Most of the configuration registers inside of ISP hold static programming information (e.g., horizontal and vertical synchronization polarities at the sensor interface). The registers are accessible by the CPU at any time. In some cases it is required to dynamically re-program the active processing data path with new parameters. All of these new parameters must not be changed during processing of a frame, but between frames or at the end of a frame. Because it cannot be ensured that the re-programming can be fully completed during the vertical blanking period between two frames, shadow registers are used.

These shadow registers are identified by the suffix _SHD. They hold the configuration values that are used for processing. Their corresponding configuration registers do not directly affect the hardware, but store the new values until the configuration update is triggered. The shadow registers get their value from the respective configuration register by an immediate or frame synchronous update procedure. Registers may contain a mixture of normal bits and bits which have corresponding shadow bits.

NOTE

ISP functionality can be accessed from Software Interface.

13.15 DeWarp

13.15.1 Overview

The Dewarp Engine provides high-performance dewarp processing for the correction of the distortion that is introduced in images produced by fisheye and wide angle lenses. It is implemented with a line/tile-cache based architecture. With configurable address mapping look up tables and per tile processing, it successfully generates a corrected output image.

13.15.1.1 Block Diagram

The block diagram of the Dewarp Engine is shown below.

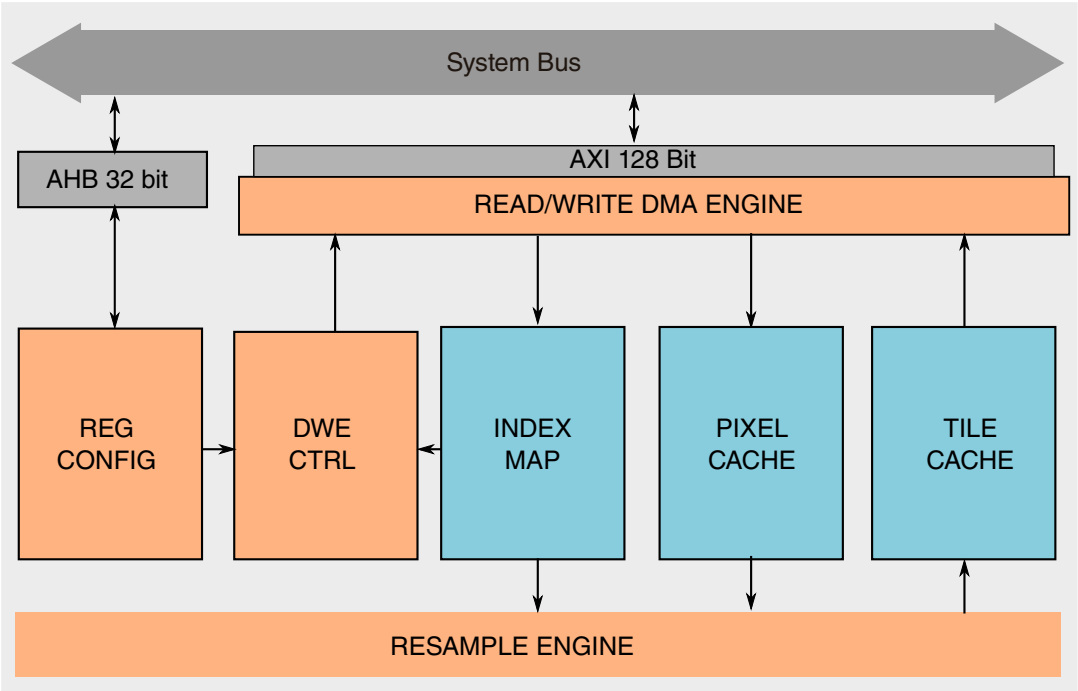

Figure 13-89. Dewarp Engine Block Diagram

13.15.1.1.1 Block Descriptions

The main functional blocks of the Dewarp Engine are described in the table below.

Table 13-42. Dewarp Engine Functional Blocks

Dewarp Engine Block	Description
Register Configuration	Generates configurable registers for dewarp control
DMA Fetch Engine	Fetches the LUT grid map and prefetches the distorted image
DWE Control	Provides configuration and execution controls for the resample engine
Index Map	Collects the image data that needs interpolation
Pixel Cache	Cache where the data manipulation occurs
Resample Engine	Performs bilinear interpolation for sets of four neighboring pixels and sends 4 byte data to the tile cache
Tile Cache	Cache for tiled output data

13.15.1.2 Features

The main features of the Dewarp Engine include:

- Line/Tile-cache based architecture and configurable map to support various lens distortions
- YUV422 and YUV420 inputs and outputs
- Configurable bilinear interpolation engine
- Grid map with 16x16 pixel macroblocks indexed using X, Y vertex coordinates
- Fisheye correction
- Wide Field of View (FOV) correction
- Keystone correction
- Scaling and 4PTZ view

13.15.2 Functional Description

The following sections provide functional information about the Dewarp Engine.

13.15.2.1 Pre-fetch and LUT Features

LUT (Look Up Table) content is fetched from DDR and used to generate the coordinates for the correct image. Macroblocks are prefetched as 16x16 MB tiles. When dewarp starts, data is fetched from the LUT according to an established fetch priority.

Table 13-43. Pre-fetch and LUT Support

LUT Data	DeWarp Support
LUT SRAM	1024 x128 bit
LUT max image size	4K image (4 lines)
Fetch Priority	Highest: Real Pixel Calculation Second Priority: Pre-fetch LUT read Lowest Priority: Pre-fetch LUT write
Macroblock (MB) Fetch	Pre-fetches image data in MBs (16 pixels x16 lines)

13.15.2.2 Pixel Calculation and Distortion Correction

The Dewarp Engine includes algorithms which provide correction for a variety of distortion effects typical of image output from pinhole cameras with fisheye or wide angled lenses.

Table 13-44. Distortion Correction Support

Distortion Correction Algorithm	Typical Visible Distortion Effects
Radial distortion correction	barrel distortion pincushion distortion mustache distortion fisheye distortion
Tangential distortion correction	parallax distortion wide field of view (FOV) distortion perspective transformation keystone effects
Scaling	size, 4PTZ(pan-tilt-zoom) view

13.15.2.3 Dewarping Remap

The image is divided into many small 16x16 blocks. If the width of the image is not divisible by 16, the size of the rightmost block is the remainder. The dewarping map only saves the vertex coordinates of the block.

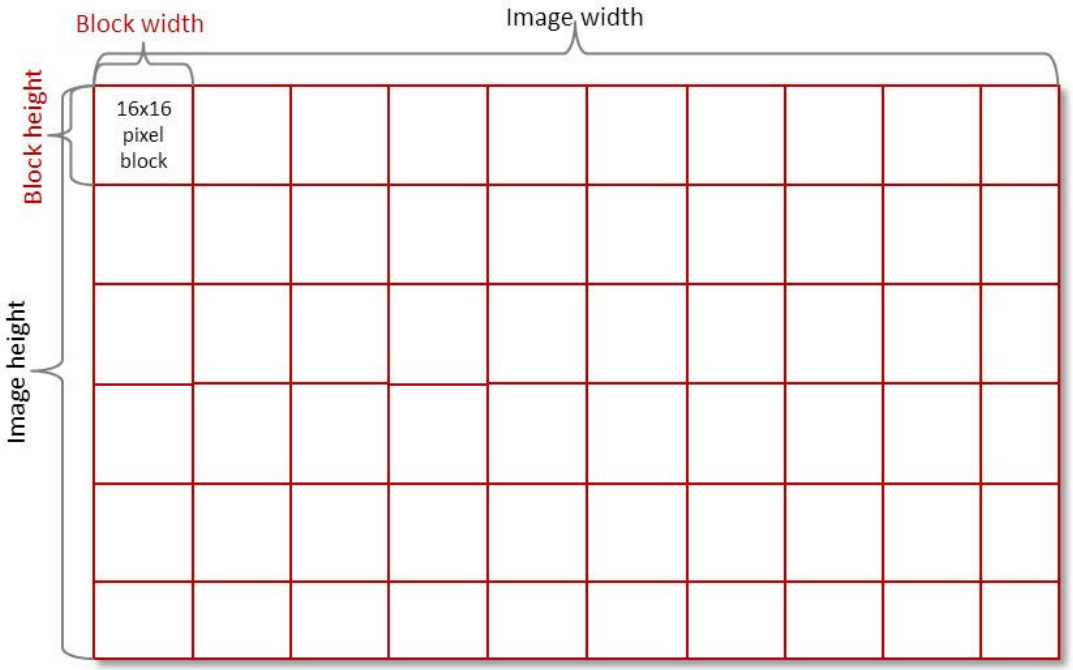

Figure 13-90. Grid of Image Blocks for Dewarping Map

The dewarping grid map is comprised of vertex coordinates for x and y. Each x, y coordinate register uses 16 bits to record the coordinate address, with the Y coordinate in the upper bits and X in the lower bits.

- 12 bits is the integer part and 4 bits is the fractional part.

The dewarping remap contains two interpolations: coordinate interpolation and pixel interpolation as shown in the figure below.

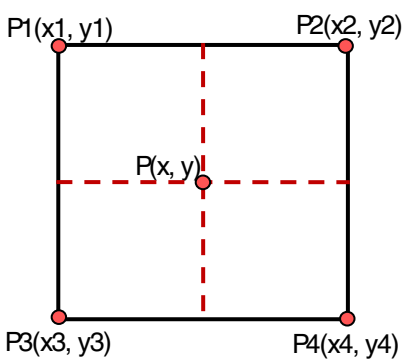

Figure 13-91. Remap with Coordinate and Pixel Interpolation

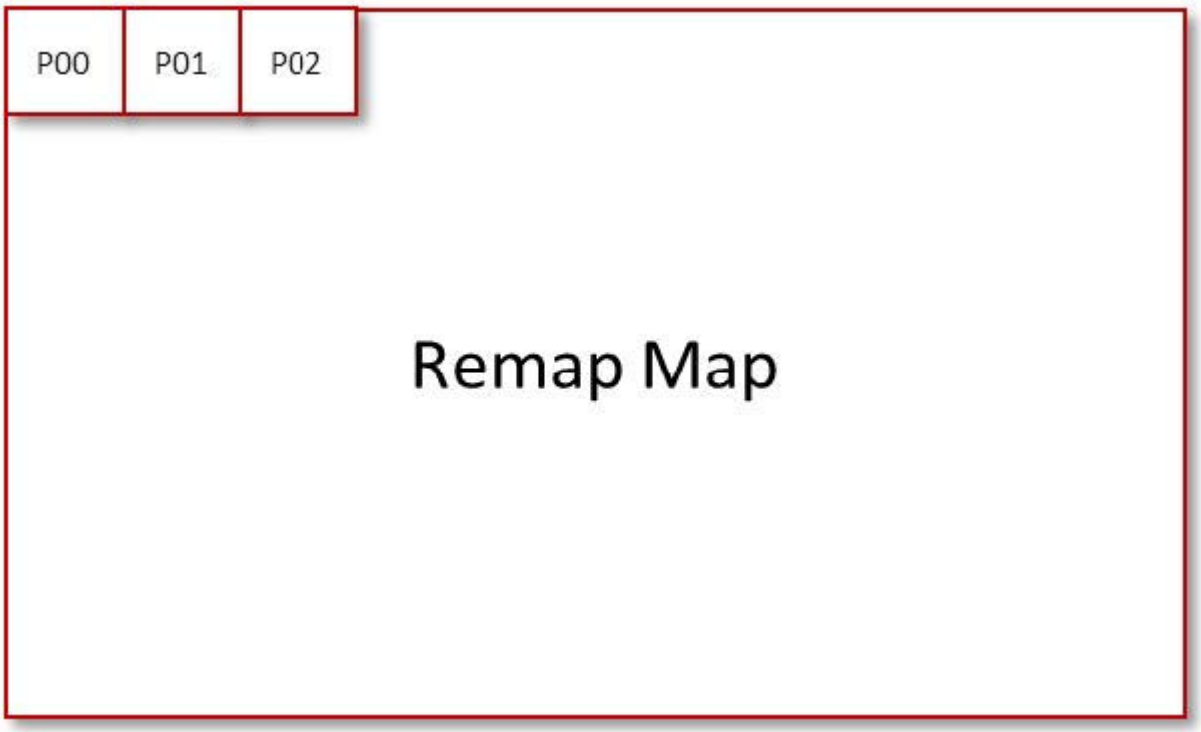

Figure 13-92. Remap Map

13.15.2.4 Output Generation

Once dewarp calculations are complete, the Dewarp Engine generates a write request for the image.

- If the mode is interleave, it generates one request, with burst length of 8 and data format YUYVY.
- If the mode is semi-planar, it generates two types of requests: one is a Y request with a burst length of 4 and data format YYYY; the second is a UV request with a burst length of 4 and data format UVUVUV.

13.15.2.5 Image Format Support

The following YUV formats are supported.

Table 13-45. YUV Input and Output Format Support

Format	Input Support	Output Support	Bits per pixel
YUV420 Semi-planar	YES	YES	12
YUV422 Interleave	YES	YES	16

Table continues on the next page...

Table 13-45. YUV Input and Output Format Support (continued)

Format	Input Support	Output Support	Bits per pixel
YUV422 Semi-planar	YES	YES (only when Input is YUV422)	16

13.15.3 External Signals

There are no external signals pinned out for this module.

13.15.4 Initialization and Application Information

The Dewarp Engine cannot be used as a standalone module. It can only be used in conjunction with the Image Signal Processor (ISP) module.

13.16 Machine Learning Neural Processing Unit (NPU)

13.16.1 Overview

The Neural Processing Unit (NPU) provides hardware acceleration for AI/ML workloads and vision functions. The IP provides enhanced performance for real-time use cases with hardware support for the OpenVX API.

13.16.2 Block Diagram

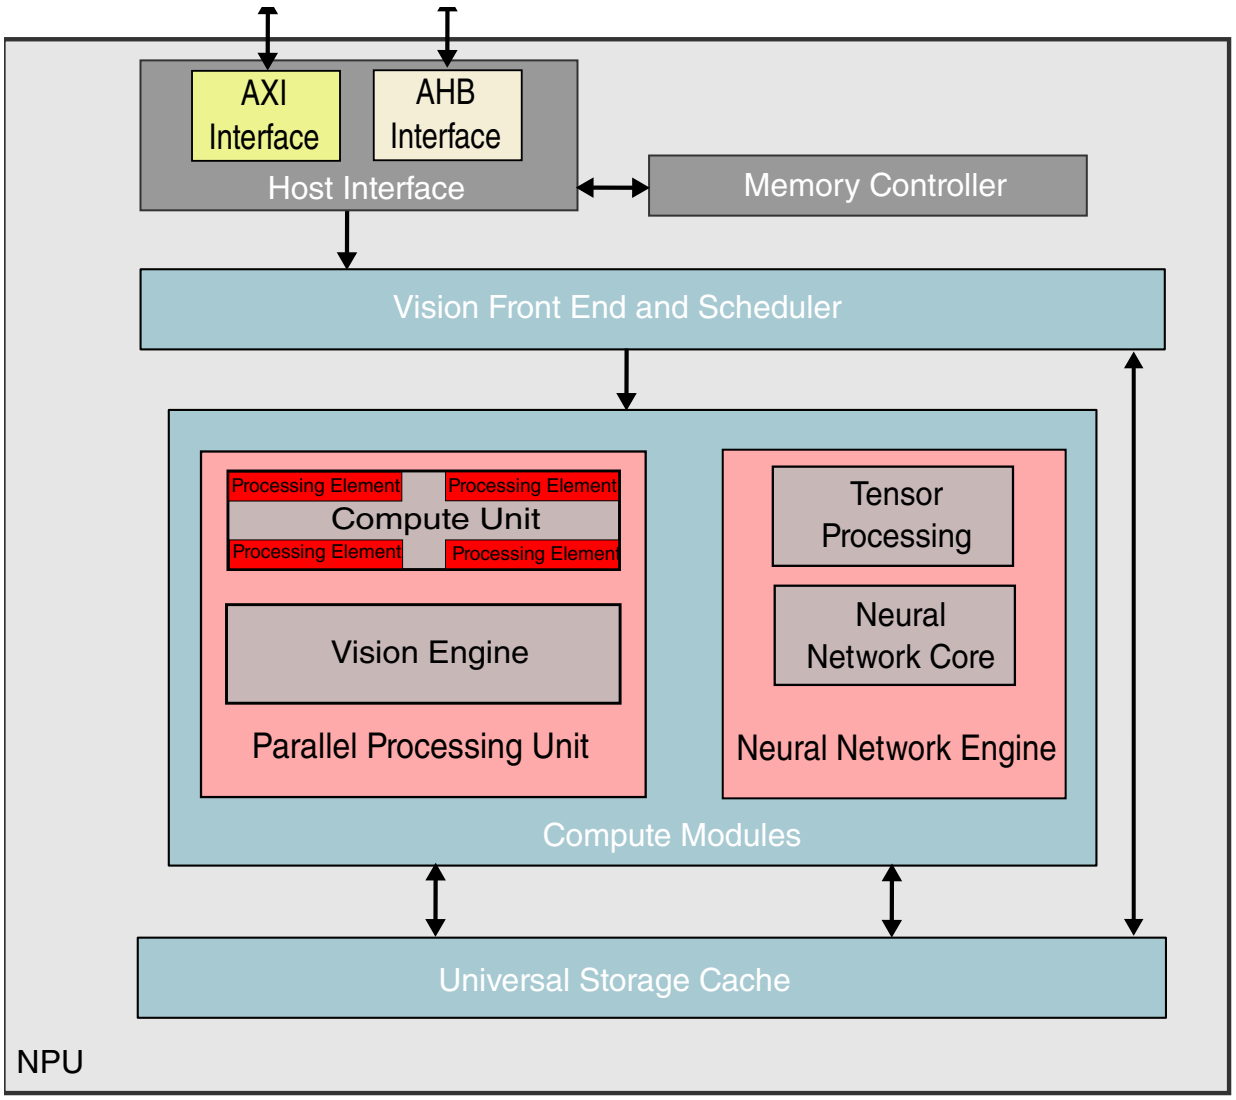

Figure 13-93. NPU High-level Block Diagram

13.16.2.1 Block Descriptions

The main functional blocks of the NPU core are described in the table below.

Table 13-46. NPU Functional Blocks

NPU Block	Description
Host Interface	Allows the NPU to communicate with external memory and the CPU through the AXI / AHB bus. In this block data crosses clock domain boundaries.

Table continues on the next page...

Table 13-46. NPU Functional Blocks (continued)

NPU Block	Description
Memory Controller	Internal memory management unit that controls the block-to-host memory request interface.
Vision Front End	Inserts high level primitives and commands into the vision pipeline.
Neural Network Core	Provides parallel convolution MAC for recognition functions using 8 or 16 bits integer.
Tensor Processing Fabric	Provides data preprocessing and supports compression and pruning for multi-dimensional array processing for Neural Nets.
Compute Unit	SIMD processor programmable execution unit that perform as a Compute Unit. The NPU block has 1 vec4 Parallel Processor Unit which also acts as 4 Processing Elements.
Vision Engine	Provides advanced image processing functions.
Universal Storage Cache	Cache shared between the Vision Front End and the Parallel Processing Unit.

13.16.3 Features

Key features of the NPU block include:

- OpenVX compliance, including extensions
- Convolutional Neural Network acceleration
- IEEE 32-bit floating-point pipeline in PPU shaders.
- Ultra-threaded parallel processing unit
- Low bandwidth at both high and low data rates
- Low CPU loading
- MMU functionality supported
- Performance Counters for DMA Profiling
- Data transfers between Neural Network Engines and the Parallel Processing Unit, with 256KB SRAM as local storage
- Neural Network Engine and Parallel Processing Unit synchronization with hardware semaphore

13.16.3.1 API Support and Architecture Features

The following table describes API support and architectural features of the NPU block.

Table 13-47. NPU Architecture Features

Feature	NPU Support
Primary APIs	OpenVX with Neural Network Extensions
Drivers	OpenVX

13.16.4 Functional Description

13.16.4.1 Parallel Processing Unit

The Parallel Processing Unit (PPU) features are noted below:

Table 13-48. Parallel Processing Unit Features

Feature	Supported
Parallel Processor Execution unit	1 compute unit, SIMD4, SFP32 Trans
FP denorm and rounding options	Denorms are flushed to zero. Supports round to nearest even and round to zero.
Maximum number of instructions	1 M (with I-cache)
Maximum number of streams	8
Maximum number of threads inflight per PPU core	256
Image Load/Store Instructions	Yes
Conditional branch support	GT, LT, EQ, GE, LE, NE, ISNAN, ISFINITY, ISINFINITY, ISNORMAL, AND, OR,XOR, NOT, ANYMSB, ALLMSB, SELMSB
Control flow instructions	Yes
Instruction rate	1-cycle throughput for all instructions
Standard derivatives	Yes
Integer pipeline	Support 8, 16, 32-bit integer operations
Universal Storage Cache	16 KB flexible allocation for both local shared memory and L1 cache

13.16.4.2 Neural Network Engine

The Neural Network Engine support features are in the table below:

Table 13-49. Neural Network Engine Features

Feature	Supported
MAC per cycle	1152
Applications	Classification, Detection, Segmentation
Network Topologies	Linear, MIMO, Fully Connected, Fully Convolutional
Network Size	2048 (Software driver limitation)
Inference Engine	TensorFlow Lite, Arm NN, ONNX, eIQ™ Inference with DeepViewRT
Configurable and Programmable	Yes
Network parameter deep compression	Yes
RNN Support	Yes

13.16.4.3 Tensor Processor

The Tensor Processor fabric support features are in the table below:

Table 13-50. Tensor Processor Features

Feature	Supported
Data format support	8/16-bit integer
Zero Weight Skipping	Yes, saving execution time
Intermediate Data Shuffling	Yes, saving CPU overhead
Local Memory for NN Weights andIntermediate Data Buffering	Yes
Local Buffer Configurations	0KB
Pooling	Max, average
Unpooling	Yes
Activation	ReLU, Leaky ReLU (LUT for other types)
Normalization	Yes
Region Proposal Support	Yes

13.16.4.4 Image Format Support

OpenVX image formats are supported. Packed formats are supported so that multiple pixels can be loaded in one shot.

13.16.4.4.1 OpenVX Support

Support for OpenVX includes the following capabilities:

Table 13-51. OpenVX Hardware Support

Feature	Supported
Enhanced Vision Instructions	EVIS 2 Instruction Set
Max kernel size	Up to 11x11, programmable
3x3 Image Filter modes	HorzMin3, HorzMed3, HorzMax3, VertMin3, VertMed3, VertMax3
Interpolation support	Lerp
Histogram support	IndexAdd, AtomicAdd
8-bit Dot Products	32x1, 16x2, 8x4, 4x8
16-bit Dot Products	16x1, 8x2 , 4x4, 2x8
Bit Manipulation modes	BitExtract
Packed Image Load/Store instructions	ImgLoad, ImgStore
Other EVIS instructions	AbsDiff, AccSq, MulShift, Clamp
Wide Uniform support	512-bit uniform reads per instruction

13.16.4.4.2 OpenVX Image Formats

The following OpenVX image formats do not require conversion.

Table 13-52. Vision Formats for OpenVX

OpenVX Formats	Description
VX_DF_IMAGE_VIRT	A virtual image of no defined type.
VX_DF_IMAGE_RGB	A single plane of 24-bit pixel as 3 interleaved 8-bit units of R then G then B data. This uses the BT709 full range by default.
VX_DF_IMAGE_RGBX	A single plane of 32-bit pixel as 4 interleaved 8-bit units of R then G then B data, then a don't care byte. This uses the BT709 full range by default.
VX_DF_IMAGE_NV12	A 2-plane YUV format of Luma (Y) and interleaved UV data at 4:2:0 sampling. This uses the BT709 full range by default.
VX_DF_IMAGE_NV21	A 2-lane YUV format of Luma (Y) and interleaved VU data at 4:2:0 sampling. This uses the BT709 full range by default.
VX_DF_IMAGE_UYVY	A single plane of 32-bit macro pixel of U0, Y0, V0, Y1 bytes. This uses the BT709 full range by default.
VX_DF_IMAGE_YUYV	A single plane of 32-bit macro pixel of Y0, U0, Y1, V0 bytes. This uses the BT709 full range by default.
VX_DF_IMAGE_IYUV	A 3 plane of 8-bit 4:2:0 sampled Y, U, V planes. This uses the BT709 full range by default.
VX_DF_IMAGE_YUV4	A 3 plane of 8 bit 4:4:4 sampled Y, U, V planes. This uses the BT709 full range by default.
VX_DF_IMAGE_U8	A single plane of unsigned 8-bit data. The range of data is not specified, as it may be extracted from a YUV or generated.
VX_DF_IMAGE_U16	A single plane of unsigned 16-bit data. The range of data is not specified, as it may be extracted from a YUV or generated.
VX_DF_IMAGE_S16	A single plane of signed 16-bit data. The range of data is not specified, as it may be extracted from a YUV or generated.
VX_DF_IMAGE_U32	A single plane of unsigned 32-bit data. The range of data is not specified, as it may be extracted from a YUV or generated.
VX_DF_IMAGE_S32	A single plane of unsigned 32-bit data. The range of data is not specified, as it may be extracted from a YUV or generated.

13.16.4.4.3 Vision Formats Requiring Conversion

Formats with eight (8) bits (or a multiple of 8 bits) per component typically do not require any conversion. Formats which do not have a component size which is a multiple of 8-bits usually require conversion. A Vision instruction can be used to do conversion if needed; conversion costs one instruction. Conversion will not be done if the application does not require it.

