i signal is asserted while the gmii_rxdv_i signal is asserted during packet reception. This error also includes carrier extension error in the GMII and half-duplex mode. Error can be of less or no extension, or error (rxd!= 0f) during extension.
19	DE	Dribble Bit Error When this bit is set, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode.
18:16	LT	Length/Type Field This field indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows: • 3'b000: The packet is a length packet • 3'b001: The packet is a type packet. • 3'b011: The packet is a ARP Request packet type • 3'b100: The packet is a type packet with VLAN Tag • 3'b101: The packet is a type packet with Double VLAN Tag • 3'b110: The packet is a MAC Control packet type • 3'b111: The packet is a OAM packet type • 3'b010: Reserved
15	ES	Error Summary When this bit is set, it indicates the logical OR of the following bits: • RDES3[24]: CRC Error • RDES3[19]: Dribble Error • RDES3[20]: Receive Error • RDES3[22]: Watchdog Timeout • RDES3[21]: Overflow Error • RDES3[23]: Giant Packet

Table continues on the next page...

Table 11-151. RDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		• RDES2[17]: Destination Address Filter Fail, when Flexible RX Parser is enabled • RDES2[16]: SA Address Filter Fail, when Flexible RX Parser is enabled This field is valid only when the LD bit of RDES3 is set.
14:0	PL	Packet Length These bits indicate the byte length of the received packet that was transferred to system memory (including CRC). This field is valid when the LD bit of RDES3 is set and Overflow Error bits are reset. The packet length also includes the two bytes appended to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet. This field is valid when the LD bit of RDES3 is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current packet.

11.7.2.11.4.3 Receive Context Descriptor

This descriptor is read-only for the application. Only the DMA can write to this descriptor. The context descriptor provides information about the extended status related to the last received packet. The Bit 30 of RDES3 indicates the context type descriptor.

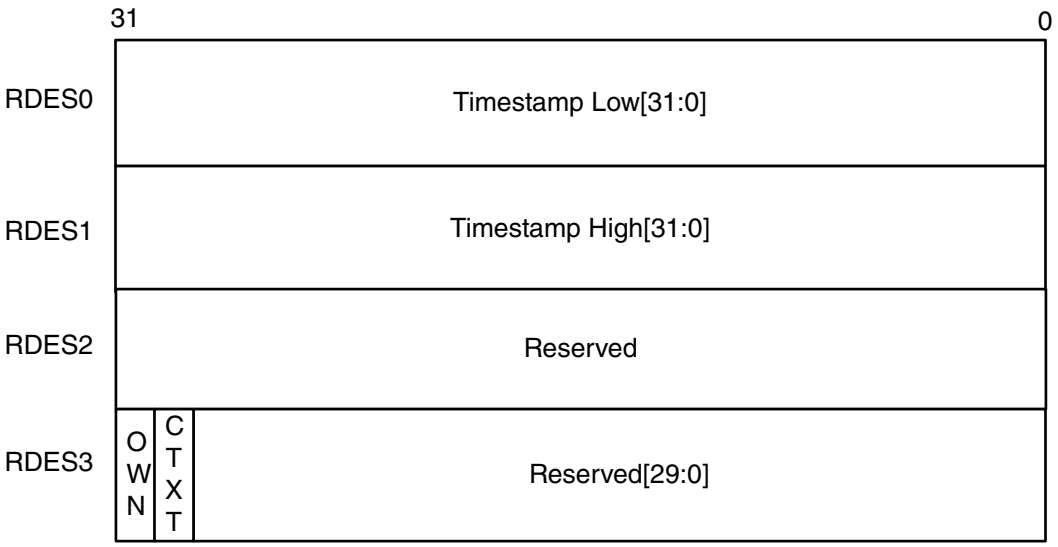

Figure 11-111. Receive Context Descriptor Format

11.7.2.11.4.3.1 RDES0 Context Descriptor

Table 11-152. RDES0 Context Descriptor

Bit	Name	Description
31:0	RTSL	Receive Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for corresponding Receive packet. When this field and the RTSH field of RDES1 show all-ones value, the timestamp must be considered as corrupt.

11.7.2.11.4.3.2 RDES1 Context Descriptor

Table 11-153. RDES1 Context Descriptor

Bit	Field	Description
31:0	RTSH	Receive Packet Timestamp High The DMA updates this field with most significant 32 bits of the timestamp captured for corresponding receive packet. When this field and the RTSL field of RDES0 show all-ones value, the timestamp must be considered as corrupt.

		register but not the RI bit even when IOC is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data.
29	DE	Descriptor Error See the CTXT bit description for details of using theDE bit along with CTXT bit.
28:0	Rsvd	Reserved

11.7.2.11.5 Enhanced Descriptor for Time-Based Scheduling

The time-based scheduling feature needs 32 bytes Enhanced Descriptors to be enabled on all the DMA channels that intend to use the feature (by setting the EDSE bit of DMA_CH(#i)_TX_Control register).

The structure of 32-byte Descriptor for the Context and the Normal Descriptor in Read and Write formats are described in the following sections.

11.7.2.11.5.1 Enhanced Normal Descriptor - Read (32-Bit Mode)

The fields present in the first 16 bytes of the Enhanced Descriptor format of normal descriptor are as follows:

- LTV

  Launch Time Valid indicates the Launch Time (LT) and GSN fields present in the descriptor are valid. The LTV must be set only if the FD bit of the descriptor is not.
- GSN

  This field indicates the GCL slot number associated with the packet.
- Launch Time (LT)

  This field indicates the Launch Time associated with the packet.

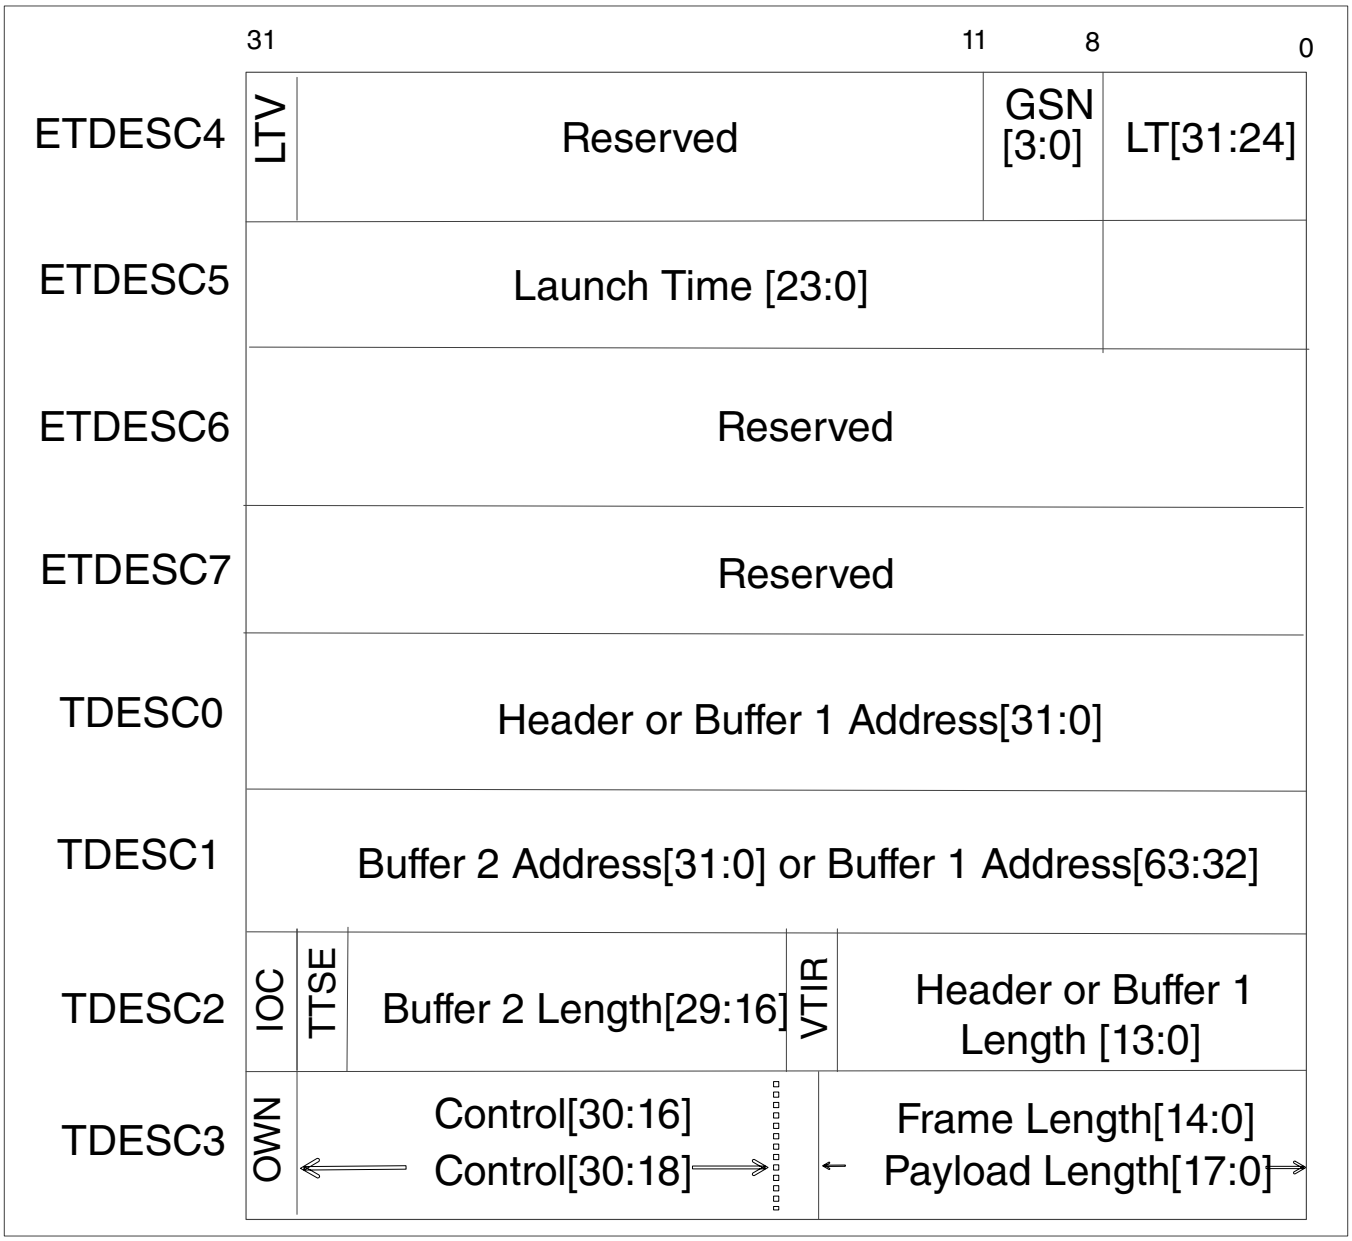

Figure 11-112. Enhanced Normal Descriptor - Read (32-Bit Mode)

11.7.2.11.5.2 Enhanced Normal Descriptor (Write, 32-Bit Mode)

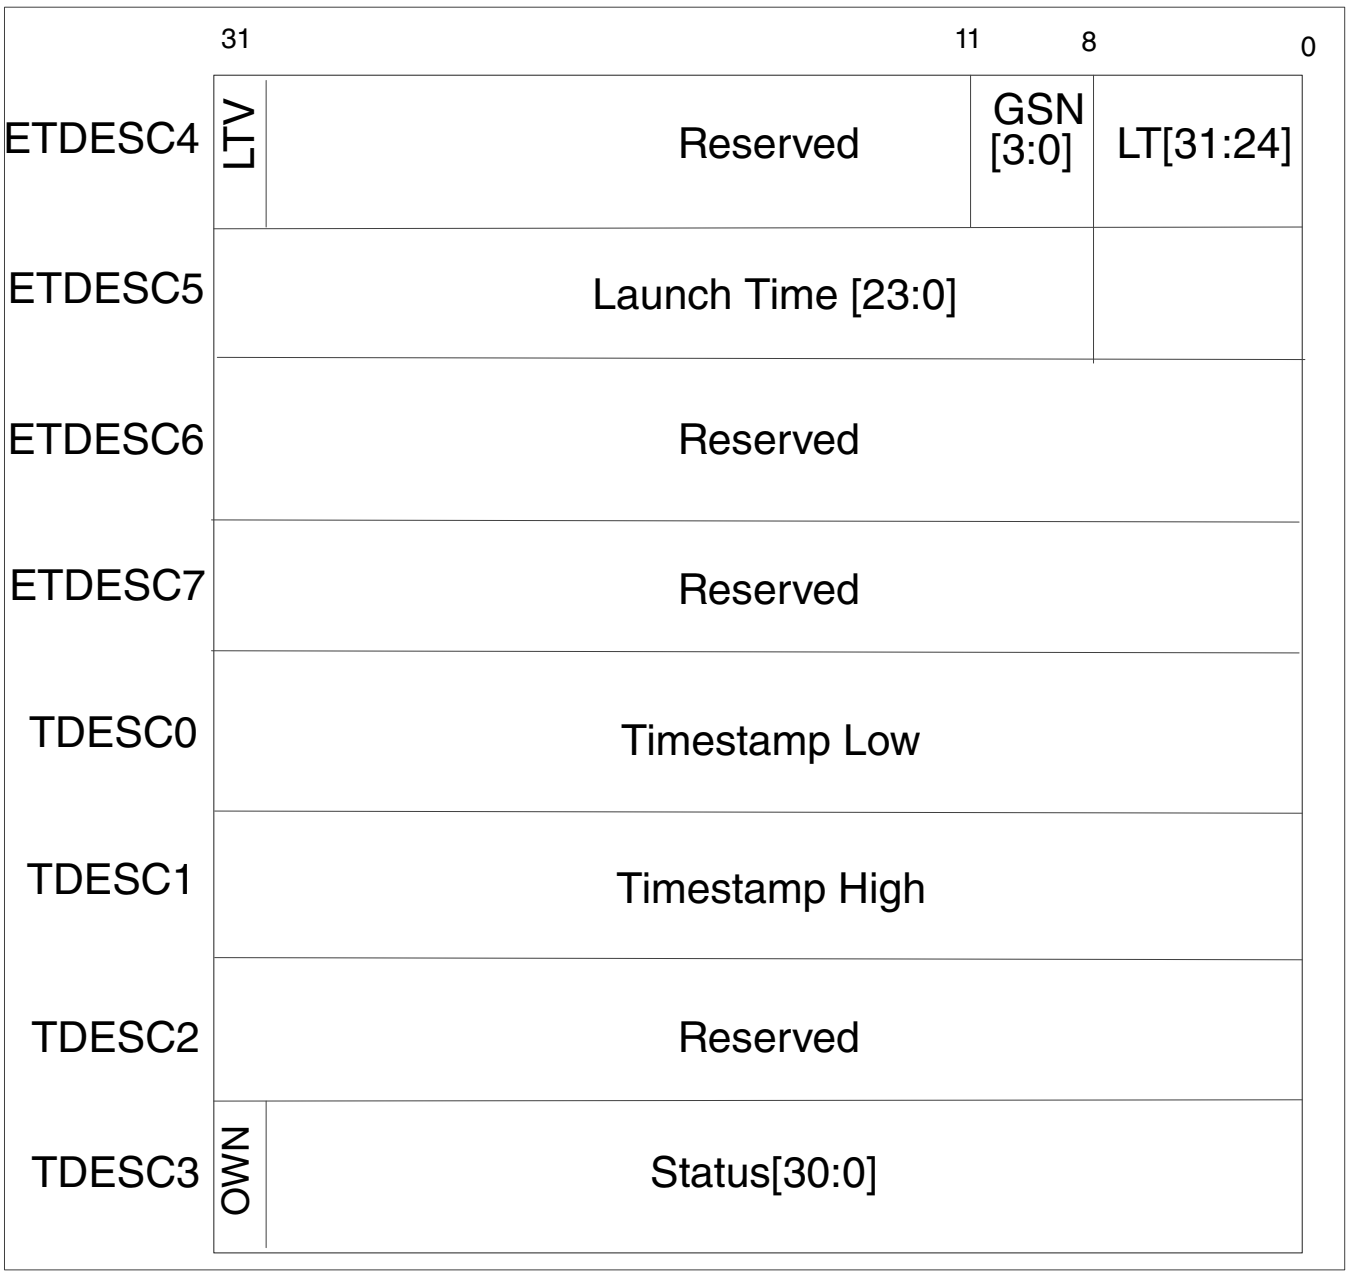

Figure 11-113. Enhanced Normal Descriptor Write (32-Bit Mode)

NOTE

- All the enhanced descriptor examples, assumes a 32-bit data width configurations. However, the same definitions are valid in 64 and 128 bit configurations.

- In both the write back formats, no modifications can be done to the extended 16 bytes. The rest of the 16 bytes (TDESC0 to TDESC3) are written back as per the previous 16 bytes Descriptor format.
- Fetch time when enabled overrides the AV slot function
- When an unaligned new GCL list (with a different CTR) is installed it is recommended not to have traffic during the installation of the new list. Any traffic during the switching of the lists might have unpredictable behavior regarding Fetch, Launch, and Launch expiry as the CTR and BTR values get updated while the frame is being processed

11.7.2.11.5.3 Enhanced Context Descriptor (Read, 32-bit Mode)

The first 16 bytes of the Enhanced context descriptor (ETDESC4 to ETDESC7) are reserved and must be zeros. The fields present in last bytes of the Descriptor (TDESC0 to TDESC3) are same as the context descriptor (TDESC0 to TDESC3) in 16 byte format.

11.7.2.12 Clocks

The table found here describes the clock sources for ENET_QOS. Please see the chip-specific clocking section for clock setting, configuration and gating information.

Table 11-156. ENET_QOS Clocks

Clock name	Description
aclk_i	Bus clock
clk_csr_i	CSR clock, same source as aclk_i
ptp_ref_i	PTP clock

11.7.3 External signals

Table 11-157. External signals

Port name	Interface	I/O	Description
1588_EVENT_AUX_IN	RMII	I	
1588_EVENT_IN	RMII	I	
1588_EVENT_OUT	RMII	O	
TX_CLK	RGMII	O for (RGMII)	RGMII: The transmit clock signal is always provided by the MAC on the TX_CLK line. Source-synchronous clocking is used: the clock signal that is output (by either the PHY or the MAC) is synchronous with the data signals.
RX_CLK	RGMII	I	RGMII: Received clock signal (recovered from incoming received data)
REF_CLK1	RMII	I/O	This 50Mhz clock used by the RMII interface. When RMII mode is selected, RX_CLK (25Mhz or 2.5Mhz) should be derived from this clock.
TX_EN	RMII, RGMII	O	The MAC drives this signal. This signal has multiple functions depending on the selected PHY interface. • RMII: When high, indicates that valid data is being transmitted on the phy_txd_o bus. Synchronous to REF_CLK. • RGMII: Contains TX_EN on the rising edge of TX_CTL, and a logical derivative of TX_EN and TX_ER (TX_EN XOR TX_ER) on the falling edge of TX_CTL.
TX_DATA	RMII, RGMII	O	This is a group of transmit data signals driven by the MAC. It has multiple functions depending on the selected PHY interface. • RMII: Bits[1:0] provide the RMII transmit data. The data is valid only

Table continues on the next page...

Table 11-157. External signals (continued)

Port name	Interface	I/O	Description
			when the TX_EN signal is high. Synchronous to REF_CLK. • RGMII: Bits[3:0] provide serial output Ethernet data
RX_DATA	RMII, RGMII	I	This is a group of data signals received from the PHY. It has multiple functions depending on the selected PHY interface. • RMII: Bits [1:0] provide the RMII receive data. The data is valid only when the RX_DV signal is high. Synchronous to REF_CLK. • RGMII: Bits [3:0] contains the Ethernet input data transferred from the PHY to the media-access controller.
MDC	RMII, RGMII	O	Management Data Clock. The MAC provides timing reference for the MDIO or MII through this periodic clock. This clock is generated from the application clock through a clock divider controlled by MAC_MDIO_ADDRESS[CR].
MDIO	RMII, RGMII	I/O	Transfers control information between the external PHY and the MAC. Data is synchronous to MDC. This signal is an input after reset.
RX_DV	MII, RMII	I	The PHY drives this signal. It has multiple functions depending on the selected PHY interface. • RMII: Contains the crs and data valid information of the Receive interface. Synchronous to REF_CLK.
RX_EN	RGMII	I	In RGMII mode, contains RX_DV on the rising edge of RX_CLK, and a logical derivative of RX_EV and RX_ER (RX_EV XOR RX_ER) on the falling edge of RX_CLK.

11.7.4 Initialization

This section provides the instructions for initializing the DMA or MAC registers in the proper sequence.

11.7.4.1 Initializing DMA

Complete the following steps to initialize the DMA:

1. Provide a software reset. This resets all of the MAC internal registers and logic (bit-0 of DMA_Mode).
2. Wait for the completion of the reset process (poll bit 0 of the DMA_MODE, which is only cleared after the reset operation is completed).
3. Program the following fields to initialize the DMA_SYSBUS_MODE register:
   a. AAL
   b. Fixed burst or undefined burst
   c. Burst mode values in case of AHB bus interface, OSR_LMT in case of AXI bus interface.
   d. If fixed length value is enabled, select the maximum burst length possible on the AXI Bus (bits [7:1])
4. Create a descriptor list for transmit and receive. In addition, ensure that the descriptors are owned by DMA (set bit 31 of descriptor TDES3/RDES3). For more information about descriptors, see Descriptors
5. Program the Transmit and Receive Ring length registers (DMA_CH(#i)_TXDESC_RING_LENGTH (for i = 0; i <= 1) and DMA_CH(#i)_RXDESC_RING_LENGTH (for i = 0; i <= 1)). The ring length programmed must be at least 4.

   NOTE

   The descriptor address from the start to the end of the ring must not cross the 4GB boundary.

6. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TXDESC_LIST_ADDRESS (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1), DMA_CH(#i)_RXDESC_LIST_ADDRESS (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)). Also, program transmit and receive tail pointer registers indicating to the DMA about the available descriptors (DMA_CH(#i)_TXDESC_TAIL_POINTER (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and

DMA_CH(#i)_RXDESC_TAIL_POINTER (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1))

NOTE

For 40-bit or 48-bit addressing mode, program the higher address List registers (DMA_CH[n]_TXDESC_LIST_HADDRESS, DMA_CH[n]_RXDESC_LIST_HADDRESS).

The tailpointer registers must be advanced to the location immediately after the descriptors that are set, for the DMA to know that additional descriptors are available.

7. Program the settings of the following registers for the parameters like maximum burst-length (PBL) initiated by DMA, descriptor skip lengths, OSP in case of TxDMA, RBSZ in case of RxDMA, and so on:
   - DMA_CH(#i)_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)
   - DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)
   - DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)
8. Enable the interrupts by programming the DMA_CH(#i)_Interrupt_Enable (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.
9. Start the Receive and Transmit DMAs by setting SR (bit 0) of the DMA_CH(#i)_RX_CONTROL (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1) and ST (bit 0) of the DMA_CH(#i)_TX_CONTROL (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.
10. Repeat steps 4 to 9 for all the Tx DMA and Rx DMA channels selected in the hardware.

11.7.4.2 Initializing MTL Registers

The Transaction Layer (MTL) registers must be initialized to establish the transmit and receive operating modes and commands.

Complete the following steps to initialize the MTL registers:

1. Program the Tx Scheduling (SCHALG) and Receive Arbitration Algorithm (RAA) fields in MTL_Operation_Mode to initialize the MTL operation in case of multiple Tx and Rx queues.
2. Program the Receive Queue to DMA mapping in MTL_RxQ_DMA_Map0 and MTL_RxQ_DMA_Map1 registers.
3. Program the following fields to initialize the mode of operation in the MTL_TxQ0_Operation_Mode register.
   a. Transmit Store And Forward (TSF) or Transmit Threshold Control (TTC) in case of threshold mode
   b. Transmit Queue Enable (TXQEN) to value 2'b10 to enable Transmit Queue0
   c. Transmit Queue Size (TQS)
4. Program the following fields to initialize the mode of operation in the MTL_RxQ0_Operation_Mode register:
   a. Receive Store and Forward (RSF) or RTC in case of Threshold mode
   b. Flow Control Activation and De-activation thresholds for MTL Receive FIFO (RFA and RFD)
   c. Error Packet and undersized good Packet forwarding enable (FEP and FUP)
   d. Receive Queue Size (RQS)
5. Repeat previous two steps for all MTL Tx and Rx queues selected in the configuration.