13.16.4.5 Power Modes

The NPU supports four (4) programmable, software-controlled power states that affect power consumption of the NPU. These states are: ON, IDLE, SUSPEND, and OFF.

Table 13-53. NPU Power States

Power State	Workload	Description
ON	Full	NPU runs at full clock speed. No clock gating.
IDLE	Minimal	NPU runs at 1/64 clock speed. No clock gating.
SUSPEND	None	NPU runs at 1/64 clock speed. AXI/core/SH are clock gated. FE stopped.
OFF	None	Same as SUSPEND, plus when this state is switched out then the NPU hardware is re-initialized. External power to the NPU can be disabled.

The kernel layer manages the power state transitions, and each state corresponds to an operating mode of the NPU:

1. Active mode
   - Power state is ON.
   - NPU is actively processing commands. One or more blocks are not in idle mode.
2. Idle mode
   - Power state is IDLE.
   - NPU is not processing any commands. All modules in the pipeline are in idle state.
   - The input clocks are on, but most of the NPU internal clocks are automatically gated off.
   - Frequency skipping is turned on with 1/64 pulse.
   - SoC reduces ACLK and HCLK frequency by 20x external to the NPU.
   - The NPU can start command processing instantly without any delay.
3. Standby mode
   - Power state is SUSPEND.
   - All input clocks to the NPU are shut off.
   - NPU clocks must be turned on and given enough time to reach idle state. Please refer to Resets section for information on the timing.
   - Once the NPU is in idle state, command processing can start.
4. Sleep mode
   - Power state is OFF.
   - The entire NPU is powered off through power gating.
   - The SoC must go through a power-on sequence in order to bring the NPU to idle state before starting command processing.

13.16.4.5.1 Low Power State Control

This NPU supports two low power state control schemes. One is the AXI Low Power state control scheme specified in the AXI spec. The other is the NPU Power Management scheme, controlled through a register which is accessible from the AHB.

13.16.4.5.1.1 AXI Low-Power Interface

The AXI Low-Power Interface is standardized in the AXI specification, and no interactions are required. However, it does not provide finer control over how the power management is configured. When exiting from the low-power state, the AQHiClock Control Register is initialized to the default value, enabling all functional blocks.

13.16.4.5.1.2 Power Management

There are two registers (AQHiClockControl and AQHiIdle) in the Host Interface (HI) module dedicated for power management. Software can control power management through these registers. Unlike the AXI Low-Power Interface, no automatic sequencing is involved in this scheme. The software needs to make sure that a block is in idle before shutting down the clock to the block. This scheme also offers a register interface to the clock scaling mechanism available in the graphics core.

13.16.4.6 Clock Domains

There are four independent clock domains in the NPU, and they are detailed in the table below.

Table 13-54. NPU Clocks

Clock	Signal name	Description
Core Clock	clkCore	Core clock is the main clock domain used by the NPU modules other than the PPU, NN, and USC.
PPU Clock	clkSh	The PPU clock domain contains the PPU, NN, and USC.
AHB Clock	hclk	The AHB Clock is the AHB Interface clock.
AXI Clock	aclk	The AXI Clock is the AXI Interface clock.

NOTE

The PPU Clock (clkSh) is the same source as the Core Clock (clkCore).

The communication between the different domains in NPU occurs mostly by way of asynchronous FIFOs. All clocks are asynchronous to each other. There is no communication between AHB and AXI clock domains.

The Core Clock in the NPU core can be scaled down dynamically without reprogramming its source. This scaling is controlled through the use of an internal register.

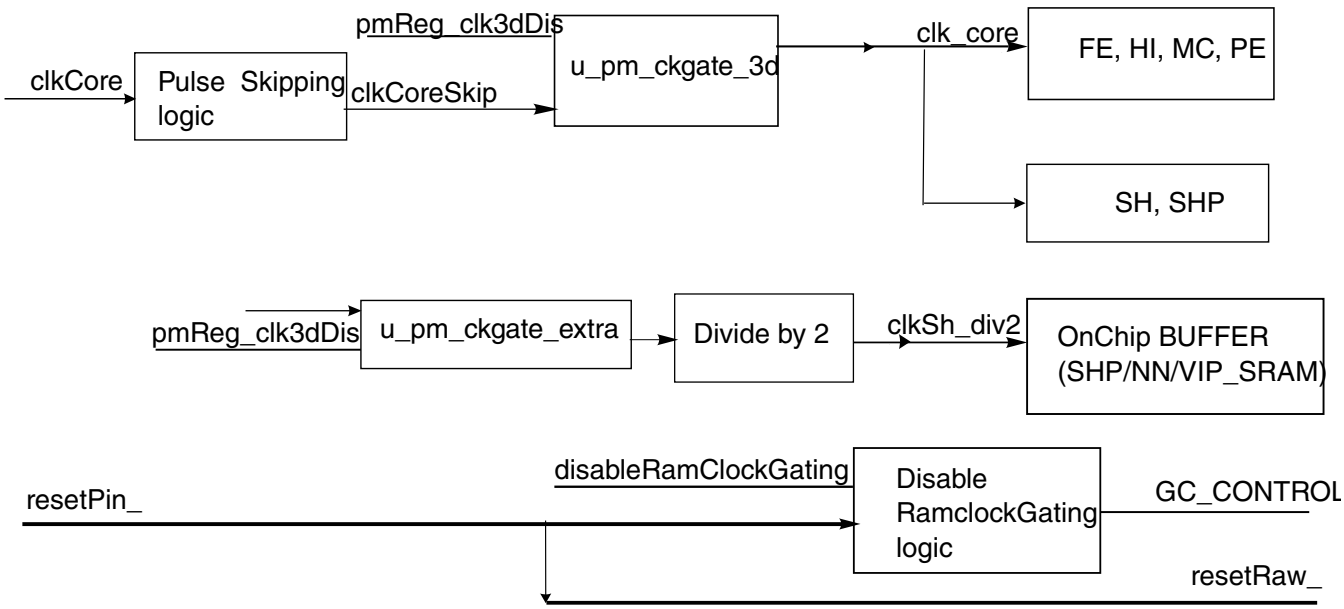

Figure 13-94. NPU Core Clock Logic Block Diagram

13.16.4.6.1 Clock Gating

Automatic localized clock gating is employed in the NPU to minimize dynamic power consumption.

13.16.4.6.1.1 Second Level Clock Gating

Block level clock gating is implemented in a majority of the blocks. If a block and the interface to the block are both idle, then the clock of that block will be gated automatically. This feature can be disabled by software.

13.16.4.6.2 Clock Disabling

The output of one of the clock gating blocks is for the Parallel Processing Unit (clkSh), and the output of the other clock gating block is for the rest of the NPU blocks (clkCore). The clock branches can be shut down independently through software control by setting the proper register bits. Please see Clock Control Register for more information.

13.16.4.6.3 Core Clock Frequency Scaling

A basic period of 64 clock cycles is chosen as the basis for clock skipping. Any number of clocks within that 64 clock period can be skipped. This yields a fine granularity of 1.6% (1/64).The scaling factor is a 7-bit value, which represents the number of clocks NOT to skip (the reset value is 64). Pulses will be skipped uniformly along the 64-cycle period to smooth out the power demand of the power supply.

Scaling is controlled by software through the use of control registers. The software determines the number of cycles not to skip within a 64-cycle period. The frequency scaling value is double-buffered as well, and it is updated at the beginning of a 64-cycle sequence. The following diagram shows an example of pulse skipping for the case of a 16 cycle period.(The actual period is 64 cycles, but 16 was chosen for ease of illustration).

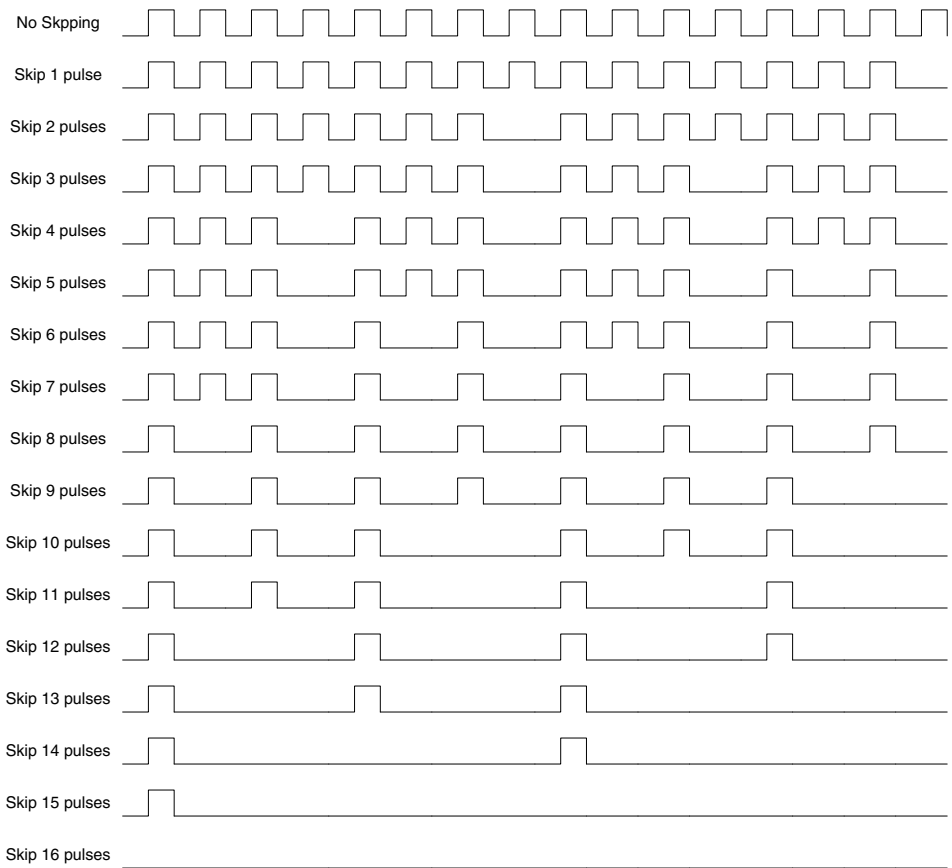

Figure 13-95. Pulse Skipping Example - Timing Diagram

Reducing the frequency of the core clock should not be a problem on the AXI side. The AXI interface is designed to handle any ratio of AXI clock vs. core clock. The AXI side can be stalled as well if the core clock side cannot accept the return data fast enough.

13.16.4.6.4 Clock Control Register

All clock control registers reside in the host clock domain.

Table 13-55. AQHiClockControl Register - Select Clock Control Bits

Bitfield	Access	Name	Description
0	R/W	CLK3D_DIS	Software core clock disable signal for core (clkCore) and 3D (clkSh) clocks. When set to “1”, these clocks are frozen. Reset value = 1’b0
1	R/W	CLK2D_DIS	Software core clock disable signal. For this core both bits CLK3D_DIS and CLK2D_DIS should be controlled by software. The AXI interface clock is the only block not stalled at that point. Reset value = 1’b0
8:2	R/W	FSCALE_VAL	Frequency scaling value. Reset value = 7’d64 (no pulse skipping)
9	R/W	FSCALE_CMD_LOAD	Frequency scaling load command. When writing a “1” to this bit, it updates the frequency scale factor with the value FSCALE_VAL[6:0]. The bit must be set back to “0” after that. Reset value = 1’b0

13.16.4.7 Resets

The NPU supports asynchronous resets that must be asserted for a minimum of of 32 core clock cycles (slowest clock). After deassertion, 128 core clock cycles (slowest clock) is required before starting any activity on AHB. During the 32 cycle assertion + 128 cycle wait, the core clock supplied into the NPU may be kept running. The clock may be gated before assertion, but because it is an asynchronous reset, it is not required.

13.16.4.8 Interrupts

The IP can send an interrupt signal to the host processor. The signal name is xaq2_intr, and it remains asserted until the host processor clears the interrupt by reading the interrupt acknowledge register (AQIntrAcknowledge). The interrupt is level triggered. The SOC should not use edge to detect the interrupt, as using edge to detect the GPU/NPU interrupt will miss some back to back interrupts. Each bit of AQIntrAcknowledge represents one of the 32 possible events that the NPU can signal to the host processor. By setting or clearing the bits of the interrupt enable register (AQIntrEnbl) the programmer can control which of those events will generate an interrupt. The bits of these registers have no predefined meaning, except for bit 31 which is used for AXI_BUS_ERROR. Instead, all of them are used by and controlled through the NPU driver. The NPU driver puts events with different event IDs (0~30) in the command buffer, and the NPU will generate an interrupt with the corresponding interrupt bit as set by the event ID in AQIntrAcknowledge. The NPU kernel driver and its interrupt

service routine (ISR) will process the interrupt accordingly to synchronize the driver/CPU with NPU. The meaning of the NPU interrupt bits are entirely private to the NPU driver. The event IDs (0~30) are arbitrarily used by the NPU driver thus the interrupt bits in AQIntrAcknowledge are also arbitrary. Chip designers need only to ensure that the xaq2_intr signal is connected to their interrupt controller. Since AQIntrEnbl is set to 0 at reset, the xaq2_intr signal will never be asserted during the chip validation phase.

13.16.5 Initialization

13.16.5.1 Power Off Sequence

The Power Off sequence for NPU is as follows:

- Chip software issues a request to go into "OFF" state or the NPU internal timer triggers a transition into the "OFF" state.
- NPU software then executes all the required preliminary steps to put the block into "OFF" state.
- NPU software issues a callback to gate the NPU clock and NPU power.
- Chip software initiates a power down sequence to the chip controller HW.
- Chip hardware asserts an isolation signal to turn on isolation from the NPU.
- Chip hardware asserts a power gate signal to turn off power to the NPU.
- Upon return of the hardware acknowledgement, chip software returns call-back status to NPU software.
- Upon receipt of a successful callback, NPU software puts the block into the "OFF" state.

13.16.5.2 Power On Sequence

The Power On sequence for NPU is as follows:

- Chip software requests a transition from the "OFF" state to the "ON" power state.
- NPU software issues a call back to enable clock and power for the NPU.
- Chip software initiates a power up sequence to the chip controller hardware.
- Chip hardware de-asserts the power gate signal to turn on power to the NPU block.
- Upon hardware acknowledgement, the chip Hardware turns on the clocks to the NPU block.
- Chip software performs an AHB domain reset.
- Chip Hardware de-asserts the isolation signal to turn off isolation from the NPU block.
- Chip software returns call-back status to NPU software.

- Upon a successful return, NPU Software performs an AHB write that will soft reset the core and AXI domains.
- NPU software enables FE and waits for commit

13.16.6 Memory Map and register definition

This section includes the NPU module memory map and detailed descriptions of key accessible registers.

The following are four modules that can be accessed via the AHB bus:

- Host Interface (HI)
- Power Management (PM)
- MMU Secure Zone (MMU)
- Memory Controller (MC)

The following table describes the registers, their corresponding AHB modules and addresses.

Table 13-56. Register Addresses and corresponding AHB Module

AHB Module	AHB Byte Offset	GPU DWord Offset
HI	0x000-0x0A8	0x0000-0x002A
PM	0x100-0x010C	0x0040-0x0043
TZ	0x388-0x3AC	0x00E2-0x00EA
MC	0x414-0x42C	0x0105-0x010B

Host Interface: The Host Interface is a bridge between the Memory Controller and the AXI interface. It also acts as a bridge between the core and the AHB bus. The Host Interface's register set contain the control settings for the clocks, AXI interface and interrupts. It also contains the identification registers and some counters that are used for debug. Users can access the Host Interface registers via the AHB bus.

Power Management Registers: The Power Management register set controls clock gating within the core. The graphics core allows the user to control the clock gating of each internal module independently of the other modules. Users can access the registers via the AHB Bus.

MMU Secure Zone Registers: These registers provide hardware mechanisms and base address information for access control.

Memory Controller Registers: All memory accesses that go to or from the AXI bus pass through the Memory Controller. It connects the Host Interface to the rest of the core. The Memory Controller's register set contains the controls for the memory interface, the

settings for the virtual memory page table, and the values of the offset registers. It also contains a variety of debug registers that are set by other blocks within the core. Users can access the Memory Controller's registers via the AHB bus.

NOTE

NPU functionality can be supported using SW interface.

MULTI_PIPE_REG_SEL	This bit is determines which HI/MC to use while reading registers.
19 ISOLATE_GPU	Isolate GPU This bit is used for power on/off, isolation only for multi-core GPUs. Please refer to Initialization section for information on its usage.
18-17 —	Reserved
16 IDLE3_D	3D pipe is idle
15-14 —	Reserved
13 DIS_RAM_PWR_OPT	Disable RAM power optimization
12-11 —	Reserved
10 DIS_RAM_CLK_GATING	Disable clock gating for RAMs
9 FSCALE_CMD_LOAD	Core clock frequency scale value enable If this bit is set and FSCALE_VAL=0 (an invalid combination), the HREADYOUT output signal will get stuck to 0. 1b - The frequency scale factor is updated with the value FSCALE_VAL[6:0]. The bit sets back to 0 after that.
8-2 FSCALE_VAL	Core clock frequency scale value
1 CLK2D_DIS	Disable 2D clock This bit is connected to the software clock disable signal. For this core, both bits CLK3D_DIS and CLK2D_DIS should be controlled by software. The AXI interface clock is the only block not stalled at that point.
0 CLK3D_DIS	Disable 3D clock Software core clock disable signal for 3D modules (clk_3d) clock. 1b - The clock is frozen

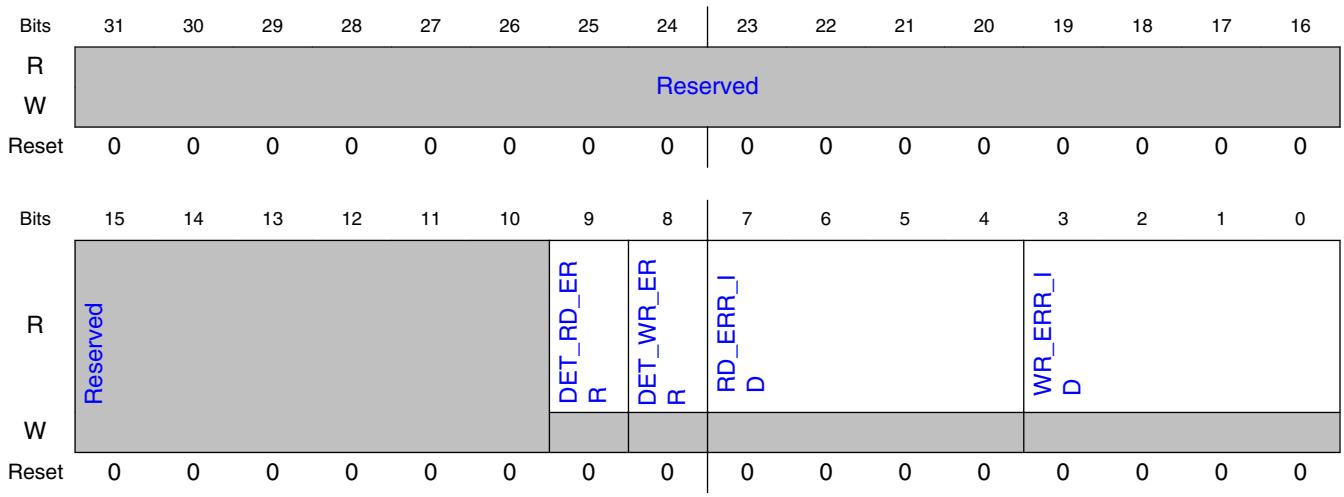
13.16.6.1.3 Idle Status Register (AQHildle)

13.16.6.1.3.1 Offset

Register	Offset
AQHiIdle	4h

13.16.6.1.3.2 Diagram

13.16.6.1.3.3 Fields



Field	Function
31 AXI_LP	AXI is in low power mode
30-4 —	Reserved
3 IDLE_SH	SH is idle
2-1 —	Reserved
0 IDLE_FE	FE is idle

13.16.6.1.4 AXI Status Register (AQAxiStatus)

Chapter 14
Audio

14.1 Audio Overview

14.1.1 Audio Interface

The device supports multiple audio interfaces as listed below:

Table 14-1. Audio Interface Summary

Interface	Function	RX Data Line	TX Data Line	Note
SAI1	External audio	8	8	Access to port is subject to pin mux constraints
SAI2	External audio	4	4	Access to port is subject to pin mux constraints
SAI3	External audio	2	2	Access to port is subject to pin mux constraints
SAI5	External audio	4	4	Access to port is subject to pin mux constraints
SAI6	External audio	1	1	Access to port is subject to pin mux constraints
SAI7	External audio	1	1	Access to port is subject to pin mux constraints
SPDIF1	External audio	1	1	The eARC interface provides SPDIF functionality
PDM	External audio	4		Supports up to 8-Microphones
HDMI Tx	External audio	N/A	0	Supported through HDMI PHY. More info can be found in the HDMI TX Controller and the HDMI TX Parallel Audio Interface (HTX_PAI) sections.
eARC	External audio	1	0	Supported through eARC PHY
ASRC	Internal audio	-	-	No external interface

In addition to the general audio input/output functions, the audio interfaces support the following features:

- SAI1 supports to up to 8 I2S/TDM Tx lanes and 8 I2S/TDM Rx lanes at 768kHz/32-bit
- SAI2/5 supports to up to 8-channels TX (4 lanes) and 8-channels RX (4 lanes) at 768kHz/32-bit
- SAI3 supports up to 4-channels TX (2 lanes) and 4-channels RX (2 lanes) at 768kHz/32-bit
- SAI6 supports to up to 2-channels TX (1 lanes) and 2-channels RX (1 lanes) at 768kHz/32-bit when multiplexed on SAI1, or up to 384kHz/32-bit when multiplexed on Ethernet primary pins
- SAI7 supports to up to 2-channels TX (1 lanes) and 2-channels RX (1 lanes) at 384kHz/32-bit
- SPDIF supports raw capture mode that can save all incoming bits into an audio buffer
- PDM supports up to 8-channels (4 lanes)

14.1.1.1 SAI Master Clock Inputs/Outputs

The MCLK pin on each SAI module can be configured as either an input or an output. When configured as an output, the SAIn_CLK_ROOT from the CCM or the MCLK_OUT from SAIn is routed to the pad output. Note that the SAIn_MCLK_OUT is always derived from the ipg_clk_sai_mclk (MCLK[1]) input. When configured as an input, the external input to the pad will be used as SAIn_MCLK and is routed to SAIn_MCLK_IN, which can be used as master clock for SAI. Below is a diagram showing both input and output options.

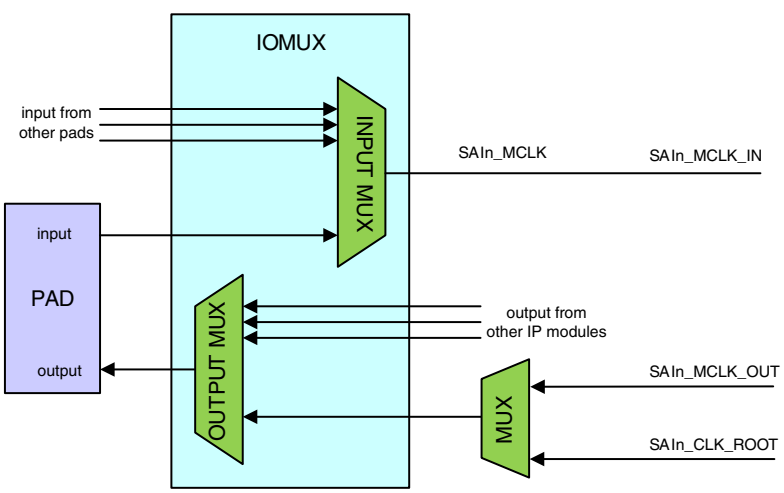

Figure 14-1. SAI MCLK Input and Output

Each SAI module supports up to 3 master clock inputs. The TX and RX sub-modules inside each SAI can independently select one of the clock inputs as their master clock. This allows the TX and RX of one SAI to run from different clock sources. The master clock inputs have the following options:

- SAIn_MCLK[1] can be selected from SAIn_CLK_ROOT from CCM or SAIn_MCLK from IOMUX. This is the most straight-forward clock routing in which SAIn only uses its own clock source from CCM or IO pad
- SAIn_MCLK[2] can be selected from the following clock sources:
  - Any of the SAIn_CLK_ROOT from CCM
  - Any of the SAIn_MCLK from IOMUX
  - Other clock sources from SPDIF
- SAIn_MCLK[3] is connected to a fixed /2 divider of the SAI CLK output of the Fractional PLL

The clock options for master clock on SAI are shown in the diagram below. The master clock options are identical for SAI1, SAI2, SAI3, SAI5,SAI6, and SAI7.