11.7.4.3 Initializing MAC

The MAC configuration registers establish the operating mode of the MAC. These registers must be initialized before initializing the DMA.

The following MAC Initialization operations can be performed after DMA initialization. If the MAC initialization is completed before the DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, received frames fill the Rx FIFO and overflow.

1. Provide the MAC address registers: MAC_ADDRESS0_HIGH and MAC_ADDRESS0_LOW. If more than one MAC address is enabled in your configuration, program the MAC addresses appropriately.
2. Program the following fields to set the appropriate filters for the incoming frames in the MAC_PACKET_FILTER register:
   a. Receive All
   b. Promiscuous mode
   c. Hash or Perfect Filter
   d. Unicast, multicast, broadcast, and control frames filter settings

3. Program the following fields for proper flow control in the MAC_Q0_TX_FLOW_CTRL register:
   a. Pause time and other Pause frame control bits
   b. Transmit Flow control bits
   c. Flow Control Busy
4. Program the MAC_INTERRUPT_ENABLE register, as required, and if applicable, for your configuration.
5. Program the appropriate fields in the MAC_CONFIGURATION register. For ex: Inter-packet gap while transmission and jabber disable.
6. Set bit 0 and 1 in MAC_CONFIGURATION register to start the MAC transmitter and receiver.

11.7.5 Application Information

11.7.5.1 Performing Normal Receive and Transmit Operation

During normal operation of the module, normal and transmit interrupts are read, descriptors polled, the DMA is suspended (if it does not own descriptors), and values of current host transmitter or receiver descriptor pointers are read for debugging.

For normal operation, complete the following steps:

1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptors, reading the status of the descriptor owned by the Host (either transmit or receive).
2. Set appropriate values for the descriptors, ensuring that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data.
3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into SUSPEND state. The transmission or reception can be resumed by freeing the descriptors and writing the descriptor tail pointer to Tx/Rx tail pointer register (DMA_CH[n]_TXDESC_TAIL_POINTER and DMA_CH[n]_RXDESC_TAIL_POINTER).
4. The values of the current host transmitter or receiver descriptor address pointer can be read for the debug process (DMA_CH[n]_CURRENT_APP_TXDESC and DMA_CH[n]_CURRENT_APP_RXDESC).
5. The values of the current host transmit buffer address pointer and receive buffer address pointer can be read for the debug process (Register DMA_CH[n]_CURRENT_APP_TXBUFFER and DMA_CH[n]_CURRENT_APP_RXBUFFER).

11.7.5.2 Stopping and Starting Transmission

Complete the following steps to pause the transmission.

NOTE

The steps are provided for Channel 0.

1. Disable the Transmit DMA (if applicable) by clearing Bit 0 (ST) of DMA_CH(#i)_TX_CONTROL (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) Register.
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of MTL_TXQ0_DEBUG Register (TRCSTS is not 01 and TXQSTS=0).
3. Disable the MAC transmitter and MAC receiver by clearing Bit (RE) and Bit 1(TE) of the MAC_Config-uration Register.
4. Disable the Receive DMA (if applicable), after making sure that the data in the Rx FIFO is transferred to the system memory (by reading the appropriate bits of MTL_TXQ0_DEBUG Register, PRXQ=0 and RXQSTS=00).
5. Make sure that both Tx Queue and Rx Queue are empty (TXQSTS is 0 in MTL_TXQ0_DEBUG Register and RXQSTS is 0 in MTL_RXQ0_DEBUG Register).
6. To restart the operation, first start the DMAs, and then enable the MAC Transmitter and Receiver.

NOTE

- Do not change the configuration (such as duplex mode, speed, port, or loop back) when the MAC is actively transmitting or receiving. These parameters are changed by software only when the MAC transmitter and receiver are not active.
- Similarly, do not change the DMA-related configuration when Transmit and Receive DMA are active.

11.7.5.3 Programming Guidelines for Switching to New Descriptor List in RxDMA

Switching to a new descriptor list is different in the Rx DMA compared to the Tx DMA. Switching to a new descriptor list is permitted when the RxDMA is in SUSPEND state, as clarified by the following points:

- Generally, RxDMA prepares the descriptors in advance.
- If the RxDMA goes to SUSPEND due to descriptors not being available, a major failure occurs (software is not able to free the filled-up descriptors/buffers). If this issue is not rectified immediately, frames will be lost because of an RxFIFO Overflow. Therefore, the software is allowed to create a new descriptor list and program the RxDMA to start using it immediately, without going into STOP state.

11.7.5.4 Programming Guidelines for Multi-Channel Multi-Queuing

11.7.5.4.1 Transmit

1. Program the Transmit queue size in the TQS field of MTL_TXQ[n]_OPERATION_MODE register. Based on the value programmed in the TQS field, the size of the queue is determined.

   In the Transmit operation, the number of channels is equal to the number of the queues. Due to this reason, the Channel-to-Queue mapping is fixed.

2. For a queue to be used, the queue must be enabled in TXQEN in the corresponding MTL_TXQ[n]_OPERATION_MODE Register. In DMA configurations, the ST bit of DMA_CH[n]_TX_CONTROL Register and corresponding TXQEN in MTL_TXQ[n]_OPERATION_MODE Register needs to be enabled.
3. The scheduling method needs to be programmed in SCHALG of MTL_OPERATION_MODE register.
4. Program the MTL_TXQ[n]_Quantum_Weight for DCB queue as per the selected algorithm. In case of CBS algorithm in AVB queues, the MTL_TXQ[n]_ETS_CONTROL, MTL_TXQ[n]_SENDSLOPECREDIT, MTL_TXQ[n]_HICREDIT and MTL_TXQ[n]_LOCREDIT registers also need to be programmed as required.
5. If DCB is enabled and PFC function is required, program MAC_TXQ_PRTY_MAP0 Register to assign a fixed priority to the queue. This priority assigned is used for determining if the corresponding queue should stop transmitting packet based on the received PFC packet.

11.7.5.4.2 Receive

1. Program the Receive queue size in the RQS field of MTL_RXQ[n]_OPERATION_MODE Register. Based on the value programmed in RQS field, the size of the queue is determined.
2. Enable the Receive Queues 0 to 4 in the fields RXQ0EN to RXQ4EN in MAC_RXQ_CTRL0 Register for AV or DCB. In DMA configurations, SR bit of

statically or dynamically mapped DMA_CH[n]_RX_CONTROL Register and corresponding RXQ[n]_EN in MAC_RXQ_CTRL0 Register needs to be enabled.

3. The MAC routes the Rx packets to the Rx Queues based on following packet types:
   a. AV PTP Packets: Based on the programming of AVPTPQ in MAC_RXQ_CTRL1 Register.
   b. AV Untagged Control packets: Based on the programming of AVCPQ in MAC_RXQ_CTRL1 Register.
   c. Data Center Bridging (DCB) related Link Layer Discovery Protocol (LLDP) packets. Program DCBCPQ in MAC_RXQ_CTRL1 Register to indicate to MAC which queue should get the DCB packets.
   d. VLAN Tag Priority field in VLAN Tagged packets: Program PSRQ4-0 of the MAC_RXQ_CTRL2 and MAC_RXQ_CTRL3 Register for the routing of tagged packets based on the USP (user Priority) field of the received packets to the Rx Queues 0 to 4.
   e. The AV tagged control and data packets are also routed based on PSRQ field of the MAC_RXQ_CTRL2 and MAC_RXQ_CTRL3 registers.

NOTE

The priorities set in PSRQ4-0 should be unique.

4. If multiple RX DMA channels are enabled, the following programming should be done for proper arbitration and mapping:
   a. Program the RAA field of MTL_OPERATION_MODE register to select the arbitration algorithm to decide which RxQ is read out from the RxFIFO memory.
   b. Program the MTL_RXQ[n]_CONTROL to decide the weights and the packet arbitration for each RxQ.
   c. If static mapping is programmed in MTL_RXQ_DMA_MAP[n] register (RXQ[n]DADMACH is reset to 0), bits RXQx2DMA and others need to be programmed to select the channel for which each queue is mapped.
   d. Set RXQ[n]DADMACH bit in MTL_RXQ_DMA_MAP0 Register to select dynamic mapping of packets in each RxQueue.
   e. In dynamic channel mapping, the routing of a packet to a specific RxDMA channel is decided by the value of DCS field in the lowest MAC Address Register.

11.7.5.4.2.1 Programming Guidelines for Recovering from DMA Channel Failure

When the DMA channel issues a bus error, follow these steps to recover from the failure.

Recovering from the Receive DMA Channel Failure

1. Set the RPF bit to 1. This flushes all the packets one after the other.

This step is optional. However, setting this bit prevents HOL (head-of-line) blocking in the Rx queues when packets sent to the RXDMA are stopped due to bus error.

2. Reprogram the specific Registers of the DMA channel.
3. Start the DMA channel.

Recovering from the Transmit DMA Channel Failure

1. Stop the specific DMA channel, even if it is in active state.
2. Flush the corresponding MTL queue.
3. Reprogram the specific Registers of the DMA channel.
4. Start the DMA channel.

NOTE

Due to the known limitations in the design, reprogramming the DMA channel registers might not always be successful in recovering from a Bus Error. If the module is not fully functional after reprogramming the DMA, as a workaround, issue a Soft Reset to recover from the Bus Error.

11.7.5.5 Programming Guidelines for IEEE 1588 Timestamping

11.7.5.5.1 Initialization Guidelines for System Time Generation

You can enable the timestamp feature by setting Bit 0 of the MAC_TIMESTAMP_CONTROL Register. However, it is essential that the timestamp counter be initialized after this bit is set. Complete the following steps during the module initialization:

1. Mask the Timestamp Trigger interrupt by clearing the bit 16 of MAC_INTERRUPT_ENABLE Register.
2. Set Bit 0 of MAC_TIMESTAMP_CONTROL Register to enable timestamping.
3. Program MAC_SUB_SECOND_INCREMENT Register based on the PTP clock frequency.
4. If you are using the Fine Correction approach, program MAC_Timestamp_Addend and set Bit 5 of MAC_TIMESTAMP_CONTROL Register.
5. Poll the MAC_TIMESTAMP_CONTROL Register until Bit 5 is cleared.
6. Program Bit 1 of MAC_TIMESTAMP_CONTROL Register to select the Fine Update method (if required).
7. Program MAC_SYSTEM_TIME_SECONDS_UPDATE Register and MAC_SYSTEM_TIME_NANOSECONDS_UPDATE Register with the appropriate time value.
8. Set Bit 2 in MAC_TIMESTAMP_CONTROL Register.

9. The timestamp counter starts operation as soon as it is initialized with the value written in the Timestamp Update registers. If one-step timestamping is enabled
   a. To enable one-step timestamping, program Bit 27 of the TDES3 Context Descriptor.
   b. Program registers MAC_TIMESTAMP_INGRESS_ASYM_CORR and MAC_TIMESTAMP_EGRESS_ASYM_CORR to update the correction field in PDelay_Req PTP messages.
10. Enable the MAC receiver and transmitter for proper timestamping.

NOTE

If timestamp operation is disabled by clearing Bit 0 of MAC_TIMESTAMP_CONTROL Register, repeat all these steps to restart the timestamp operation.

11.7.5.5.2 System Time Correction

11.7.5.5.2.1 Coarse Correction Method

To synchronize or update the system time in one process (coarse correction method):

1. Set the offset (positive or negative) in the Timestamp Update registers(MAC_SYSTEM_TIME_SECONDS_UPDATE and MAC_SYSTEM_TIME_NANOSECONDS_UPDATE).
2. Set Bit 3 (TSUPDT) of MAC_TIMESTAMP_CONTROL REGISTER.

The value in the Timestamp Update registers is added to or subtracted from the system time when the TSUPDT bit is cleared.

11.7.5.5.2.2 Fine Correction Method

To synchronize or update the system time to reduce system-time jitter (fine correction method):

1. With the help of the algorithm, calculate the rate by which you want to make the system time increments slower or faster.
2. Update the MAC_TIMESTAMP_ADDEND with the new value and set Bit 5 of the MAC_TIMESTAMP_CONTROL Register.
3. Wait for the time for which you want the new value of the Addend register to be active. You can do this by enabling the Timestamp Trigger interrupt after the system time reaches the target value.
4. Program the required target time in MAC_PPS[n]_TARGET_TIME_SECONDS Register and MAC_PPS[n]_TARGET_TIME_NANOSECONDS Register.

5. Enable the Timestamp interrupt in bit 12 of MAC_INTERRUPT_ENABLE register.
6. Set bit 4 in Register MAC_Timestamp_Control.
7. When this trigger causes an interrupt, read MAC_INTERRUPT_STATUS Register.
8. Reprogram MAC_TIMESTAMP_ADDEND Register with the old value and set bit 5 again.

11.7.5.6 Programming Guidelines for AV Feature

After you enable the AV feature in the module controller, there are several programming tasks to be followed:

- Initializing the DMA for QOS-AHB configurations only
- Enabling slot number checking
- Enabling average bits per slot reporting
- Disabling flow control for AV-enabled queues (transmit and receive flow control)

11.7.5.6.1 Initializing the DMA in Audio Video Feature

The first step in programming the AV feature in a QOS-AHB configuration is to initialize the DMA.

Use this initialization sequence for QOS-AHB/QOS-AXI configurations with AV feature.

1. Provide a software reset to reset all QOS internal registers and logic (bit 0 in DMA_MODE register).
2. Wait for the completion of the reset process. Poll bit 0 of the DMA_MODE register), which is cleared only after the reset operation is completed.
3. Program the fields to initialize the DMA register by setting the values in DMA_MODE register.
4. Create a proper descriptor list for transmit and receive. In addition, ensure that the DMA owns the Transmit and Receive descriptors. When OSF mode is used, at least two TX descriptors are required.

   For more information about descriptors, see Descriptors.

5. Make sure that your software creates three or more different transmit or receive descriptors in the list before reusing any of the descriptors.
6. Program the Transmit and Receive Ring length registers (DMA_CH(#i)_TXDESC_RING_LENGTH (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RXDESC_RING_LENGTH (for i = 0; i <=

DWC_EQOS_NUM_DMA_RX_CH-1)). The ring length programmed must be at least 4.

7. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TXDESC_LIST_ADDRESS (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1), DMA_CH(#i)_TXDESC_LIST_ADDRESS (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)). In addition, you must program the Transmit and Receive tail pointer registers indicating to the DMA about the available descriptors (DMA_CH(#i)_TXDESC_TAIL_POINTER (for i = 0; i <= DWC_EQOS_NUM_D-MA_TX_CH-1) and DMA_CH(#i)_RXDESC_TAIL_POINTER (for i = 0; i <= DWC_EQOS_NUM_D-MA_RX_CH-1)).
8. Program the following fields to initialize the mode of operation in the MTL_TXQ0_OPERATION_MODE register:
   a. Transmit Store And Forward (TSF)
   b. Transmit Threshold Control (TTC)
   c. Transmit Queue Enable (TXQEN) to value 2‘b10 to enable Transmit Queue0
   d. Transmit Queue Size (TQS)
9. Enable the interrupts by programming the DMA_CH(#i)_INTERRUPT_ENABLE (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.
10. Repeat steps 4 through 9 for all additional channels of AV feature.
11. Program the CBS control register, idleSlope, sendSlope, hiCredit, and loCredit registers of the AV Queues.
12. Start the Receive and Transmit DMA by setting bit 0 of the DMA_CH(#i)_TX_CONTROL (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register and bit 0 of the DMA_CH(#i)_RX_CONTROL (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1) register.

11.7.5.6.2 Enabling Slot Number Checking

You can enable slot number checking to specify the intervals at which the DMA channels mapped to AV Queues fetch the frames from the AHB/AXI system bus.

These steps should be completed after step 11 and before step 12 of "Initializing DMA".

You can use the slot number check feature to specify the intervals at which the DMA Channels mapped to AV Queues fetch the frames from the AHB/AXI system bus. This feature is useful for a uniform and periodic transfer of the AV traffic from the host memory. The feature is available only when you enable timestamping and program the MAC_SUB_SECOND_INCREMENT register. To enable the slot number checking:

1. Enable timestamping by following the steps described in "Initialization Guidelines for System Time Generation".
2. Make sure that the SLOTNUM field (bits 22:19) of TDES3 Normal Descriptor (Read Format) contains a valid slot number. You can read the current reference slot number from the DMA_CH(#i)_Slot_Function_Control_Status (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1).
3. Set Bit 0 (ESC) of the Slot Function Control and Status register of a channel to enable the slot number checking.

11.7.5.6.3 Enabling Average Bits Per Slot Reporting

You can enable the reporting of the average bits that are transmitted in a slot.

The CBS Status register of the additional AV channels provides information about the average bits that are transmitted in a slot. The software can asynchronously read this register to retrieve information about the average bits transmitted per slot. To enable average bits per slot reporting:

1. Enable timestamping by following the steps described in the Initialization Guidelines for System Time Generation.
2. Program Bits [6:4], SLC, of the MTL_TXQ[n]_ETS_CONTROL register of a channel with the number of slots over which the average transmitted bits per slot need to be computed.
3. Enable Bit 9(ABPSSIE) of the MTL_Q[n]_INTERRUPT_CONTROL_STATUS register of a channel to generate the average bits per slot interrupt.

NOTE

- The frequency of this interrupt depends on the value programmed in step 2. For example, when you program value 0 in the SLC field, the interrupt is generated at every 125 microsecond.
- When not required, you can disable this interrupt to stop the interrupt flooding.

4. Read Bits [16:0], ABS, from the MTL_TXQ[n]_ETS_STATUS register of a channel on each interrupt.

NOTE

The software can read the ABS bits in polling mode even if the ABPSIE bit is not enabled. When high, bit 1 (ABPSIS) of the MTL_TXQ[n]_ETS_STATUS register indicates that a new value is updated in the ABS field.

11.7.5.6.4 Disabling Flow Control for AV Enabled Queues

11.7.5.6.4.1 Transmit Flow

Program the EHFC (Enable Hardware Flow Control) bit of corresponding Rx Queue's MTL_RXQ[n]_OPERATION_MODE register to 0.

11.7.5.6.4.2 Receive Flow Control

Program the PSTQ[n] field corresponding to AV enabled Tx Queue in MAC_TXQ_PRTY_MAP0/1 register to 0.

11.7.5.6.5 Programming Guidelines for Flexible Pulse-Per-Second Output

After you enable the Flexible Pulse-Per-Second Output feature in the module controller, you can perform the following tasks:

- Generating Single Pulse on PPS
- Generating Next Pulse on PPS
- Generating a Pulse Train on PPS
- Generating an Interrupt without Affecting the PPS

11.7.5.6.5.1 Generating Single Pulse on PPS

To generate single pulse on PPS:

1. Program 11 or 10 (for interrupt) in Bits [6:5], TRGTMODSEL, of MAC_PPS_CONTROL Register. This instructs the MAC to use the Target Time registers (MAC_PPS0_TARGET_TIME_SECONDS and MAC_PPS0_TARGET_TIME_NANOSECONDS) for start time of PPS signal output.
2. Program the start time value in the Target Time registers (MAC_PPS0_TARGET_TIME_SECONDS and MAC_PPS0_TARGET_TIME_NANOSECONDS).
3. Program the width of the PPS signal output in MAC_PPS(#i)_WIDTH (for i = 0; i <= 3) Register.
4. Program Bits [3:0], PPSCMD, of MAC_PPS_CONTROL to 0001. This instructs the MAC to generate single pulse on the PPS signal output at the time programmed in the Target Time registers.

11.7.5.6.5.2 Generating Next Pulse on PPS

When the PPSCMD is executed (PPSCMD bits = 0), you can cancel the pulse generation by giving the Cancel Start Command (PPSCMD=0011) before the programmed start time elapses. You can also program the behavior of the next pulse in advance.

To program the next pulse:

1. Program the start time for the next pulse in the Target Time registers. This time should be more than the time at which the falling edge occurs for the previous pulse.
2. Program the width of the next PPS signal output in MAC_PPS(#i)_WIDTH (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1).
3. Program Bits [3:0], PPSCMD, of MAC_PPS_CONTROL to generate a single pulse after the time at which the previous pulse is de-asserted. This instructs the MAC to generate single pulse on the PPS signal output, at the time programmed in Target Time registers.

   If you give this command before the previous pulse becomes low, then the new command overwrites the previous command and the QOS may generate only 1 extended pulse.

11.7.5.6.5.3 Generating a Pulse Train on PPS

To generate a pulse train on PPS:

1. Program 11 or 10 (for interrupt) in Bits [6:5], TRGTMODSEL, of MAC_PPS_Control Register. This instructs the MAC to use the Target Time registers for start time of the PPS signal output.
2. Program the start time value in the Target Time registers.
3. Program the interval value between the train of pulses on the PPS signal output in MAC_PPS(#i)_INTERVAL (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) Register.
4. Program the width of the PPS signal output in MAC_PPS(#i)_WIDTH (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) Register.
5. Program Bits[3:0], PPSCMD, of MAC_PPS_CONTROL Register to 0010. This instructs the MAC to generate train of pulses on the PPS signal output with start time programmed in Target Time registers.

   By default, the PPS pulse train is free-running unless stopped by ‘STOP Pulse train at time’ or ‘STOP Pulse Train immediately’ commands.

6. Program the stop value in the Target Time registers. Ensure that Bit 31 (TSTRBUSY) of MAC_PPS(#i)_TARGET_TIME_NANOSECONDS (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) Register is reset before programming the Target Time registers again.
7. Program the PPSCMD field (bit 3:0) of MAC_PPS_CONTROL to 0100. This stops the train of pulses on PPS signal output after the programmed stop time specified in Step 6 elapses.

   You can stop the pulse train at any time by programming 0101 in the PPSCMD field. Similarly, you can cancel the Stop Pulse train command (given in Step 7) by programming 0110 in the PPSCMD field before the time (programmed in Step 6) elapses. You can cancel the pulse train generation by programming 0011 in the PPSCMD field before the programmed start time (in Step 2) elapses.

11.7.5.6.5.4 Generating an Interrupt without Affecting the PPS

You can use bits[6:5], TRGTMODSEL, of the MAC_PPS_CONTROL Register to program the Target Time registers to do any one of the following:

- Generate only interrupts.
- Generate interrupts and the PPS start and stop time.
- Generate only PPS start and stop time.

To program the Target Time registers to generate only interrupt events:

1. Program 00 (for interrupt) in Bits [6:5], TRGTMODSEL, of MAC_PPS_CONTROL Register. This instructs the MAC to use the Target Time registers for target time interrupt.
2. Program a target time value in the Target Time registers. This instructs the MAC to generate an interrupt when the target time elapses.

   If Bits [6:5], TRGTMODSEL, are changed (for example, to control the PPS), then the interrupt generation is overwritten with the new mode and new programmed Target Time register value.

11.7.5.6.6 Programming Guidelines for VLAN Filtering on Receive

To program VLAN filtering on receive:

1. Program MAC_VLAN_TAG register for the following bit to select the filtering method:

a. ETV: Enable 12-Bit VLAN Tag Comparison or 16-bit VLAN Tag comparison.
b. VTHM: VLAN Tag Hash Table Match Enable.
c. ERIVLT: Enable inner VLAN Tag or outer VLAN Tag (to enable the inner or outer VLAN Tag filtering, Double VLAN Processing should enabled by setting EDVLP)
d. ERSVLM: Enable Receive S-VLAN Match or C-VLAN match (for S-VLAN processing to be enabled, set ESVL)
e. DOVLTC: Ignores VLAN Type for Tag Match
f. VTIM: to enable VLAN Tag Inverse Match instead of the normal VLAN Tag matching

2. Program VL of MAC_VLAN_Tag Register for the 12-bit or 16-bit VLAN tag.
3. If Hash filtering of VLAN tag is enabled, program MAC_VLAN_HASH_TABLE Register. When ETV bit is reset, upper 4 bits of the calculated CRC-32 of VLAN Tag are inverted and used to index the content of MAC_VLAN_Hash_Table register. When ETV bit is set, upper 4 bits of calculated CRC-32 of VLAN Tag are used to index the content of MAC_VLAN_HASH_TABLE register. For example, when ETV bit is set, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table. When ETV bit is reset a hash value of 4'b1000 selects Bit 7 of the VLAN Hash table.

11.7.5.6.7 Programming Guidelines for Extended VLAN Filtering and Routing on Receive

For the indirect access of the per VLAN Tag registers, follow these steps.

- Write

  a. Write the required data into the MAC VLAN Tag Data register.

  b. Program the VLAN Tag Control Register's OFS field with the required Filter Register's offset and command type to the CT field. For a write command, set this bit to 0.

  c. Write 1 to the OB field and wait till the OB bit is reset to do the next write. This will guarantee that the appropriate VLAN Tag Filter Register has been programmed.