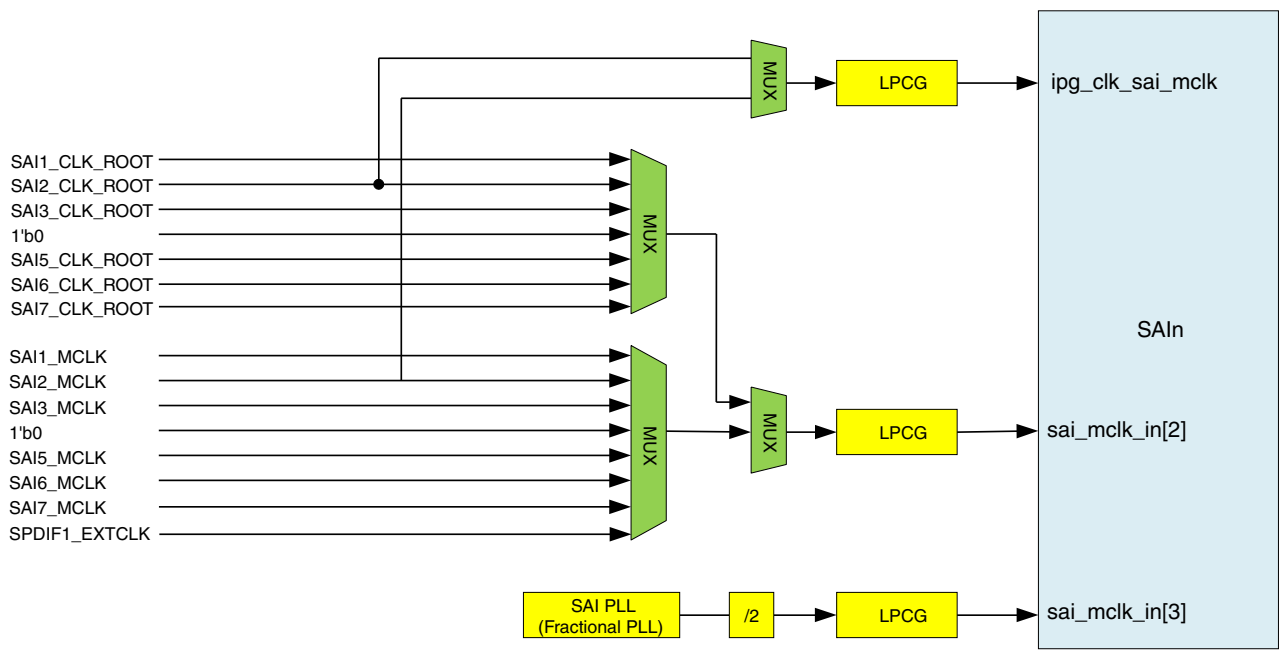

Figure 14-2. SAI Master Clock Options

The configuration of the MUX for master clock is controlled by the AUDIO BLK_CTRL registers. They should be configured before the SAI clock is enabled to avoid glitches on the clock.

14.1.1.2 SDMA Support

All of the SAI and SPDIF instances have SDMA support. In order to meet the audio data rate, two dedicated SDMA modules are used. The DMA requests from all audio interface modules will be routed to both SMDA modules, and both SDMA modules' IPG master port are connected to the SPBA. (SPBA has 3 master ports, one for chip-level IPG bus, two for the SDMAs). With this implementation, the two SDMA modules can be flexibly allocated to all the audio interfaces, based on the needs of audio use cases.

The SDMA2/3 target frequency is 400MHz IPG and 400MHz AHB, always 1:1 mode, to make sure there is enough throughput for all the audio use cases.

Table 14-2. SDMA Assignment for Audio Interface

SDMA	Audio Interface	Note
SDMA2/3 400MHz AHB, 400MHz IPG	SAI1	8 TX + 8 RX
	SAI2	4 TX + 1 RX
	SAI3	1 TX + 1 RX
	Audio Transceiver (eARC)	TX + RX
	PDM	8 RX
	SAI5	4 TX + 4 RX
	SAI6	1 TX + 1 RX
	SAI7	1 TX + 1 RX
	ASRC	-

14.1.1.3 eDMA Support

This chip also supports one eDMA for memory-to-memory copies (no DMA requests connected from any peripheral). It is generally controlled by the Audio DSP.

14.1.1.4 ASRC

The ASRC can process 4 groups of audio channels with an independent time-base, simultaneously. A group of channels with the same time-base (or resampling ratio) is referred to as a context. Each context has independent processing pipelines. Contexts can be configured to start and stop at any time without affecting the processing of other contexts. The ASRC supports up to 32 audio channels. The 32 audio channels can either be assigned to a single context or spread across multiple contexts.

The ASRC supports the following features:

- Simultaneous processing of up to 32 audio channels
- 4 independent contexts – groups of channels with an independent time base

- Fully independent and concurrent control of all 4 contexts
- Programmable filter characteristics for each context
- 32-bit floating and 32, 24, 20 and 16-bit fixed point audio sample support
- 8 kHz to 384 kHz sample rate
- 1/16 to 16x sample rate conversion ratio
- Software control of fine conversion ratio

14.1.2 Audio DSP (HiFi 4)

The HiFi 4 Audio Engine is a highly optimized audio processor geared for efficient execution of audio and voice codecs and pre- and post-processing modules.

See the Audio DSP (HiFi 4 DSP) section for more details.

NOTE

The Hifi4 DSP is integrated into the audio subsystem, which includes the AUDIO BLK_CTRL, MICFIL, SAI, ASRC and eARC instances. The subsystem shares one reset (controlled by the SRC), and the Hifi4 DSP doesn't have an individual reset. If the Hifi4 needs to be reset, then the entire audio subsystem must be reset.

14.2 AUDIO BLK_CTRL

14.2.1 Overview

The AUDIOMIX domain contains control and status registers known as Audio Block Control (AUDIO BLK_CTRL). These registers have miscellaneous top-level controls for peripherals within the AUDIOMIX domain. Some of these controls includes clocking, interrupt, and reset sources. Please see the clock control chapter and interrupt chapter for more information regarding the clock input sources and IRQ event mapping to AUDIOMIX.

14.2.1.1 Block Diagram

The AUDIO BLK_CTRL interface connects to the AUDIOMIX domain peripherals. A block diagram illustrating the AUDIOMIX domain is shown below.

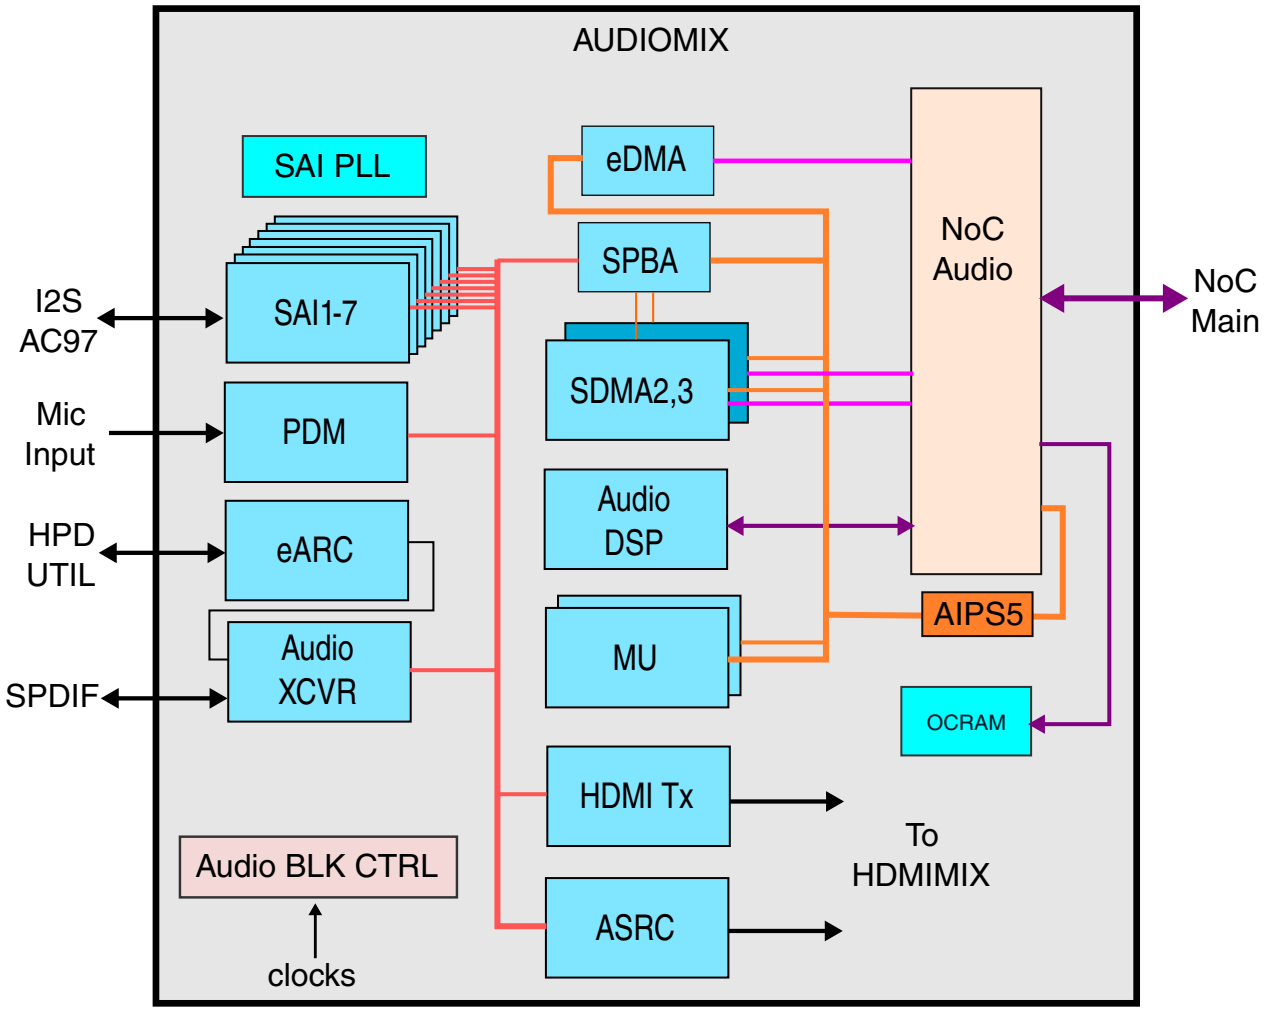

Figure 14-3. AUDIOMIX Block Diagram

14.2.2 Clocks and Resets

The Audio BLK_CTRL contains clock distribution and gating controls, as well as reset handling to several of the AUDIOMIX peripherals. The BLK_CTRL also handles the MCLK routing for SAI. A figure illustrating the supporting MCLK connections is shown below. Please see related clock and reset controls in the BLK_CTRL register description. For more information about the input clocks, system-level resets, and IRQ to the domain, please see the related block guide and system-level assignments in the control blocks for clocks, reset, and IRQ assignments.

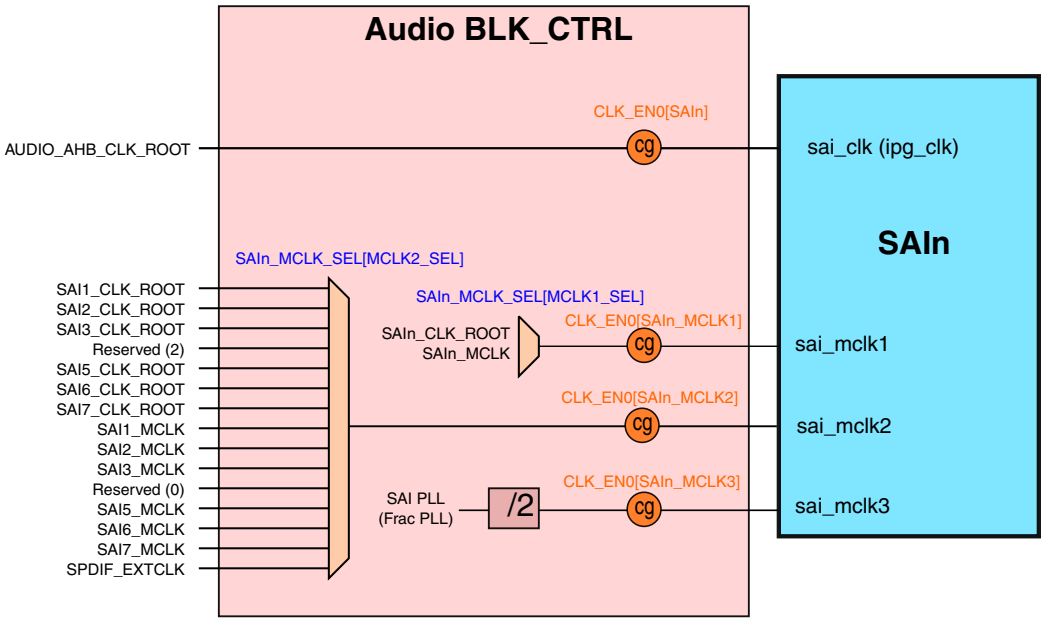

Figure 14-4. Audio BLK_CTRL MCLK Generation

14.2.3 Memory Map and register definition

This section includes the AUDIO BLK_CTRL module memory map and detailed descriptions of all registers.

14.2.3.1 register descriptions

14.2.3.1.1 memory map

AUDIO_BLK_CTRL base address: 30E2_0000h

14.3 PDM Microphone Interface (MICFIL)

14.3.1 Overview

The Pulse Density Modulated Microphone Interface (MICFIL) is a popular way to deliver audio from microphones to the processor in several applications, such as mobile telephones. However, current digital-audio systems use multibit audio signal (also known as multibit PCM) to represent the signal. This block implements the required digital interface to provide a 24-bits audio signal from a PDM microphone bitstream in a configurable output sampling rate.

The implementation of this digital interface is based on the application of digital signal processing techniques in hardware. The PDM Microphone Interface architecture was designed to save gate count and minimize power consumption. It implements a series of filters to transform a PDM bitstream to a 24-bit PCM signal in the audio band.

The whole module is implemented to work in a multichannel mode. All channels have the same configuration but each input channel could be turned on/off independently.

14.3.1.1 Block Diagram

Figure 14-5 shows the block diagram for the PDM Microphone Interface module. It consists of the following:

- an input interface for each pair of PDM microphones.
- a decimation filter by channel.
- a FIFO by channel.
- a time generation unit.
- shared interfaces to DMA, interrupts and SoC.
- A Hardware Voice Activity Detector (HWVAD).

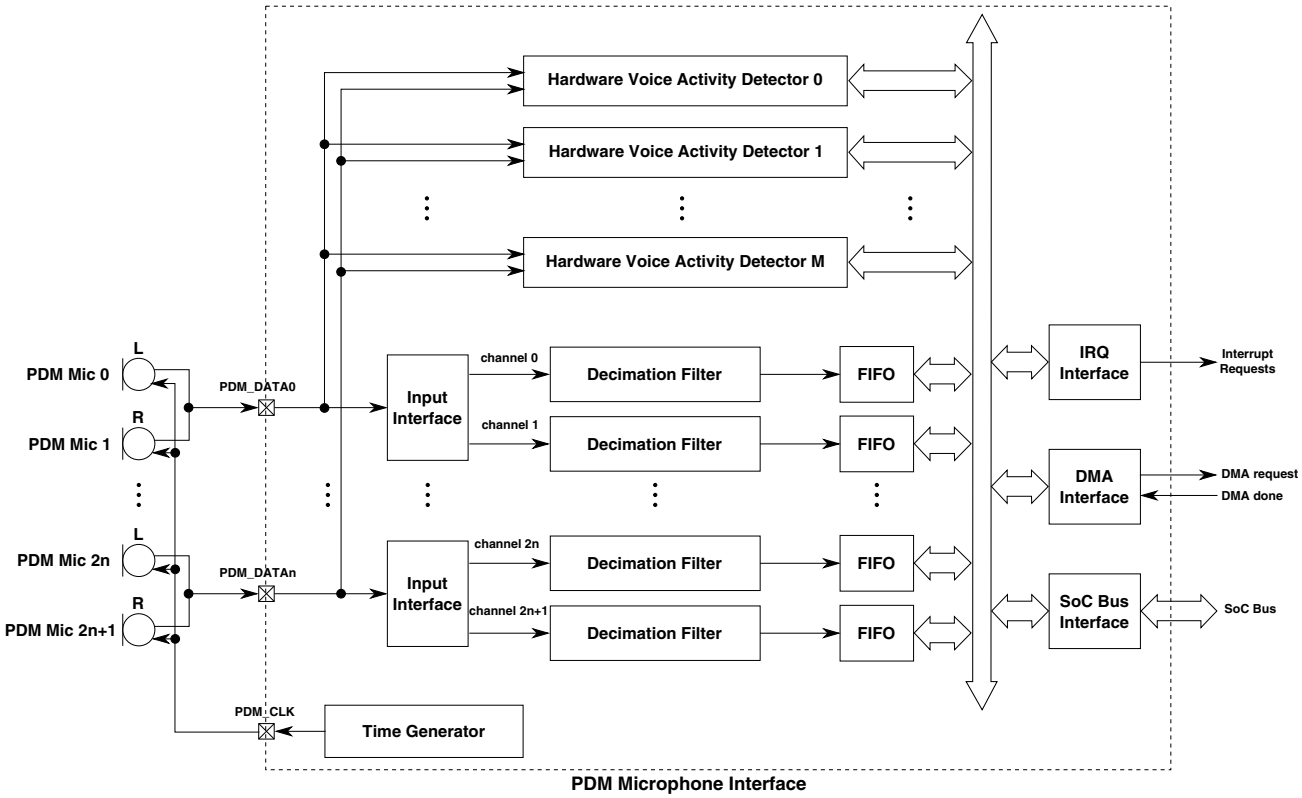

Figure 14-5. PDM Microphone Interface Block Diagram

The Time Generator unit delivers the PDM_CLK to all microphones. All microphones must operate at the same clock frequency. Each input interface receives a time multiplexed PDM bitstream from two PDM microphones and it separates the two audio information in two channels: left (0) and right (1). Each channel is processed separately.

The Decimation Filter is composed internally by a CIC filter, a DC remover and Half Band filters. The filtering results are stored in individual FIFOs; a FIFO by channel. The FIFOs have overflow and underflow detectors to deliver an error interrupt request.

An interrupt request or DMA request could be delivered by the MICFIL. Then the filters results stored in FIFOs could be accessed by the SoC or DMA respectively via the internal bus interface .

The HWVAD takes data from the input of a selected PDM microphone to detect if there is any voice activity. When a voice activity is detected, an interrupt could be delivered to the system.

14.3.1.2 Features

The PDM Microphone Interface (MICFIL) includes the following features:

- Decimation filters:

    - Fixed-point filtering
    - 24-bit PCM audio output
    - Internal clock divider for a programmable PDM clock generation
    - Full or partial set of channels operation with individual enable control
    - Programmable decimation rate
    - Programmable DC remover
    - Range adjustement capability
    - FIFOs with interrupt and DMA capability
        - Each FIFO with 32 entries length
- Hardware Voice Activity Detector (HWVAD)
    - Interrupt capability
    - Zero-Crossing Detection (ZCD) option

14.3.2 Functional Description

Figure 14-5 shows the PDM Microphone Interface (MICFIL) block diagram. Basically this module is composed by a Decimation Filter and a FIFO by channel, an Input Interface for each pair of microphones, a shared Time Generator unit, a shared bus interface, a shared DMA interface and a shared interrupt interface.

The Decimation Filter implements a low-pass filter in the audio band (20Hz-22.5kHz @48kHz output sampling rate by default) with a configurable decimation rate. It is implemented using a series of CIC, Half Band and DC remover filters.

The Time Generator unit generates the PDM_CLK to the microphones. This clock is the same for all the PDM microphones and it is active for all the microphones, i.e. there is not possiblity to turn off the PDM_CLK for one microphone only.

The output of each Decimation Filter is stored into a FIFO buffer. Each FIFO is mapped in the DATACHn registers. It is possible to generate either an interrupt or a DMA request when, in each FIFO of all enabled channels, the number of data stored surpasses a configured watermark.

Also, independently on decimation filters, there is a Hardware Voice Activity Detector(HWVAD) which implements voice-detection algorithms to generate wake-up interrupts.

14.3.2.1 Modes of operation

This section describes the MICFIL operation modes which depends on the SoC power mode , the SoC Doze mode , the SoC Debug mode and MDIS, DBGE, DBG and DOZEN bitfields as summarized in Table 14-3.

Table 14-3. Operation Mode Selection

Mode	MDIS	SoC Doze & DOZEN= 1	SoC Power Mode	DOZEN	SoC Debug | DBG	DBGE	CPU clock	MICFIL internal clock	Decimation Filter state	HWVAD[n] state
Normal	0	0	RUN	Any	0	Any	Enabled	Enabled	Run (Depends on PDMIEN and CHENn)	Run (Depends on PDMIEN and VADEN)
Debug					1	1				
						0			Stop	Stop
Low Power			SLEEP	0	Any	Any	Gated (Externally)		Run (Depends on PDMIEN and CHENn)	Run (Depends on PDMIEN and VADEN)[1]
			DEEPSLEEP						Stop	
Disable/Low Leakage			SLEEP/ DEEPSLEEP	1				Gated		Stop
		1	Any	Any			Enabled			
	1	Any					Gated (Internally)			

1. HWVAD[n] will run in DEEPSLEEP only if it is placed on an always-on power domain in the SoC.

14.3.2.1.1 Normal mode

This is the default MICFIL operational mode. In this mode the channels can be enabled to perform filtering operation.

14.3.2.1.2 Low Power mode

In Low Power mode the MICFIL is able to filter the PDM microphone data and perform voice detection such as in Normal mode and can generate a wake up event through asynchronous DMA/IRQ requests depending on CHENn, VADEN and PDMIEN values.

The Low Power mode is entered when the SoC enters to SLEEP or DEEPSLEEP modes and DOZEN =0. In this mode the CPU clock is gated externally and MICFIL could be kept running.

In case a SoC SLEEP mode is requested, the decimation filter is kept running such as Normal mode and the SoC SLEEP mode is acknowledged immediately.

In case a SoC DEEPSLEEP mode is requested it is waited until the last input samples are processed to acknowledge the SoC mode and stop the decimation filter.

During this mode, VAD will continue running if it was previously enabled (VADEN=1) during Normal mode.

The DMA and IRQ requests can be generated asynchronously to wake up the CPU. .

NOTE

The asynchronous DMA or asynchronous interrupt requests are generated only in this mode.

14.3.2.1.3 Debug mode

This mode is used to check the status of the IP when requested. In this mode the MICFIL can be stopped after the remaining data processing has finished depending on the DBGE bit value. This mode can be actived by a SoC debug request or asserting the DBG bitfield.

In DBGE=0 case, if a debug request is received or DBG is asserted while the module is running, it will be stopped after finish to process the remaining data. Otherwise, if DBGE=1, the module will be kept running.

The PDM Microphone Interface cannot enter Debug mode once in Disable/Low Leakage or Low Power mode.

The Debug mode request affects all channels in the MICFIL. Access to output buffers remain operational, as well as their related flags.

NOTE

Once a debug request is issued, it can not be aborted.

14.3.2.1.4 Disable/Low Leakage mode

In this mode, MICFIL is stopped after the remaining data processing has finished. MICFIL is in Disable/Low Leakage (DLL) mode when:

- The SoC is in SLEEP and DEEPSLEEP modes and DOZEN=1.
- The SoC is in Doze and DOZEN bit is asserted.
- MDIS is asserted.

When Disable/Low Leakage (DLL) mode is requested while the module is running, it will be stopped after finish to process the remaining data.

Writes only to CTRL_1 and CTRL_2 registers are allowed with the exception of writes to the DBG and SRES bits, which are ignored, but read is still available for these bits.

14.3.2.2 Output Rate

The output rate is the sampling rate at the decimation filter output. It depends on the sampling rate of the microphone input and the configured quality mode (refer to Quality Modes) . Common audio sampling rates are 48kHz and 16kHz. On this document the output rate is referred sometimes as FS.

14.3.2.3 Quality Modes

Independently on the power mode selected, if the decimation filter is running, the MICFIL can operate in 6 different quality modes, those can be selected by the QSEL bitfield. The decimation and interpolation rates in internal blocks are shown in Table 14-4 where OSR depends on the CICOSR as shown in Equation 1 on page 5982.

$$OSR = 16\text{-}CICOSR$$

Equation 1. Oversampling Rate (OSR)

The quality selected can be configured dinamically when the Decimation Filter is running, the output rate is mantained in every quality selected.

The passband of the Decimation Filter depends on the quality mode, refer to Overall Passband for more information.

In order to mantain the same output rate in the Decimation Filter when the quality is changed, the PDM_CLK rate changes depending on the quality selected. For more details about the PDM_CLK, refer to Time Generator.

The Sampler and the Half Band filters are whether enabled or not depending on the quality selected, achieving a low power consumption when they are disabled. The CIC filter decimation rate is also whether doubled or not depending on the quality selected. For more information, refer to Decimation Filter.

NOTE

In order to get a better audio performance, the RANGEADJn bitfield need to be adjusted depending on the quality mode selected as pointed out on its description. For more information, refer to Overall Filter Gain.

Table 14-4. Quality Modes

Quality Mode	QSEL bitfield	Sampler Interpolation	CIC Filter Decimation	1st Half Band Filter Decimation	2nd Half Band Filter Decimation	PDM_CLK Rate	Passband
High Quality	001	-	:(2OSR)	:2	:2	Output Rate x 8 x OSR	To ~0.5 x Output Rate
Medium Quality	000	-	:OSR	:2	:2	Output Rate x 4 x OSR	To ~0.5 x Output Rate
Low Quality	111	x2	:OSR	:2	:2	Output Rate x 2 x OSR	To ~0.5 x Output Rate
Very Low Quality 0	110	-	:(2OSR)	:2	-	Output Rate x 4 x OSR	To ~0.25 x Output Rate
Very Low Quality 1	101	-	:OSR	:2	-	Output Rate x 2 x OSR	To ~0.25 x Output Rate
Very Low Quality 2	100	x2	:OSR	:2	-	Output Rate x OSR	To ~0.25 x Output Rate

14.3.2.4 Time Generator

The Time Generator is the responsible to generate the PDM_CLK to the microphones.