- Read

  a. Program the VLAN Tag Control Register's OFS Field with the required register's offset and command type to the CT field. For a read command, set this bit to 1.

  b. Write 1 to the OB field and wait till the OB bit is reset. The appropriate VLAN Tag Filter register's value is available in the MAC VLAN Tag Data Register.

11.7.5.6.8 Programming Sequence for Queue/Channel Based VLAN Inclusion Register

To program the queue/channel-based VLAN inclusion register:

NOTE

Indirect VLAN include registers are not accessed while setting the CBTI bit.

1. Set the CBTI bit of MAC_VLAN_INCL register to 1, to enable queue/channel based VLAN Tag insertion on all transmitted packets. This bit must be set before any indirect access to the queue/channel specific MAC_VLAN_INCL(#i) register.
2. Program the VLAN Tag and VLAN Type to be inserted in packets from a particular queue/channel in VLT and CSVL fields of MAC_VLAN_INCL register; corresponding offset address in ADDR field (0 for queue/channel 0, 1 for queue/channel 1, and so on) must be set. Set the RDWR bit to 0 to indicate write access. The write to byte 0 (byte 3 in Big Endian mode) of MAC_VLAN_INCL register initiates access to indirect access MAC_VLAN_INCL(#i) register.
3. The BUSY bit of MAC_VLAN_INCL register is set by the module to indicate the progress of access to indirect access MAC_VLAN_INCL(#i) register. On completion of the access, the BUSY bit is cleared. The application must not attempt subsequent access to MAC_VLAN_INCL(#i) register when the BUSY bit is 1.
4. Repeat step 2 and step 3 to program VLAN Tag and VLAN Type to be inserted in packets from the remaining queues/channels. The application must ensure that the required VLAN Tag and VLAN Type for all the queues/channels are programmed; otherwise unintended VLAN Tag and VLAN Type might be inserted.

11.7.5.7 Programming Guidelines for EST

Program the gate control values and time intervals in the Software Owned Gate Control List (SWOL) along with the other EST related registers that are described in ENET_QOS register descriptions to appropriate values. The following sub-sections provide step by step details for programming the GCL and the other EST related registers.

11.7.5.7.1 Programming the GCL and GCL Linked Registers

To program the Gate Control List (GCL) and the four other registers implemented per GCL:

1. The GCL and the four other GCL-linked registers should be accessed via indirect addressing using the MTL_EST_GCL_CONTROL and MTL_EST_GCL_DATA registers. The SWOL bit of the MTL_EST_STATUS register indicates if GCL0 or GCL1 is owned by software.

2. To program the GCL, write the 32-bit write data to MTL_EST_GCL_DATA register. Then program TL_EST_GCL_CONTROL register to write the write address and other control information.
3. In the MTL_EST_GCL_DATA register, Write Data consists of up to 8 bits (5 configurable, 3 reserved) of Gate Controls and up to 24 bits (configurable) of Time Interval. Gate Close is indicated by programming a '0' and Gate Open is indicated by programming a '1'. For a 4-TC and 20-bit Time Interval Configuration, the data width is 24-bits and the remaining 8-bits are reserved/read-only. The data should be written in the following format.

   {8'h0, TC3, TC2, TC1, TC0, 20-bit Time Interval} where TCx = 0 or 1.

4. MTL_EST_GCL_CONTROL register: Program the SRWO bit to 1 (to start a Write Op) and program the address and R/W fields appropriately.
5. Poll and check for the SRWO bit to be cleared by hardware to indicate the completion of the previous operation before initiating a new R/W operation via the same indirect addressing mode.
6. Repeat steps 3, 4, 5 until the programming of the GCL is completed.
7. Using the same indirect addressing method described above, program the BTR, CTR, TER and LLR registers. Set the GCRR bit in the MTL_EST_GCL_CONTROL register appropriately. The GCRR bit interprets the address field as belonging to these registers (instead of the GCL).

After programming of the GCL and the related registers, program the MTL_EST_CONTROL register to allow hardware to own and process the GCL.When the List Length (as indicated in LLR) is 1, the associated Time Interval should be smaller than the value of the Cycle Time Register. Otherwise, an error is reported (as detailed in the Error handling section) as a single set of gate controls add no value in the TSN context.

NOTE

The time unit in all the GCL related registers is seconds and nanoseconds. In cases where internally generated PTP System Time is used, the nanoseconds field must be programmed to use the Digital Rollover mode. (TSCTRLSSR field of MAC_TIMESTAMP_CONTROL must be set to value '1')

11.7.5.7.2 Programming the EST Registers

After completing the steps mentioned in "Programming the GCL and GCL Linked Registers" , program the MTL_EST_CONTROL register.

1. Set the Current Time Offset Value and Time Internal Left Shift fields of the MTL_EST_CONTROL register appropriately. Also, set the Enable EST (EEST) and Switch to SWOL (SWOL) bits.

NOTE

The CTOV recommendations for GMII for SPRAM configurations are:

- 96 * Tx clock period, for 32 and 64 bit data width configurations.
- 128 * Tx clock period for 128 bit data width configurations.

The CTOV recommendations for GMII for non-SPRAM configurations are:

- 30 * Tx clock period, when SA/VLAN insertion is enabled.
- 22 * Tx clock period, when SA/VLAN insertion is not enabled.

2. This will enable the hardware to own and process the new GCL and make a switch to the new GCL at the BTR value. The hardware provides an interrupt (if enabled) when the switch to the new list happens.
3. Appropriate action has to be taken by software to address any other interrupts (explained in the Inter-rupts section) received during the hardware execution of the GCL.

Set the SSWL (Switch to Software Owned List) bit in the MTL_EST_CONTROL register to handoff to hardware. Software is not allowed to write to the GCL and GCL linked registers when the SSWL bit is set, because the new GCL might be in use by the hardware.

The SSWL is reset/cleared by the hardware when it successfully switches to the new list. The hardware also flips the SWOL bit to indicate the new GCL that the software owns.

To install a new GCL, program the GCL it owns (indicated by SWOL bit) as described in "Programming the GCL and GCL Linked Registers" and then program the MTL_EST_CONTROL register as described above. Ensure that the new BTR is set to an appropriate value to avoid BTRError that might need software intervention in some cases.

To avoid transmission overruns, the packet length (frame size) information should be available at all times. Therefore, in the DMA configurations, program the packet length in the first descriptor of every Tx frame. Similarly, in the MTL configuration, provide the packet length in the control word.

NOTE

To avoid transmission overruns, the Packet Length provided in the Transmit Descriptor should account for the SA and VLAN insertion, if applicable, that is, Packet Length should represent the actual packet length on the Ethernet line.

11.7.5.8 Programming the Launch Time in Time-Based Scheduling

The Launch Time is programmed in the Enhanced Normal Transmit Descriptors in DMA configurations and is driven as a control word in MTL configurations as follows:

The OSTC and Launch Time features are mutually exclusive and should not be used together; in case of a conflict (if OSTC = LTV = 1 in MTL configuration), priority is given to OSTC and the Launch Time is ignored.

In DMA configuration, if a context descriptor is received with a valid OSTC values immediately before receiving a first normal descriptor with LTV bit set, then the LTV is ignored.

11.7.5.9 Programming Guidelines for Media Clock Generation and Recovery

11.7.5.9.1 Programming Guidelines for Media Clock Generation

1. To set the PPS instance in Media Clock generation mode, program the appropriate Presentation Time Control (supported generation modes "1001-1011") to PPSCTRL_PPSCMD (for 0th instance)/PPSCMD#i (for 1,2,3 instances) of MAC_PPS_CONTROL register.
2. Based on the selected PPS instance, application must drive the appropriate trigger signal to the corresponding mcg_pst_trig_i[#i].
3. Based on the programmed mode, DUT captures the timestamp and programs it in the MAC_PPS(#i)_TARGET_TIME_SECONDS register. Then, mcgr_dma_req_o[#i] is set.
4. For every request generated by the DUT, the module reads the corresponding MAC_PPS(#i)_TARGET_TIME_SECONDS register and acknowledge the read request by asserting the corresponding mcgr_dma_ack_i[#i].

11.7.5.9.2 Programming Guidelines for Media Clock Recovery

1. Enable the Current Presentation Time (CPT) Counter by setting the PTGE field of MAC_TIMESTAMP_CONTROL register. In addition to programming the initialization values for the System Time, update the MAC_PRESN_TIME_UPDT register with the equivalent Presentation Time init value. Only then the TSINIT field of MAC_TIMESTAMP_CONTROL register is set.
2. The Increment values used for the System time is also used for the Current Presentation time. This is because, the increment value is in Sub-seconds and Sub-nanoseconds.
3. When an update is needed, along with programming the update values for the System Time, the MAC_PRESN_TIME_UPDT register should be updated with the equivalent Presentation Time update value (32-bit ns). Finally, TSUPDT field of MAC_TIMESTAMP_CONTROL register must be set for the update to happen.
4. Program the MCGREN#i of MAC_PPS_CONTROL register to enable the PPS instance to operate in MCGR mode.
5. To set the PPS instance in Media Clock recovery mode, program the appropriate Presentation Time Control (supported recovery modes "0001 - 0011") to PPSCTRL_PPSCMD (for 0th instance)/PPSCMD#i (for 1,2,3 instances) of MAC_PPS_Control register.
6. After PPS instance is set in recovery mode, corresponding mcgr_dma_req_o[#i] is set by the DUT. For every request generated by the DUT, program the target presentation time into the MAC_PPS(#i)_TARGET_TIME_SECONDS register and acknowledge the request by asserting the corresponding mcgr_d-ma_ack_i[#i]. Acknowledgment can be given before/after programming the Target presentation time.
7. Observe the recovered media clock on the corresponding ptp_pps_o[#i].

11.7.5.10 Programming Guidelines for ECC Protection for Memories

1. Enable the ECC feature for the respective memory by setting the appropriate bit in MTL_ECC_CONTROL register.
2. A correctable interrupt (sbd_sfty_ce_intr_o) or an uncorrectable interrupt (sbd_sfty_ue_intr_o) are generated to indicate to the application if any correctable/ uncorrectable/address errors are detected. Appropriate status is indicated in the DMA/MTL_ECC_INTERRUPT_STATUS register.

3. Debug mode is provided for each memory to specify errors.

NOTE

Enable the ECC feature before the traffic is online (or after the reset), otherwise false interrupts might be triggered.

11.7.5.10.1 Programming Guidelines for ECC Hardware Error Injection (Debug Mode)

1. Enable the ECC error injection feature for MTL TX/RX and DMA TSO, by setting the appropriate bit in the MTL_DBG_CTL register.
2. Enable the ECC error injection feature for the EST memory by setting the appropriate bit in the EST_GCL_CONTROL register.
3. Enable the ECC error injection for RX Parser memory by setting the appropriate bit in the MTL_RXP_INDIRECT_ACC_CONTROL_STATUS register. To access Rx Parser memory in debug mode, disable the Rx Parser feature by setting the FRPE bit of MTL_OPERATION_MODE register to 0.
4. Where multiple CSR writes are required, for writing single data word into the memory, the application should ensure that all the CSR writes corresponding to one memory write should have the same value for the error injection control word.

11.7.5.11 Programming Guidelines for On-Chip Datapath Parity Protection

Follow the below steps for on-chip datapath parity protection:

1. Set the EDPP bit of MTL_DPP_CONTROL register to enable the generation of parity and detection of parity Mismatch on datapath.
2. An uncorrectable interrupt (sbd_sfty_ue_intr_o) is generated to indicate to the application whether any parity Mismatches are detected and the appropriate status will be indicated in DMA/MTL_SAFETY_INTERRUPT_STATUS and MAC_DPP_FSM_INTERRUPT_STATUS register.
3. Debug mode is supported for each parity generator, to insert error.

NOTE

To avoid false safety interrupts, enable the datapath parity protection before the start of Rx or Tx traffic.

11.7.5.12 Programming Guidelines for FSM Parity and Timeout

To program the FSM parity and timeout:

1. Set the PRTYEN and TMOUTEN fields of MAC_FSM_CONTROL register to enable the FSM parity and timeout feature respectively.
2. For parity error detection, force the FSMs to enter into a state with even number of 1s and wait for the safety uncorrectable interrupt to be set with FSMPES of MAC_DPP_FSM_INTERRUPT_STATUS.
3. For Error Injection mode in FSM parity, select the appropriate clock domain for which parity error injection should be set using the [23:16] bits of MAC_FSM_CONTROL register. Wait for the safety uncorrectable interrupt to be set with FSMPES of MAC_DPP_FSM_INTERRUPT_STATUS.
4. For FSM Timeouts, program the large and normal mode values indicated by LTMRMD and NTMRMD of MAC_FSM_ACT_TIMER register.
5. Select large or normal mode tic generation per clock domain by using the [31:24] bits of MAC_FSM_CONTROL Register.
6. Set the TMR field of the MAC_ACT_TIMER field with the appropriate number of CSR clock cycles used to generate 1-microsecond tic.
7. Force the FSM in a particular clock domain to be in an active state for Timeout duration (for example, T-2T). Check for the safety interrupt and the status bit for the corresponding clock domain getting set in [15:8] bits of MAC_DPP_FSM_INTERRUPT_STATUS register.
8. For Error Injection mode in FSM timeout, select the appropriate clock domain for which timeout error injection must be set using the [15:8] bits of MAC_FSM_CONTROL register. Wait for the safety uncorrectable interrupt along with the corresponding error status set in MAC_DPP_FSM_INTERRUPT_STATUS.
9. For application/CSR interface timeout, only normal mode tic generation is used. Based on the timeouts of the configured interface, appropriate fields (MSTTES, SLVTES) of MAC_DPP_FSM_INTERRUPT_STATUS are set along with the safety interrupt.

11.7.6 Memory Map and register definition

This section includes the ENET_QOS module memory map and detailed descriptions of all registers.

11.7.6.1 ENET_QOS register descriptions

11.7.6.1.1 ENET_QOS memory map

ENET_QOS base address: 4043_C000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)

11.7.6.1.2.3 Fields

Field	Description
31 —	Reserved
30-28 SARC	Source Address Insertion or Replacement Control This field controls the source address insertion or replacement for all transmitted packets. Bit 30 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits[29:28]: 2'b0x: - The mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation. 2'b10: - If Bit 30 is set to 0, the MAC inserts the content of the MAC Address 0 registers in the SA field of all transmitted packets. - If Bit 30 is set to 1 and the Enable MAC Address Register 1 option is selected while configuring the core, the MAC inserts the content of the MAC Address 1 registers in the SA field of all transmitted packets. 2'b11: - If Bit 30 is set to 0, the MAC replaces the content of the MAC Address 0 registers in the SA field of all transmitted packets. - If Bit 30 is set to 1 and the MAC Address Register 1 is enabled, the MAC replaces the content of the MAC Address 1 registers in the SA field of all transmitted packets. Note: - Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. 000 - mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation 010 - Contents of MAC Addr-0 inserted in SA field 011 - Contents of MAC Addr-0 replaces SA field 110 - Contents of MAC Addr-1 inserted in SA field 111 - Contents of MAC Addr-1 replaces SA field
27 IPC	Checksum Offload When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled. The Layer 3 and Layer 4 Packet Filter and Enable Split Header features automatically selects the IPC Full Checksum Offload Engine on the Receive side. When any of these features are enabled, you must set the IPC bit. 0 - IP header/payload checksum checking is disabled 1 - IP header/payload checksum checking is enabled
26-24 IPG	Inter-Packet Gap These bits control the minimum IPG between packets during transmission. Inter-Packet Gap These bits control the minimum IPG between packets during transmission.

Table continues on the next page...

Field	Description
	This range of minimum IPG is valid in full-duplex mode. In the half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered. When a JAM pattern is being transmitted because of backpressure activation, the MAC does not consider the minimum IPG. The above function (IPG less than 96 bit times) is valid only when EIPGEN bit in MAC_EXT_CONFIGURATION register is reset. When EIPGEN is set, then the minimum IPG (greater than 96 bit times) is controlled as per the description given in EIPG field in MAC_EXT_CONFIGURATION register. 000 - 96 bit times IPG 001 - 88 bit times IPG 010 - 80 bit times IPG 011 - 72 bit times IPG 100 - 64 bit times IPG 101 - 56 bit times IPG 110 - 48 bit times IPG 111 - 40 bit times IPG
23 GPSLCE	Giant Packet Size Limit Control Enable When this bit is set, the MAC considers the value in GPSL field in MAC_EXT_CONFIGURATION register to declare a received packet as Giant packet. This field must be programmed to more than 1,518 bytes. Otherwise, the MAC considers 1,518 bytes as giant packet limit. When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1,518 bytes (1522 bytes for tagged packet). The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9,018 bytes (9,022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2,000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit should be less than the watchdog limit to get the giant packet status. 0 - Giant Packet Size Limit Control is disabled 1 - Giant Packet Size Limit Control is enabled
22 S2KP	IEEE 802. IEEE 802.3as Support for 2K Packets When this bit is set, the MAC considers all packets with up to 2,000 bytes length as normal packets. When the JE bit is not set, the MAC considers all received packets of size more than 2K bytes as Giant packets. When this bit is reset and the JE bit is not set, the MAC considers all received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. For more information about how the setting of this bit and the JE bit impact the Giant packet status, see the Table, Gaint Packet Status based on S2KP and JE Bits. Note: When the JE bit is set, setting this bit has no effect on the giant packet status. 0 - Support upto 2K packet is disabled 1 - Support upto 2K packet is Enabled
21 CST	CRC stripping for Type packets When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application.

Table continues on the next page...

Field	Description
	CRC stripping for Type packets When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application. Note: For information about how the settings of the ACS bit and this bit impact the packet length, see the Table, Packet Length based on the CST and ACS Bits. 0 - CRC stripping for Type packets is disabled 1 - CRC stripping for Type packets is enabled
20 ACS	Automatic Pad or CRC Stripping When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. Automatic Pad or CRC Stripping When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. All received packets with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all incoming packets to the application, without any modification. Note: For information about how the settings of CST bit and this bit impact the packet length, see the Table, Packet Length based on the CST and ACS Bit . 0 - Automatic Pad or CRC Stripping is disabled 1 - Automatic Pad or CRC Stripping is enabled
19 WD	Watchdog Disable When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16,383 bytes. When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2,048 bytes. 0 - Watchdog is enabled 1 - Watchdog is disabled
18 BE	Packet Burst Enable When this bit is set, the MAC allows packet bursting during transmission in the GMII half-duplex mode. 0 - Packet Burst is disabled 1 - Packet Burst is enabled
17 JD	Jabber Disable When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16,383 bytes. When this bit is reset, if the application sends more than 2,048 bytes of data (10,240 if JE is set high) during transmission, the MAC does not send rest of the bytes in that packet. 0 - Jabber is enabled 1 - Jabber is disabled
16 JE	Jumbo Packet Enable When this bit is set, the MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status. 0 - Jumbo packet is disabled 1 - Jumbo packet is enabled
15 PS	Port Select This bit selects the Ethernet line speed.

Table continues on the next page...

Field	Description
	This bit, along with Bit 14, selects the exact line speed. In the 10/100 Mbps-only (always 1) or 1000 Mbps-only (always 0) configurations, this bit is read-only (RO) with appropriate value. In default 10/100/1000 Mbps configurations, this bit is read-write (R/W). The mac_speed_o[1] signal reflects the value of this bit. 0 - For 1000 or 2500 Mbps operations 1 - For 10 or 100 Mbps operations
14 FES	Speed This bit selects the speed mode. The mac_speed_o[0] signal reflects the value of this bit. 0 - 10 Mbps when PS bit is 1 and 1 Gbps when PS bit is 0 1 - 100 Mbps when PS bit is 1 and 2.5 Gbps when PS bit is 0
13 DM	Duplex Mode When this bit is set, the MAC operates in the full-duplex mode in which it can transmit and receive simultaneously. This bit is RO with default value of 1'b1 in the full-duplex-only configurations. 0 - Half-duplex mode 1 - Full-duplex mode
12 LM	Loopback Mode When this bit is set, the MAC operates in the loopback mode at GMII. The (G)MII Rx clock input (clk_rx_i) is required for the loopback to work properly. This is because the Tx clock is not internally looped back. 0 - Loopback is disabled 1 - Loopback is enabled
11 ECRSFD	Enable Carrier Sense Before Transmission in Full-Duplex Mode When this bit is set, the MAC transmitter checks the CRS signal before packet transmission in the full-duplex mode. The MAC starts the transmission only when the CRS signal is low. When this bit is reset, the MAC transmitter ignores the status of the CRS signal. 0 - ECRSFD is disabled 1 - ECRSFD is enabled
10 DO	Disable Receive Own When this bit is set, the MAC disables the reception of packets when the gmii_txen_o is asserted in the half-duplex mode. When this bit is reset, the MAC receives all packets given by the PHY. This bit is not applicable in the full-duplex mode. 0 - Enable Receive Own 1 - Disable Receive Own
9 DCRS	Disable Carrier Sense During Transmission When this bit is set, the MAC transmitter ignores the (G)MII CRS signal during packet transmission in the half-duplex mode. As a result, no errors are generated because of Loss of Carrier or No Carrier during transmission. When this bit is reset, the MAC transmitter generates errors because of Carrier Sense. The MAC can even abort the transmission. 0 - Enable Carrier Sense During Transmission 1 - Disable Carrier Sense During Transmission
8	Disable Retry

Table continues on the next page...

Field	Description
DR	When this bit is set, the MAC attempts only one transmission. When a collision occurs on the GMII interface, the MAC ignores the current packet transmission and reports a Packet Abort with excessive collision error in the Tx packet status. When this bit is reset, the MAC retries based on the settings of the BL field. This bit is applicable only in the half-duplex mode. 0 - Enable Retry 1 - Disable Retry
7 —	Reserved
6-5 BL	Back-Off Limit The back-off limit determines the random integer number (r) of slot time delays (4,096 bit times for 1000/2500 Mbps; 512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. n = retransmission attempt. The random integer r takes the value in the range 0 <= r < 2^k This bit is applicable only in the half-duplex mode. 00 - k = min(n,10) 01 - k = min(n,8) 10 - k = min(n,4) 11 - k = min(n,1)
4 DC	Deferral Check When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288 bit times in 10 or 100 Mbps mode. If the MAC is configured for 1000/2500 Mbps operation, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on GMII. The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0, and it is restarted. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode. 0 - Deferral check function is disabled 1 - Deferral check function is enabled
3-2 PRELEN	Preamble Length for Transmit packets These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the full-duplex mode. 00 - 7 bytes of preamble 01 - 5 bytes of preamble 10 - 3 bytes of preamble 11 - Reserved

Table continues on the next page...

Field	Description
1 TE	Transmitter Enable When this bit is set, the Tx state machine of the MAC is enabled for transmission on the GMII interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets. 0 - Transmitter is disabled 1 - Transmitter is enabled
0 RE	Receiver Enable When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the GMII interface. When this bit is reset, the MAC Rx state machine is disabled after it completes the reception of the current packet. The Rx state machine does not receive any more packets from the GMII interface. 0 - Receiver is disabled 1 - Receiver is enabled

11.7.6.1.3 MAC Extended Configuration Register (MAC_EXT_CONFIGURATION)

The MAC Extended Configuration Register establishes the operating mode of the MAC.