NOTE

The Time Generator is affected by soft-reset. The PDM_CLK starts with a rising edge after a soft reset is issued.

14.3.2.4.1 Clock divider

The sampling rate of the microphone input depends on the PDM_CLK rate. The PDM_CLK rate can be trimmed using an internal clock divider, configuring the quality mode (refer to Table 14-4) or trimming the MICFIL's root clock frequency (MICFIL_CLK_ROOT rate).

The internal clock divider frequency is defined by the CLKDIV bitfield value which must be configured following Equation 2 on page 5983.

$$CLKDIV = \frac{\text{MICFIL_CLK_ROOT rate}}{8(16\text{-CICOSR})(\text{Output Rate})}$$

Equation 2. CLKDIV bitfield value

Once calculated the CLKDIV value, the generated PDM_CLK rate can be estimated as shown in Equation 3 on page 5983, where the K factor value depends on the quality mode as shown in Table 14-5 and floor(x) is the function that takes as input a real number x and gives as output the greatest integer less than or equal to x.

$$\text{PDM_CLK rate} = \frac{\text{MICFIL_CLK_ROOT rate}}{2 \cdot \text{floor}(K \cdot CLKDIV)}$$

Equation 3. PDM_CLK rate

Table 14-5. K factor value

Quality mode	K factor
High Quality	1/2
Medium Quality, Very Low Quality 0	1
Low Quality, Very Low Quality 1	2
Very Low Quality 2	4

14.3.2.4.1.1 Minimum Required CLKDIV

NOTE

This minimum CLKDIV condition is required only if any decimation filter channel is enabled and the clock divider is enabled, otherwise this condition should be ignored.

To work properly the CLKDIV bitfield value must have a minimum value according to the quality mode configured (see Quality Modes), the number of enabled channels (EC), Equation 1 on page 5982 and K factor (see Input/Output Timing Requirements). When this condition is not met the LOWFREQF bit is asserted and an error interrupt can be issued (in case ERREN=1).

The equations to estimate the minimum required CLKDIV bitfield value depending on the configured quality mode are shown in Equation 4 on page 5984 (for medium, high and low quality modes) and Equation 5 on page 5984 (for very low quality modes), on these equations floor(x) is the function that takes as input a real number x and gives as output the greatest integer less than or equal to x.

$$\text{floor}(\text{K x CLKDIV}) >= \text{K x } \frac{10 + 93EC}{8 \text{ x OSR}}$$

Equation 4. Minimum required CLKDIV value in Medium, High and Low Quality modes

$$\text{floor}(\text{K x CLKDIV}) >= \text{K x } \frac{10 + 43EC}{8 \text{ x OSR}}$$

Equation 5. Minimum required CLKDIV value in Very Low Quality modes

14.3.2.4.2 MICFIL_CLK_ROOT rate and CLKDIV calculation examples

Example 1:

If it is required an output rate=16kHz and enable 4 channels (EC=4). A valid configuration is following:

1. Configure High Quality mode and CIC decimation by 32 (CICOSR =0, then OSR=16), .
2. Check the PDM_CLK rate for High Quality mode in Table 14-4. PDM_CLK rate = 16kHz x 8 x OSR = 16kHz x 8 x 16 = 2.048MHz.
3. Check the K factor value for High Quality mode in Table 14-5. K factor is 1/2.
4. Calculate minimum CLKDIV value (see Equation 4 on page 5984): floor(K x CLKDIV) >= K x (10 + 93EC)/(8 x OSR) then floor(K x CLKDIV) >= 2.984375. Finally, CLKDIV >= 5.96875.
5. Calculate the minimum MICFIL_CLK_ROOT rate:
   - From Equation 2 on page 5983 : MICFIL_CLK_ROOT rate = 8 x (16-CICOSR) x CLKDIV x (Output rate)
   - From step 4 result: CLKDIV>=4, then MICFIL_CLK_ROOT rate >= 8 x (16-CICOSR) x 5.96875 x 16kHz.
   - Finally: MICFIL_CLK_ROOT rate >= 12224kHz
   - Select the MICFIL_CLK_ROOT rate in that range.
6. Check if selected MICFIL_CLK_ROOT rate and CLKDIV value satisfies the Table 14-6.
7. Finally, check again if the selected MICFIL_CLK_ROOT rate satisfies Equation 2 on page 5983. If not, adjust CLKDIV or change MICFIL_CLK_ROOT rate accordingly.

Example 2:

If it is required an output rate=48kHz and enable 4 channels (EC=4). A valid configuration is following:

1. Configure Medium Quality mode and CIC decimation by 16 (CICOSR =0, then OSR=16), .
2. Check the PDM_CLK rate for Medium Quality mode in Table 14-4. PDM_CLK rate = 48kHz x 4 x OSR = 48kHz x 4 x 16 = 3.072MHz.
3. Check the K factor value for Medium Quality mode in Table 14-5. K factor is 1.
4. Calculate minimum CLKDIV value (see Equation 4 on page 5984): floor(K x CLKDIV) >= K x (10 + 93EC)/(8 x OSR) then floor(K x CLKDIV) >= 2.984375. Finally, CLKDIV >= 2.984375.
5. Calculate the minimum MICFIL_CLK_ROOT rate:
   - From Equation 2 on page 5983 : MICFIL_CLK_ROOT rate = 8 x (16-CICOSR) x CLKDIV x (Output rate)
   - From step 4 result: CLKDIV>=2.984375, then MICFIL_CLK_ROOT rate >= 8 x (16-CICOSR) x 2.984375 x 48kHz.

- Finally: MICFIL_CLK_ROOT rate >= 18336kHz
- Select the MICFIL_CLK_ROOT rate in that range.

6. Check if selected MICFIL_CLK_ROOT rate and CLKDIV value satisfies the Table 14-6.
7. Finally, check again if the selected MICFIL_CLK_ROOT rate satisfies Equation 2 on page 5983. If not, adjust CLKDIV or change MICFIL_CLK_ROOT rate accordingly.

14.3.2.4.3 Input/Output Timing Requirements

The PDM microphones must meet the setup and hold timing requirements shown in Table 14-6 and Figure 14-6. The "k" factor value in Table 14-6 depends on the selected quality mode as shown in Table 14-5.

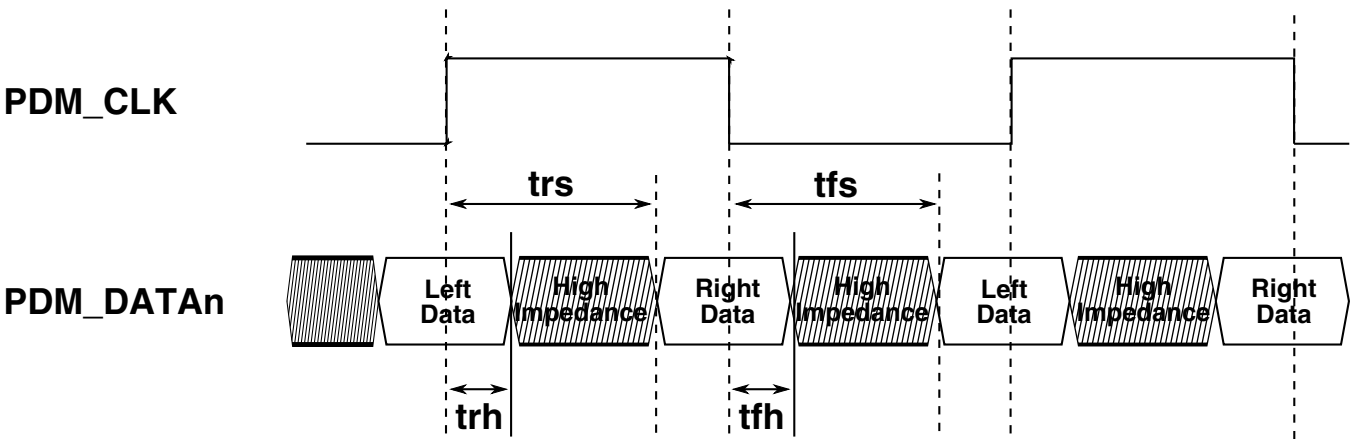

Figure 14-6. Input/Output TIming Requirements

Table 14-6. Timing parameters

Parameter	Value
trs, tfs	$<= \frac{\text{floor}(K \times CLKDIV) - 1}{\text{MICFIL_CLK_ROOT rate}}$ [1]
trh. tfh	>=0

1. Depending on K value, the user must make sure floor(K x CLKDIV) > 1 to avoid timing problems.

14.3.2.5 Decimation Filter

Figure 14-7 shows the block diagram of the Decimation Filter. This block is composed by a CIC filter, a DC remover, two Half Band filters for each channel.

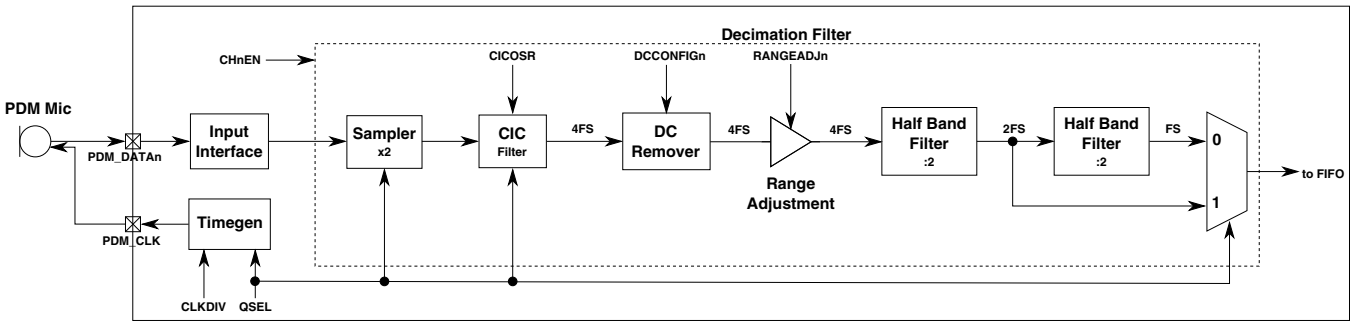

Figure 14-7. Decimation Filter Block Diagram

The Sampler block is activated depending on the quality mode selected (QSEL bitfield). This one samples twice the PDM_DATAn incoming from the Input Interface.

The CIC filter (Cascaded Integrator Comb filter) is a low pass filter commonly used to filter the sigma-delta modulator output signal.

The DC remover is a high pass filter used to remove the DC component of the processed signal with configurable cut-off frequency.

Each Half Band filter implements a low pass digital filter with decimation by 2. They are used to compensate the high CIC drop in passband and helps the FIR filter block to flat the overall passband response.

The Decimation Filter output depends on the quality mode selected by the QSEL bitfield, so it can come from any of the Half Band filters output. In case, the last Half Band filter stage is bypassed, power consumption should be reduced.

The range of each Decimation Filter can be adjusted by a Range Adjustment block so that, in case a adjustment overflows or underflows is detected. an error interrupt is raised.

14.3.2.5.1 Filter Performance

14.3.2.5.1.1 Overall Filter Gain

The overall filter gain depends on the quality mode, the Equation 8 on page 5989 and the RANGEADJn bitfield as shown in Equation 6 on page 5987.

$$OverallFilterGain\ (dB) = \begin{cases} 140 \cdot \log_{10}(32 - 2CICOSR) + 6.02RANGEADJn - 162.54 & ;if\ QSEL \in [HQ, VLQ0] \\ 140 \cdot \log_{10}(16 - CICOSR) + 6.02RANGEADJn - 162.54 & ;others \end{cases}$$

Equation 6. Overall Filter Gain

Finally, the input and output dBFS levels are related as shown in Equation 7 on page 5987.

$$Output(dBFS) = Input(dBFS) + OverallFilterGain(dB)$$

Equation 7. Filter input and output relationship

14.3.2.5.1.2 Overall Passband

The Decimation Filter passband depends on the quality mode and the output rate (FS). For instance, the overall filter passband for different output data rates when the MICFIL is in High, Medium and Low Quality modes is shown in Table 14-7.

Table 14-7. Filter Passband in HQ, MQ and LQ modes (DCCONFIGn=00)

Output Data Rate	Overall Filter Passband
FS	**0.0004FS - 0.4688FS**
16kHz	6.67Hz - 7.50kHz
48kHz	20Hz - 22.5kHz

The overall filter passband for different output data rates when the MICFIL is in Very Low Quality modes is shown in Table 14-8.

Table 14-8. Filter Passband in VLQn modes (DCCONFIGn=00)

Output Data Rate	Overall Filter Passband
FS	**0.0002FS - 0.2344FS**
16kHz	3.33Hz - 3.75kHz
48kHz	10.00Hz - 11.25kHz
96kHz	20Hz - 22.5kHz

14.3.2.5.2 Input Interface

The timing diagram of the input interface signals is shown in Figure 14-8. The bitstream incoming from the microphone data input "n" (PDM_DATAn) in the first half (Right microphone) of the PDM_CLK is directed to the Channel "2n+1" and the data generated during the last half (Left microphone) is directed to the Channel "2n".

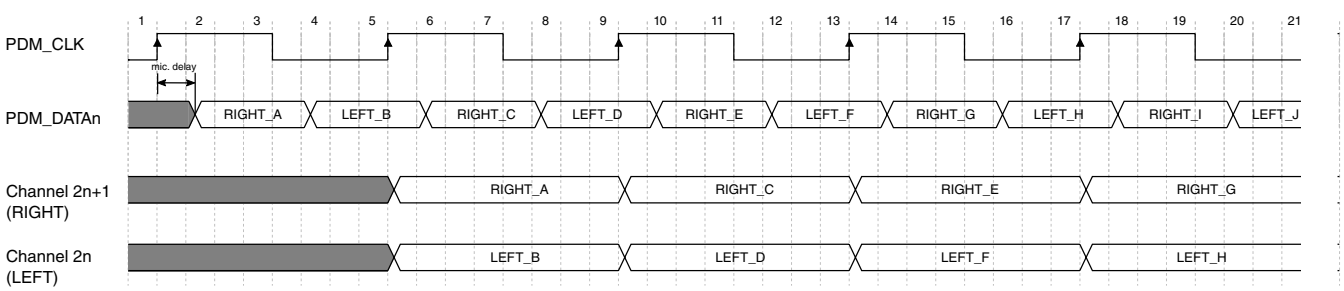

Figure 14-8. Input Interface signals

14.3.2.5.3 CIC Filter

The CIC filter is an optimized implementation of the low pass Sinc filter with multiple stages. It is widely used because it requires just adders and subtractors. The CIC filter is composed by sub-blocks called: integrator and comb. The CIC decimation rate is defined by the CICOSR bitfield and the selected quality mode as shown in Equation 8 on page 5989.

$$\text{CIC Decimation Rate} = \begin{cases} 2*(16-\text{CICOSR}) & ;\text{if HQ or VLQ0} \\ 16-\text{CICOSR} & ;\text{others} \end{cases}$$

Equation 8. CIC Decimation Rate

14.3.2.5.4 DC Remover

There are two DC removers in the filter chain, one in the input and another in the output. The former is integrated in the CIC filter, and the later is placed just before the FIFO. Both can be bypassed independently.

The block removes the DC level component of the signal using a high-pass filter with a very low cut-off frequency selected by the DCCONFIGn bitfield. This filter is bypassed when DCCONFIGn=11.

14.3.2.5.5 Half Band Filters

A half band filter divides the signal base-band into two equal subbands before to be decimated by 2. It also compensates the CIC filter drop in passband and helps to flatten the overall passband response. MICFIL has two half band filter stages, with the possibility of bypass the last one.

14.3.2.6 Hardware Voice Activity Detector

The Hardware Voice Activity Detector (HWVAD) is a block responsible for detect voice activity in a channel selected by the user as shown in the Figure 14-9 and Figure 14-10. It can be configured in Envelope-based or Energy-based mode and it should be configured as described in Initialization.

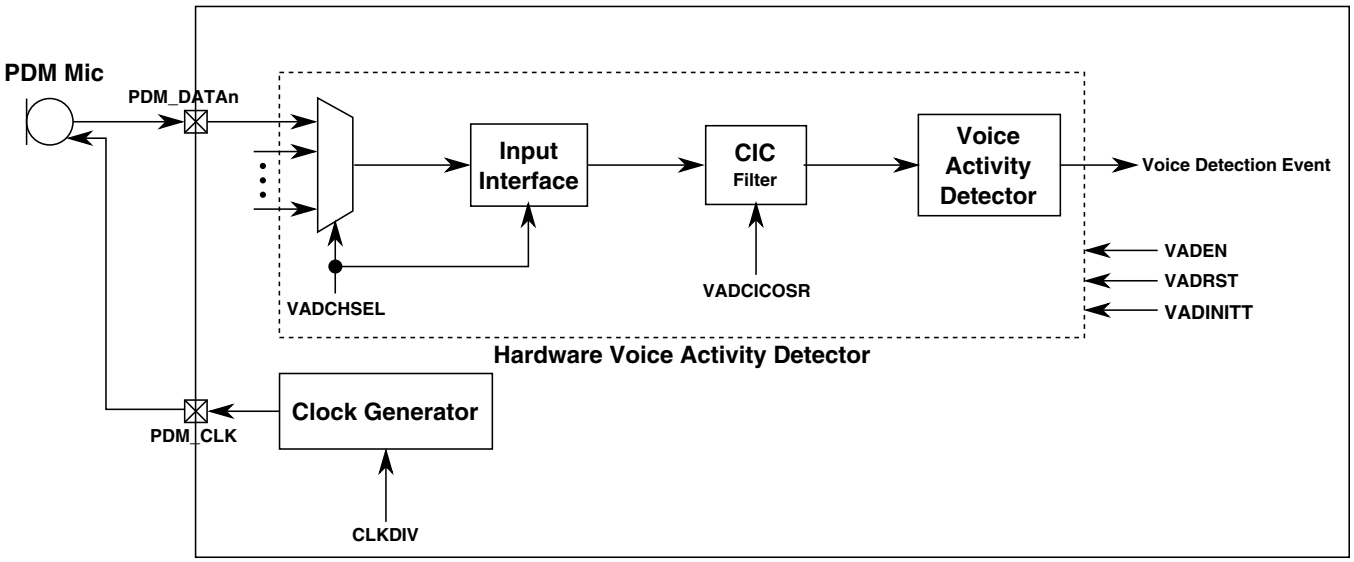

Figure 14-9. HWVAD Block Diagram

The HWVAD can divide the incoming PCM signal from its internal CIC in frames, the frame energy is used to estimate the background noise. Both frame energy and noise energy are examinated, a voice activity is detected when a specific delta between them is detected, then a interrupt will be issued. Optionally a Zero-Crossing Detection block (ZCD) could be enabled to avoid low energy voiced speech be missed, improving the voice detection performance.

The HWVAD detector can be enabled by the VADEN bit (VAD_CTRL_1 register) and could be reset by software through the VADRST bit (VAD_CTRL_1 register) . It is important to remark that the HWVAD detector could be enabled and/or reset only when the MICFIL isn't running i.e. when the BSY_FIL bit in STAT register is cleared.

To perform voice detection a Noise Filter and Signal Filter are used as shown Figure 14-10. In addition, a minimum block in the output of the Noise Filter and a maximum block in the ouput of the Signal Filter can be used. The result of both blocks can be scaled by gain blocks. Finally, the signal and noise estimated are compared, voice is detected when signal is greater than noise.

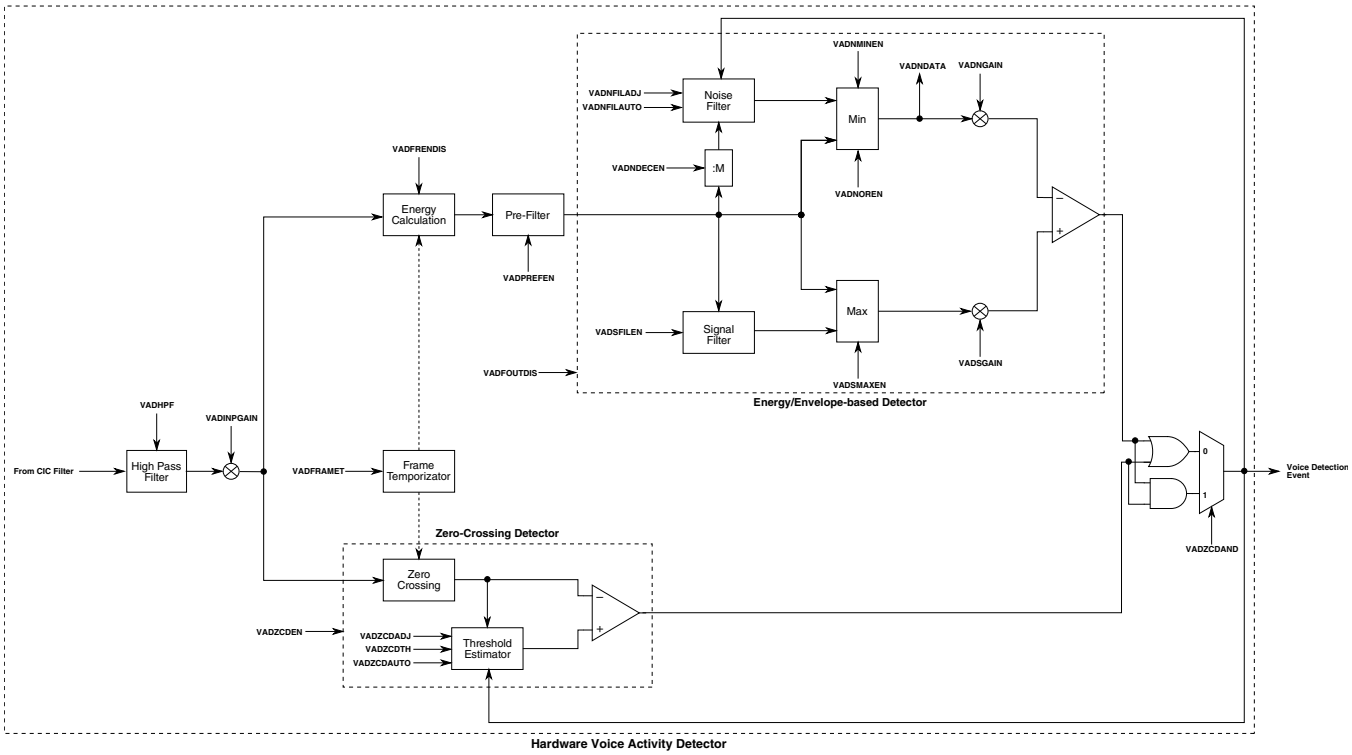

Figure 14-10. HWVAD Block Diagram (cont.)

14.3.2.6.1 High-Pass Filter

The purpose of the High-Pass Filter is to remove the low frequency components. The cut-off frequency is selected by the VADHPF bitfield. This filter is bypassed when VADHPF=00.

14.3.2.6.2 Input Setting

The HWVAD input has internally a user configurable High-Pass filter (see VADHPF bit description) and a user configurable gain (see VADINPGAIN). Both controls could be used to configure the module based on external noise conditions.

14.3.2.6.3 Frame Time Setting

In order to perform voice detection the signal frames incoming from the CIC filter can be divided in frames whose duration can be configured. The frame time will depend on the CIC output rate, the value of the VADFRAMET bitfield and a constant as is defined in Equation 9 on page 5991.

$$frame\ \ time = \frac{VADFRAMET \times 192}{CIC\ \ output\ \ rate}$$

Equation 9. Frame Time

For instance, in the typical case of the CIC filter output rate would be 192kHz, the frame time would be 10ms when VADFRAMET is 10.

14.3.2.6.4 Initialization Time

An initialization time can be configured by the VADINITT bitfield. During this initialization time no voice detection event is issued, all detectors are kept disabled.

$$initialization\ \ time = (\text{VADINITT}+1) \times frame\ \ time$$

Equation 10. Initialization Time

14.3.2.6.5 Energy Calculation

In case VADFRENDIS = 0, the sum of the absolute values of all the samples of each frame are used to detect voice. Otherwise, if VADFRENDIS=1, the absolute value of the samples are used to detect voice i.e. the data incoming from CIC is not divided in frames.

14.3.2.6.6 Pre-Filter

The Pre-FIlter block is a low-pass filter which can be enabled when VADPREFEN=1 .

14.3.2.6.7 Energy/Envelope-based Detector

To perform voice detection a Noise Filter and Signal Filter are used as shown Figure 14-10. In addition, a minimum block in the output of the Noise Filter and a maximum block in the ouput of the Signal Filter can be used. The result of both blocks can be scaled by gain blocks. Finally, the signal and noise estimated are compared, voice is detected when signal is greater than noise.

14.3.2.6.7.1 Noise Filter

The Noise Filter is a low-pass filter . This filter could be adjusted by the VADNFILADJ bitfield . In case VADNFILAUTO=1 the noise filter is enabled only when voice is not detected, when voice is detected the filter output does not change. In case VADNFILAUTO=0 the filter is always enabled.

A decimation stage in the input of the Noise Filter can be enabled by the VADNDECEN bitfield.

14.3.2.6.7.2 Minimum Noise

In order to estimate the noise, a block which calculates the minimum value between the input and output of the noise filter is used. This block can be enabled by VADNMINEN, otherwise the output of the noise filter is passed directly.

The estimated noise of the output of this block is stored in the VADNDATA register for post-processing via software.

14.3.2.6.7.3 Signal Filter

The Signal Filter is a low-pass filter . This filter will be enabled when VADSFILEN=1, otherwise the filter will be bypassed.

14.3.2.6.7.4 Maximum Signal

In order to estimate the signal, a block which calculates the maximum value between the input and output of the signal filter can be used. This block can be enabled by VADSMAXEN.

14.3.2.6.7.5 Filter Result Gain Setting

There are two gain adjustment controls, one for the estimated noise (VADNGAIN) and another for signal estimated (VADSGAIN). Both gain adjustments outputs are compared, the comparison result determines whether or not there is voice in the channel.

14.3.2.6.8 Zero-Crossing Detector

Optionally, the HWVAD performance can be increased by the use of a Zero-Crossing Detection (ZCD) circuit. It is enabled by a VADZCDEN bit.

The threshold of the ZCD could be static or calculated dynamically depending on the VADZCDAUTO bit. When it is dynamically determined (VADZCDAUTO = 1) the threshold is calculated automatically taking the VADZCDTH bit-field as initial value, otherwise (VADZCDAUTO=0) the threshold is static in the VADZCDTH user configurable value.

The ZCD result can be AND'ed or OR'ed with the energy-based or envelope-based detection, it is selected by the VADZCDAND bit.The filter coefficient is equal to (VADZCDADJ+1)*2^(-4).

14.3.2.6.9 Interrupt

The HWVAD issues an interrupt when voice activity is detected and the VADIE bit in the VAD_CTRL_1 register is enabled. The voice activity event also will set the VADIF flag in the VAD_STAT register, this bit will be cleared when it is written 1.

14.3.2.6.10 Extended Operation

The VADIF bit could be used for a HWVAD extended operation i.e. using the VADNDATA bitfield value to determine a more accurate voice detection event by software. The procedure to follow will be:

1. An interrupt is issued by the HWVAD, the VADIF is set.
2. Leave the VADIF asserted while sofware is processing the VADNDATA bitfield content.
3. When software finishes to process the VADNDATA and detects voice activity:
   - If Envelope-based Detection is used, pulse VADST10 by more than 2-cycles and clear VADIF flag.
   - If Energy-based Detection is used, clear VADIF flag.

14.3.2.6.11 VAD Soft-reset

The VAD soft-reset is requested by writing 1 to the VADRST bit. It resets the following blocks and/or registers:

- VADIF, VADINSATF bitfields.
- All internal VAD buffers.

14.3.2.7 Bus Interface

The Bus Interface manages the Direct Memory Access (DMA) transactions, the interrupt requests and the user register interface with the SoC.

14.3.2.7.1 FIFO

The FIFO is a First-In, First-Out buffer that saves the overall filtering results. Each FIFO is 32 entries length. There is one FIFO for each channel. A push writes data into the FIFO, and a read pops data from FIFO. The push and pop operations from FIFO are in different clock domains, the push operation is made using the MICFIL clock while the pop operation uses the CPU clock . The FIFO has a configurable watermark FIFOWMK in the FIFO_CTRL register. When the amount of data in all the FIFOs of the enabled channels is greater than the watermark value (FIFO_CTRL[FIFOWMK]) a DMA/IRQ is requested depending on the DISEL field in the CTRL_1 register. After the filters are enabled by PDMIEN, the initial FIR results are discarded and not written into the FIFOs.

About 68 initial FIR results are not stored on FIFOs (FIR_RDY=0). After the STAT[FIR_RDY] register is set the data generated by the filter is valid and starts to push the results in FIFO.

A new filtered result is discarded (not stored) when the FIFO is full and overflow flag FIFOOVFn rises. Similarly, when trying a pop and FIFO is empty no valid data is read and underflow flag rises. In both cases, when overflow or underflow occurs they are flagged in the FIFO_STAT register to the respective channel, and an error interrupt is generated if the ERREN in the CTRL_1 register is asserted.

When the FIFO is reset by asserting the SRES soft-reset bit, zero values fills all FIFO positions, as well as push and pop pointers are set to initial position.

14.3.2.7.2 DMA

If DISEL=01 the FIFO stored samples will be read through DMA transactions. Then if there is at least one enabled channel and all FIFOs of all enabled channels reach their watermark the output interface makes a request for DMA transaction. When the PDMIEN is set and the filters start to operate, there is a period to wait the filter results to stabilize and no filter results are stored on the FIFOs. Therefore the first DMA request takes longer to occur than the following ones.

The CHnF flags in the STAT register are cleared when a DMA transaction is finished.

When the MICFIL is in Low Power mode and the watermark level is surpassed an asynchronous DMA request is delivered to the system, then the system wakes up the CPU clock, returning to Normal mode, to read FIFOs data.

14.3.2.7.3 Interrupt Requests

If DISEL=10 then an interrupt request is used to indicate that filtering results are stored in the FIFOs to be read by CPU. Also in this case the data can be read in the DATACHn registers and the flag CHnF of the STAT register are asserted for the enabled channels when the CHn FIFO surpasses the watermark level.

When the module is in Low Power mode the CPU clock is disabled, but the MICFIL clock remains enabled. In this case, an asynchronous interrupt is delivered to the system, it wakes up the CPU clock, returning to Normal mode. The system could read the FIFOs data and after should clear the CHnF flags to get a new interrupt request.

An error interrupt request can be generated also when an exceptional condition happens, such as a overflow or underflow in any channel output, an overflow or underflow of any FIFO, or the MICFIL clock rate is not the minimum value required to the MICFIL working (see Minimum Required CLKDIV). This one is enabled by the ERREN bit and

the type of error is signalized by its respective status flag: OUTOVFn and OUTUNFn for channel outputs errors, FIFOOVF and FIFOUND flags for FIFO errors, and LOWFREQF for MICFIL clock rate.

14.3.3 External Signals

Note

The PDM Microphone Interface module does not provide metastability protection or filtering for input data. The data must be generated using the provided PDM_CLK.

Table 14-9. PDM Microphone Interface External Signals

Signal	Description	Direction
PDM_DATAn	The data bitstreams received from *n*th PDM microphone pair throughout the input interface	I
PDM_CLK	The clock delivered to the PDM microphones from the clock generator	O

14.3.4 Initialization

Following are some simple initialization steps to be done before using the MICFIL block.

14.3.4.1 Initialization Procedure without HWVAD

The sequence of steps for the block initialization without enabling voice activity detector, i.e. using decimation filters only, is as follows:

1. Program the bit-fields as desired for your application (CLKDIV, CHnEN, FIFOWMK, DISEL, ERREN etc.). For more details see MICFIL_CLK_ROOT rate and CLKDIV calculation examples.
2. Start the overall module asserting the PDMIEN bit.
3. The module is ready to receive data from the input ports of the enabled channels.

14.3.4.2 Initialization Procedure with HWVAD

In this section is described the initialization procedures to initialize MICFIL with the voice activity detector.

The voice activity detector can work in two modes: Energy-based mode or Envelope-based mode. Optionally, a Zero-Crossing Detector can be enabled to improve the voice detection.

The Energy-based method separates the audio signal in frames and estimates the energy of these frames to detect voice activity. In the other hand, the Envelope-based method calculates the audio signal envelope to detect voice.

Both methods have the same detection performance, but the Energy-based is recommended for low power applications where is expected that the chip is asleep for long periods. Envelope-based detection is recommended for applications where the device require to wake faster and it is not asleep for long periods.

The Zero-Crossing Detector is recommended to improve detection with fricatives phonemes (/e.g. /f/ or /s/) in noisy environments.

14.3.4.2.1 HWVAD in Energy-based mode

The sequence of steps to initialize the voice activity detector in Energy-based mode is as follows:

1. Program the control bitfields as desired for your application (CLKDIV, CHnEN, FIFOWMK, DISEL, ERREN etc.). For more details see MICFIL_CLK_ROOT rate and CLKDIV calculation examples.
2. Configure general HWVAD parameters:
   a. CIC oversampling rate (VADCICOSR bitfield).
   b. Configure the voice source channel (VADCHSEL bitfield).
   c. Configure the internal initialization timer (VADINITT bitfield) if required. More details in Initialization Time.
   d. Assert VADEN bitfield.
3. Configure input, noise and signal gains according to the environmental noise conditions:
   a. Configure the input gain (VADINPGAIN bitfield).
   b. Configure the signal gain (VADSGAIN bitfield).
   c. Configure the noise gain (VADNGAIN bitfield).
4. Enable the high-pass filter if required (VADHPF bitfield).
5. Configure the VADNFILADJ bitfield according to environmental noise conditions (VADNFILADJ = 16 is recommended).
6. Put HWVAD in energy-based mode (default values):
   a. Keep the VADFRENDIS bitfield cleared.
   b. Keep the VADPREFEN bitfield cleared.
   c. Keep the VADSFILEN bitfield cleared.
   d. Keep the VADSMAXEN bitfield cleared.

e. Keep the VADNFILAUTO bitfield asserted.
f. Keep the VADNMINEN bitfield cleared.
g. Keep the VADNDECEN bitfield cleared.
h. Keep the VADNOREN bitfield cleared.

7. Initialize the Zero-Crossing Detector (Zero-Crossing Detector Initialization) if required.
8. Enable interrupts if required (VADIE and VADERIE bitfields).
9. Start the overall module asserting the PDMIEN bit.
10. The module is ready to receive data from the input ports of the enabled channels and to trigger interrupts when voice is detected.

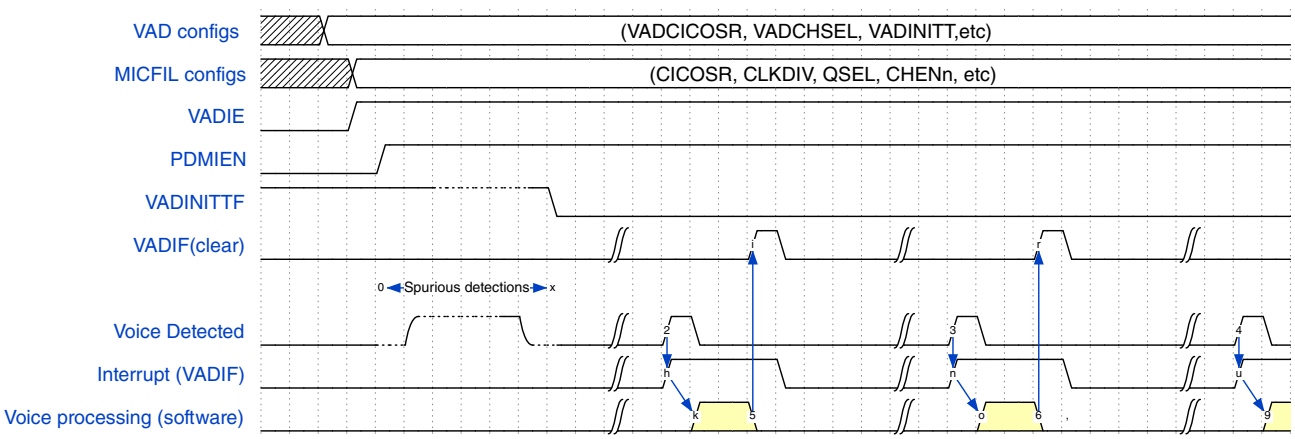

Figure 14-11. Energy-based initialization sequence

14.3.4.2.2 HWVAD in Envelope-based mode

The sequence of steps to initialize MICIL with the voice activity detector in Envelope-based mode is as follows:

1. Program the control bitfields as desired for your application (CLKDIV, CHnEN, FIFOWMK, DISEL, ERREN etc.). For more details see MICFIL_CLK_ROOT rate and CLKDIV calculation examples.
2. Configure general HWVAD parameters:
   a. CIC oversampling rate (VADCICOSR bitfield).
   b. Configure the voice source channel (VADCHSEL bitfield).
   c. Configure the internal initialization timer (VADINITT bitfield) if required. More details in Initialization Time.
   d. Assert VADEN bitfield.
3. Configure input, noise and signal gains according the environment noise conditions:
   a. Configure the input gain (VADINPGAIN bitfield).
   b. Configure the signal gain (VADSGAIN bitfield).
   c. Configure the noise gain (VADNGAIN bitfield).
4. Enable the high-pass filter if required (VADHPF bitfield).

5. Put HWVAD in envelope-based mode:
   a. Keep VADNFILADJ bitfield cleared.
   b. Assert the VADFRENDIS bitfield.
   c. Assert the VADPREFEN bitfield.
   d. Assert the VADSFILEN bitfield.
   e. Assert the VADSMAXEN bitfield.
   f. Clear the VADNFILAUTO bitfield.
   g. Assert the VADNMINEN bitfield.
   h. Assert the VADNDECEN bitfield.
   i. Assert the VADNOREN bitfield.
6. Initialize the Zero-Crossing Detector (Zero-Crossing Detector Initialization) if required.
7. Start the overall module asserting the PDMIEN bit.
8. Wait for VADINITF to be cleared.
9. Write VADST10 bitfield three times.
10. Enable interrupts if required (VADIE and VADERIE bitfields).
11. The module is ready to receive data from the input ports of the enabled channels and to trigger interrupts when voice is detected.

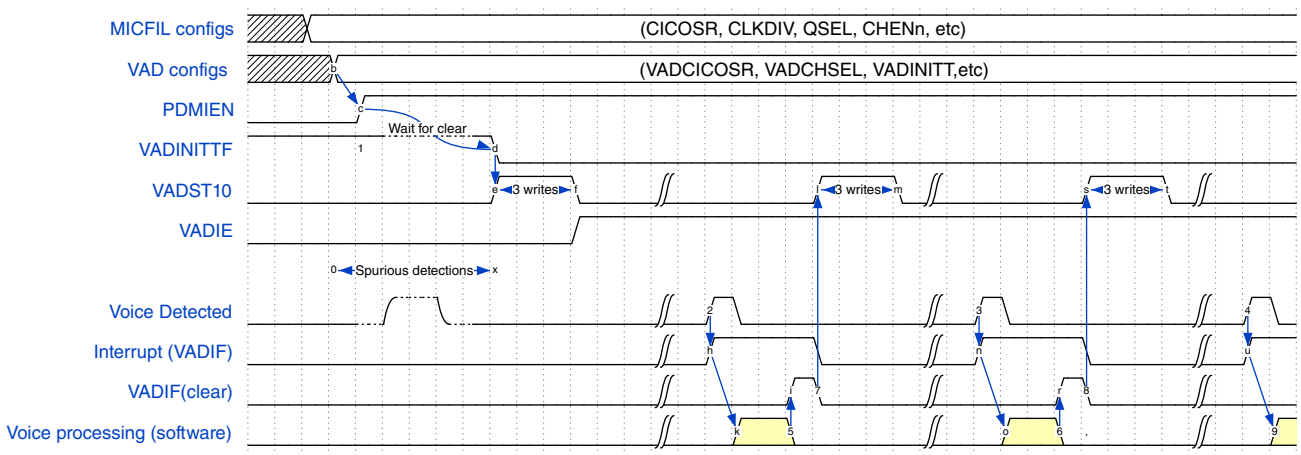

Figure 14-12. Envelope-based initialization sequence

14.3.4.2.3 Zero-Crossing Detector Initialization

The sequence of steps to initialize the Zero-Crossing Detector in Automatic mode is as follows:

1. Configure VADZCDADJ bitfield.
2. Configure an initial threshold in VADZCDTH according to the environmental noise conditions if required.
3. Configure VADZCDAND bitfield.
4. Keep VADZCDAUTO bitfield asserted.

5. Assert VADZCDEN.

The sequence of steps to initialize the Zero-Crossing Detector in Manual mode is as follows:

1. Configure a threshold in VADZCDTH according to the environmental noise conditions if required.
2. Configure VADZCDAND bitfield.
3. Clear VADZCDAUTO bitfield.
4. Assert VADZCDEN.

14.3.5 Application Information

14.3.5.1 Reconfiguration Procedure

The sequence of steps for the block reconfiguration is as follows:

1. Deassert PDMIEN bit.
2. Wait to BSY_FIL to be cleared.
3. Run a soft-reset cycle.
4. Run a initilialization procedure as described in Initialization Procedure without HWVAD or Initialization Procedure with HWVAD.

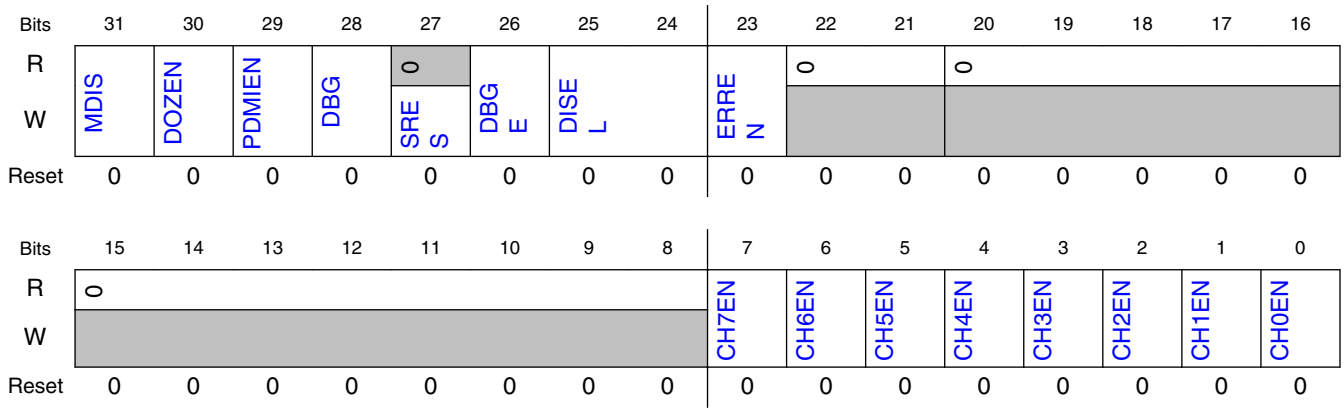
14.3.6 MICFIL register descriptions

This section provides the memory map and detailed description of all MICFIL registers. Any access to reserved areas can issue a slave bus error indication.

The registers allocated in this memory map are implemented for up to 4 pairs of microphones, that means 8 channels are available.

14.3.6.1 MICFIL memory map

MICFIL base address: 30CA_0000h



Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	MICFIL Control register 1 (CTRL_1)	32	RW	0000_0000
4	MICFIL Control register 2 (CTRL_2)	32	RW	0000_0000
8	MICFIL Status register (STAT)	32	W1C	0000_0000
10	MICFIL FIFO Control register (FIFO_CTRL)	32	RW	0000_001F
14	MICFIL FIFO Status register (FIFO_STAT)	32	W1C	0000_0000
24 - 40	MICFIL Output Result Register (DATACH0 - DATACH7)	32	RO	0000_0000
64	MICFIL DC Remover Control register (DC_CTRL)	32	RW	0000_0000
74	MICFIL Range Control register (RANGE_CTRL)	32	RW	0000_0000
7C	MICFIL Range Status register (RANGE_STAT)	32	W1C	0000_0000
90	Voice Activity Detector 0 Control register (VAD0_CTRL_1)	32	RW	0000_0000
94	Voice Activity Detector 0 Control register (VAD0_CTRL_2)	32	RW	000A_0000
98	Voice Activity Detector 0 Status register (VAD0_STAT)	32	W1C	8000_0000
9C	Voice Activity Detector 0 Signal Configuration (VAD0_SCONFIG)	32	RW	0000_0000
A0	Voice Activity Detector 0 Noise Configuration (VAD0_NCONFIG)	32	RW	8000_0000
A4	Voice Activity Detector 0 Noise Data (VAD0_NDATA)	32	RO	0000_0000
A8	Voice Activity Detector 0 Zero-Crossing Detector (VAD0_ZCD)	32	RW	0000_0004

14.3.6.2 MICFIL Control register 1 (CTRL_1)

14.3.6.2.1 Offset

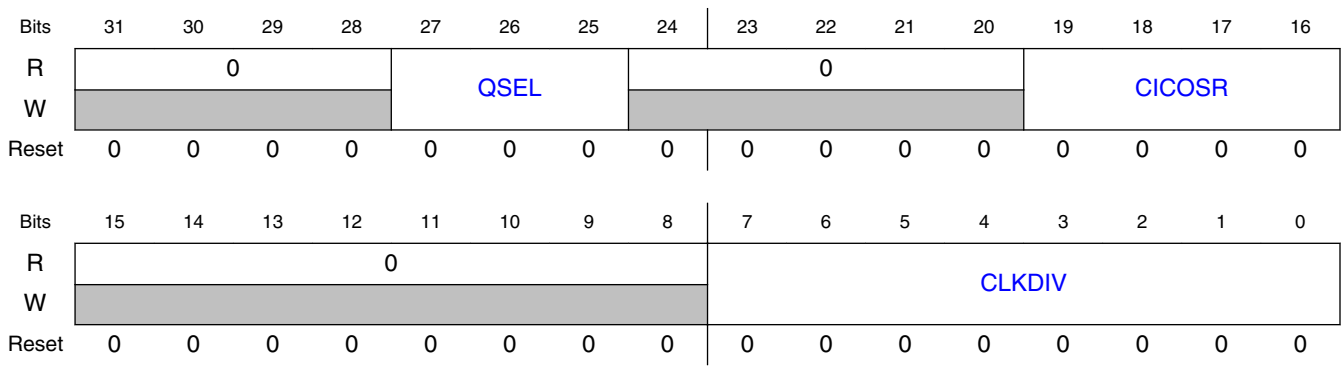
Register	Offset
CTRL_1	0h

14.3.6.2.2 Diagram

14.3.6.2.3 Fields

Field	Description
31 MDIS	Module Disable Puts the whole MICFIL in Disable/Low Leakage mode. The generated PDM_CLK is stopped and consequently no data is generated by the microphones. **NOTE:** When MDIS=1, writes to CTRL_1 and CTRL_2 only are allowed with the exception of writes to the DBG and SRES bits. A slave bus error indication will be issued when any register except CTRL_1 and CTRL_2 is written when MDIS=1. 0 - Normal Mode 1 - Disable/Low Leakage Mode
30 DOZEN	DOZE enable When SoC is in Doze mode and DOZEN is active the module enters to Disable/Low Leakage mode.
29 PDMIEN	MICFIL Enable Starts the module operation. Only the channels enabled by CHnEN or VAD enabled by VADEN will start to operate. When it is cleared, the whole module is stopped after to finish the pending filtering. **NOTE:** This field must be the latest to be enabled, for more information refer to Initialization . 0 - MICFIL stopped 1 - MICFIL operation started
28 DBG	Debug Mode Enables the Debug mode. The module can run on this mode depending on the DBGE bit value. **NOTE:** This bit is writable only when MDIS is cleared. 0 - Normal Mode 1 - Debug Mode
27 SRES	Software-reset bit Provides the CPU with the capability to initialize the MICFIL module through the slave-bus interface. This bit always reads as zero, and this bit is only effective when MDIS is cleared. This bit is self-cleared. **NOTE:** This bit must be asserted only when BSY_FIL=0

Table continues on the next page...



Field	Description
	This bit can be used to clear all data in the filters. It resets the following blocks and/or registers: • All internal buffers in decimation filters and Voice Activity Detectors. • All FIFOs. • All CHnF flags and LOWFREQF flag on the STAT register, and the FIFO_STAT register. • Time Generator. 0 - No action 1 - Software reset
26 DBGE	Module Enable in Debug Enables operation in Debug mode. 0 - Disabled after completing the current frame 1 - Enabled
25-24 DISEL	DMA Interrupt Selection Selects if the module performs DMA requests or filter interrupt requests when the number of FIFO elements surpasses the configured watermark. Note that requests are only generated from the channels whose CHnEN bits are asserted. **NOTE:** This bit mustn't change when BSY_FIL bit is asserted 00 - DMA and interrupt requests disabled 01 - DMA requests enabled 10 - Interrupt requests enabled 11 - Reserved
23 ERREN	Error Interruption Enable Enables error interrupts (exceptions). This error could be caused by: • an overflow or underflow in the FIFOs (FIFOOVF or FIFOUND bits), • an overflow or underflow in the decimations filters (the RANGEOVF or RANGEUNF bits), or • not enough MICFIL internal clock frequency (LOWFREQF bit). **NOTE:** This bit mustn't change when BSY_FIL bit is asserted 0 - Error Interrupts disabled 1 - Error Interrupts enabled
22-21 —	Reserved
20-16 —	Reserved
15-8 —	Reserved
7-0 CHnEN	Channel n Enable Enables the decimation filter channel n. Refer to Initialization for more information. **NOTE:** This bit mustn't change when BSY_FIL bit is asserted.