11.7.6.1.3.1 Offset

Register	Offset
MAC_EXT_CONFIGURATION	4h

11.7.6.1.3.2 Diagram

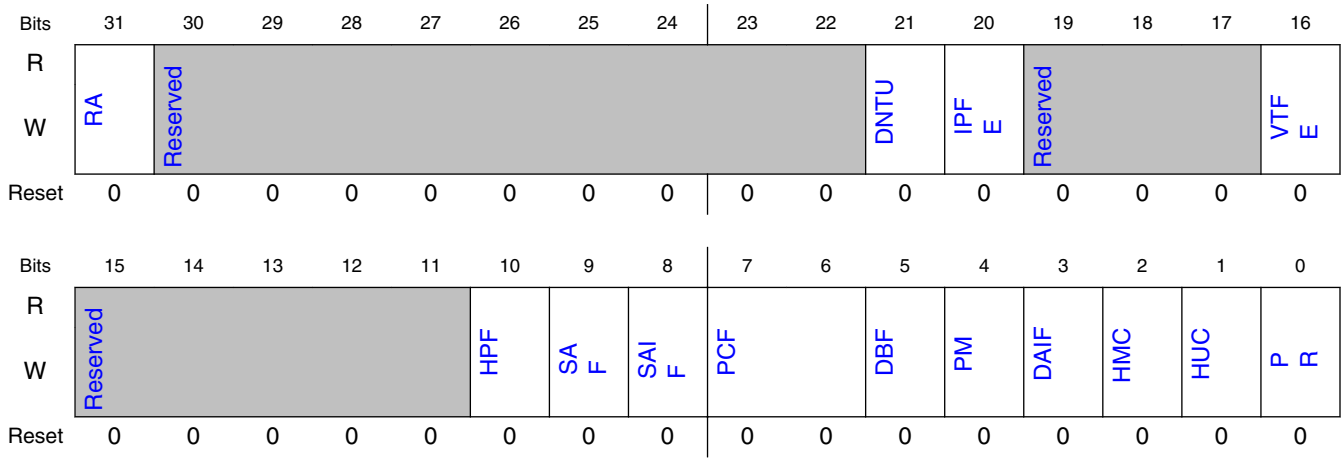
11.7.6.1.3.3 Fields

Field	Description
31 —	Reserved
30 —	Reserved
29-25 EIPG	Extended Inter-Packet Gap The value in this field is applicable when the EIPGEN bit is set. This field (as Most Significant bits), along with IPG field in CONFIGURATION register, gives the minimum IPG greater than 96 bit times in steps of 8 bit times: {EIPG, IPG} 8'h00 - 104 bit times 8'h01 - 112 bit times 8'h02 - 120 bit times ---------- 8'hFF - 2144 bit times
24 EIPGEN	Extended Inter-Packet Gap Enable When this bit is set, the MAC interprets EIPG field and IPG field in CONFIGURATION register together as minimum IPG greater than 96 bit times in steps of 8 bit times. When this bit is reset, the MAC ignores EIPG field and interprets IPG field in CONFIGURATION register as minimum IPG less than or equal to 96 bit times in steps of 8 bit times. Note: The extended Inter-Packet Gap feature must be enabled when operating in Full-Duplex mode only. There may be undesirable effects on back-pressure function and frame transmission if it is enabled in Half-Duplex mode. 0 - Extended Inter-Packet Gap is disabled 1 - Extended Inter-Packet Gap is enabled
23 —	Reserved
22-20 —	Reserved
19 PDC	Packet Duplication Control When this bit is set, the received packet with Multicast/Broadcast Destination address is routed to multiple Receive DMA Channels. The Receive DMA Channels is identified by the DCS field of MAC_ADDRESS(#i)_HIGH register corresponding to the MAC Address register that matches the Multicast/Broadcast Destination address in the received packet. The DCS field is interpreted to be a one-hot value, each bit corresponding to the Receive DMA Channel. When this bit is reset, the received packet is routed to single Receive DMA Channel. The Receive DMA Channel is identified by the DCS field of ADDRESS(#i)_High register corresponding to the MAC Address register that matches the Destination address in the received packet. The DCS field is interpreted as a binary value. 0 - Packet Duplication Control is disabled 1 - Packet Duplication Control is enabled
18	Unicast Slow Protocol Packet Detect

Table continues on the next page...

Field	Description
USP	When this bit is set, the MAC detects the Slow Protocol packets with unicast address of the station specified in the MAC_ADDRESS0_HIGH and MAC_ADDRESS0_LOW registers. The MAC also detects the Slow Protocol packets with the Slow Protocols multicast address (01-80-C2-00-00-02). When this bit is reset, the MAC detects only Slow Protocol packets with the Slow Protocol multicast address specified in the IEEE 802.3-2015, Section 5. 0 - Unicast Slow Protocol Packet Detection is disabled 1 - Unicast Slow Protocol Packet Detection is enabled
17 SPEN	Slow Protocol Detection Enable When this bit is set, MAC processes the Slow Protocol packets (Ether Type 0x8809) and provides the Rx status. The MAC discards the Slow Protocol packets with invalid sub-types. When this bit is reset, the MAC forwards all error-free Slow Protocol packets to the application. The MAC considers such packets as normal Type packets. 0 - Slow Protocol Detection is disabled 1 - Slow Protocol Detection is enabled
16 DCRCC	Disable CRC Checking for Received Packets When this bit is set, the MAC receiver does not check the CRC field in the received packets. When this bit is reset, the MAC receiver always checks the CRC field in the received packets. 0 - CRC Checking is enabled 1 - CRC Checking is disabled
15-14 —	Reserved
13-0 GPSL	Giant Packet Size Limit If the received packet size is greater than the value programmed in this field in units of bytes, the MAC declares the received packet as Giant packet. The value programmed in this field must be greater than or equal to 1,518 bytes. Any other programmed value is considered as 1,518 bytes. For VLAN tagged packets, the MAC adds 4 bytes to the programmed value. When the Enable Double VLAN Processing option is selected, the MAC adds 8 bytes to the programmed value for double VLAN tagged packets. The value in this field is applicable when the GPSLCE bit is set in MAC_CONFIGURATION register.



11.7.6.1.4 MAC Packet Filter (MAC_PACKET_FILTER)

The MAC Packet Filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

11.7.6.1.4.1 Offset

Register	Offset
MAC_PACKET_FILTER	8h

11.7.6.1.4.2 Diagram

11.7.6.1.4.3 Fields

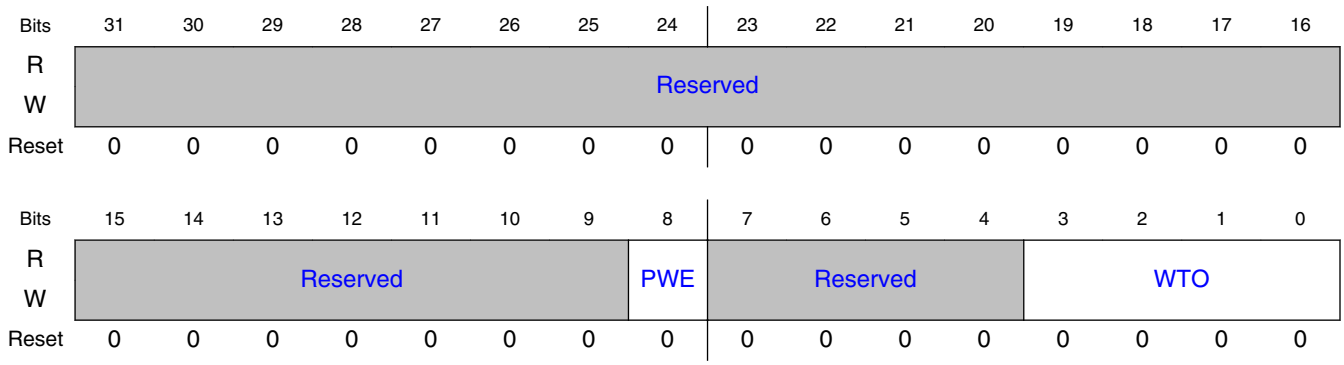
Field	Description
31 RA	Receive All When this bit is set, the MAC Receiver module passes all received packets to the application, irrespective of whether they pass the address filter or not. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bit in the Rx Status Word. When this bit is reset, the Receiver module passes only those packets to the application that pass the SA or DA address filter. 0 - Receive All is disabled 1 - Receive All is enabled
30-22 —	Reserved
21 DNTU	Drop Non-TCP/UDP over IP Packets When this bit is set, the MAC drops the non-TCP or UDP over IP packets. The MAC forward only those packets that are processed by the Layer 4 filter. When this bit is reset, the MAC forwards all non-TCP or UDP over IP packets. 0 - Forward Non-TCP/UDP over IP Packets 1 - Drop Non-TCP/UDP over IP Packets
20 IPFE	Layer 3 and Layer 4 Filter Enable When this bit is set, the MAC drops packets that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect. When this bit is reset, the MAC forwards all packets irrespective of the match status of the Layer 3 and Layer 4 fields. 0 - Layer 3 and Layer 4 Filters are disabled 1 - Layer 3 and Layer 4 Filters are enabled

Table continues on the next page...

Field	Description
19-17 —	Reserved
16 VTFE	VLAN Tag Filter Enable When this bit is set, the MAC drops the VLAN tagged packets that do not match the VLAN Tag. When this bit is reset, the MAC forwards all packets irrespective of the match status of the VLAN Tag. 0 - VLAN Tag Filter is disabled 1 - VLAN Tag Filter is enabled
15-11 —	Reserved
10 HPF	Hash or Perfect Filter When this bit is set, the address filter passes a packet if it matches either the perfect filtering or hash filtering as set by the HMC or HUC bit. When this bit is reset and the HUC or HMC bit is set, the packet is passed only if it matches the Hash filter. 0 - Hash or Perfect Filter is disabled 1 - Hash or Perfect Filter is enabled
9 SAF	Source Address Filter Enable When this bit is set, the MAC compares the SA field of the received packets with the values programmed in the enabled SA registers. If the comparison fails, the MAC drops the packet. When this bit is reset, the MAC forwards the received packet to the application with updated SAF bit of the Rx Status depending on the SA address comparison. Note: According to the IEEE specification, Bit 47 of the SA is reserved. However, in DWC_ether_qos, the MAC compares all 48 bits. The software driver should take this into consideration while programming the MAC address registers for SA. 0 - SA Filtering is disabled 1 - SA Filtering is enabled
8 SAIF	SA Inverse Filtering When this bit is set, the Address Check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the SA registers, it is marked as failing the SA Address filter. When this bit is reset, if the SA of a packet does not match the values programmed in the SA registers, it is marked as failing the SA Address filter. 0 - SA Inverse Filtering is disabled 1 - SA Inverse Filtering is enabled
7-6 PCF	Pass Control Packets These bits control the forwarding of all control packets (including unicast and multicast Pause packets). 00 - MAC filters all control packets from reaching the application 01 - MAC forwards all control packets except Pause packets to the application even if they fail the Address filter 10 - MAC forwards all control packets to the application even if they fail the Address filter 11 - MAC forwards the control packets that pass the Address filter
5 DBF	Disable Broadcast Packets

Table continues on the next page...

Field	Description
	When this bit is set, the AFM module blocks all incoming broadcast packets. In addition, it overrides all other filter settings. When this bit is reset, the AFM module passes all received broadcast packets. 0 - Enable Broadcast Packets 1 - Disable Broadcast Packets
4 PM	Pass All Multicast When this bit is set, it indicates that all received packets with a multicast destination address (first bit in the destination address field is '1') are passed. When this bit is reset, filtering of multicast packet depends on HMC bit. 0 - Pass All Multicast is disabled 1 - Pass All Multicast is enabled
3 DAIF	DA Inverse Filtering When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When this bit is reset, normal filtering of packets is performed. 0 - DA Inverse Filtering is disabled 1 - DA Inverse Filtering is enabled
2 HMC	Hash Multicast When this bit is set, the MAC performs the destination address filtering of received multicast packets according to the hash table. When this bit is reset, the MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programmed in DA registers. 0 - Hash Multicast is disabled 1 - Hash Multicast is enabled
1 HUC	Hash Unicast When this bit is set, the MAC performs the destination address filtering of unicast packets according to the hash table. When this bit is reset, the MAC performs a perfect destination address filtering for unicast packets, that is, it compares the DA field with the values programmed in DA registers. 0 - Hash Unicast is disabled 1 - Hash Unicast is enabled
0 PR	Promiscuous Mode When this bit is set, the Address Filtering module passes all incoming packets irrespective of the destination or source address. The SA or DA Filter Fails status bits of the Rx Status Word are always cleared when PR is set. 0 - Promiscuous Mode is disabled 1 - Promiscuous Mode is enabled



11.7.6.1.5 Watchdog Timeout (MAC_WATCHDOG_TIMEOUT)

The Watchdog Timeout register controls the watchdog timeout for received packets.

11.7.6.1.5.3 Fields

Field	Description
31-9 —	Reserved
8 PWE	Programmable Watchdog Enable When this bit is set and the WD bit of the MAC_CONFIGURATION register is reset, the WTO field is used as watchdog timeout for a received packet. When this bit is cleared, the watchdog timeout for a received packet is controlled by setting of WD and JE bits in MAC_CONFIGURATION register. 0 - Programmable Watchdog is disabled 1 - Programmable Watchdog is enabled
7-4 —	Reserved
3-0 WTO	Watchdog Timeout When the PWE bit is set and the WD bit of the MAC_CONFIGURATION register is reset, this field is used as watchdog timeout for a received packet. If the length of a received packet exceeds the value of this field, such packet is terminated and declared as an error packet. Note: When the PWE bit is set, the value in this field should be more than 1,522 (0x05F2). Otherwise, the IEEE 802.3-specified valid tagged packets are declared as error packets and then dropped. 0000 - 2 KB 0001 - 3 KB 0010 - 4 KB 0011 - 5 KB

11.7.6.1.6 MAC Hash Table Register 0 (MAC_HASH_TABLE_REG0)

The Hash Table Register 0 contains the first 32 bits of the hash table, when the width of the hash table is 128 or 256 bits. You can specify the width of the hash table by using the Hash Table Size option in coreConsultant.

The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1, a value of 7b'1110000 (in 128-bit Hash) selects Bit 16 of the Hash Table Register 3 and a value of 8b'10111111 (in 256-bit Hash) selects Bit 31 of the Hash Table Register 5.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).

- Perform bitwise reversal for the value obtained in Step 1.

- Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.

If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written.

If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

11.7.6.1.6.3 Fields

Field	Description
31-0 HT31T0	MAC Hash Table First 32 Bits This field contains the first 32 Bits [31:0] of the Hash table.

11.7.6.1.7 MAC Hash Table Register 1 (MAC_HASH_TABLE_REG1)

The Hash Table Register 1 contains the second 32 bits of the hash table. You can specify the width of the hash table by using the Hash Table Size option in coreConsultant.

The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1, a value of 7b'1110000 (in 128-bit Hash) selects Bit 16 of the Hash Table Register 3 and a value of 8b'10111111 (in 256-bit Hash) selects Bit 31 of the Hash Table Register 5.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).

- Perform bitwise reversal for the value obtained in Step 1.

- Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.

If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written.

If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

11.7.6.1.8.3 Fields

Field	Description
31 EIVLRXS	Enable Inner VLAN Tag in Rx Status When this bit is set, the MAC provides the inner VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the inner VLAN Tag in Rx status. 0 - Inner VLAN Tag in Rx status is disabled 1 - Inner VLAN Tag in Rx status is enabled
30 —	Reserved
29-28 EIVLS	Enable Inner VLAN Tag Stripping on Receive This field indicates the stripping operation on inner VLAN Tag in received packet. 00 - Do not strip 01 - Strip if VLAN filter passes 10 - Strip if VLAN filter fails 11 - Always strip
27 ERIVLT	ERIVLT 0 - Inner VLAN tag is disabled 1 - Inner VLAN tag is enabled
26 EDVLP	Enable Double VLAN Processing When this bit is set, the MAC enables processing of up to two VLAN Tags on Tx and Rx (if present). When this bit is reset, the MAC enables processing of up to one VLAN Tag on Tx and Rx (if present). 0 - Double VLAN Processing is disabled 1 - Double VLAN Processing is enabled
25 VTHM	VLAN Tag Hash Table Match Enable When this bit is set, the most significant four bits of CRC of VLAN Tag (ones-complement of most significant four bits of CRC of VLAN Tag when ETV bit is reset) are used to index the content of the MAC_VLAN_Hash_Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the packet matched the VLAN hash table.

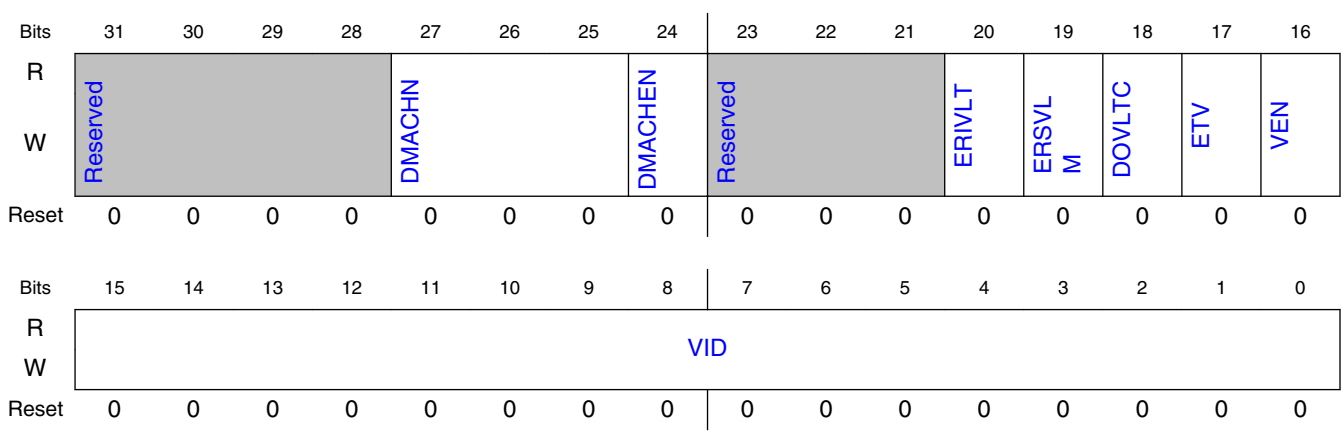
Table continues on the next page...

Field	Description
	When the ETV bit is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison. When the ETV bit is reset, the ones-complement of the CRC of the 16-bit VLAN tag is used for comparison. When this bit is reset, the VLAN Hash Match operation is not performed. 0 - VLAN Tag Hash Table Match is disabled 1 - VLAN Tag Hash Table Match is enabled
24 EVLRXS	Enable VLAN Tag in Rx status When this bit is set, MAC provides the outer VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the outer VLAN Tag in Rx status. 0 - VLAN Tag in Rx status is disabled 1 - VLAN Tag in Rx status is enabled
23 —	Reserved
22-21 EVLS	Enable VLAN Tag Stripping on Receive This field indicates the stripping operation on the outer VLAN Tag in received packet. 00 - Do not strip 01 - Strip if VLAN filter passes 10 - Strip if VLAN filter fails 11 - Always strip
20-19 —	Reserved
18 ESVL	Enable S-VLAN When this bit is set, the MAC transmitter and receiver consider the S-VLAN packets (Type = 0x88A8) as valid VLAN tagged packets. 0 - S-VLAN is disabled 1 - S-VLAN is enabled
17 VTIM	VLAN Tag Inverse Match Enable When this bit is set, this bit enables the VLAN Tag inverse matching. The packets without matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The packets with matched VLAN Tag are marked as matched. 0 - VLAN Tag Inverse Match is disabled 1 - VLAN Tag Inverse Match is enabled
16-7 —	Reserved
6-2 OFS	Offset This field holds the address offset of the MAC VLAN Tag Filter Register which the application is trying to access. The width of the field depends on the number of MAC VLAN Tag Registers enabled.
1 CT	Command Type This bit indicates if the current register access is a read or a write. When set, it indicate a read operation. When reset, it indicates a write operation. 0 - Write operation 1 - Read operation

Table continues on the next page...

Field	Description
0 OB	Operation Busy This bit is set along with a read or write command for initiating the indirect access to per VLAN Tag Filter register. This bit is reset when the read or write command to per VLAN Tag Filter indirect access register is complete. The next indirect register access can be initiated only after this bit is reset. During a write operation, the bit is reset only after the data has been written into the Per VLAN Tag register. During a read operation, the data should be read from the VLAN_TAG_DATA register only after this bit is reset. 0 - Operation Busy is disabled 1 - Operation Busy is enabled

11.7.6.1.9 MAC VLAN Tag Data (MAC_VLAN_TAG_DATA)



This register holds the read/write data for Indirect Access of the Per VLAN Tag registers. During the read access, this field contains valid read data only after the OB bit is reset.

During the write access, this field should be valid prior to setting the OB bit in the MAC_VLAN_Tag_Ctrl Register.

11.7.6.1.9.1 Offset

Register	Offset
MAC_VLAN_TAG_DATA	54h

11.7.6.1.9.2 Diagram

11.7.6.1.9.3 Fields

Field	Description
31-28 —	Reserved
27-25 DMACHN	DMA Channel Number The DMA Channel number to which the VLAN Tagged Frame is to be routed if it passes this VLAN Tag Filter is programmed in this field. If the Routing based on VLAN Tag Filter is not necessary, this field need not be programmed.
24 DMACHEN	DMA Channel Number Enable This bit is the Enable for the DMA Channel Number value programmed in the field DMACH. When this bit is reset, the Routing does not occur based on VLAN Filter result. The frame is routed based on DA Based DMA Channel Routing. 0 - DMA Channel Number is disabled 1 - DMA Channel Number is enabled
23-21 —	Reserved
20 ERIVLT	Enable Inner VLAN Tag Comparison This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit and the EDVLP field are set, the MAC receiver enables operation on the inner VLAN Tag (if present). When this bit is reset, the MAC receiver enables operation on the outer VLAN Tag (if present). 0 - Inner VLAN tag comparison is disabled 1 - Inner VLAN tag comparison is enabled
19 ERSVLM	Enable S-VLAN Match for received Frames This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets. 0 - Receive S-VLAN Match is disabled 1 - Receive S-VLAN Match is enabled
18 DOVLTC	Disable VLAN Type Comparison This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC does not check whether the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit is of type S-VLAN or C-VLAN. When this bit is reset, the MAC filters or matches the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit only when VLAN Tag type is similar to the one specified by the Enable S-VLAN Match for received Frames bit. 0 - VLAN type comparison is enabled 1 - VLAN type comparison is disabled
17 ETV	12bits or 16bits VLAN comparison This bit is valid only when VEN of the Filter is set.

Table continues on the next page...

Field	Description
	When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. 0 - 16 bit VLAN comparison 1 - 12 bit VLAN comparison
16 VEN	VLAN Tag Enable This bit is used to enable or disable the VLAN Tag. When this bit is set, the MAC compares the VLAN Tag of received packet with the VLAN Tag ID. When this bit is reset, no comparison is performed irrespective of the programming of the other fields. 0 - VLAN Tag is disabled 1 - VLAN Tag is enabled
15-0 VID	VLAN Tag ID This field holds the VLAN Tag value which is used by the MAC for perfect comparison. It is valid when VLAN Tag Enable is set.

11.7.6.1.10 MAC VLAN Hash Table (MAC_VLAN_HASH_TABLE)

When VTHM bit of the MAC_VLAN_TAG register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of MAC_VLAN_TAG Register) in the incoming packet is passed through the CRC logic. When ETV bit of MAC_VLAN_TAG register is set, the upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. When ETV bit of MAC_VLAN_TAG register is reset, the ones-complement of upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, when ETV bit is set a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table, whereas when ETV bit is reset a hash value of 4b'1000 selects Bit 7 of the VLAN Hash table.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the VLAN tag or ID (For steps to calculate CRC32, see Section 3.2.8 of IEEE 802.3).

- Perform bitwise reversal for the value obtained in step 1.

- Take the upper four bits from the value obtained in step 2.

If the VLAN hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written.

- If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

11.7.6.1.11.3 Fields

Field	Description
31 BUSY	Busy This bit indicates the status of the read/write operation of indirect access to the queue/channel specific VLAN inclusion register. For write operation write to a register is complete when this bit is reset. For read operation the read data is valid when the bit is reset. The application must make sure that this bit is reset before attempting subsequent access to this register. 0 - Busy status not detected 1 - Busy status detected
30 RDWR	Read write control This bit controls the read or write operation for indirectly accessing the queue/channel specific VLAN Inclusion register. When set indicates write operation and when reset indicates read operation. This does not have any effect when CBTI is reset. 0 - Read operation of indirect access 1 - Write operation of indirect access
29-27 —	Reserved
26-24 ADDR	Address This field selects one of the queue/channel specific VLAN Inclusion register for read/write access.