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

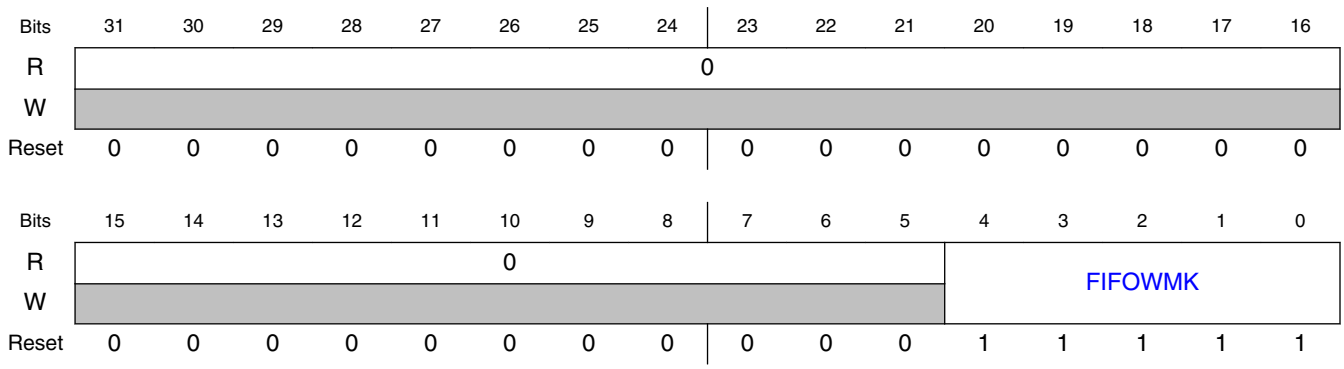
14.3.6.4.3 Fields



Field	Description
31 BSY_FIL	Busy Flag Signalizes when at least a decimation filter channel or at least a HWVAD is running and the PDM_CLK is being generated. This bit could be used as a confirmation that all decimation filters are stopped in a transition to Debug (when DBGE=0) or Disable/Low Leakage mode. 0 - MICFIL is stopped 1 - MICFIL is running
30 FIR_RDY	Filter Data Ready Indicates that all the decimation filter buffers have been updated, and all data provided from now on will be reliable. 0 - Filter data is not reliable 1 - Filter data is reliable
29 LOWFREQF	Low Frequency Flag Indicates that the CLKDIV bitfield value is not high enough to filter all enabled channels , and the half band filters didn't finish their operations before the next sample arrived. See Minimum Required CLKDIV . Write a logic 1 to this field to clear this flag. **NOTE:** The filtering results in this condition are unpredictable. 0 - CLKDIV value is OK 1 - CLKDIV value is too low
28-16 —	Reserved
15-8 —	Reserved
7-0 CHnF	Channel n Output Data Flag Indicates that the FIFO from this channel has surpassed its watermark value and the data is available at the DATACHn register. This flag contributes to generate an Interrupt or DMA request if enabled by DISEL in the CTRL_1. Write a logic 1 to this field to clear this flag. If DMA request is set (DISEL = 01) the CHnF flag will be set according to watermark level and will be cleared , in the other cases (IRQ included) the CHnF flag will be set according to the watermark level and will be cleared with the w1c functionality of the bit. **NOTE:** If DMA is enabled, this flag is self-cleared when the DMA transaction is finished . 0 - Channel's FIFO did not reach the number of elements configured in watermark bit-field 1 - Channel's FIFO reached the number of elements configured in watermark bit-field

14.3.6.11.3 Fields

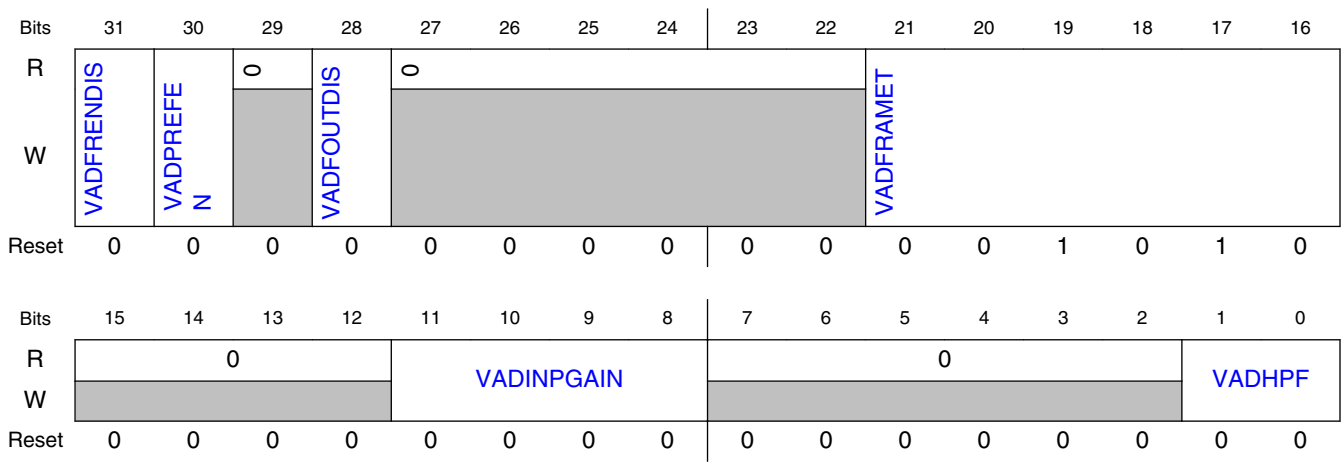
Field	Description
31-27 —	Reserved
26-24 VADCHSEL	Voice Activity Detector Channel Selector Selects the number of channel which the hardware voice activity detector will work.

Table continues on the next page...

Field	Description
	NOTE: This bitfield mustn't change when BSY_FIL is asserted.
23-22 —	Reserved
21-20 —	Reserved
19-16 VADCICOSR	Voice Activity Detector CIC Oversampling Rate Defines the oversampling rate of the CIC filter. The oversampling rate is (16-CICOSR). **NOTE:** This bitfield mustn't change when BSY_FIL is asserted.
15-13 —	Reserved
12-8 VADINITT	Voice Activity Detector Initialization Time Selects the number of frames to be used to initialize the voice detection. During this period the output of the voice activity detector is forced to inactive. For more information, refer to Initialization Time . **NOTE:** The initialization time will be the time taken by [VADINITT+1] frames. **NOTE:** This bitfield mustn't change when BSY_FIL is asserted.
7-5 —	Reserved
4 VADST10	Voice Activity Detector Internal Filters Initialization Initializes the signal and noise filter with pre-filter value. **NOTE:** If the use of this bit is required, it should be stay pulsed by more than 2 cycles of system clock . **NOTE:** There is not voice activity detection when VADST10 is asserted. 0 - Normal operation. 1 - Filters are initialized.
3 VADERIE	Voice Activity Detector Error Interruption Enable Enables Error Interrupts in the MICFIL. This error could be caused by an overflow in the input of the HWVAD and it is signalized by the VADINSATF flag. 0 - HWVAD Error Interrupts disabled 1 - HWVAD Error Interrupts enabled
2 VADIE	Voice Activity Detector Interruption Enable Enables interrupts in the MICFIL when voice activity event has been detected by the Hardware Voice Activity Detector (HWVAD). See the VADIF for more information. 0 - HWVAD Interrupts disabled 1 - HWVAD Interrupts enabled
1 VADRST	Voice Activity Detector Reset Provides the CPU with the capability to initialize the VAD through the slave-bus interface. This bit always reads as zero. This bit is self-cleared. See VAD Soft-reset.
0 VADEN	Voice Activity Detector Enable Enables the use of the Hardware Voice Activity Detector. **NOTE:** This bitfield mustn't change when BSY_FIL is asserted. 0 - The HWVAD is disabled

Field	Description
	1 - The HWVAD is enabled

14.3.6.12 Voice Activity Detector 0 Control register (VAD0_CTRL_2)



NOTE

This register mustn't change when BSY_FIL is asserted.

25-16 VADZCDTH	Zero-Crossing Detector Threshold Configures the initial value taken to estimate the ZCD threshold when it is estimated automatically (VASDZCDAUTO = 1), otherwise (VADZCDAUTO = 0) this bit-field is the static value of the ZCD threshold.
15-12 —	Reserved
11-8 VADZCDADJ	Zero-Crossing Detector Adjustment Selects the adjustment value of the threshold estimator. For more information, refer to Zero-Crossing Detector .
7-5 —	Reserved
4 VADZCDAND	Zero-Crossing Detector AND Behavior Selects whether the Zero-Crossing detector results will be AND'ed or OR'ed with the energy-based detection to form the voice activity detection event. 0 - The ZCD result is OR'ed with the energy-based detection.

Table continues on the next page...

Field	Description
	1 - The ZCD result is AND'ed with the energy-based detection.
3 —	Reserved
2 VADZCDAUTO	Zero-Crossing Detector Automatic Threshold Enables the automatic estimation of the ZCD threshold. 0 - The ZCD threshold is not estimated automatically 1 - The ZCD threshold is estimated automatically
1 —	Reserved
0 VADZCDEN	Zero-Crossing Detector Enable Enables the Zero-Crossing Detector (ZCD) in the Hardware Voice Activity Detector (HWVAD). 0 - The ZCD is disabled 1 - The ZCD is enabled

14.4 Synchronous Audio Interface (SAI)

14.4.1 Overview

The Synchronous Audio Interface (SAI) provides an interface that supports full-duplex serial interfaces with frame synchronization formats such as I^2S, AC97, TDM, and codec/DSP interfaces.

14.4.1.1 Block diagram

The following block diagram also shows the module clocks.

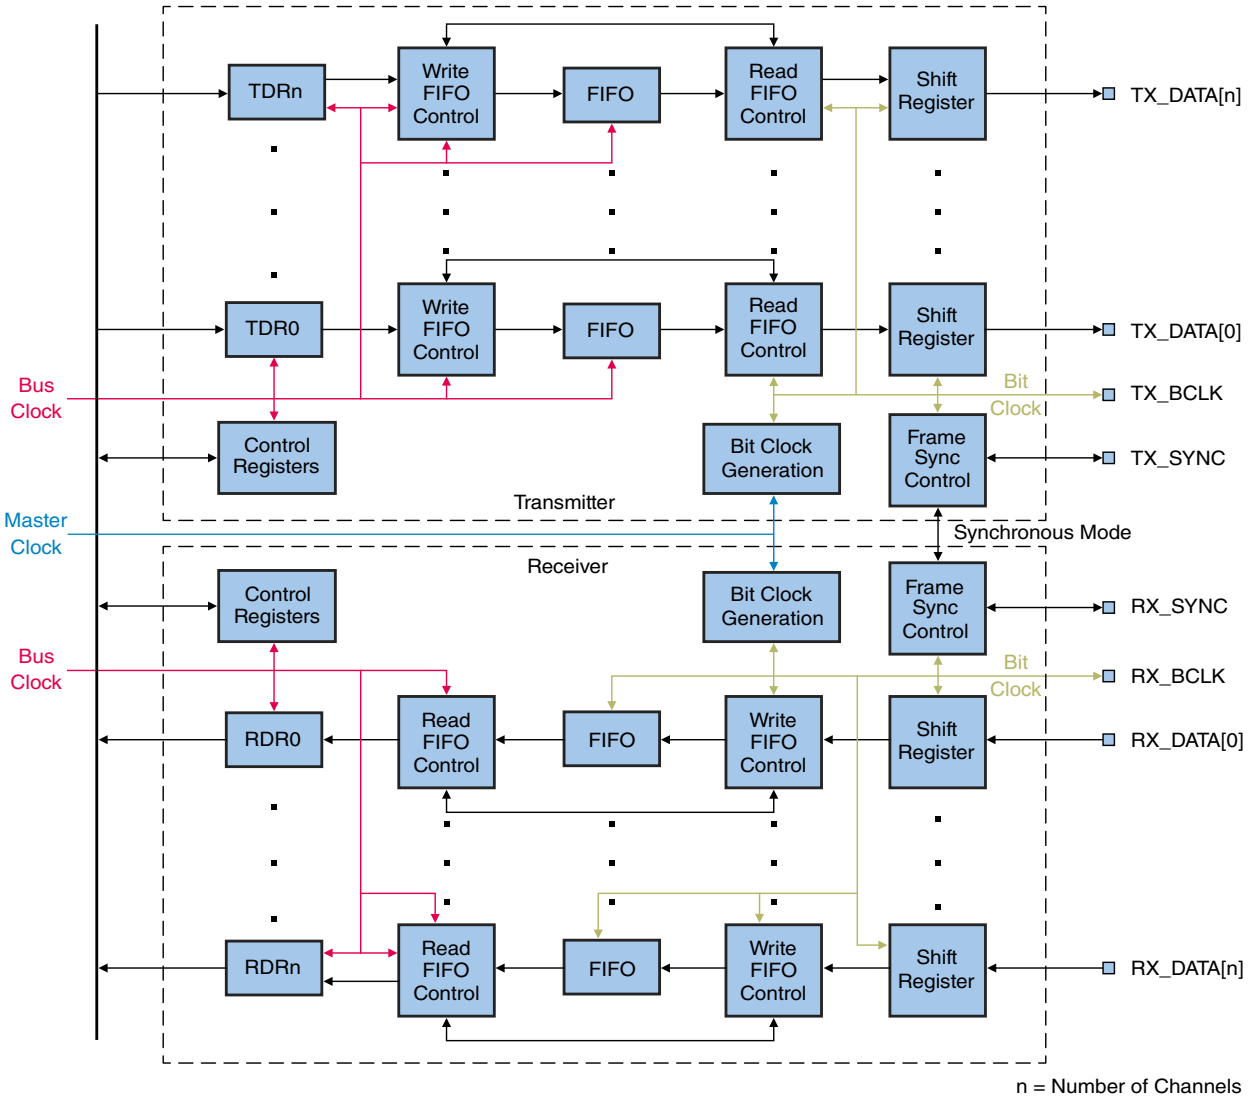

Figure 14-13. SAI block diagram

14.4.1.2 Features

Some of the features are not supported across all SAI instances; see the chip-specific SAI information in the first section of this chapter.

- Transmitter with independent bit clock and frame sync supporting 8 data lines
- Receiver with independent bit clock and frame sync supporting 8 data lines
- Each data line can support a maximum frame size of 32 words
- 8- to 32-bit word size
- Word size configured separately for the first word and remaining words in a frame
- Asynchronous 128 x 32-bit FIFO for each transmit and receive data line supporting:
  - Graceful restart after FIFO error

  - Automatic restart after FIFO error without software intervention
  - 8-bit and 16-bit data packing into each 32-bit FIFO word
  - Multiple data line FIFOs combining into single data line FIFO
- Independent 32-bit timestamp counters and bit counters for monitoring transmit and receive progress

14.4.2 Functional description

This section provides a complete functional description of the block.

14.4.2.1 Modes of operation

Module power modes include Run mode.

14.4.2.1.1 Run mode

In Run mode, the SAI transmitter and receiver operate normally.

14.4.2.2 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other or synchronously to other SAI peripheral instances.

14.4.2.2.1 Synchronous mode

The SAI transmitter and receiver can be configured to operate with synchronous bit clock and frame sync.

If both the transmitter and receiver use the transmitter bit clock and frame sync:

- Configure the transmitter for asynchronous operation and the receiver for synchronous operation.
- Enable the receiver in synchronous mode only after both the transmitter and receiver are enabled.
- Enable the transmitter last and disable the tranmitter first.

If both the transmitter and receiver use the receiver bit clock and frame sync:

- Configure the receiver for asynchronous operation and the transmitter for synchronous operation.

- Enable the transmitter in synchronous mode only after both the receiver and transmitter are enabled.
- Enable the receiver last and disable the receiver first.

When operating in synchronous mode, the transmitter and receiver share only the bit clock, frame sync, and transmitter/receiver enable. Otherwise, the transmitter and receiver operate independently, although the configuration registers must be configured consistently across both the transmitter and receiver.

14.4.2.2.2 Multiple SAI Synchronous mode

Synchronous operation between multiple SAI peripherals is not supported on all devices. This mode requires the source of the bit clock and frame sync to be configured for asynchronous operation and the remaining users of the bit clock and frame sync to be configured for synchronous operation.

Synchronous operation between multiple SAI transmitters or receivers also requires the source of the bit clock and frame sync to be enabled for any of the synchronous transmitters or receivers to also be enabled. It is recommended that the source of the bit clock and frame sync is the last enabled and the first disabled.

When operating in Synchronous mode, only the bit clock, frame sync, and transmitter/receiver enable are shared. The separate SAI peripherals otherwise operate independently, although configuration registers must be configured consistently across both the transmitter and receiver.

14.4.2.3 Frame sync configuration

When enabled, the SAI continuously transmits and/or receives frames of data. Each frame consists of a fixed number of words and each word consists of a fixed number of bits. Within each frame, any given word can be masked causing the receiver to ignore that word and the transmitter to tri-state for the duration of that word.

The frame sync signal indicates the start of each frame. A valid frame sync requires a rising edge (if active high) or falling edge (if active low) to be detected and the transmitter or receiver cannot be busy with a previous frame. A valid frame sync is also ignored (slave mode) or not generated (master mode) for the first four bit clock cycles after enabling the transmitter or receiver.

The transmitter and receiver frame sync can be configured independently with any of the following options:

- Generate externally or internally

- Require active high or active low
- Assert with the first bit in frame or assert one bit early
- Assert for a duration of between 1 bit clock and the first word length
- Set frame length from 1 to 32 words per frame
- Support word length of 8 to 32 bits per word
  - First word length and remaining word lengths can be configured separately
- Transmit/Receive words MSB first or LSB first

These configuration options cannot be changed after enabling the SAI transmitter or receiver.

14.4.2.4 Data FIFO

Each transmit and receive channel includes a 128 x 32-bit size FIFO. To access the FIFO data use the SAI Transmit/Receive Data Registers.

14.4.2.4.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit wide register through the use of the First Bit Shifted configuration field, which selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required First Bit Shifted configuration are illustrated in Figure 14-14 for LSB First configurations and Figure 14-15 for MSB First configurations.

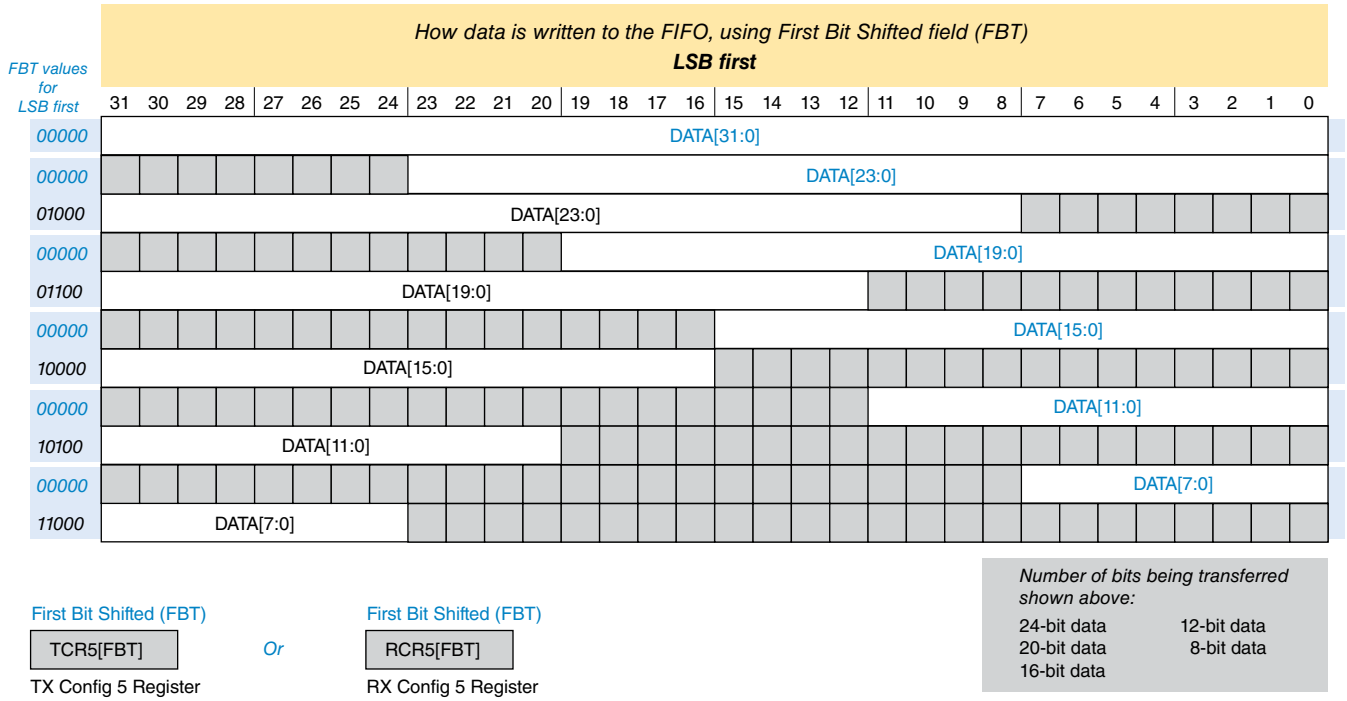

Figure 14-14. SAI first bit shifted, LSB first

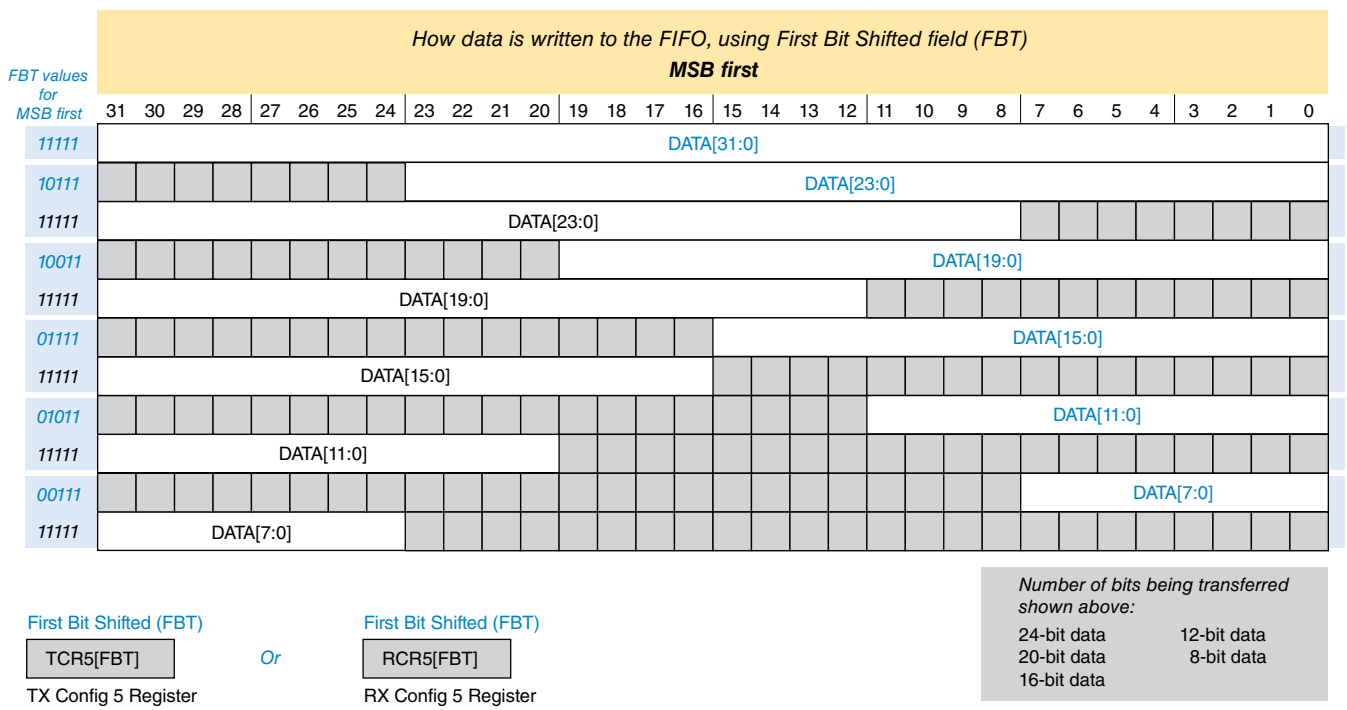

Figure 14-15. SAI first bit shifted, MSB first

14.4.2.4.2 FIFO pointers

When writing to a Transmit Data Register (TDR*n*), the Write FIFO Pointer (WFP) of the corresponding Transmit FIFO Register (TFR*n*) increments after each valid write. The SAI supports 8-bit, 16-bit, and 32-bit writes to the Transmit Data Register and the FIFO pointer increments after each individual write. Note that 8-bit writes should only be used when transmitting up to 8-bit data; 16-bit writes should only be used when transmitting up to 16-bit data.

- If the Transmit FIFO is full, writes to a Transmit Data Register are ignored.
- If the Transmit FIFO is empty, to avoid a FIFO underrun, write to the Transmit Data Register at least 3 bit clocks before the start of the next unmasked word. Before enabling the transmitter, initialize the Transmit FIFO with data (because after enabling the transmitter, the transmitter starts a new frame, and if no data is in the FIFO, then the transmitter immediately give an error).

When reading a Receive Data Register (RDR*n*), the Read FIFO Pointer (RFP) of the corresponding Receive FIFO Register (RFR*n*) increments after each valid read. The SAI supports 8-bit, 16-bit and 32-bit reads from the RDR and the FIFO pointer will increment after each individual read. Note that 8-bit reads should only be used when receiving up to 8-bit data; 16-bit reads should only be used when receiving up to 16-bit data.

- If the Receive FIFO is empty, reads from a Receive Data Register are ignored.
- If the Receive FIFO is full, to avoid a FIFO overrun, read the Receive Data Register at least 3 bit clocks before the end of an unmasked word.

14.4.2.4.3 FIFO packing

FIFO packing supports storing multiple 8-bit or 16-bit data words in one 32-bit FIFO word for the transmitter and/or receiver. While this can be emulated by adjusting the number of bits per word and number of words per frame (for example, one 32-bit word per frame versus two 16-bit words per frame), FIFO packing does not require even multiples of words per frame and fully supports word masking. When FIFO packing is enabled, the FIFO pointers only increment when the full 32-bit FIFO word has been written (transmit) or read (receive) by software, supporting scenarios where different words within each frame are loaded/stored in different areas of memory.

Using 16-bit FIFO packing for transmit, the transmit shift register loads at the start of each frame and after every second unmasked transmit word. The first word transmitted is taken from 16-bit word at byte offset 0x0 (the first bit is selected by TCR5[FBT] and must be configured within this 16-bit word) and the second word transmitted is taken from the 16-bit word at byte offset 0x2 (the first bit is selected by TCR5[FBT][3:0]). The transmitter transmits logic zero until the start of the next word once the 16-bit word has been transmitted.