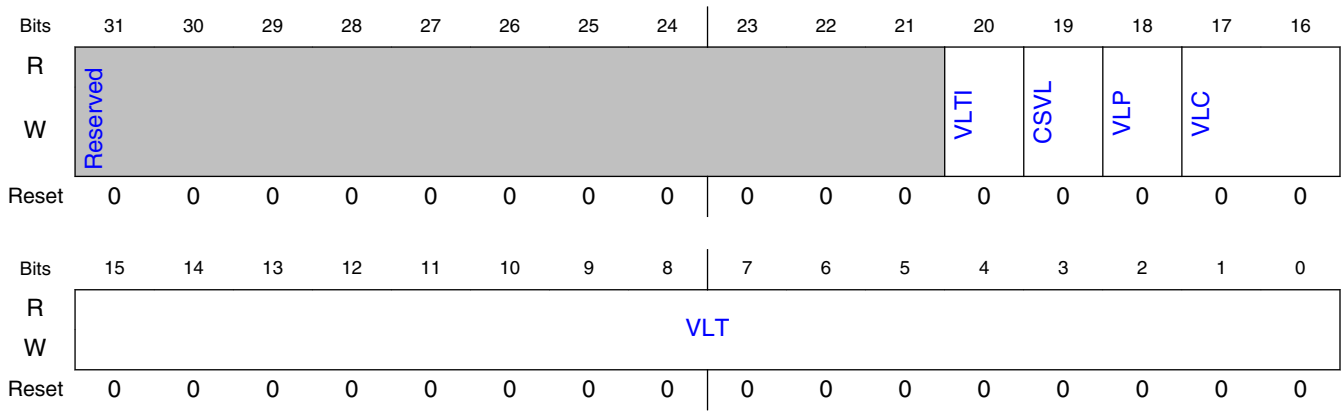
Table continues on the next page...

Field	Description
	This does not have any effect when CBTI is reset.
23-22 —	Reserved
21 CBTI	Channel based tag insertion When this bit is set, outer VLAN tag is inserted for every packets transmitted by the MAC. The tag value is taken from the queue/channel specific VLAN tag register. The VLTI, VLP, VLC, and VLT fields of this register are ignored when this bit is set. When this bit is set, a write operation to byte 3 of this register initiates the read/write access to the indirect register. When reset, outer VLAN operation is based on the setting of VLTI, VLP, VLC and VLT fields of this register. 0 - Channel based tag insertion is disabled 1 - Channel based tag insertion is enabled
20 VLTI	VLAN Tag Input When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from: - The Tx descriptor 0 - VLAN Tag Input is disabled 1 - VLAN Tag Input is enabled
19 CSVL	C-VLAN or S-VLAN When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets. 0 - C-VLAN type (0x8100) is inserted or replaced 1 - S-VLAN type (0x88A8) is inserted or replaced
18 VLP	VLAN Priority Control When this bit is set, the control bits[17:16] are used for VLAN deletion, insertion, or replacement. When this bit is reset, the mti_vlan_ctrl_i control input is used and bits[17:16] are ignored. 0 - VLAN Priority Control is disabled 1 - VLAN Priority Control is enabled
17-16 VLC	VLAN Tag Control in Transmit Packets - 2'b00: No VLAN tag deletion, insertion, or replacement - 2'b01: VLAN tag deletion The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags. VLAN Tag Control in Transmit Packets - 2'b00: No VLAN tag deletion, insertion, or replacement - 2'b01: VLAN tag deletion The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags. - 2'b10: VLAN tag insertion The MAC inserts VLT in bytes 15 and 16 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 13 and 14. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. - 2'b11: VLAN tag replacement The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted packets (Bytes 13 and 14 are 0x8100 or 0x88a8).

Table continues on the next page...

Field	Description
	Note: Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. 00 - No VLAN tag deletion, insertion, or replacement 01 - VLAN tag deletion 10 - VLAN tag insertion 11 - VLAN tag replacement
15-0 VLT	VLAN Tag for Transmit Packets This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority field, Bit 12 is the CFI/DEI field, and Bits[11:0] are the VID field in the VLAN tag. The following list describes the bits of this field: - Bits[15:13]: User Priority - Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) - Bits[11:0]: VLAN Identifier (VID) field of VLAN tag

11.7.6.1.12 MAC Inner VLAN Tag Inclusion or Replacement (MAC_INNER_VLAN_INCL)



The Inner VLAN Tag Inclusion or Replacement register contains the inner VLAN tag to be inserted or replaced in the Transmit packet.

The Inner VLAN Tag Inclusion or Replacement register contains the inner VLAN tag to be inserted or replaced in the Transmit packet. It also contains the inner VLAN tag insertion controls.

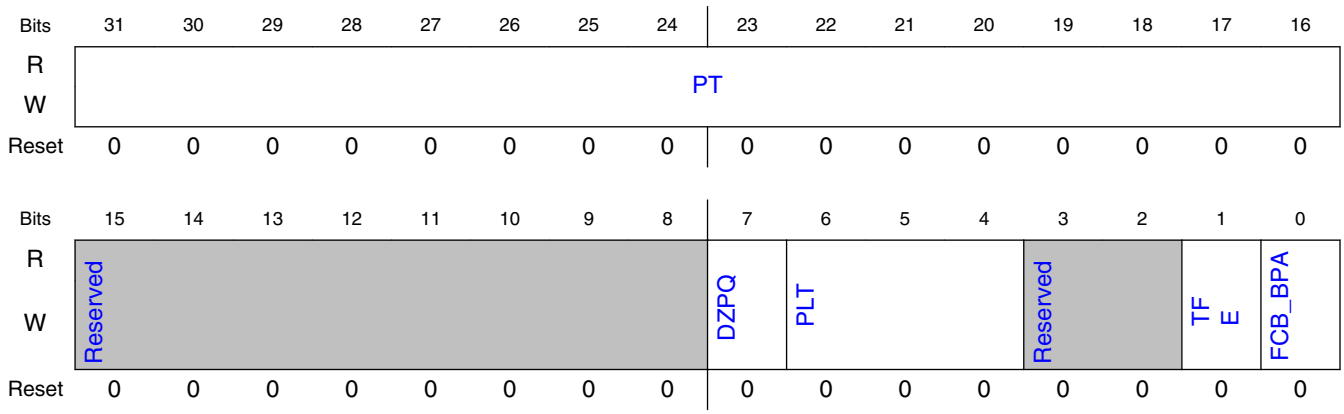
11.7.6.1.13 MAC Q0 Tx Flow Control (MAC_Q0_TX_FLOW_CTRL)

The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC.



The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register.

When the PFCE bit in the MAC_Q0_RX_FLOW_CTRL register is enabled, this register controls the generation of Priority Flow Control (PFC) frames with priorities mapped according to PSRQ0 in the MAC_Q0_RXQ_CTRL2 register.

11.7.6.1.13.1 Offset

Register	Offset
MAC_Q0_TX_FLOW_CTRL	70h

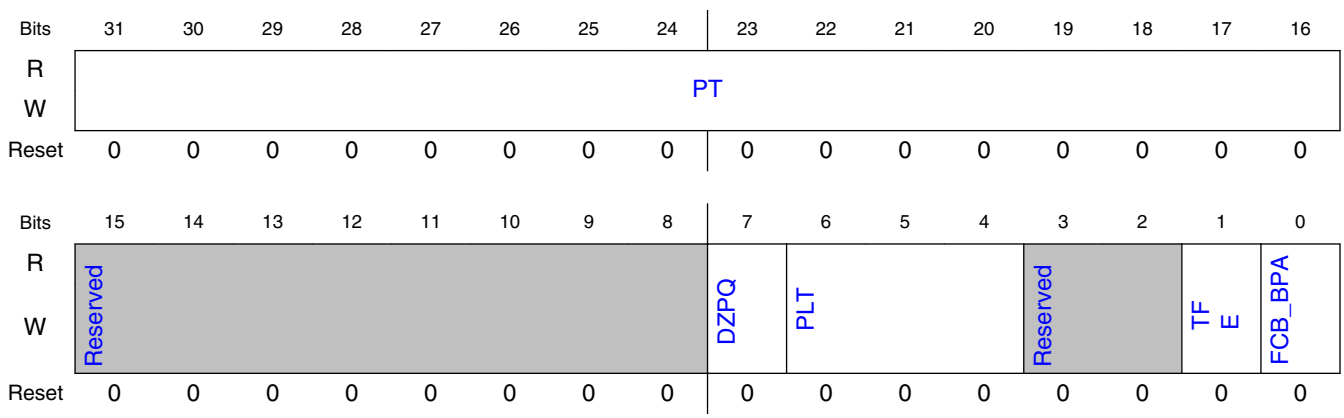
11.7.6.1.13.2 Diagram

11.7.6.1.13.3 Fields

Field	Description
31-16 PT	Pause Time This field holds the value to be used in the Pause Time field in the Tx control packet. If the Pause Time bits are configured to be double-synchronized to the (G)MII clock domain, consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.
15-8 —	Reserved
7 DZPQ	Disable Zero-Quanta Pause When this bit is set, it disables the automatic generation of the zero-quanta Pause packets on de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i or mti_flowctrl_i). When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled. 0 - Zero-Quanta Pause packet generation is enabled 1 - Zero-Quanta Pause packet generation is disabled
6-4 PLT	Pause Low Threshold This field configures the threshold of the Pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the Pause packet. The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256-28) slot times after the first Pause packet is transmitted.

Table continues on the next page...

Field	Description
	The following list provides the threshold values for different values. The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times. 000 - Pause Time minus 4 Slot Times (PT -4 slot times) 001 - Pause Time minus 28 Slot Times (PT -28 slot times) 010 - Pause Time minus 36 Slot Times (PT -36 slot times) 011 - Pause Time minus 144 Slot Times (PT -144 slot times) 100 - Pause Time minus 256 Slot Times (PT -256 slot times) 101 - Pause Time minus 512 Slot Times (PT -512 slot times) 110 - Reserved
3-2 —	Reserved
1 TFE	Transmit Flow Control Enable Full-Duplex Mode: In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets. Half-Duplex Mode: In the half-duplex mode, when this bit is set, the MAC enables the backpressure operation. When this bit is reset, the backpressure feature is disabled. 0 - Transmit Flow Control is disabled 1 - Transmit Flow Control is enabled
0 FCB_BPA	Flow Control Busy or Backpressure Activate This bit initiates a Pause packet in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. Full-Duplex Mode: In the full-duplex mode, this bit should be read as 1'b0 before writing to this register. To initiate a Pause packet, the application must set this bit to 1'b1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets this bit to 1'b0. You should not write to this register until this bit is cleared. Half-Duplex Mode: When this bit is set (and TFE bit is set) in the half-duplex mode, the MAC asserts the backpressure. During backpressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - Flow Control Busy or Backpressure Activate is disabled 1 - Flow Control Busy or Backpressure Activate is enabled



11.7.6.1.14 MAC Q1 Tx Flow Control (MAC_Q1_TX_FLOW_CTRL)

This register controls the generation of PFC Control packets of priorities mapped as per the PSRQi field in the MAC_Q1_RXQ_CTRL2/MAC_Q1_RXQ_CTRL3 registers.

11.7.6.1.14.1 Offset

Register	Offset
MAC_Q1_TX_FLOW_CTRL	74h

11.7.6.1.14.2 Diagram

11.7.6.1.14.3 Fields

Field	Description
31-16 PT	Pause Time This field holds the value to be used in the Pause Time field in the Tx control packet. If the Pause Time bits are configured to be double-synchronized to the (G)MII clock domain, consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.
15-8 —	Reserved
7 DZPQ	Disable Zero-Quanta Pause When this bit is set, it disables the automatic generation of the zero-quanta Pause packets on de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i or mti_flowctrl_i). When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled. 0 - Zero-Quanta Pause packet generation is enabled 1 - Zero-Quanta Pause packet generation is disabled

Table continues on the next page...

Field	Description
6-4 PLT	Pause Low Threshold This field configures the threshold of the Pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the Pause packet. The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256-28) slot times after the first Pause packet is transmitted. The following list provides the threshold values for different values. The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times. 000 - Pause Time minus 4 Slot Times (PT -4 slot times) 001 - Pause Time minus 28 Slot Times (PT -28 slot times) 010 - Pause Time minus 36 Slot Times (PT -36 slot times) 011 - Pause Time minus 144 Slot Times (PT -144 slot times) 100 - Pause Time minus 256 Slot Times (PT -256 slot times) 101 - Pause Time minus 512 Slot Times (PT -512 slot times) 110 - Reserved

11.7.6.1.18 MAC Rx Flow Control (MAC_RX_FLOW_CTRL)

The Receive Flow Control register controls the pausing of MAC Transmit based on the received Pause packet.

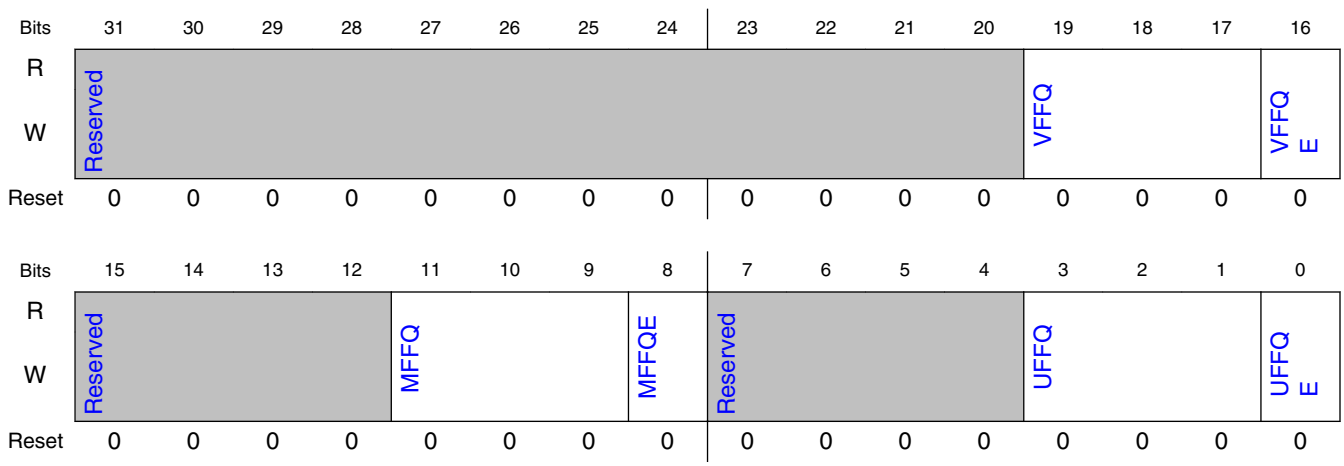
11.7.6.1.18.1 Offset

Register	Offset
MAC_RX_FLOW_CTRL	90h

11.7.6.1.18.2 Diagram

11.7.6.1.18.3 Fields

Field	Description
31-9 —	Reserved
8 PFCE	Priority Based Flow Control Enable When this bit is set, it enables generation and reception of priority-based flow control (PFC) packets. When this bit is reset, it enables generation and reception of 802.3x Pause control packets. 0 - Priority Based Flow Control is disabled 1 - Priority Based Flow Control is enabled
7-2 —	Reserved
1 UP	Unicast Pause Packet Detect A pause packet is processed when it has the unique multicast address specified in the IEEE 802.3. When this bit is set, the MAC can also detect Pause packets with unicast address of the station. This unicast address should be as specified in MAC_ADDRESS0_HIGH and MAC_ADDRESS0_LOW. When this bit is reset, the MAC only detects Pause packets with unique multicast address. Note: The MAC does not process a Pause packet if the multicast address is different from the unique multicast address. This is also applicable to the received PFC packet when the Priority Flow Control (PFC) is enabled. The unique multicast address (0x01_80_C2_00_00_01) is as specified in IEEE 802.1 Qbb-2011. 0 - Unicast Pause Packet Detect disabled 1 - Unicast Pause Packet Detect enabled
0 RFE	Receive Flow Control Enable When this bit is set and the MAC is operating in full-duplex mode, the MAC decodes the received Pause packet and disables its transmitter for a specified (Pause) time. When this bit is reset or the MAC is operating in half-duplex mode, the decode function of the Pause packet is disabled. When PFC is enabled, flow control is enabled for PFC packets. The MAC decodes the received PFC packet and disables the Transmit queue, with matching priorities, for a duration of received Pause time. 0 - Receive Flow Control is disabled 1 - Receive Flow Control is enabled



11.7.6.1.19 Receive Queue Control 4 (MAC_RXQ_CTRL4)

The Receive Queue Control 4 register controls the routing of unicast and multicast packets that fail the Destination or Source address filter to the Rx queues.

11.7.6.1.19.1 Offset

Register	Offset
MAC_RXQ_CTRL4	94h

26-24 FPRQ	Frame Preemption Residue Queue This field holds the Rx queue number to which the residual preemption frames must be forwarded. Preemption frames that are tagged and pass the SA/DA/VLAN filtering are routed based on PSRQ and all other frames are treated as residual frames and is routed to the queue number mentioned in this field. The Queue-0 is used as a default queue for express frames, so this field cannot be programmed to a value 0.
23-22 TPQC	Tagged PTP over Ethernet Packets Queuing Control. This field controls the routing of the VLAN Tagged PTPoE packets. If DWC_EQOS_AV_ENABLE is selected in the configuration, the following programmable options are allowed. - 2'b00: VLAN Tagged PTPoE packets are routed as generic VLAN Tagged packet (based on PSRQ for only non-AV enabled Rx Queues). - 2'b01: VLAN Tagged PTPoE packets are routed to Rx Queue specified by PTPQ field (That Rx Queue can be enabled for AV or non-AV traffic). - 2'b10: VLAN Tagged PTPoE packets are routed to only AV enabled Rx Queues based on PSRQ. - 2'b11: Reserved If DWC_EQOS_AV_ENABLE is not selected in the configuration, the following programmable options are allowed. - 1'b0: VLAN Tagged PTPoE packets are routed as generic VLAN Tagged packet (based on PSRQ for DCB/Generic enabled Rx Queues). - 1'b1: VLAN Tagged PTPoE packets are routed to Rx Queues specified by PTPQ field.
21 TACPQE	Tagged AV Control Packets Queuing Enable. When set, the MAC routes the received Tagged AV Control packets to the Rx queue specified by AVCPQ field.

Table continues on the next page...

Field	Description
	When reset, the MAC routes the received Tagged AV Control packets based on the tag priority matching the PSRQ fields in MAC_RXQ_CTRL2 and MAC_RXQ_CTRL3 registers. 0 - Tagged AV Control Packets Queuing is disabled 1 - Tagged AV Control Packets Queuing is enabled
20 MCBCQEN	Multicast and Broadcast Queue Enable This bit specifies that Multicast or Broadcast packets routing to the Rx Queue is enabled and the Multicast or Broadcast packets must be routed to Rx Queue specified in MCBCQ field. 0 - Multicast and Broadcast Queue is disabled 1 - Multicast and Broadcast Queue is enabled
19 —	Reserved
18-16 MCBCQ	Multicast and Broadcast Queue This field specifies the Rx Queue onto which Multicast or Broadcast Packets are routed. Any Rx Queue enabled for Generic/DCB/AV traffic can be used to route the Multicast or Broadcast Packets. 000 - Receive Queue 0 001 - Receive Queue 1 010 - Receive Queue 2 011 - Receive Queue 3 100 - Receive Queue 4 101 - Reserved 110 - Reserved 111 - Reserved
15 —	Reserved
14-12 UPQ	Untagged Packet Queue This field indicates the Rx Queue to which Untagged Packets are to be routed. Any Rx Queue enabled for Generic/DCB/AV traffic can be used to route the Untagged Packets. 000 - Receive Queue 0 001 - Receive Queue 1 010 - Receive Queue 2 011 - Receive Queue 3 100 - Receive Queue 4 101 - Reserved 110 - Reserved 111 - Reserved
11 —	Reserved
10-8 DCBCPQ	DCB Control Packets Queue This field specifies the Rx queue on which the received DCB control packets are routed. The DCB data packets are routed based on the PSRQ field of the Transmit Flow Control Register of corresponding queue.

Table continues on the next page...

Field	Description
	000 - Receive Queue 0 001 - Receive Queue 1 010 - Receive Queue 2 011 - Receive Queue 3 100 - Receive Queue 4 101 - Reserved 110 - Reserved 111 - Reserved
7 —	Reserved
6-4 PTPQ	PTP Packets Queue This field specifies the Rx queue on which the PTP packets sent over the Ethernet payload (not over IPv4 or IPv6) are routed. When the AV8021ASMEN bit of MAC_TIMESTAMP_CONTROL register is set, only untagged PTP over Ethernet packets are routed on an Rx Queue. If the bit is not set, then based on programming of TPQC field, both tagged and untagged PTPoE packets can be routed to this Rx Queue. 000 - Receive Queue 0 001 - Receive Queue 1 010 - Receive Queue 2 011 - Receive Queue 3 100 - Receive Queue 4 101 - Reserved 110 - Reserved 111 - Reserved
3 —	Reserved
2-0 AVCPQ	AV Untagged Control Packets Queue This field specifies the Receive queue on which the received AV tagged and untagged control packets are routed. The AV tagged (when TACPQE bit is set) and untagged control packets are routed to Receive queue specified by this field. 000 - Receive Queue 0 001 - Receive Queue 1 010 - Receive Queue 2 011 - Receive Queue 3 100 - Receive Queue 4 101 - Reserved 110 - Reserved 111 - Reserved

11.7.6.1.24 Receive Queue Control 2 (MAC_RXQ_CTRL2)

This register controls the routing of tagged packets based on the USP (user Priority) field of the received packets to the RxQueues 0 to 3.

11.7.6.1.24.1 Offset

Register	Offset
MAC_RXQ_CTRL2	A8h

11.7.6.1.24.2 Diagram

11.7.6.1.24.3 Fields

Field	Description
31-24 PSRQ3	Priorities Selected in the Receive Queue 3 This field decides the priorities assigned to Rx Queue 3. All packets with priorities that match the values set in this field are routed to Rx Queue 3. For example, if PSRQ3[6, 3] are set, packets with USP field equal to 3 or 6 are routed to Rx Queue 3. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. This field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 3 crosses the flow control threshold settings.
23-16 PSRQ2	Priorities Selected in the Receive Queue 2 This field decides the priorities assigned to Rx Queue 2. All packets with priorities that match the values set in this field are routed to Rx Queue 2. For example, if PSRQ2[1, 0] are set, packets with USP field equal to 1 or 0 are routed to Rx Queue 2. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. this field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 2 crosses the flow control threshold settings.

Table continues on the next page...

Field	Description
15-8 PSRQ1	Priorities Selected in the Receive Queue 1 This field decides the priorities assigned to Rx Queue 1. All packets with priorities that match the values set in this field are routed to Rx Queue 1. For example, if PSRQ1[4] is set, packets with USP field equal to 4 are routed to Rx Queue 1. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. this field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 1 crosses the flow control threshold settings.
7-0 PSRQ0	Priorities Selected in the Receive Queue 0 This field decides the priorities assigned to Rx Queue 0. All packets with priorities that match the values set in this field are routed to Rx Queue 0. For example, if PSRQ0[5] is set, packets with USP field equal to 5 are routed to Rx Queue 0. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. this field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 0 crosses the flow control threshold settings.

11.7.6.1.25 Receive Queue Control 3 (MAC_RXQ_CTRL3)

This register controls the routing of tagged packets based on the USP (user Priority) field of the received packets to Rx Queue 4.

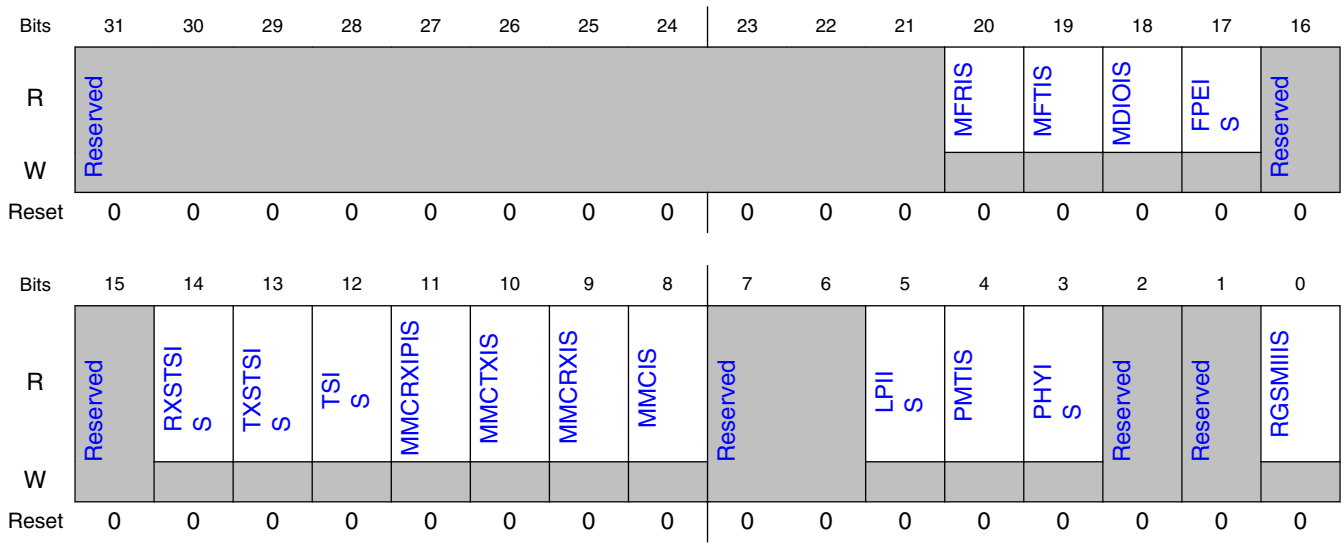
23-16 —	Reserved
15-8 —	Reserved
7-0 PSRQ4	Priorities Selected in the Receive Queue 4 This field decides the priorities assigned to Rx Queue 4. All packets with priorities that match the values set in this field are routed to Rx Queue 4. For example, if PSRQ4[7:4] is set, packets with USP field equal to 7, 6, 5, or 4 are routed to Rx Queue 4. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. This field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 4 crosses the flow control threshold settings.



11.7.6.1.26 Interrupt Status (MAC_INTERRUPT_STATUS)

The Interrupt Status register contains the status of interrupts.

11.7.6.1.26.1 Offset

Register	Offset
MAC_INTERRUPT_STATUS	B0h

11.7.6.1.26.2 Diagram

11.7.6.1.26.3 Fields

Field	Description
31-21 —	Reserved
20 MFRIS	MMC FPE Receive Interrupt Status This bit is set high when an interrupt is generated in the MMC FPE Receive Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option along with FPE support. 0 - MMC FPE Receive Interrupt status not active 1 - MMC FPE Receive Interrupt status active
19 MFTIS	MMC FPE Transmit Interrupt Status This bit is set high when an interrupt is generated in the MMC FPE Transmit Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option along with FPE support. 0 - MMC FPE Transmit Interrupt status not active 1 - MMC FPE Transmit Interrupt status active
18 MDIOIS	MDIO Interrupt Status This bit indicates an interrupt event after the completion of MDIO operation. To reset this bit, the application has to read this bit/Write 1 to this bit when RCWE bit of CSR_SW_CTRL register is set. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - MDIO Interrupt status not active 1 - MDIO Interrupt status active
17 FPEIS	Frame Preemption Interrupt Status

Table continues on the next page...

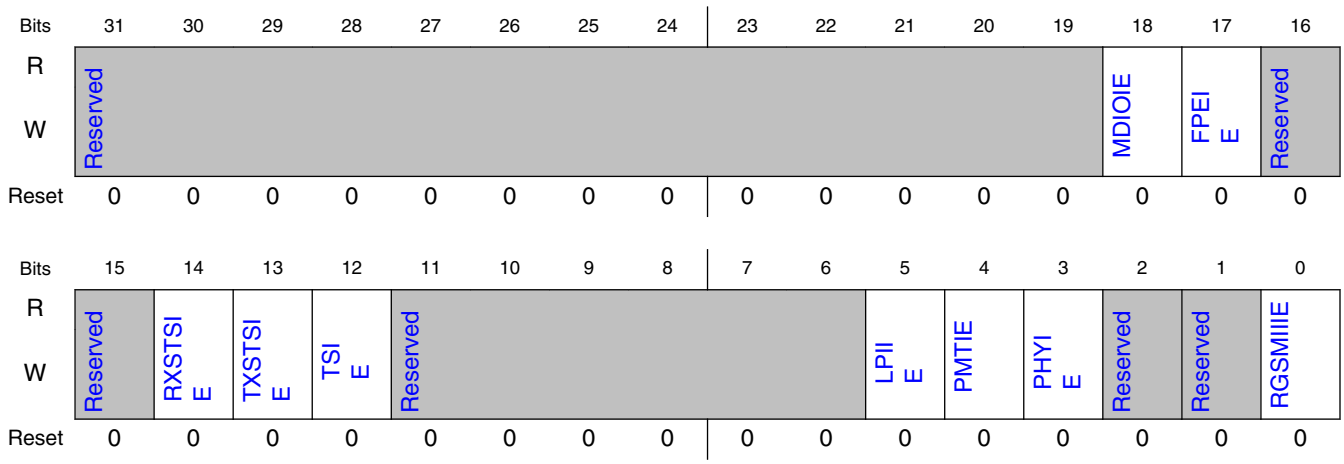
Field	Description
	This bit indicates an interrupt event during the operation of Frame Preemption (Bits[19:16] of MAC_FPE_CTRL_STS register is set). To reset this bit, the application must clear the event in MAC_FPE_CTRL_STS that has caused the Interrupt. 0 - Frame Preemption Interrupt status not active 1 - Frame Preemption Interrupt status active
16 —	Reserved
15 —	Reserved
14 RXSTSIS	Receive Status Interrupt This bit indicates the status of received packets. This bit is set when the RWT bit is set in the MAC_RX_TX_STATUS register. This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of CSR_SW_CTRL register is set) in the MAC_RX_TX_STATUS register. 0 - Receive Interrupt status not active 1 - Receive Interrupt status active
13 TXSTSIS	Transmit Status Interrupt This bit indicates the status of transmitted packets. This bit is set when any of the following bits is set in the MAC_RX_TX_STATUS register: - Excessive Collision (EXCOL) - Late Collision (LCOL) - Excessive Deferral (EXDEF) - Loss of Carrier (LCARR) - No Carrier (NCARR) - Jabber Timeout (TJT) This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of CSR_SW_CTRL register is set) in the MAC_RX_TX_STATUS register. 0 - Transmit Interrupt status not active 1 - Transmit Interrupt status active
12 TSIS	Timestamp Interrupt Status If the Timestamp feature is enabled, this bit is set when any of the following conditions is true: - The system time value is equal to or exceeds the value specified in the Target Time High and Low registers. - There is an overflow in the Seconds register. - The Target Time Error occurred, that is, programmed target time already elapsed. If the Auxiliary Snapshot feature is enabled, this bit is set when the auxiliary snapshot trigger is asserted. In configurations other than EQOS_CORE, when drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the MAC_TX_TIMESTAMP_STATUS_NANOSECONDS and MAC_TXTIMESTAMP_STATUS_SECONDS registers.

Table continues on the next page...

Field	Description
	When PTP offload feature is enabled, this bit is set when the captured transmit timestamp is updated in the MAC_TX_TIMESTAMP_STATUS_NANOSECONDS and MAC_TX_TIMESTAMP_STATUS_SECONDS registers, for PTO generated Delay Request and Pdelay request packets. This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of CSR_SW_CTRL register is set) in the MAC_TIMESTAMP_STATUS register. 0 - Timestamp Interrupt status not active 1 - Timestamp Interrupt status active
11 MMCRXIPIS	MMC Receive Checksum Offload Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Checksum Offload Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) and Enable Receive TCP/IP Checksum Check options. 0 - MMC Receive Checksum Offload Interrupt status not active 1 - MMC Receive Checksum Offload Interrupt status active
10 MMCTXIS	MMC Transmit Interrupt Status This bit is set high when an interrupt is generated in the MMC Transmit Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option. 0 - MMC Transmit Interrupt status not active 1 - MMC Transmit Interrupt status active
9 MMCRXIS	MMC Receive Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option. 0 - MMC Receive Interrupt status not active 1 - MMC Receive Interrupt status active
8 MMCIS	MMC Interrupt Status This bit is set high when Bit 11, Bit 10, or Bit 9 is set high. This bit is cleared only when all these bits are low. This bit is valid only when you select the Enable MAC Management Counters (MMC) option. 0 - MMC Interrupt status not active 1 - MMC Interrupt status active
7-6 —	Reserved
5 LPIIS	LPI Interrupt Status When the Energy Efficient Ethernet feature is enabled, this bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver. This bit is cleared when the corresponding interrupt source bit of MAC_LPI_CONTROL_STATUS register is read (or corresponding interrupt source bit of MAC_LPI_CONTROL_STATUS register is written to 1 when RCWE bit of MAC_CSR_SW_CTRL register is set). 0 - LPI Interrupt status not active 1 - LPI Interrupt status active
4	PMT Interrupt Status

Table continues on the next page...

Field	Description
PMTIS	This bit is set when a Magic packet or Wake-on-LAN packet is received in the power-down mode (RWKPRCVD and MGKPRCVD bits in MAC_PMT_CONTROL_STATUS register). This bit is cleared when corresponding interrupt source bit are cleared because of a Read operation to the MAC_PMT_CONTROL_STATUS register (or corresponding interrupt source bit of MAC_PMT_CONTROL_STATUS register is written to 1 when RCWE bit of CSR_SW_CTRL register is set). This bit is valid only when you select the Enable Power Management option. 0 - PMT Interrupt status not active 1 - PMT Interrupt status active
3 PHYIS	PHY Interrupt This bit is set when rising edge is detected on the phy_intr_i input. This bit is cleared when this register is read (or this bit is written to 1 when RCWE bit of CSR_SW_CTRL register is set). 0 - PHY Interrupt not detected 1 - PHY Interrupt detected
2 —	Reserved
1 —	Reserved
0 RGSMIIIS	RGMII or SMII Interrupt Status This bit is set because of any change in value of the Link Status of RGMII or SMII interface (LNKSTS bit in MAC_PHYIF_CONTROL_STATUS register). This bit is cleared when the PHYIF_CONTROL_STATUS register is read (or LNKSTS bit of MAC_PHYIF_CONTROL_STATUS register is written to 1 when RCWE bit of MAC_CSR_SW_CTRL register is set). This bit is valid only when you select the optional RGMII or SMII PHY interface. 0 - RGMII or SMII Interrupt Status is not active 1 - RGMII or SMII Interrupt Status is active



11.7.6.1.27 Interrupt Enable (MAC_INTERRUPT_ENABLE)

The Interrupt Enable register contains the masks for generating the interrupts.

11.7.6.1.27.1 Offset

Register	Offset
MAC_INTERRUPT_ENABLE	B4h

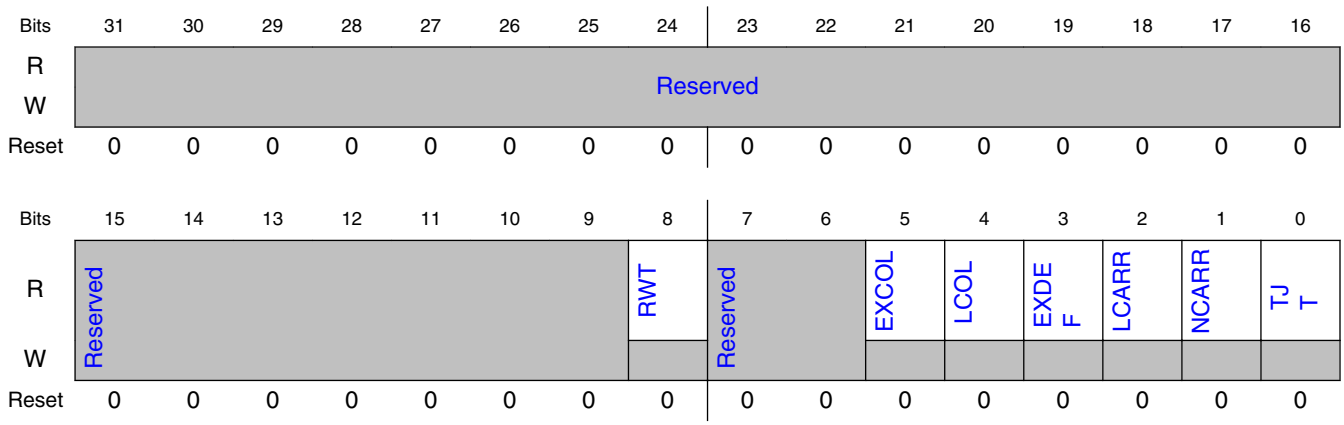
11.7.6.1.27.2 Diagram

11.7.6.1.27.3 Fields

Field	Description
31-19 —	Reserved
18 MDIOIE	MDIO Interrupt Enable When this bit is set, it enables the assertion of the interrupt when MDIOIS field is set in the MAC_INTERRUPT_STATUS register. 0 - MDIO Interrupt is disabled 1 - MDIO Interrupt is enabled
17 FPEIE	Frame Preemption Interrupt Enable When this bit is set, it enables the assertion of the interrupt when FPEIS field is set in the MAC_INTERRUPT_STATUS. 0 - Frame Preemption Interrupt is disabled 1 - Frame Preemption Interrupt is enabled
16 —	Reserved
15 —	Reserved
14 RXSTSIE	Receive Status Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of MAC_INTERRUPT_STATUS[RXSTSIS]. 0 - Receive Status Interrupt is disabled 1 - Receive Status Interrupt is enabled
13 TXSTSIE	Transmit Status Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of MAC_INTERRUPT_STATUS[TXSTSIS]. 0 - Timestamp Status Interrupt is disabled 1 - Timestamp Status Interrupt is enabled
12 TSIE	Timestamp Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of MAC_INTERRUPT_STATUS[TSIS]. 0 - Timestamp Interrupt is disabled

Table continues on the next page...

Field	Description
	1 - Timestamp Interrupt is enabled
11-6 —	Reserved
5 LPIIE	LPI Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of MAC_INTERRUPT_STATUS[LPIIS]. 0 - LPI Interrupt is disabled 1 - LPI Interrupt is enabled
4 PMTIE	PMT Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of MAC_INTERRUPT_STATUS[PMTIS]. 0 - PMT Interrupt is disabled 1 - PMT Interrupt is enabled
3 PHYIE	PHY Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of MAC_INTERRUPT_STATUS[PHYIS]. 0 - PHY Interrupt is disabled 1 - PHY Interrupt is enabled
2 —	Reserved
1 —	Reserved
0 RGSMIIIE	RGMII or SMII Interrupt Enable When this bit is set, it enables the assertion of the interrupt signal because of the setting of RGSMIIIS bit in MAC_INTERRUPT_STATUS register. 0 - RGMII or SMII Interrupt is disabled 1 - RGMII or SMII Interrupt is enabled



11.7.6.1.28 Receive Transmit Status (MAC_RX_TX_STATUS)

The Receive Transmit Status register contains the Receive and Transmit Error status.

11.7.6.1.28.1 Offset

Register	Offset
MAC_RX_TX_STATUS	B8h

11.7.6.1.28.2 Diagram

11.7.6.1.28.3 Fields

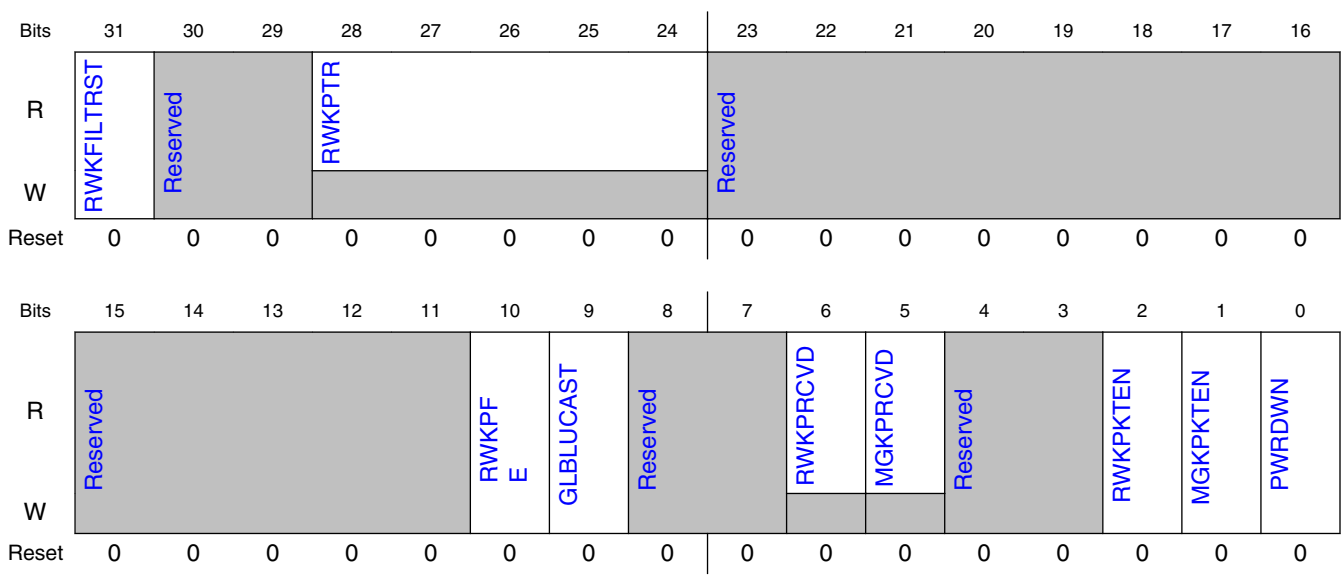
Field	Description
31-9 —	Reserved
8 RWT	Receive Watchdog Timeout This bit is set when a packet with length greater than 2,048 bytes is received (10, 240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the MAC_CONFIGURATION register. Receive Watchdog Timeout This bit is set when a packet with length greater than 2,048 bytes is received (10, 240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the MAC_CONFIGURATION register. This bit is set when a packet with length greater than 16,383 bytes is received and the WD bit is set in the MAC_CONFIGURATION register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - No receive watchdog timeout 1 - Receive watchdog timed out
7-6 —	Reserved
5 EXCOL	Excessive Collisions When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. Excessive Collisions When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the CONFIGURATION register, this bit is set after the first collision and the packet transmission is aborted. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - No collision 1 - Excessive collision is sensed

Table continues on the next page...

Field	Description
4 LCOL	Late Collision When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the packet transmission aborted because a collision occurred after the collision window (512 bytes including Preamble and Carrier Extension in GMII mode). Late Collision When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the packet transmission aborted because a collision occurred after the collision window (512 bytes including Preamble and Carrier Extension in GMII mode). This bit is not valid if the Underflow error occurs. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - No collision 1 - Late collision is sensed
3 EXDEF	Excessive Deferral When the DTXSTS bit is set in the MAC_OPERATION_MODE register and the DC bit is set in the MAC_CONFIGURATION register, this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 in 1000/2500 Mbps mode or when Jumbo packet is enabled). Excessive Deferral When the DTXSTS bit is set in the MAC_OPERATION_MODE register and the DC bit is set in the MAC_CONFIGURATION register, this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 in 1000/2500 Mbps mode or when Jumbo packet is enabled). Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - No Excessive deferral 1 - Excessive deferral
2 LCARR	Loss of Carrier When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the loss of carrier occurred during packet transmission, that is, the phy_crs_i signal was inactive for one or more transmission clock periods during packet transmission. Loss of Carrier When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the loss of carrier occurred during packet transmission, that is, the phy_crs_i signal was inactive for one or more transmission clock periods during packet transmission. This bit is valid only for packets transmitted without collision. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - Carrier is present 1 - Loss of carrier
1 NCARR	No Carrier When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission. No Carrier When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - Carrier is present 1 - No carrier

Table continues on the next page...

Field	Description
0 TJT	Transmit Jabber Timeout This bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2,048 bytes (10,240 bytes when the Jumbo packet is enabled) and JD bit is reset in the MAC_CONFIGURATION register. Transmit Jabber Timeout This bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2,048 bytes (10,240 bytes when the Jumbo packet is enabled) and JD bit is reset in the MAC_CONFIGURATION register. This bit is set when the packet size exceeds 16,383 bytes and the JD bit is set in the MAC_CONFIGURATION register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - No Transmit Jabber Timeout 1 - Transmit Jabber Timeout occurred



11.7.6.1.29 PMT Control and Status (MAC_PMT_CONTROL_STATUS)

The PMT Control and Status Register.

11.7.6.1.29.1 Offset

Register	Offset
MAC_PMT_CONTROL_STATUS	C0h

11.7.6.1.29.2 Diagram

11.7.6.1.29.3 Fields

Field	Description
31 RWKFILTRST	Remote Wake-Up Packet Filter Register Pointer Reset When this bit is set, the remote wake-up packet filter register pointer is reset to 3'b000. Remote Wake-Up Packet Filter Register Pointer Reset When this bit is set, the remote wake-up packet filter register pointer is reset to 3'b000. It is automatically cleared after 1 clock cycle. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - Remote Wake-Up Packet Filter Register Pointer is not Reset 1 - Remote Wake-Up Packet Filter Register Pointer is Reset
30-29 —	Reserved
28-24 RWKPTR	Remote Wake-up FIFO Pointer This field gives the current value (0 to 7, 15, or 31 when 4, 8, or 16 Remote Wake-up Packet Filters are selected) of the Remote Wake-up Packet Filter register pointer. Remote Wake-up FIFO Pointer This field gives the current value (0 to 7, 15, or 31 when 4, 8, or 16 Remote Wake-up Packet Filters are selected) of the Remote Wake-up Packet Filter register pointer. When the value of this pointer is equal to maximum for the selected number of Remote Wake-up Packet Filters, the contents of the Remote Wake-up Packet Filter Register are transferred to the clk_rx_i domain when a Write occurs to that register.
23-11 —	Reserved
10 RWKPFE	Remote Wake-up Packet Forwarding Enable When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected Wake-up frame. Remote Wake-up Packet Forwarding Enable When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected Wake-up frame. All frames after that event including the received wake-up frame are forwarded to application. This bit is then self-cleared on receiving the wake-up packet. The application can also clear this bit before the expected wake-up frame is received. In such cases, the MAC reverts to the default behavior where packets received are forwarded to the application. This bit must only be set when RWKPKTEN is set high and PWRDWN is set low. The setting of this bit has no effect when PWRDWN is set high. Note: If Magic Packet Enable and Wake-Up Frame Enable are both set along with setting of this bit and Magic Packet is received prior to wake-up frame, this bit is self-cleared on receiving Magic Packet, the received Magic packet is dropped, and all frames after received Magic Packet are forwarded to application. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - Remote Wake-up Packet Forwarding is disabled 1 - Remote Wake-up Packet Forwarding is enabled
9 GLBLUCAST	Global Unicast When this bit set, any unicast packet filtered by the MAC (DAF) address recognition is detected as a remote wake-up packet. 0 - Global unicast is disabled 1 - Global unicast is enabled

Table continues on the next page...

Field	Description
8-7 —	Reserved
6 RWKPRCVD	Remote Wake-Up Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a remote wake-up packet. Remote Wake-Up Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a remote wake-up packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - Remote wake-up packet is received 1 - Remote wake-up packet is received
5 MGKPRCVD	Magic Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. Magic Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - No Magic packet is received 1 - Magic packet is received
4-3 —	Reserved
2 RWKPKTEN	Remote Wake-Up Packet Enable When this bit is set, a power management event is generated when the MAC receives a remote wake-up packet. 0 - Remote wake-up packet is disabled 1 - Remote wake-up packet is enabled
1 MGKPKTEN	Magic Packet Enable When this bit is set, a power management event is generated when the MAC receives a magic packet. 0 - Magic Packet is disabled 1 - Magic Packet is enabled
0 PWRDWN	Power Down When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wake-up packet. Power Down When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wake-up packet. This bit is then self-cleared and the power-down mode is disabled. The software can clear this bit before the expected magic packet or remote wake-up packet is received. The packets received by the MAC after this bit is cleared are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Remote Wake-Up Packet Enable bit is set high. Note: You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - Power down is disabled 1 - Power down is enabled

11.7.6.1.30 Remote Wakeup Filter (MAC_RWK_PACKET_FILTER)

The Remote Wakeup Filter registers are implemented as 8, 16, or 32 indirect access registers (wkuppktfilter_reg#i) based on whether 4, 8, or 16 Remote Wakeup Filters are selected in the configuration and accessed by application through MAC_RWK_PACKET_FILTER register.

The Remote Wakeup Filter registers are implemented as 8, 16, or 32 indirect access registers (wkuppktfilter_reg#i) based on whether 4, 8, or 16 Remote Wakeup Filters are selected in the configuration and accessed by application through MAC_RWK_PACKET_FILTER register. When the Remote Wakeup Filters are to be programmed, the entire set of wkuppktfilter_reg registers must be written. The wkuppktfilter_reg register is programmed by sequentially writing the eight, sixteen or thirty-two register values in MAC_RWK_PACKET_FILTER register for wkuppktfilter_REG0, wkuppktfilter_REG1, ..., wkuppktfilter_REG31 respectively. The wkuppktfilter_reg register is read in a similar way. The MAC updates the wkuppktfilter_reg register current pointer value in RWKPTR field of MAC_PMT_CONTROL_STATUS register.

The Remote Wakeup Filters are arranged in blocks of 4 filters each and each such block have eight 32-bit wide registers, viz. wkuppktfilter_REG0-7, wkuppktfilter_reg8-15, wkuppktfilter_REG16-23 and wkuppktfilter_REG24-31. The fields of Remote Wakeup Filter are described as follows:

Filter i Byte Mask: The filter i byte mask register defines the bytes of the packet that are examined by filter i (0, 1, 2, 3, .., 15) to determine whether or not a packet is a wake-up packet.