Using 16-bit FIFO packing for receive, the receive shift register is stored after every second unmasked received word, and at the end of each frame if there is an odd number of unmasked received words in each frame. The first word received is stored in the 16-bit word at byte offset 0x0 (the first bit is selected by RCR5[FBT] and must be configured within this 16-bit word) and the second word received is stored in the 16-bit word at byte offset 0x2 (the first bit is selected by RCR5[FBT][3:0]). The receiver ignores received data until the start of the next word once the 16-bit word has been received.

The 8-bit FIFO packing is similar to 16-bit packing except four words are loaded or stored into each 32-bit FIFO word. The first word is loaded/stored in byte offset 0x0, second word in byte offset 0x1, third word in byte offset 0x2 and fourth word in byte offset 0x3. The TCR5[FBT] and/or RCR5[FBT] must be configured within byte offset 0x0.

14.4.2.4.4 FIFO Combine

FIFO Combining mode allows the separate FIFOs for multiple data channels to be used as a single FIFO for either software accesses or a single data channel or both. Note that the enabled data channels must be contiguous and data channel 0 must be enabled when using FIFO Combine mode.

Combining FIFOs for software access (writing transmit FIFO registers, reading receive FIFO registers) allows a DMA controller or software to read or write multiple FIFOs without incrementing the address that is accessed. Once enabled, the first software access to a FIFO register accesses the first enabled channel FIFO, while the second access to a FIFO register accesses the second enabled channel FIFO. This continues until software accesses the last enabled channel FIFO and the pointer resets back to the first enabled channel FIFO. To reset the pointer manually, software can reset the FIFOs or disable FIFO combining on software accesses.

Combining FIFOs for transmit data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with identical data output on each enabled data channel. The transmit shift registers for all enabled data channels load at the start of each frame and every N unmasked words (where N is the number of enabled data channels). The first word transmitted loads from the first enabled channel FIFO, while the second word transmitted loads from the second enabled channel FIFO, and so on until the end of the frame. Because the first word in each frame always loads from the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Combining FIFOs for receive data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with received data from channel 0 stored into each enabled data channel. The receive shift register for all enabled data channels are stored after every

N unmasked words (where N is the number of enabled data channels). The first word received stores to the first enabled channel FIFO, while the second word received stores to the second enabled channel FIFO, and so on until the end of the frame. Because the first word in each frame always stores to the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Note that combining FIFOs for data channels loads or stores each channel FIFO at the same time. This means that FIFO error conditions are only checked every N words (where N is the number of enabled data channels) and that the FIFO warning and request flags assert if any of the enabled data channel meets the warning flag or request flag conditions.

14.4.2.5 Word mask register

The SAI transmitter and receiver each contain a word mask register (TMR and RMR) that can be used to mask any word in the frame. Because the word mask register is double buffered, software can update it before the end of each frame to mask a particular word in the next frame.

The TMR causes the Transmit Data pin to be tri-stated for the length of each selected word and the transmit FIFO is not read for masked words.

The RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

14.4.2.6 Timestamp Counter

The transmitter and receiver implement separate timestamp counters and bit counters. The bit counter increments at the end of each bit in a frame whenever the transmitter or receiver is enabled. The bit counter continues to increment if a word is masked or a FIFO underrun or overrun condition occurs, but does not increment if an external frame sync is configured and no frame sync is detected. The bit counter can be reset by software, due to synchronization delays it can take up to 3 bit clock cycles for the bit clock counter to continue incrementing after a bit counter reset.

The timestamp counter increments on the bus interface clock whenever it is enabled, but can be configured to synchronize to the bit counter by waiting for the bit counter to increment first (if configured, this synchronization is performed whenever the time counter is reset). The current value of the timestamp counter is latched whenever the bit counter increments. Reading the bit counter register will cause the latched timestamp

value to be saved in the bit counter timestamp register. The timestamp counter can be reset by software, this also resets the latched timestamp value and the bit counter timestamp register.

The timestamp counter and bit counter can be used by software to track the progress of the transmitter and receiver. It can also be used to calculate the relative frequency of the bit clock against the bus interface clock.

14.4.2.7 Interrupts and DMA requests

The SAI transmitter and receiver generate separate interrupts and separate DMA requests, but support the same status flags. Asynchronous interrupts are only generated when the system clock is gated provided the corresponding BCLK continues.

14.4.2.7.1 FIFO request flag

The FIFO request flag sets based on the number of entries in the FIFO and the FIFO watermark configuration.

The transmit FIFO request flag sets when the number of entries in any of the enabled transmit FIFOs is less than or equal to the transmit FIFO watermark configuration and clears when the number of entries in each enabled transmit FIFO is greater than the transmit FIFO watermark configuration.

The receive FIFO request flag sets when the number of entries in any of the enabled receive FIFOs is greater than the receive FIFO watermark configuration and clears when the number of entries in each enabled receive FIFO is less than or equal to the receive FIFO watermark configuration.

The FIFO request flag can generate an interrupt or a DMA request.

14.4.2.7.2 FIFO warning flag

The FIFO warning flag sets based on the number of entries in the FIFO.

The transmit warning flag sets when the number of entries in any of the enabled transmit FIFOs is empty and clears when the number of entries in each enabled transmit FIFO is not empty.

The receive warning flag sets when the number of entries in any of the enabled receive FIFOs is full and clears when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an Interrupt or a DMA request.

14.4.2.7.3 FIFO error flag

The Transmit FIFO Error Flag (TCSR[FEF] = 1]) sets when any of the enabled transmit FIFOs underrun. After the error flag sets, all enabled transmit channels transmit zero data before TCSR[FEF] clears.

When FIFO Continue on Error is enabled (TCR4[FCONT] = 1), the FIFO continues transmitting data following an underrun without software intervention. To ensure that data transmits in the correct order, the transmitter continues from the same word number in the frame that caused the FIFO to underrun, but only after new data writes to the transmit FIFO. Software should still clear the TCSR[FEF] flag, but without reinitializing the transmit FIFOs.

The Receive FIFO Error Flag sets (RCSR[FEF] = 1) when any of the enabled receive FIFOs overflow. After the flag is set, all enabled receive channels discard received data until RCSR[FEF] clears and the next receive frame starts. Empty all enabled receive FIFOs before RCSR[FEF] clears.

When Receive FIFO Continue on Error is enabled (RCR4[FCONT] = 1) the FIFO continues receiving data following an overflow without software intervention. To ensure that data is received in the correct order, the receiver continues from the same word number in the frame that caused the FIFO to overflow, but only after data has been read from the receive FIFO. Software should still clear the RCSR[FEF] flag, but without emptying the receive FIFOs.

The FIFO Error Flag can generate only an interrupt.

14.4.2.7.4 Sync error flag

The Sync Error Flag, TCSR[SEF] or RCSR[SEF], sets when configured for an externally generated frame sync and the external frame sync asserts when the transmitter or receiver is busy with the previous frame. The external frame sync assertion is ignored and the sync error flag sets. When the Sync Error Flag sets, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

The Sync Error Flag can only generate an interrupt.

14.4.2.7.5 Word start flag

The Word Start Flag sets (TCSR[WSF] = 1) at the start of the second bit clock for the selected word, as configured by the Word Flag Configuration field (TCR3[WDFL]).

The Word Start Flag can generate an interrupt only.

14.4.2.8 SAI clocking

The SAI clocks include:

- Audio master clock
- Bit clock
- Bus clock

14.4.2.8.1 Audio master clock

The audio master clock generates the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio master clocks to generate the bit clock.

The SAI peripheral controls the pin direction and post-divider of an audio master clock. The post-divide can be used to divide down the clock output on the MCLK signal pin, without affecting the audio master clock used by the transmitter and receiver.

The audio master clock generation and selection is chip-specific. Refer to chip-specific clocking information about how the audio master clocks are generated.

14.4.2.8.2 Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that can be generated internally from an audio master clock or supplied externally. There is also the option for synchronous bit clock and frame sync operation between the receiver and transmitter or between multiple SAI peripherals.

- If both transmitter and receiver are configured for asynchronous operation, then the transmitter and receiver will each use *their own* bit clock and frame sync.
- If the *transmitter* is configured for asynchronous mode and the receiver is configured for synchronous mode, then both transmitter and receiver will use the *transmitter* bit clock and frame sync.
- If the *receiver* is configured for asynchronous mode and the transmitter is configured for synchronous mode, then both transmitter and receiver will use the *receiver* bit clock and frame sync.

Note that the software configures synchronous or asynchronous mode, and that choice selects the bit clock/frame sync used.

Externally generated bit clocks must be:

- Enabled before the SAI transmitter or receiver is enabled
- Disabled after the SAI transmitter or receiver is disabled and completes its current frames

If the SAI transmitter or receiver uses an externally generated bit clock in asynchronous mode and that bit clock is generated by an SAI that is disabled in stop mode, then the transmitter or receiver should be disabled by software before entering stop mode. This issue does not apply when the transmitter or receiver is in a synchronous mode because all synchronous SAIs are enabled and disabled simultaneously.

14.4.2.8.3 Bus clock

The bus clock is used by the control and configuration registers and to generate synchronous interrupts and DMA requests.

NOTE

Although there is no minimum bus clock frequency specified, the bus clock frequency must be fast enough (relative to the bit clock frequency) to ensure that the FIFOs can be serviced, without generating either a transmitter FIFO underrun or receiver FIFO overflow condition.

14.4.2.9 SAI resets

The SAI is asynchronously reset on system reset. The SAI has a software reset and a FIFO reset.

14.4.2.9.1 Software reset

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. This software reset does not reset the configuration registers. The software reset remains asserted until cleared by software.

The SAI receiver includes a software reset that resets all receiver internal logic, including the bit clock generation, status flags and FIFO pointers. This software reset does not reset the configuration registers. The software reset remains asserted until cleared by software.

14.4.2.9.2 FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the same value as the FIFO read pointer. This FIFO reset empties the FIFO contents and is used after TCSR[FEF] is set, and before the FIFO is re-initialized and TCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI transmitter can also reset the FIFO of individual data channels by setting the appropriate TCR3[CFR] bit. This should only be done when the corresponding TCR3[TCE] bit is clear.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the same value as the FIFO write pointer. This empties the FIFO contents and is to be used after the RCSR[FEF] is set and any remaining data has been read from the FIFO, and before the RCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI receiver can also reset the FIFO of individual data channels by setting the appropriate RCR3[CFR] bit. This should only be done when the corresponding RCR3[RCE] bit is clear.

14.4.3 External signals

Name	Function	I/O
TX_BCLK	Transmit Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
TX_SYNC	Transmit Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O
TX_DATA[7:0]	Transmit Data. The transmit data is generated synchronously by the bit clock and is tristated whenever not transmitting a word.	O
RX_BCLK	Receive Bit Clock. The bit clock is an input when externally generated and an output when internally generated.	I/O
RX_SYNC	Receive Frame Sync. The frame sync is an input sampled synchronously by the bit clock when externally generated and an output generated synchronously by the bit clock when internally generated.	I/O
RX_DATA[7:0]	Receive Data. The receive data is sampled synchronously by the bit clock.	I
MCLK	Audio Master Clock. The audio master clock is an input when externally generated and an output when internally generated.	I/O

14.4.4 Memory map and register definition

A read or write access to an address from offset 0x108 and above will result in a bus error.

Table continues on the next page...

Field	Description
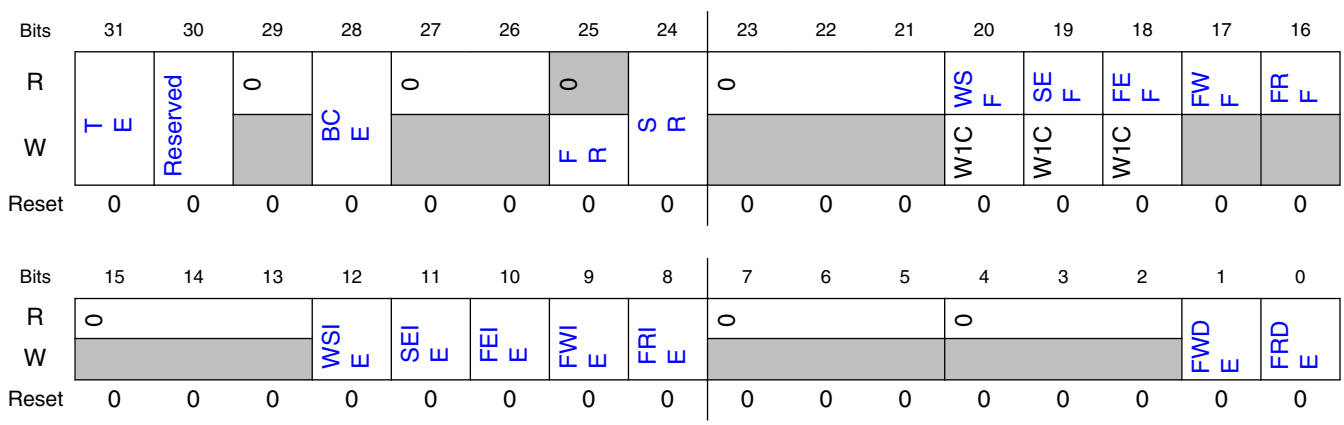
19-16 FRAME	Frame Size The maximum number of slots per frame is 2^FRAME.
15-12 —	Reserved
11-8 FIFO	FIFO Size The number of words in each FIFO is 2^FIFO.
7-4 —	Reserved
3-0 DATALINE	Number of Datalines The number of datalines implemented.



14.4.4.1.4 Transmit Control (TCSR)

Contains transmitter enable fields including resets, error and interrupt enable fields, and error flag fields.

14.4.4.1.4.1 Offset

Register	Offset
TCSR	8h

14.4.4.1.4.2 Diagram

14.4.4.1.4.3 Fields

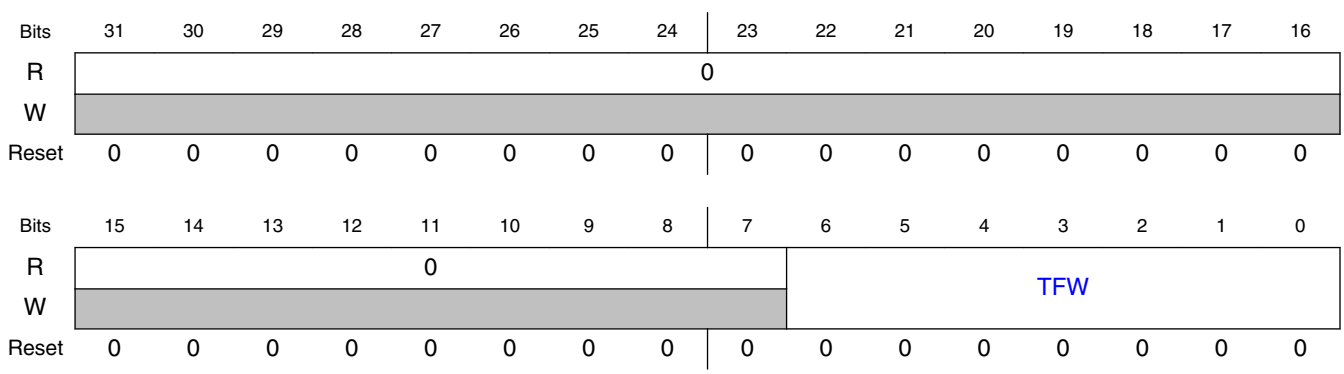
Field	Description
31 TE	Transmitter Enable Enables/disables the transmitter. When software clears this field, the transmitter remains enabled, and this bit remains set, until the end of the current frame. 0 - Transmitter is disabled. 1 - Transmitter is enabled, or transmitter has been disabled and has not yet reached end of frame.
30 —	Reserved Software should only write zero to this reserved bit.
29 —	Reserved
28 BCE	Bit Clock Enable Enables the transmit bit clock, separately from the TE. This field is automatically set whenever TE is set. When software clears this field, the transmit bit clock remains enabled, and this bit remains set, until the end of the current frame. 0 - Transmit bit clock is disabled. 1 - Transmit bit clock is enabled.
27-26 —	Reserved
25 FR	FIFO Reset Empties the FIFO, and sets the FIFO read and write pointers to the same value, which may or may not be zero. Reading this field will always return zero. FIFO pointers should only be reset when the transmitter is disabled or the FIFO error flag is set. 0 - No effect. 1 - FIFO reset.
24 SR	Software Reset When set, resets the internal transmitter logic including the FIFO read and write pointers. Software-visible registers are not affected, except for the status registers. 0 - No effect. 1 - Software reset.
23-21 —	Reserved
20 WSF	Word Start Flag Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag. 0 - Start of word not detected. 1 - Start of word detected.
19 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0 - Sync error not detected. 1 - Frame sync error detected.

Table continues on the next page...

Field	Description
18 FEF	FIFO Error Flag Indicates that an enabled transmit FIFO has underrun. Write a logic 1 to this field to clear this flag. 0 - Transmit underrun not detected. 1 - Transmit underrun detected.
17 FWF	FIFO Warning Flag Indicates that an enabled transmit FIFO is empty. 0 - No enabled transmit FIFO is empty. 1 - Enabled transmit FIFO is empty.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled transmit channel FIFO is less than or equal to the transmit FIFO watermark. 0 - Transmit FIFO watermark has not been reached. 1 - Transmit FIFO watermark has been reached.
15-13 —	Reserved
12 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0 - Disables interrupt. 1 - Enables interrupt.
11 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0 - Disables interrupt. 1 - Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0 - Disables the interrupt. 1 - Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts. 0 - Disables the interrupt. 1 - Enables the interrupt.
8 FRIE	FIFO Request Interrupt Enable Enables/disables FIFO request interrupts. 0 - Disables the interrupt. 1 - Enables the interrupt.
7-5 —	Reserved
4-2 —	Reserved

Table continues on the next page...

Field	Description
1 FWDE	FIFO Warning DMA Enable Enables/disables DMA requests. 0 - Disables the DMA request. 1 - Enables the DMA request.
0 FRDE	FIFO Request DMA Enable Enables/disables DMA requests. 0 - Disables the DMA request. 1 - Enables the DMA request.



14.4.4.1.5 Transmit Configuration 1 (TCR1)

Configures the watermark level for all enabled transmit channels.

14.4.4.1.6.3 Fields

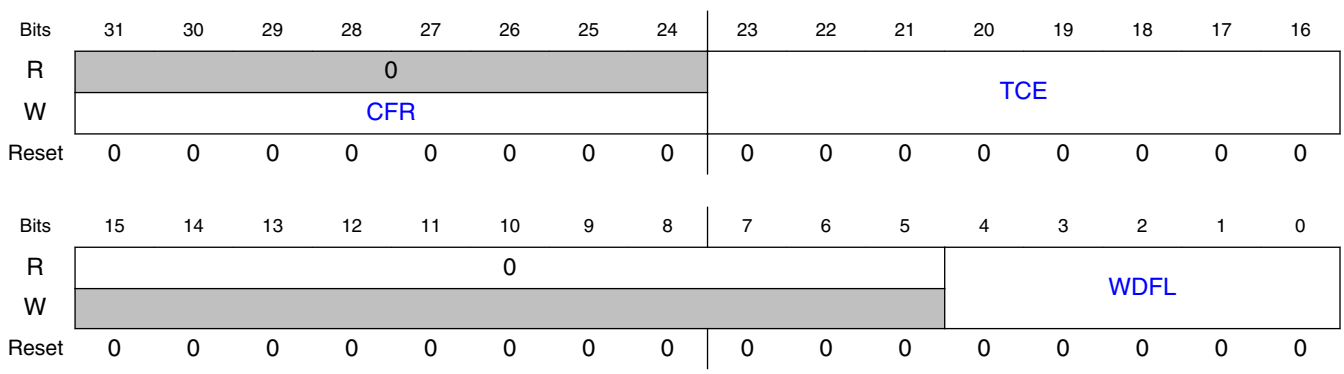
Field	Description
31-30 SYNC	Synchronous Mode Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the receiver or other SAI peripheral must be configured for asynchronous operation. 00 - Asynchronous mode. 01 - Synchronous with receiver. 10 - Synchronous with another SAI transmitter

Table continues on the next page...

Field	Description
	11 - Synchronous with another SAI receiver
29 BCS	Bit Clock Swap This field swaps the bit clock used by the transmitter. When the transmitter is configured in asynchronous mode and this bit is set, the transmitter is clocked by the receiver bit clock (RX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the transmitter continues to use the transmit frame sync (TX_SYNC). When the transmitter is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the transmitter bit clock (TX_BCLK) but use the receiver frame sync (RX_SYNC). This field has no effect when synchronous to another SAI peripheral. 0 - Use the normal bit clock source. 1 - Swap the bit clock source.
28 BCI	Bit Clock Input When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the transmitter is delayed by the pad output delay (the transmitter is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time. The slave mode timing from the datasheet should be used for the transmitter when this bit is set. In synchronous mode, this bit allows the transmitter to use the slave mode timing from the datasheet, while the receiver uses the master mode timing. This field has no effect when configured for an externally generated bit clock or when synchronous to another SAI peripheral . 0 - No effect. 1 - Internal logic is clocked as if bit clock was externally generated.
27-26 MSEL	MCLK Select Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. **NOTE:** Depending on the device, some Master Clock options might not be available. See the chip-specific information for the meaning of each option. 00 - Bus Clock selected. 01 - Master Clock (MCLK) 1 option selected. 10 - Master Clock (MCLK) 2 option selected. 11 - Master Clock (MCLK) 3 option selected.
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0 - Bit clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1 - Bit clock is active low with drive outputs on falling edge and sample inputs on rising edge.
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0 - Bit clock is generated externally in Slave mode. 1 - Bit clock is generated internally in Master mode.
23 BYP	Bit Clock Bypass Bypasses the bit clock divider, internal bit clock is divide by 1 of the audio master clock. 0 - Internal bit clock is generated from bit clock divider.

Table continues on the next page...

Field	Description
	1 - Internal bit clock is divide by one of the audio master clock.
22-8 —	Reserved
7-0 DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2.



14.4.4.1.7 Transmit Configuration 3 (TCR3)

Contains the transmit channel settings.

14.4.4.1.7.1 Offset

Register	Offset
TCR3	14h

14.4.4.1.7.2 Diagram

14.4.4.1.7.3 Fields

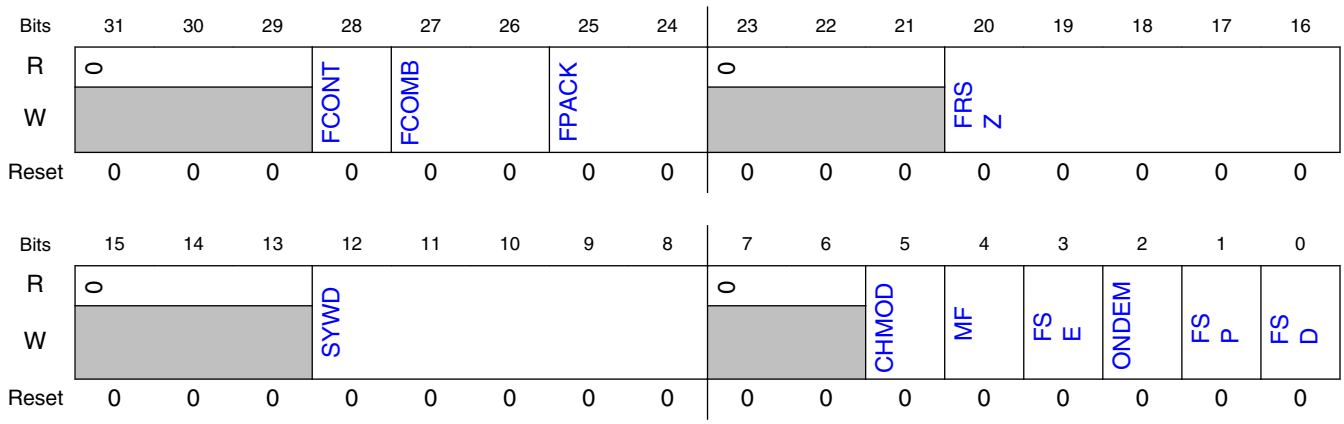
Field	Description
31-24 CFR	Channel FIFO Reset Resets the FIFO pointers for a specific channel. Reading this field always returns zero. FIFO pointers should only be reset when a channel is disabled or the FIFO error flag is set.

Table continues on the next page...

Field	Description
	The width of CFR field = the number of transmit channels (call it N). For example, if CFR is 2 bits wide, then bit position 24 refers to transmit channel 1 FIFO pointer and bit position 25 refers to transmit channel 2 FIFO pointer. Setting bit 24 resets transmit channel 1 FIFO pointer, and setting bit 25 enables transmit channel 2 FIFO pointer. Setting bit N will reset transmit channel N FIFO pointer. **NOTE:** When there is only a single channel, there is no need for individual channel FIFO reset (TCR3[CFR]). In the case of a single channel, use the global FIFO reset (TCSR[FR]). 0b - No effect. 1b - Transmit data channel N FIFO is reset.
23-16 TCE	Transmit Channel Enable Enables the corresponding data channel for transmit operation. Changing TCE field will take effect immediately for generating the FIFO request and warning flags, but at the end of each frame for transmit operation. The width of TCE field = the number of transmit channels (call it N). For example, if TCE field is 2 bits wide, then bit position 16 refers to transmit channel 1 and bit position 17 refers to transmit channel 2. Setting bit 16 enables transmit channel 1, and setting bit 17 enables transmit channel 2. Setting bit N will enable transmit channel N. 0b - Transmit data channel N is disabled. 1b - Transmit data channel N is enabled.
15-5 —	Reserved
4-0 WDFL	Word Flag Configuration Configures which word sets the start of word flag. The value written must be one less than the word number. For example, writing 0 configures the first word in the frame. When configured to a value greater than TCR4[FRSZ], then the start of word flag is never set.