- The MSB (31st bit) must be zero.

- Bit j[30:0] is the byte mask.

- If Bit j (byte number) of the byte mask is set, the CRC block processes the Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored.

Filter i Command: The 4-bit filter i command controls the filter i operation.

- Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet.

- Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC-16 value. Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as "Pattern 1 AND NOT Pattern 2".

- Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. The details are provided below:

-- The And_Previous bit setting is applicable within a set of 4 filters.

-- Setting of And_Previous bit of filter that is not enabled has no effect, that is setting And_Previous bit of lowest number filter in the set of 4 filters has no effect. For example, setting of And_Previous bit of Filter 0 has no effect.

-- If And_Previous bit is set for filter to form AND chained filter, the AND chain breaks at the point any filter is not enabled. For example: If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set) but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result ANDed with Filter 3 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 2 is not enabled (bit 0 in Filter 2 command is reset), then since setting of Filter 2 And_Previous bit has no effect only Filter 1 result ORed with Filter 3 result is considered.

-- If filters chained by And_Previous bit setting have complementary programming, then a frame may never pass the AND chained filter. For example, if Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 1 Address_Type bit is set (bit 3 in Filter 1 command is set) indicating multicast detection and Filter 2 Address_Type bit is reset (bit 3 in Filter 2 command is reset) indicating unicast detection or vice versa, a remote wakeup frame does not pass the AND chained filter as a remote wakeup frame cannot be of both unicast and multicast address type.

- Bit 0 is the enable for filter i. If Bit 0 is not set, filter i is disabled.

Filter i Offset: The filter i offset register defines the offset (within the packet) from which the filter i examines the packets.

- This 8-bit pattern-offset is the offset for the filter i first byte to be examined.

- The minimum allowed offset is 12, which refers to the 13th byte of the packet.

- The offset value 0 refers to the first byte of the packet.

Filter i CRC-16: The filter i CRC-16 register contains the CRC-16 value calculated from the pattern and the byte mask programmed in the Remote Wakeup filter register.

- The 16-bit CRC calculation uses the following polynomial: G(x) = x^16 + x^15 + x^2 + 1

- Each mask, used in the hash function calculation, is compared with a 16-bit value associated with that mask. Each filter has the following:

-- 32-bit Mask: Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1, the corresponding byte is taken into the CRC-16 calculation.

-- 8-bit Offset Pointer: Specifies the byte to start the CRC-16 computation. The pointer and the mask are used together to locate the bytes to be used in the CRC-16 calculations.

The structure of the RWK Filter registers is shown in "Figure 10-11 Remote Wake-Up Packet Filter Register".

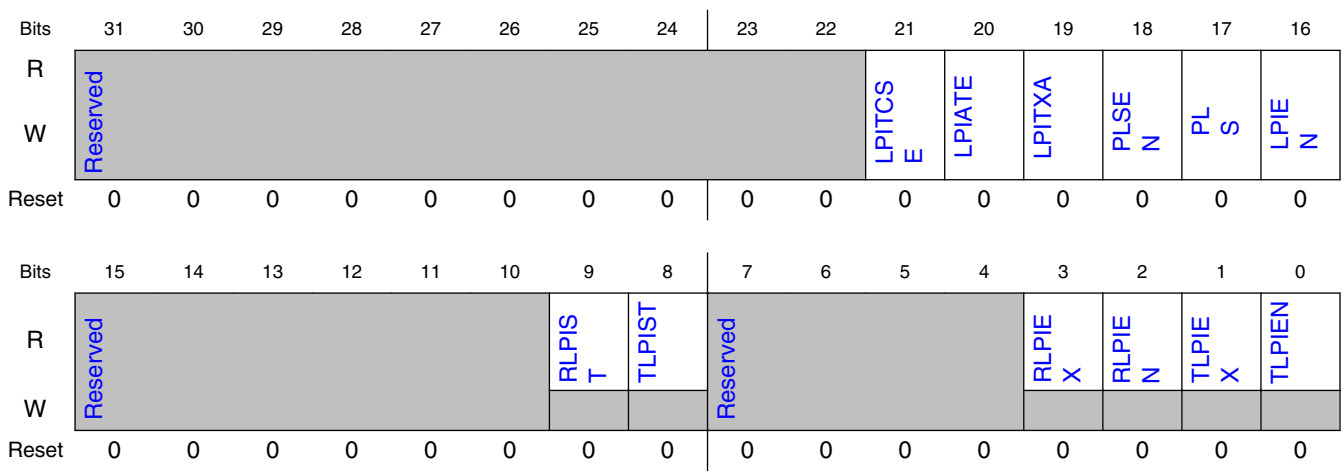
11.7.6.1.31 LPI Control and Status (MAC_LPI_CONTROL_STATUS)



The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status.

The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status. The status bits are cleared when this register is read.

11.7.6.1.31.1 Offset

Register	Offset
MAC_LPI_CONTROL_STATUS	D0h

11.7.6.1.31.2 Diagram

11.7.6.1.31.3 Fields

Field	Description
31-22 —	Reserved
21 LPITCSE	LPI Tx Clock Stop Enable When this bit is set, the MAC asserts sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode to indicate that the Tx clock to MAC can be stopped. LPI Tx Clock Stop Enable When this bit is set, the MAC asserts sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode to indicate that the Tx clock to MAC can be stopped. When this bit is reset, the MAC does not assert sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode.

Table continues on the next page...

Field	Description
	If RGMII Interface is selected, the Tx clock is required for transmitting the LPI pattern. The Tx Clock cannot be gated and so the LPITCSE bit cannot be programmed. 0 - LPI Tx Clock Stop is disabled 1 - LPI Tx Clock Stop is enabled
20 LPIATE	LPI Timer Enable This bit controls the automatic entry of the MAC Transmitter into and exit out of the LPI state. LPI Timer Enable This bit controls the automatic entry of the MAC Transmitter into and exit out of the LPI state. When LPIATE, LPITXA and LPIEN bits are set, the MAC Transmitter enters LPI state only when the complete MAC TX data path is IDLE for a period indicated by the MAC_LPI_ENTRY_TIMER register. After entering LPI state, if the data path becomes non-IDLE (due to a new packet being accepted for transmission), the Transmitter exits LPI state but does not clear LPIEN bit. This enables the re-entry into LPI state when it is IDLE again. When LPIATE is 0, the LPI Auto timer is disabled and MAC Transmitter enters LPI state based on the settings of LPITXA and LPIEN bit descriptions. 0 - LPI Timer is disabled 1 - LPI Timer is enabled
19 LPITXA	LPI Tx Automate This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the Transmit side. LPI Tx Automate This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the Transmit side. This bit is not functional in the EQOS-CORE configurations in which the Tx clock gating is done during the LPI mode. If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding packets (in the core) and pending packets (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any packet for transmission or the application issues a Tx FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If Tx FIFO Flush is set in the FTQ bit of MAC_TXQ0_OPERATION_MODE register, when the MAC is in the LPI mode, it exits the LPI mode. When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode. 0 - LPI Tx Automate is disabled 1 - LPI Tx Automate is enabled
18 PLSEN	PHY Link Status Enable This bit enables the link status received on the RGMII, SGMII, or SMII Receive paths to be used for activating the LPI LS TIMER. PHY Link Status Enable This bit enables the link status received on the RGMII, SGMII, or SMII Receive paths to be used for activating the LPI LS TIMER. When this bit is set, the MAC uses the link-status bits of the MAC_PHYIF_CONTROL_STATUS register and the PLS bit for the LPI LS Timer trigger. When this bit is reset, the MAC ignores the link-status bits of the MAC_PHYIF_CONTROL_STATUS register and takes only the PLS bit. 0 - PHY Link Status is disabled 1 - PHY Link Status is enabled
17	PHY Link Status This bit indicates the link status of the PHY.

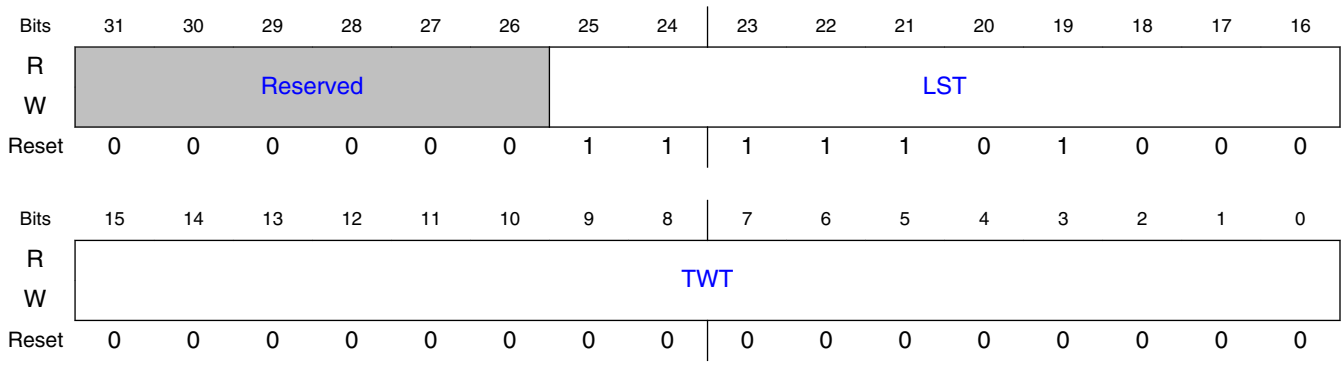
Table continues on the next page...

Field	Description
PLS	PHY Link Status This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (OKAY) at least for the time indicated by the LPI LS TIMER. When this bit is set, the link is considered to be okay (UP) and when this bit is reset, the link is considered to be down. 0 - link is down 1 - link is okay (UP)
16 LPIEN	LPI Enable When this bit is set, it instructs the MAC Transmitter to enter the LPI state. LPI Enable When this bit is set, it instructs the MAC Transmitter to enter the LPI state. When this bit is reset, it instructs the MAC to exit the LPI state and resume normal transmission. This bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission. 0 - LPI state is disabled 1 - LPI state is enabled
15-10 —	Reserved
9 RLPIST	Receive LPI State When this bit is set, it indicates that the MAC is receiving the LPI pattern on the GMII interface. 0 - Receive LPI state not detected 1 - Receive LPI state detected
8 TLPIST	Transmit LPI State When this bit is set, it indicates that the MAC is transmitting the LPI pattern on the GMII interface. 0 - Transmit LPI state not detected 1 - Transmit LPI state detected
7-4 —	Reserved
3 RLPIEX	Receive LPI Exit When this bit is set, it indicates that the MAC Receiver has stopped receiving the LPI pattern on the GMII interface, exited the LPI state, and resumed the normal reception. Receive LPI Exit When this bit is set, it indicates that the MAC Receiver has stopped receiving the LPI pattern on the GMII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in CSR_SW_CTRL register is set). Note: This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock. 0 - Receive LPI exit not detected 1 - Receive LPI exit detected
2 RLPIEN	Receive LPI Entry When this bit is set, it indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. Receive LPI Entry When this bit is set, it indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in CSR_SW_CTRL register is set).

Table continues on the next page...

Field	Description
	Note: This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock. 0 - Receive LPI entry not detected 1 - Receive LPI entry detected
1 TLPIEX	Transmit LPI Exit When this bit is set, it indicates that the MAC transmitter exited the LPI state after the application cleared the LPIEN bit and the LPI TW Timer has expired. Transmit LPI Exit When this bit is set, it indicates that the MAC transmitter exited the LPI state after the application cleared the LPIEN bit and the LPI TW Timer has expired. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in CSR_SW_CTRL register is set). 0 - Transmit LPI exit not detected 1 - Transmit LPI exit detected
0 TLPIEN	Transmit LPI Entry When this bit is set, it indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. Transmit LPI Entry When this bit is set, it indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in CSR_SW_CTRL register is set). 0 - Transmit LPI entry not detected 1 - Transmit LPI entry detected

11.7.6.1.32 LPI Timers Control (MAC_LPI_TIMERS_CONTROL)



The LPI Timers Control register controls the timeout values in the LPI states.

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

11.7.6.1.32.1 Offset

Register	Offset
MAC_LPI_TIMERS_CONTROL	D4h

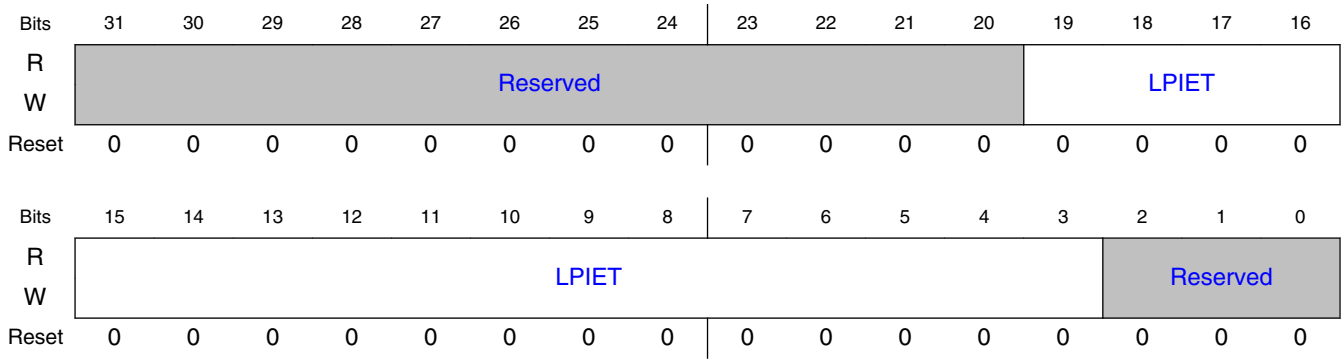
Field	Description
31-26 —	Reserved
25-16 LST	LPI LS Timer This field specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY. LPI LS Timer This field specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY. The MAC does not transmit the LPI pattern even when the LPIEN bit is set unless the LPI LS Timer reaches the programmed terminal count. The default value of the LPI LS Timer is 1000 (1 sec) as defined in the IEEE standard.
15-0 TWT	LPI TW Timer This field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. LPI TW Timer This field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPIEX status bit is set after the expiry of this timer.

11.7.6.1.33 Tx LPI Entry Timer Control (MAC_LPI_ENTRY_TIMER)



This register controls the Tx LPI entry timer.

This register controls the Tx LPI entry timer. This counter is enabled only when bit[20] (LPITE) bit of MAC_LPI_CONTROL_STATUS is set to 1.

11.7.6.1.33.1 Offset

11.7.6.1.42 MDIO Address (MAC_MDIO_ADDRESS)

The MDIO Address register controls the management cycles to external PHY through a management interface.

11.7.6.1.42.1 Offset

Register	Offset
MAC_MDIO_ADDRESS	200h

11.7.6.1.42.2 Diagram

11.7.6.1.42.3 Fields

Field	Description
31-28 —	Reserved
27 PSE	Preamble Suppression Enable When this bit is set, the SMA suppresses the 32-bit preamble and transmits MDIO frames with only 1 preamble bit. Preamble Suppression Enable When this bit is set, the SMA suppresses the 32-bit preamble and transmits MDIO frames with only 1 preamble bit. When this bit is 0, the MDIO frame always has 32 bits of preamble as defined in the IEEE specifications. 0 - Preamble Suppression disabled 1 - Preamble Suppression enabled
26 BTB	Back to Back transactions When this bit is set and the NTC has value greater than 0, then the MAC informs the completion of a read or write command at the end of frame transfer (before the trailing clocks are transmitted).

Table continues on the next page...

Field	Description
	Back to Back transactions When this bit is set and the NTC has value greater than 0, then the MAC informs the completion of a read or write command at the end of frame transfer (before the trailing clocks are transmitted). The software can thus initiate the next command which is executed immediately irrespective of the number trailing clocks generated for the previous frame. When this bit is reset, then the read/write command completion (GB is cleared) only after the trailing clocks are generated. In this mode, it is ensured that the NTC is always generated after each frame. This bit must not be set when NTC=0. 0 - Back to Back transactions disabled 1 - Back to Back transactions enabled
25-21 PA	Physical Layer Address This field indicates which Clause 22 PHY devices (out of 32 devices) the MAC is accessing. Physical Layer Address This field indicates which Clause 22 PHY devices (out of 32 devices) the MAC is accessing. This field indicates which Clause 45 capable PHYs (out of 32 PHYs) the MAC is accessing.
20-16 RDA	Register/Device Address These bits select the PHY register in selected Clause 22 PHY device. Register/Device Address These bits select the PHY register in selected Clause 22 PHY device. These bits select the Device (MMD) in selected Clause 45 capable PHY.
15 —	Reserved
14-12 NTC	Number of Trailing Clocks This field controls the number of trailing clock cycles generated on gmii_mdc_o (MDC) after the end of transmission of MDIO frame. Number of Trailing Clocks This field controls the number of trailing clock cycles generated on gmii_mdc_o (MDC) after the end of transmission of MDIO frame. The valid values can be from 0 to 7. Programming the value to 3'h3 indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer.
11-8 CR	CSR Clock Range The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency used in your design: - 0000: CSR clock = 60-100 MHz; MDC clock = CSR clock/42 - 0001: CSR clock = 100-150 MHz; MDC clock = CSR clock/62 - 0010: CSR clock = 20-35 MHz; MDC clock = CSR clock/16 - 0011: CSR clock = 35-60 MHz; MDC clock = CSR clock/26 - 0100: CSR clock = 150-250 MHz; MDC clock = CSR clock/102 - 0101: CSR clock = 250-300 MHz; MDC clock = CSR clock/124 - 0110: CSR clock = 300-500 MHz; MDC clock = CSR clock/204 - 0111: CSR clock = 500-800 MHz; MDC clock = CSR clock/324 The suggested range of CSR clock frequency applicable for each value (when Bit 11 = 0) ensures that the MDC clock is approximately between 1. CSR Clock Range The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency used in your design: - 0000: CSR clock = 60-100 MHz; MDC clock = CSR clock/42 - 0001: CSR clock = 100-150 MHz; MDC clock = CSR clock/62 - 0010: CSR clock = 20-35 MHz; MDC clock = CSR clock/16

Table continues on the next page...

Field	Description
	- 0011: CSR clock = 35-60 MHz; MDC clock = CSR clock/26 - 0100: CSR clock = 150-250 MHz; MDC clock = CSR clock/102 - 0101: CSR clock = 250-300 MHz; MDC clock = CSR clock/124 - 0110: CSR clock = 300-500 MHz; MDC clock = CSR clock/204 - 0111: CSR clock = 500-800 MHz; MDC clock = CSR clock/324 The suggested range of CSR clock frequency applicable for each value (when Bit 11 = 0) ensures that the MDC clock is approximately between 1.0 MHz to 2.5 MHz freqency range. When Bit 11 is set, you can achieve a higher frequency of the MDC clock than the frequency limit of 2.5 MHz (specified in the IEEE 802.3) and program a clock divider of lower value. For example, when CSR clock is of 100 MHz frequency and you program these bits as 1010, the resultant MDC clock is of 12.5 MHz which is above the range specified in IEEE 802.3. Program the following values only if the interfacing chips support faster MDC clocks: - 1000: CSR clock/4 - 1001: CSR clock/6 - 1010: CSR clock/8 - 1011: CSR clock/10 - 1100: CSR clock/12 - 1101: CSR clock/14 - 1110: CSR clock/16 - 1111: CSR clock/18 These bits are not used for accessing RevMII. These bits are read-only if the RevMII interface is selected as single PHY interface.
7-5 —	Reserved
4 SKAP	Skip Address Packet When this bit is set, the SMA does not send the address packets before read, write, or post-read increment address packets. Skip Address Packet When this bit is set, the SMA does not send the address packets before read, write, or post-read increment address packets. This bit is valid only when C45E is set. 0 - Skip Address Packet is disabled 1 - Skip Address Packet is enabled
3 GOC_1	GMII Operation Command 1 This bit is higher bit of the operation command to the PHY or RevMII, GOC_1 and GOC_O is encoded as follows: - 00: Reserved - 01: Write - 10: Post Read Increment Address for Clause 45 PHY - 11: Read When Clause 22 PHY or RevMII is enabled, only Write and Read commands are valid. 0 - GMII Operation Command 1 is disabled 1 - GMII Operation Command 1 is enabled
2 GOC_0	GMII Operation Command 0 This is the lower bit of the operation command to the PHY or RevMII. GMII Operation Command 0 This is the lower bit of the operation command to the PHY or RevMII. When in SMA mode (MDIO master) this bit along with GOC_1 determines the operation to be performed to the PHY. When only RevMII is selected in configuration this bit is read-only and tied to 1. 0 - GMII Operation Command 0 is disabled

Table continues on the next page...

Field	Description
	1 - GMII Operation Command 0 is enabled
1 C45E	Clause 45 PHY Enable When this bit is set, Clause 45 capable PHY is connected to MDIO. Clause 45 PHY Enable When this bit is set, Clause 45 capable PHY is connected to MDIO. When this bit is reset, Clause 22 capable PHY is connected to MDIO. 0 - Clause 45 PHY is disabled 1 - Clause 45 PHY is enabled
0 GB	GMII Busy The application sets this bit to instruct the SMA to initiate a Read or Write access to the MDIO slave. GMII Busy The application sets this bit to instruct the SMA to initiate a Read or Write access to the MDIO slave. The MAC clears this bit after the MDIO frame transfer is completed. Hence the software must not write or change any of the fields in MAC_MDIO_ADDRESS and MAC_MDIO_DATA registers as long as this bit is set. For write transfers, the application must first write 16-bit data in the GDI field (and also RA field when C45E is set) in MAC_MDIO_DATA register before setting this bit. When C45E is set, it should also write into the RA field of MAC_MDIO_DATA register before initiating a read transfer. When a read transfer is completed (GB=0), the data read from the PHY register is valid in the GD field of the MAC_MDIO_DATA register. Note: Even if the addressed PHY is not present, there is no change in the functionality of this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - GMII Busy is disabled 1 - GMII Busy is enabled

11.7.6.1.43 MAC MDIO Data (MAC_MDIO_DATA)

The MAC_MDIO_DATA register stores the Write data to be written to the PHY register located at the address specified in MAC_MDIO_ADDRESS. This register also stores the Read data from the PHY register located at the address specified by MAC_MDIO_ADDRESS register.

11.7.6.1.43.1 Offset

11.7.6.1.47.3 Fields

Field	Description
31-0 MPTU	MAC 1722 Presentation Time Update This field holds the init value or the update value for the presentation time. MAC 1722 Presentation Time Update This field holds the init value or the update value for the presentation time. When used for update, this field holds the 32-bit value in ns, that should be added to the Current Presentation Time Counter value. Init happens when TSINIT is set, and update happens when the TSUPDT bit is set (TSINIT and TSINIT defined in MAC_TIMESTAMP_CONTROL register). When ADDSUB field of MAC_SYSTEM_TIME_NANOSECONDS_UPDATE is set, this value is directly used for subtraction

11.7.6.1.48 MAC Address0 High (MAC_ADDRESS0_HIGH)

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station.

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if

0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

11.7.6.1.57.3 Fields

Field	Description
31-0 ADDRLO	MAC ADDRESS1 [31:0] This field contains the lower 32 bits of second 6-byte MAC address. MAC ADDRESS1 [31:0] This field contains the lower 32 bits of second 6-byte MAC address. The content of this field is undefined until loaded by the application after the initialization process.

11.7.6.1.58 MAC Address5 High (MAC_ADDRESS5_HIGH)

The MAC ADDRESS1 High register holds the upper 16 bits of the second 6-byte MAC address of the station.

The MAC ADDRESS1 High register holds the upper 16 bits of the second 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC ADDRESS1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

11.7.6.1.58.1 Offset

11.7.6.1.81.3 Fields

Field	Description
31-0 ADDRLO	MAC ADDRESS1 [31:0] This field contains the lower 32 bits of second 6-byte MAC address. MAC ADDRESS1 [31:0] This field contains the lower 32 bits of second 6-byte MAC address. The content of this field is undefined until loaded by the application after the initialization process.

11.7.6.1.82 MAC Address17 High (MAC_ADDRESS17_HIGH)

The MAC ADDRESS1 High register holds the upper 16 bits of the second 6-byte MAC address of the station.

The MAC ADDRESS1 High register holds the upper 16 bits of the second 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC ADDRESS1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

11.7.6.1.93.3 Fields

Field	Description
31-0 ADDRLO	MAC ADDRESS1 [31:0] This field contains the lower 32 bits of second 6-byte MAC address. MAC ADDRESS1 [31:0] This field contains the lower 32 bits of second 6-byte MAC address. The content of this field is undefined until loaded by the application after the initialization process.

11.7.6.1.94 MAC Address23 High (MAC_ADDRESS23_HIGH)

The MAC ADDRESS1 High register holds the upper 16 bits of the second 6-byte MAC address of the station.

The MAC ADDRESS1 High register holds the upper 16 bits of the second 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC ADDRESS1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

11.7.6.1.94.1 Offset

The MAC ADDRESS32 High register holds the upper 16 bits of the 33rd 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address Low Register are written. For proper synchronization updates, you should perform the consecutive writes to the MAC Address Low Register after at least four clock cycles of the destination clock.

11.7.6.1.149.3 Fields

Field	Description
31-0 ADDRLO	MAC ADDRESS32 [31:0] This field contains the lower 32 bits of the 33rd 6-byte MAC address. MAC ADDRESS32 [31:0] This field contains the lower 32 bits of the 33rd 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process.

11.7.6.1.150 MAC Address51 High (MAC_ADDRESS51_HIGH)

The MAC ADDRESS32 High register holds the upper 16 bits of the 33rd 6-byte MAC address of the station.

The MAC ADDRESS32 High register holds the upper 16 bits of the 33rd 6-byte MAC address of the station.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address Low Register are written. For proper synchronization updates, you should perform the consecutive writes to the MAC Address Low Register after at least four clock cycles of the destination clock.

11.7.6.1.176.3 Fields

Field	Description
31-9 —	Reserved
8 UCDBC	Update MMC Counters for Dropped Broadcast Packets Note: The CNTRST bit has a higher priority than the CNTPRST bit. Update MMC Counters for Dropped Broadcast Packets Note: The CNTRST bit has a higher priority than the CNTPRST bit. Therefore, when the software tries to set both bits in the same write cycle, all counters are cleared and the CNTPRST bit is not set. When set, the MAC updates all related MMC Counters for Broadcast packets that are dropped because of the setting of the DBF bit of MAC_Packet_Filter register. When reset, the MMC Counters are not updated for dropped Broadcast packets. 0 - Update MMC Counters for Dropped Broadcast Packets is disabled 1 - Update MMC Counters for Dropped Broadcast Packets is enabled
7-6 —	Reserved
5 CNTPRSTLVL	Full-Half Preset When this bit is low and the CNTPRST bit is set, all MMC counters get preset to almost-half value. Full-Half Preset

Table continues on the next page...

Field	Description
	When this bit is low and the CNTPRST bit is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (Half 2KBytes) and all packet-counters gets preset to 0x7FFF_FFF0 (Half 16). When this bit is high and the CNTPRST bit is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (Full 2KBytes) and all packet-counters gets preset to 0xFFFF_FFF0 (Full 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and packet counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0. 0 - Full-Half Preset is disabled 1 - Full-Half Preset is enabled
4 CNTPRST	Counters Preset When this bit is set, all counters are initialized or preset to almost full or almost half according to the CNTPRSTLVL bit. Counters Preset When this bit is set, all counters are initialized or preset to almost full or almost half according to the CNTPRSTLVL bit. This bit is cleared automatically after 1 clock cycle. This bit, along with the CNTPRSTLVL bit, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. 0 - Counters Preset is disabled 1 - Counters Preset is enabled
3 CNTFREEZ	MMC Counter Freeze When this bit is set, it freezes all MMC counters to their current value. MMC Counter Freeze When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received packet. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode. 0 - MMC Counter Freeze is disabled 1 - MMC Counter Freeze is enabled
2 RSTONRD	Reset on Read When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). Reset on Read When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (Bits[7:0]) is read. 0 - Reset on Read is disabled 1 - Reset on Read is enabled
1 CNTSTOPRO	Counter Stop Rollover When this bit is set, the counter does not roll over to zero after reaching the maximum value. 0 - Counter Stop Rollover is disabled 1 - Counter Stop Rollover is enabled
0 CNTRST	Counters Reset When this bit is set, all counters are reset. Counters Reset When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle. Access restriction applies. Self-cleared. Setting 0 clears. Setting 1 sets. 0 - Counters are not reset

Field	Description
	1 - All counters are reset

11.7.6.1.177 MMC Rx Interrupt (MAC_MMC_RX_INTERRUPT)

This register maintains the interrupts generated from all Receive statistics counters.

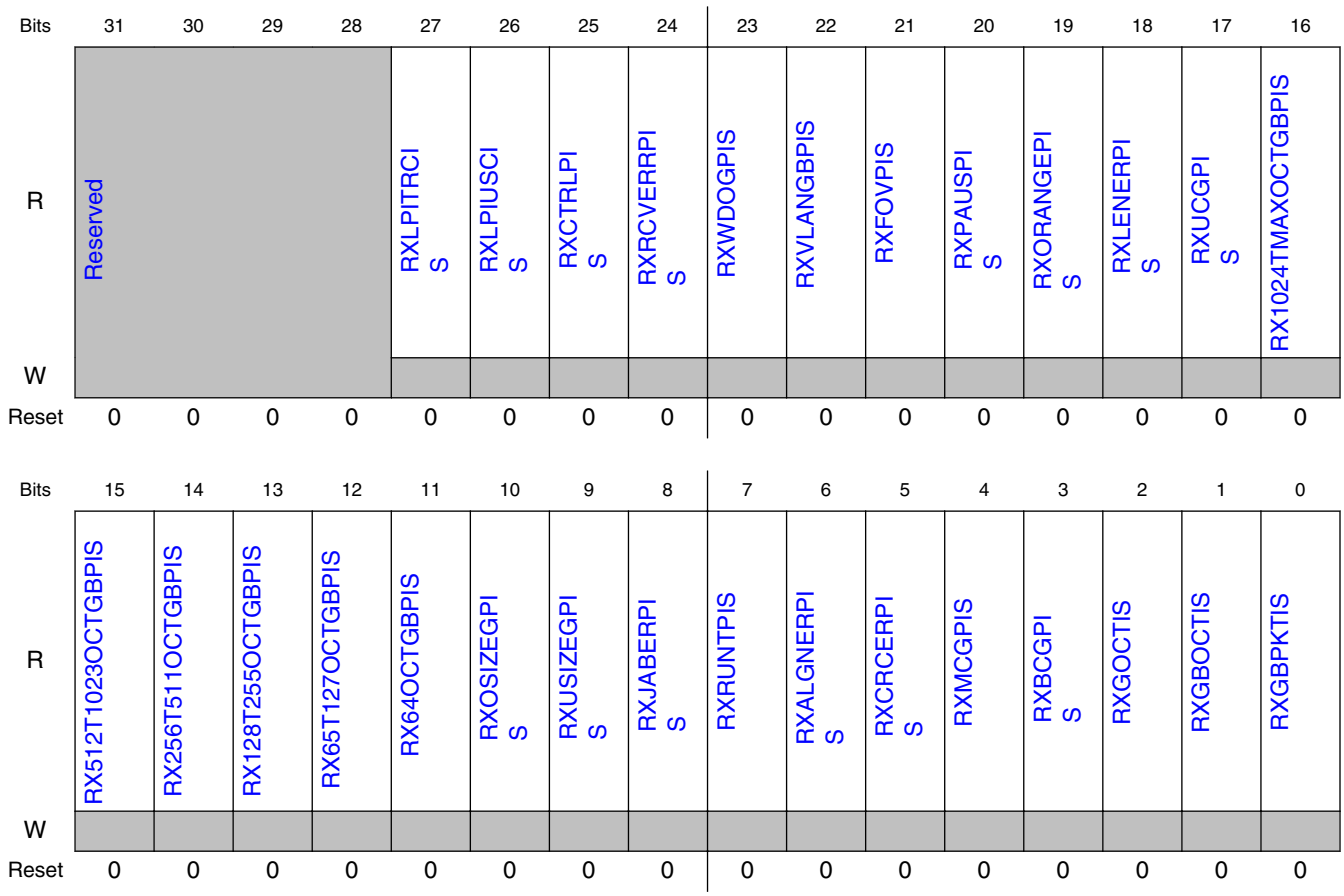
This register maintains the interrupts generated from all Receive statistics counters.

The MMC Receive Interrupt register maintains the interrupts that are generated when the following occur:

- Receive statistic counters reach half of their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter).

- Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32 bit counter and 0xFFFF for 16 bit counter).

When the Counter Stop Rollover is set, interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register



is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

Note: R_SS_RC means that this register bit is set internally, and it is cleared when the Counter register is read.

Self-set to 1 on internal event. 0 - MMC Receive Out Of Range Error Packet Counter Interrupt Status not detected 1 - MMC Receive Out Of Range Error Packet Counter Interrupt Status detected
18 RXLENERPIS	MMC Receive Length Error Packet Counter Interrupt Status This bit is set when the rxlengtherror counter reaches half of the maximum value or the maximum value. MMC Receive Length Error Packet Counter Interrupt Status This bit is set when the rxlengtherror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Receive Length Error Packet Counter Interrupt Status not detected 1 - MMC Receive Length Error Packet Counter Interrupt Status detected
17 RXUCGPIS	MMC Receive Unicast Good Packet Counter Interrupt Status This bit is set when the rxunicastpackets_g counter reaches half of the maximum value or the maximum value. MMC Receive Unicast Good Packet Counter Interrupt Status This bit is set when the rxunicastpackets_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Receive Unicast Good Packet Counter Interrupt Status not detected 1 - MMC Receive Unicast Good Packet Counter Interrupt Status detected
16 RX1024TMAXOCTGBPIS	MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value. MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Status not detected 1 - MMC Receive 1024 to Maximum Octet Good Bad Packet Counter Interrupt Status detected
15 RX512T1023OCTGBPIS	MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx512to1023octets_gb counter reaches half of the maximum value or the maximum value. MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Status

Table continues on the next page...

Field	Description
	This bit is set when the rx512to1023octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Status not detected 1 - MMC Receive 512 to 1023 Octet Good Bad Packet Counter Interrupt Status detected
14 RX256T511OCTGBPIS	MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx256to511octets_gb counter reaches half of the maximum value or the maximum value. MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx256to511octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Status not detected 1 - MMC Receive 256 to 511 Octet Good Bad Packet Counter Interrupt Status detected
13 RX128T255OCTGBPIS	MMC Receive 128 to 255 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx128to255octets_gb counter reaches half of the maximum value or the maximum value. MMC Receive 128 to 255 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx128to255octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Receive 128 to 255 Octet Good Bad Packet Counter Interrupt Status not detected 1 - MMC Receive 128 to 255 Octet Good Bad Packet Counter Interrupt Status detected
12 RX65T127OCTGBPIS	MMC Receive 65 to 127 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx65to127octets_gb counter reaches half of the maximum value or the maximum value. MMC Receive 65 to 127 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx65to127octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Receive 65 to 127 Octet Good Bad Packet Counter Interrupt Status not detected 1 - MMC Receive 65 to 127 Octet Good Bad Packet Counter Interrupt Status detected
11 RX64OCTGBPIS	MMC Receive 64 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx64octets_gb counter reaches half of the maximum value or the maximum value. MMC Receive 64 Octet Good Bad Packet Counter Interrupt Status This bit is set when the rx64octets_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Receive 64 Octet Good Bad Packet Counter Interrupt Status not detected 1 - MMC Receive 64 Octet Good Bad Packet Counter Interrupt Status detected
10 RXOSIZEGPIS	MMC Receive Oversize Good Packet Counter Interrupt Status This bit is set when the rxoversize_g counter reaches half of the maximum value or the maximum value. MMC Receive Oversize Good Packet Counter Interrupt Status This bit is set when the rxoversize_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Receive Oversize Good Packet Counter Interrupt Status not detected

Table continues on the next page...

Field	Description
	1 - MMC Receive Oversize Good Packet Counter Interrupt Status detected
9 RXUSIZEGPIS	MMC Receive Undersize Good Packet Counter Interrupt Status This bit is set when the rxundersize_g counter reaches half of the maximum value or the maximum value. MMC Receive Undersize Good Packet Counter Interrupt Status This bit is set when the rxundersize_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Receive Undersize Good Packet Counter Interrupt Status not detected 1 - MMC Receive Undersize Good Packet Counter Interrupt Status detected
8 RXJABERPIS	MMC Receive Jabber Error Packet Counter Interrupt Status This bit is set when the rxjabbererror counter reaches half of the maximum value or the maximum value. MMC Receive Jabber Error Packet Counter Interrupt Status This bit is set when the rxjabbererror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Receive Jabber Error Packet Counter Interrupt Status not detected 1 - MMC Receive Jabber Error Packet Counter Interrupt Status detected
7 RXRUNTPIS	MMC Receive Runt Packet Counter Interrupt Status This bit is set when the rxrunterror counter reaches half of the maximum value or the maximum value. MMC Receive Runt Packet Counter Interrupt Status This bit is set when the rxrunterror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Receive Runt Packet Counter Interrupt Status not detected 1 - MMC Receive Runt Packet Counter Interrupt Status detected
6 RXALGNERPIS	MMC Receive Alignment Error Packet Counter Interrupt Status This bit is set when the rxalignmenterror counter reaches half of the maximum value or the maximum value. MMC Receive Alignment Error Packet Counter Interrupt Status This bit is set when the rxalignmenterror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Receive Alignment Error Packet Counter Interrupt Status not detected 1 - MMC Receive Alignment Error Packet Counter Interrupt Status detected
5 RXCRCERPIS	MMC Receive CRC Error Packet Counter Interrupt Status This bit is set when the rxcrcerror counter reaches half of the maximum value or the maximum value. MMC Receive CRC Error Packet Counter Interrupt Status This bit is set when the rxcrcerror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Receive CRC Error Packet Counter Interrupt Status not detected 1 - MMC Receive CRC Error Packet Counter Interrupt Status detected
4 RXMCGPIS	MMC Receive Multicast Good Packet Counter Interrupt Status This bit is set when the rxmulticastpackets_g counter reaches half of the maximum value or the maximum value. MMC Receive Multicast Good Packet Counter Interrupt Status

Table continues on the next page...

Field	Description
	This bit is set when the rxmulticastpackets_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Receive Multicast Good Packet Counter Interrupt Status not detected 1 - MMC Receive Multicast Good Packet Counter Interrupt Status detected
3 RXBCGPIS	MMC Receive Broadcast Good Packet Counter Interrupt Status This bit is set when the rxbroadcastpackets_g counter reaches half of the maximum value or the maximum value. MMC Receive Broadcast Good Packet Counter Interrupt Status This bit is set when the rxbroadcastpackets_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Receive Broadcast Good Packet Counter Interrupt Status not detected 1 - MMC Receive Broadcast Good Packet Counter Interrupt Status detected
2 RXGOCTIS	MMC Receive Good Octet Counter Interrupt Status This bit is set when the rxoctetcount_g counter reaches half of the maximum value or the maximum value. MMC Receive Good Octet Counter Interrupt Status This bit is set when the rxoctetcount_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Receive Good Octet Counter Interrupt Status not detected 1 - MMC Receive Good Octet Counter Interrupt Status detected
1 RXGBOCTIS	MMC Receive Good Bad Octet Counter Interrupt Status This bit is set when the rxoctetcount_gb counter reaches half of the maximum value or the maximum value. MMC Receive Good Bad Octet Counter Interrupt Status This bit is set when the rxoctetcount_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Receive Good Bad Octet Counter Interrupt Status not detected 1 - MMC Receive Good Bad Octet Counter Interrupt Status detected
0 RXGBPKTIS	MMC Receive Good Bad Packet Counter Interrupt Status This bit is set when the rxpacketcount_gb counter reaches half of the maximum value or the maximum value. MMC Receive Good Bad Packet Counter Interrupt Status This bit is set when the rxpacketcount_gb counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Receive Good Bad Packet Counter Interrupt Status not detected 1 - MMC Receive Good Bad Packet Counter Interrupt Status detected

11.7.6.1.178 MMC Tx Interrupt (MAC_MMC_TX_INTERRUPT)

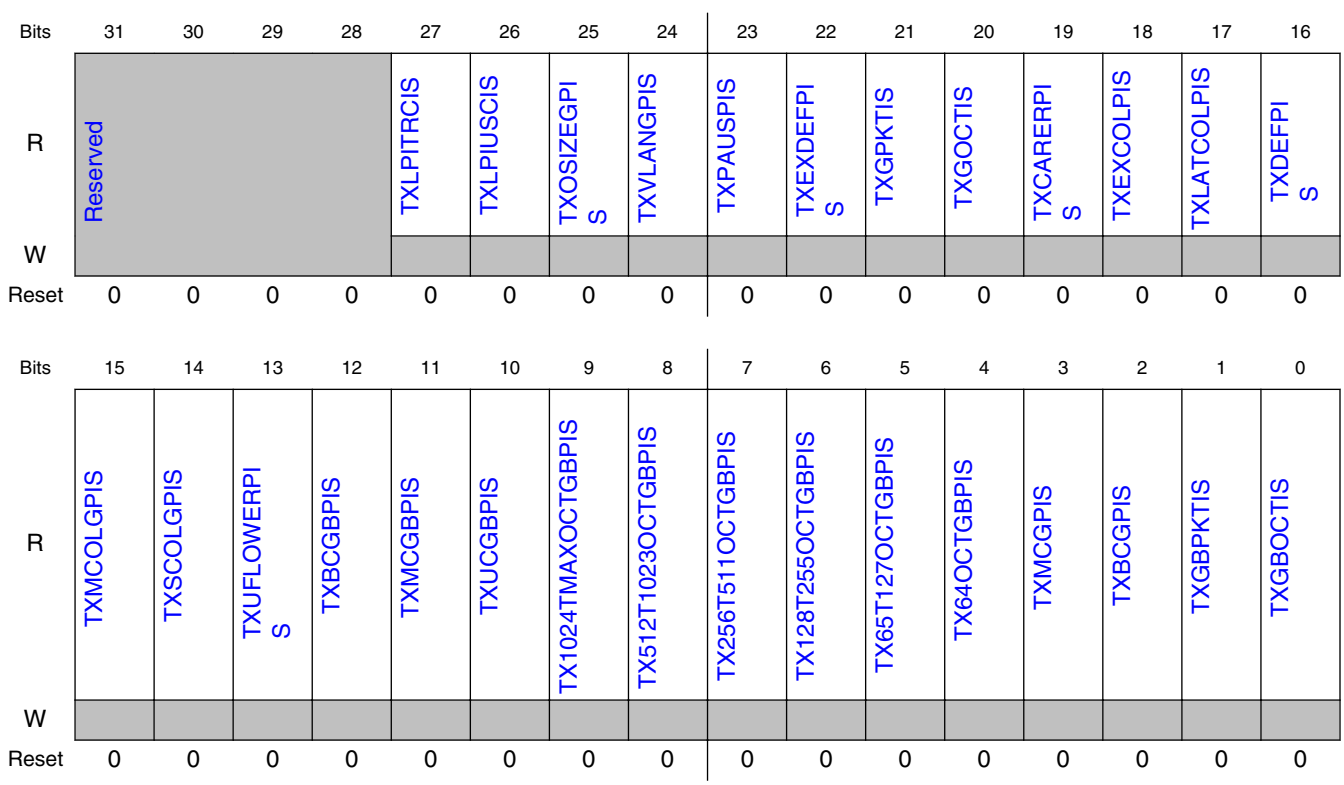
This register maintains the interrupts generated from all Transmit statistics counters.

This register maintains the interrupts generated from all Transmit statistics counters.

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values

(0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter).

When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones.



The MMC Transmit Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read.

The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

11.7.6.1.178.1 Offset

Register	Offset
MAC_MMC_TX_INTERRUPT	708h

11.7.6.1.178.2 Diagram

11.7.6.1.178.3 Fields

Field	Description
31-28 —	Reserved
27 TXLPITRCIS	MMC Transmit LPI transition counter interrupt status This bit is set when the Tx_LPI_Tran_Cntr counter reaches half of the maximum value or the maximum value. MMC Transmit LPI transition counter interrupt status This bit is set when the Tx_LPI_Tran_Cntr counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Transmit LPI transition Counter Interrupt Status not detected 1 - MMC Transmit LPI transition Counter Interrupt Status detected
26 TXLPIUSCIS	MMC Transmit LPI microsecond counter interrupt status This bit is set when the Tx_LPI_USEC_Cntr counter reaches half of the maximum value or the maximum value. MMC Transmit LPI microsecond counter interrupt status This bit is set when the Tx_LPI_USEC_Cntr counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Transmit LPI microsecond Counter Interrupt Status not detected 1 - MMC Transmit LPI microsecond Counter Interrupt Status detected
25 TXOSIZEGPIS	MMC Transmit Oversize Good Packet Counter Interrupt Status This bit is set when the txoversize_g counter reaches half of the maximum value or the maximum value. MMC Transmit Oversize Good Packet Counter Interrupt Status This bit is set when the txoversize_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Transmit Oversize Good Packet Counter Interrupt Status not detected 1 - MMC Transmit Oversize Good Packet Counter Interrupt Status detected
24 TXVLANGPIS	MMC Transmit VLAN Good Packet Counter Interrupt Status This bit is set when the txvlanpackets_g counter reaches half of the maximum value or the maximum value. MMC Transmit VLAN Good Packet Counter Interrupt Status This bit is set when the txvlanpackets_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Transmit VLAN Good Packet Counter Interrupt Status not detected 1 - MMC Transmit VLAN Good Packet Counter Interrupt Status detected
23 TXPAUSPIS	MMC Transmit Pause Packet Counter Interrupt Status This bit is set when the txpausepacketserror counter reaches half of the maximum value or the maximum value. MMC Transmit Pause Packet Counter Interrupt Status This bit is set when the txpausepacketserror counter reaches half of the maximum value or the maximum value.

Table continues on the next page...

Field	Description
	Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Transmit Pause Packet Counter Interrupt Status not detected 1 - MMC Transmit Pause Packet Counter Interrupt Status detected
22 TXEXDEFPIS	MMC Transmit Excessive Deferral Packet Counter Interrupt Status This bit is set when the txexcessdef counter reaches half of the maximum value or the maximum value. MMC Transmit Excessive Deferral Packet Counter Interrupt Status This bit is set when the txexcessdef counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Transmit Excessive Deferral Packet Counter Interrupt Status not detected 1 - MMC Transmit Excessive Deferral Packet Counter Interrupt Status detected
21 TXGPKTIS	MMC Transmit Good Packet Counter Interrupt Status This bit is set when the txpacketcount_g counter reaches half of the maximum value or the maximum value. MMC Transmit Good Packet Counter Interrupt Status This bit is set when the txpacketcount_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Transmit Good Packet Counter Interrupt Status not detected 1 - MMC Transmit Good Packet Counter Interrupt Status detected
20 TXGOCTIS	MMC Transmit Good Octet Counter Interrupt Status This bit is set when the txoctetcount_g counter reaches half of the maximum value or the maximum value. MMC Transmit Good Octet Counter Interrupt Status This bit is set when the txoctetcount_g counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Transmit Good Octet Counter Interrupt Status not detected 1 - MMC Transmit Good Octet Counter Interrupt Status detected
19 TXCARERPIS	MMC Transmit Carrier Error Packet Counter Interrupt Status This bit is set when the txcarriererror counter reaches half of the maximum value or the maximum value. MMC Transmit Carrier Error Packet Counter Interrupt Status This bit is set when the txcarriererror counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Transmit Carrier Error Packet Counter Interrupt Status not detected 1 - MMC Transmit Carrier Error Packet Counter Interrupt Status detected
18 TXEXCOLPIS	MMC Transmit Excessive Collision Packet Counter Interrupt Status This bit is set when the txexesscol counter reaches half of the maximum value or the maximum value. MMC Transmit Excessive Collision Packet Counter Interrupt Status This bit is set when the txexesscol counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Transmit Excessive Collision Packet Counter Interrupt Status not detected 1 - MMC Transmit Excessive Collision Packet Counter Interrupt Status detected

Table continues on the next page...

Field	Description
17 TXLATCOLPIS	MMC Transmit Late Collision Packet Counter Interrupt Status This bit is set when the txlatecol counter reaches half of the maximum value or the maximum value. MMC Transmit Late Collision Packet Counter Interrupt Status This bit is set when the txlatecol counter reaches half of the maximum value or the maximum value. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0 - MMC Transmit Late Collision Packet Counter Interrupt Status not detected 1 - MMC Transmit Late Collision Packet Counter Interrupt Status detected