14.4.4.1.8 Transmit Configuration 4 (TCR4)

Contains the transmit fields for FIFO Combine Mode, FIFO Packing Mode, and frame sync settings.



NOTE

This register must not be altered when TCSR[TE] is set.

14.4.4.1.8.1 Offset

Register	Offset
TCR4	18h

14.4.4.1.8.2 Diagram

14.4.4.1.8.3 Fields

Field	Description
31-29 —	Reserved
28 FCONT	FIFO Continue on Error Configures when the SAI will continue transmitting after a FIFO error has been detected. 0 - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared. 1 - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.
27-26 FCOMB	FIFO Combine Mode When FIFO combine mode is enabled for FIFO writes, software writing to any FIFO data register will alternate the write among the enabled data channel FIFOs. For example, if two data channels are enabled then the first write will be performed to the first enabled data channel FIFO and the second write will be performed to the second enabled data channel FIFO. Reseting the FIFO or disabling FIFO combine mode for FIFO writes will reset the pointer back to the first enabled data channel. When FIFO combine mode is enabled for FIFO reads from the transmit shift registers, the transmit data channel output will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked word will be transmitted from the first enabled data channel FIFO and the second unmasked word will be transmitted from the second enabled data channel FIFO. Since the first word of the frame is always transmitted from the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels. 00 - FIFO combine mode disabled. 01 - FIFO combine mode enabled on FIFO reads (from transmit shift registers). 10 - FIFO combine mode enabled on FIFO writes (by software). 11 - FIFO combine mode enabled on FIFO reads (from transmit shift registers) and writes (by software).
25-24 FPACK	FIFO Packing Mode

Table continues on the next page...

Field	Description
	Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are loaded from the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO write pointer will only increment when the full 32-bit FIFO word has been written by software. 00 - FIFO packing is disabled. 01 - Reserved 10 - 8-bit FIFO packing is enabled. 11 - 16-bit FIFO packing is enabled.
23-21 —	Reserved
20-16 FRSZ	Frame size Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.
15-13 —	Reserved
12-8 SYWD	Sync Width Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.
7-6 —	Reserved
5 CHMOD	Channel Mode Configures if transmit data pins are configured for TDM mode or Output mode. 0 - TDM mode, transmit data pins are tri-stated when slots are masked or channels are disabled. 1 - Output mode, transmit data pins are never tri-stated and will output zero when slots are masked or channels are disabled.
4 MF	MSB First Configures whether the LSB or the MSB is transmitted first. 0 - LSB is transmitted first. 1 - MSB is transmitted first.
3 FSE	Frame Sync Early 0 - Frame sync asserts with the first bit of the frame. 1 - Frame sync asserts one bit before the first bit of the frame.
2 ONDEM	On Demand Mode When set, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is clear. 0 - Internal frame sync is generated continuously. 1 - Internal frame sync is generated when the FIFO warning flag is clear.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync.

Table continues on the next page...

Field	Description
	0 - Frame sync is active high. 1 - Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0 - Frame sync is generated externally in Slave mode. 1 - Frame sync is generated internally in Master mode.

14.4.4.1.9 Transmit Configuration 5 (TCR5)

Contains transmit word width and bit index settings.

NOTE

This register must not be altered when TCSR[TE] is set.

Field	Description
31-29	Reserved

Table continues on the next page...

Field	Description
—	
28-24 WNW	Word N Width Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported.
23-21 —	Reserved
20-16 W0W	Word 0 Width Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame.
15-13 —	Reserved
12-8 FBT	First Bit Shifted Configures the bit index for the first bit transmitted for each word in the frame. If configured for MSB First, the index of the next bit transmitted is one less than the current bit transmitted. If configured for LSB First, the index of the next bit transmitted is one more than the current bit transmitted. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First.
7-0 —	Reserved

14.4.4.1.10 Transmit Data (TDR0 - TDR7)

Writes to this register when the transmit FIFO is not full will push the data written into the transmit data FIFO. Writes to this register when the transmit FIFO is full are ignored.

14.4.4.1.10.1 Offset

For a = 0 to 7:

Register	Offset

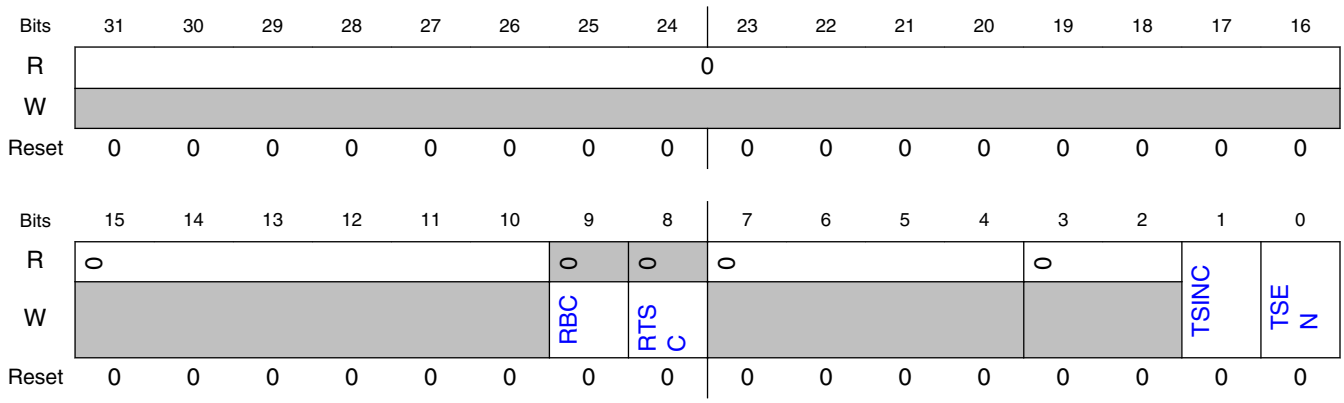
14.4.4.1.12.3 Fields

Field	Description
31-0 TWM	Transmit Word Mask Configures whether the transmit word is masked (transmit data pins are tri-stated or drive zero and transmit data not read from FIFO) for the corresponding word in the frame. 00000000000000000000000000000000 - Word N is enabled. 00000000000000000000000000000001 - Word N is masked. The transmit data pins are tri-stated or drive zero when masked.



14.4.4.1.13 Transmit Timestamp Control (TTCR)

This register controls the transmit timestamp counter and bit clock counter.

14.4.4.1.13.1 Offset

Register	Offset
TTCR	70h

14.4.4.1.13.2 Diagram

14.4.4.1.13.3 Fields

Field	Description
31-10 —	Reserved
9 RBC	Reset Bit Counter Reset the bit counter. 0 - Bit counter is not reset. 1 - Bit counter is reset.
8 RTSC	Reset Timestamp Counter Reset the timestamp counter. 0 - Timestamp counter is not reset. 1 - Timestamp counter is reset.
7-4 —	Reserved
3-2 —	Reserved
1 TSINC	Timestamp Increment Configures when the timestamp counter starts to increment. 0 - Timestamp counter starts to increment when enabled and the bit counter has incremented. 1 - Timestamp counter starts to increment when enabled.
0 TSEN	Timestamp Enable Enables the timestamp counter to increment on the bus interface clock. 0 - Timestamp counter is disabled. 1 - Timestamp counter is enabled.

14.4.4.1.14 Transmit Timestamp (TTSR)

This register returns the current value of the transmit timestamp counter.

14.4.4.1.14.1 Offset

Register	Offset
TTSR	74h

14.4.4.1.14.2 Diagram

14.4.4.1.14.3 Fields

Field	Description
31-0 TSC	Timestamp Counter Current value of the timestamp counter.

14.4.4.1.15 Transmit Bit Count (TBCR)

This register returns the current value of the transmit bit counter. The bit counter increments for each bit in a frame when the SAI transmitter is enabled. Reading this register causes the Bit Count Timestamp Regsiter to update with the value of the timestamp counter that correponds to the bit count register value.

14.4.4.1.15.1 Offset

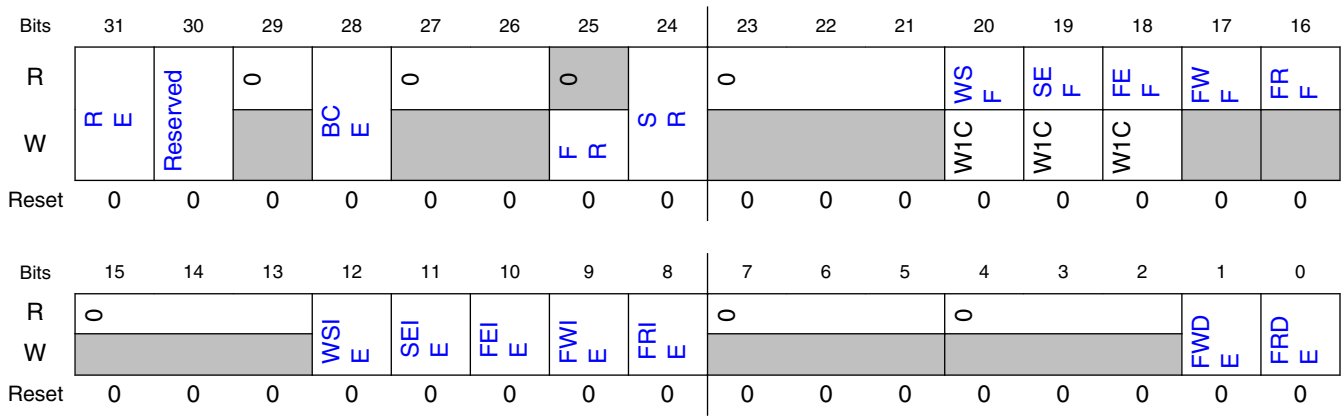
14.4.4.1.16.3 Fields

Field	Description
31-0 BCTS	Bit Timestamp Returns the timestamp counter value that matches the last read of the bit count register.



14.4.4.1.17 Receive Control (RCSR)

Contains receiver enable fields including resets, error and interrupt enable fields, and error flag fields.

14.4.4.1.17.1 Offset

Register	Offset
RCSR	88h

14.4.4.1.17.2 Diagram

14.4.4.1.17.3 Fields

Field	Description
31 RE	Receiver Enable Enables/disables the receiver. When software clears this field, the receiver remains enabled, and this bit remains set, until the end of the current frame. 0 - Receiver is disabled. 1 - Receiver is enabled, or receiver has been disabled and has not yet reached end of frame.
30 —	Reserved Software should only write zero to this reserved bit.
29 —	Reserved
28 BCE	Bit Clock Enable Enables the receive bit clock, separately from RE. This field is automatically set whenever RE is set. When software clears this field, the receive bit clock remains enabled, and this field remains set, until the end of the current frame. 0 - Receive bit clock is disabled. 1 - Receive bit clock is enabled.
27-26 —	Reserved
25 FR	FIFO Reset Empties the FIFO, and sets the FIFO read and write pointers to the same value, which may or may not be zero. Reading this field will always return zero. FIFO pointers should only be reset when the receiver is disabled or the FIFO error flag is set. 0 - No effect. 1 - FIFO reset.
24 SR	Software Reset Resets the internal receiver logic including the FIFO pointers. Software-visible registers are not affected, except for the status registers.

Table continues on the next page...

Field	Description
	0 - No effect. 1 - Software reset.
23-21 —	Reserved
20 WSF	Word Start Flag Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag. 0 - Start of word not detected. 1 - Start of word detected.
19 SEF	Sync Error Flag Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag. 0 - Sync error not detected. 1 - Frame sync error detected.
18 FEF	FIFO Error Flag Indicates that an enabled receive FIFO has overflowed. Write a logic 1 to this field to clear this flag. 0 - Receive overflow not detected. 1 - Receive overflow detected.
17 FWF	FIFO Warning Flag Indicates that an enabled receive FIFO is full. 0 - No enabled receive FIFO is full. 1 - Enabled receive FIFO is full.
16 FRF	FIFO Request Flag Indicates that the number of words in an enabled receive channel FIFO is greater than the receive FIFO watermark. 0 - Receive FIFO watermark not reached. 1 - Receive FIFO watermark has been reached.
15-13 —	Reserved
12 WSIE	Word Start Interrupt Enable Enables/disables word start interrupts. 0 - Disables interrupt. 1 - Enables interrupt.
11 SEIE	Sync Error Interrupt Enable Enables/disables sync error interrupts. 0 - Disables interrupt. 1 - Enables interrupt.
10 FEIE	FIFO Error Interrupt Enable Enables/disables FIFO error interrupts. 0 - Disables the interrupt.

Table continues on the next page...

Field	Description
	1 - Enables the interrupt.
9 FWIE	FIFO Warning Interrupt Enable Enables/disables FIFO warning interrupts. 0 - Disables the interrupt. 1 - Enables the interrupt.
8 FRIE	FIFO Request Interrupt Enable Enables/disables FIFO request interrupts. 0 - Disables the interrupt. 1 - Enables the interrupt.
7-5 —	Reserved
4-2 —	Reserved
1 FWDE	FIFO Warning DMA Enable Enables/disables DMA requests. 0 - Disables the DMA request. 1 - Enables the DMA request.
0 FRDE	FIFO Request DMA Enable Enables/disables DMA requests. 0 - Disables the DMA request. 1 - Enables the DMA request.

14.4.4.1.18 Receive Configuration 1 (RCR1)

Configures the watermark level for all enabled receiver channels.

14.4.4.1.18.1 Offset

Register	Offset
RCR1	8Ch

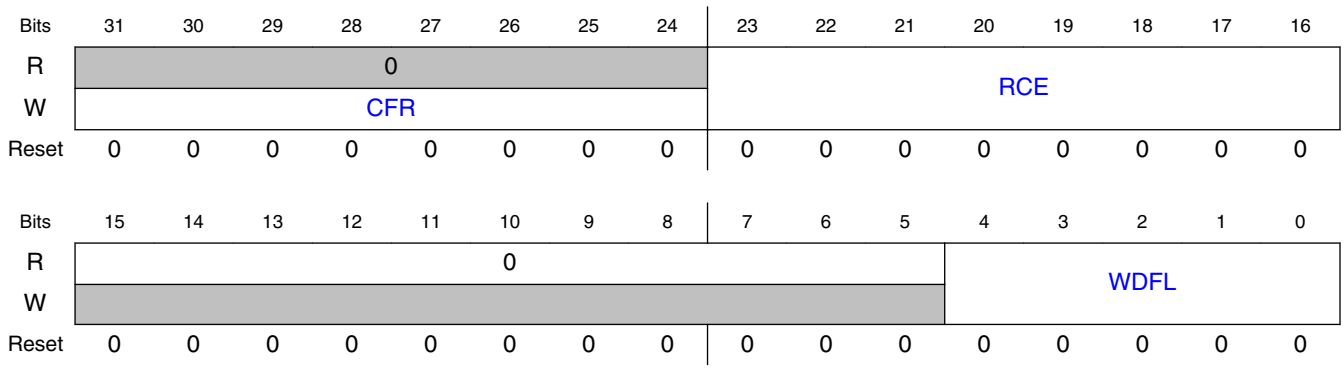
14.4.4.1.19.3 Fields

Field	Description
31-30 SYNC	Synchronous Mode Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the transmitter or other SAI peripheral must be configured for asynchronous operation. 00 - Asynchronous mode. 01 - Synchronous with transmitter. 10 - Synchronous with another SAI receiver. 11 - Synchronous with another SAI transmitter.
29 BCS	Bit Clock Swap This field swaps the bit clock used by the receiver. When the receiver is configured in asynchronous mode and this bit is set, the receiver is clocked by the transmitter bit clock (TX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the receiver continues to use the receiver frame sync (RX_SYNC). When the receiver is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the receiver bit clock (RX_BCLK) but use the transmitter frame sync (TX_SYNC). This field has no effect when synchronous to another SAI peripheral. 0 - Use the normal bit clock source. 1 - Swap the bit clock source.
28 BCI	Bit Clock Input When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the receiver is delayed by the pad output delay (the receiver is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time. The slave mode timing from the datasheet should be used for the receiver when this bit is set. In synchronous mode, this bit allows the receiver to use the slave mode timing from the datasheet, while the transmitter uses the master mode timing. This field has no effect when configured for an externally generated bit clock or when synchronous to another SAI peripheral . 0 - No effect.

Table continues on the next page...

Field	Description
	1 - Internal logic is clocked as if bit clock was externally generated.
27-26 MSEL	MCLK Select Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. **NOTE:** Depending on the device, some Master Clock options might not be available. See the chip-specific information for the availability and chip-specific meaning of each option. 00 - Bus Clock selected. 01 - Master Clock (MCLK) 1 option selected. 10 - Master Clock (MCLK) 2 option selected. 11 - Master Clock (MCLK) 3 option selected.
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. 0 - Bit Clock is active high with drive outputs on rising edge and sample inputs on falling edge. 1 - Bit Clock is active low with drive outputs on falling edge and sample inputs on rising edge.
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0 - Bit clock is generated externally in Slave mode. 1 - Bit clock is generated internally in Master mode.
23 BYP	Bit Clock Bypass Bypasses the bit clock divider, internal bit clock is divide by 1 of the audio master clock. 0 - Internal bit clock is generated from bit clock divider. 1 - Internal bit clock is divide by one of the audio master clock.
22-8 —	Reserved
7-0 DIV	Bit Clock Divide Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is (DIV + 1) * 2.



14.4.4.1.20 Receive Configuration 3 (RCR3)

Contains the receive channel settings.

14.4.4.1.20.1 Offset

Register	Offset
RCR3	94h

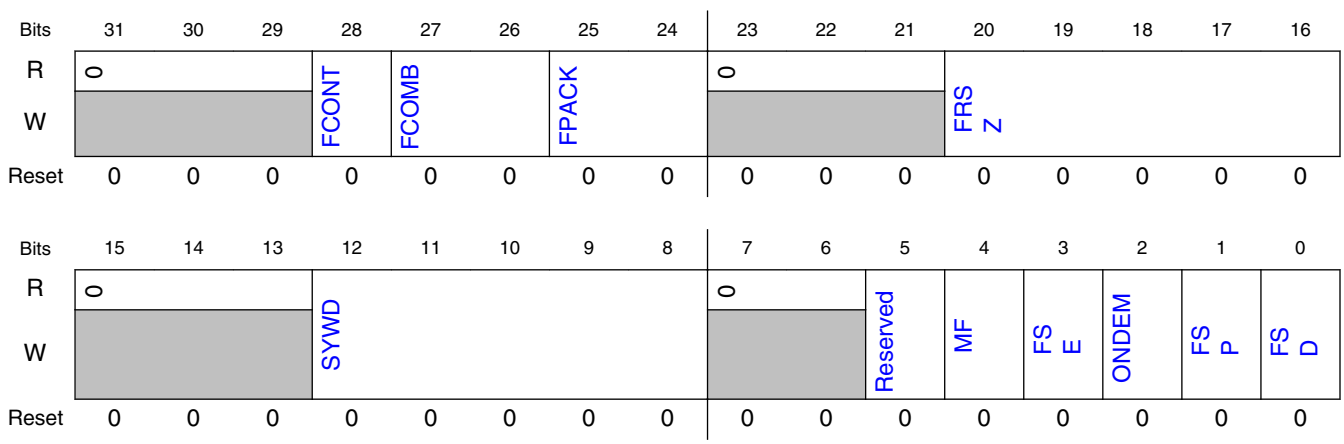
14.4.4.1.20.2 Diagram

14.4.4.1.20.3 Fields

Field	Description
31-24 CFR	Channel FIFO Reset Resets the FIFO pointers for a specific channel. Reading this field will always return zero. FIFO pointers should only be reset when a channel is disabled or the FIFO error flag is set. The width of CFR field = the number of receive channels (call it N). For example, if CFR is 2 bits wide, then bit position 24 refers to receive channel 1 FIFO pointer and bit position 25 refers to receive channel 2 FIFO pointer. Setting bit 24 resets receive channel 1 FIFO pointer, and setting bit 25 enables receive channel 2 FIFO pointer. Setting bit N will reset receive channel N FIFO pointer. 0b - No effect. 1b - Receive data channel N FIFO is reset.
23-16 RCE	Receive Channel Enable Enables the corresponding data channel for receive operation. Changing this field will take effect immediately for generating the FIFO request and warning flags, but at the end of each frame for receive operation. The width of RCE field = the number of receive channels (call it N). For example, if RCE field is 2 bits wide, then bit position 16 refers to receive channel 1 and bit position 17 refers to receive channel 2. Setting bit 16 enables receive channel 1, and setting bit 17 enables receive channel 2. Setting bit N will enable receive channel N. **NOTE:** When there is only a single channel, there is no need for individual channel FIFO reset (RCR3[CFR]). In the case of a single channel, use the global FIFO reset (RCSR[FR]). 0b - Receive data channel N is disabled. 1b - Receive data channel N is enabled.
15-5 —	Reserved
4-0 WDFL	Word Flag Configuration Configures which word the start of word flag is set. The value written should be one less than the word number (for example, write zero to configure for the first word in the frame). When configured to a value greater than the Frame Size field, then the start of word flag is never set.

14.4.4.1.21 Receive Configuration 4 (RCR4)

Contains the receive fields for FIFO Combine Mode, FIFO Packing Mode, and frame sync settings.



NOTE

This register must not be altered when RCSR[RE] is set.

14.4.4.1.21.1 Offset

Register	Offset
RCR4	98h

14.4.4.1.21.2 Diagram

14.4.4.1.21.3 Fields

Field	Description
31-29 —	Reserved
28 FCONT	FIFO Continue on Error Configures when the SAI will continue receiving after a FIFO error has been detected. 0 - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared. 1 - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared.
27-26	FIFO Combine Mode

Table continues on the next page...

Field	Description
FCOMB	When FIFO combine mode is enabled for FIFO reads, software reading any FIFO data register will alternate the read among the enabled data channel FIFOs. For example, if two data channels are enabled then the first read will be performed to the first enabled data channel FIFO and the second read will be performed to the second enabled data channel FIFO. Reseting the FIFO or disabling FIFO combine mode for FIFO reads will reset the pointer back to the first enabled data channel. When FIFO combine mode is enabled for FIFO writes from the receive shift registers, the first enabled data channel input will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked received word will be stored in the first enabled data channel FIFO and the second unmasked received word will be stored in the second enabled data channel FIFO. Since the first word of the frame is always stored in the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels. 00 - FIFO combine mode disabled. 01 - FIFO combine mode enabled on FIFO writes (from receive shift registers). 10 - FIFO combine mode enabled on FIFO reads (by software). 11 - FIFO combine mode enabled on FIFO writes (from receive shift registers) and reads (by software).
25-24 FPACK	FIFO Packing Mode Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are stored to the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO read pointer will only increment when the full 32-bit FIFO word has been read by software. 00 - FIFO packing is disabled 01 - Reserved. 10 - 8-bit FIFO packing is enabled 11 - 16-bit FIFO packing is enabled
23-21 —	Reserved
20-16 FRSZ	Frame Size Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.
15-13 —	Reserved
12-8 SYWD	Sync Width Configures the length of the frame sync in number of bit clocks. The value written must be one less than the number of bit clocks. For example, write 0 for the frame sync to assert for one bit clock only. The sync width cannot be configured longer than the first word of the frame.
7-6 —	Reserved
5 —	Reserved Software should only write zero to this bit.
4 MF	MSB First Configures whether the LSB or the MSB is received first. 0 - LSB is received first.

Table continues on the next page...

Field	Description
	1 - MSB is received first.
3 FSE	Frame Sync Early 0 - Frame sync asserts with the first bit of the frame. 1 - Frame sync asserts one bit before the first bit of the frame.
2 ONDEM	On Demand Mode When set, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is clear. 0 - Internal frame sync is generated continuously. 1 - Internal frame sync is generated when the FIFO warning flag is clear.
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0 - Frame sync is active high. 1 - Frame sync is active low.
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0 - Frame Sync is generated externally in Slave mode. 1 - Frame Sync is generated internally in Master mode.

14.4.4.1.22 Receive Configuration 5 (RCR5)

This register must not be altered when RCSR[RE] is set.

14.4.4.1.22.1 Offset

Register	Offset
RCR5	9Ch

14.4.4.1.22.2 Diagram

14.4.4.1.22.3 Fields

Field	Description
31-29 —	Reserved
28-24 WNW	Word N Width Configures the number of bits in each word, for each word except the first in the frame. The value written must be one less than the number of bits per word. Word width of less than 8 bits is not supported.
23-21 —	Reserved
20-16 W0W	Word 0 Width Configures the number of bits in the first word in each frame. The value written must be one less than the number of bits in the first word. Word width of less than 8 bits is not supported if there is only one word per frame.
15-13 —	Reserved
12-8 FBT	First Bit Shifted Configures the bit index for the first bit received for each word in the frame. If configured for MSB First, the index of the next bit received is one less than the current bit received. If configured for LSB First, the index of the next bit received is one more than the current bit received. The value written must be greater than or equal to the word width when configured for MSB First. The value written must be less than or equal to 31-word width when configured for LSB First.
7-0 —	Reserved

14.4.4.1.23 Receive Data (RDR0 - RDR7)

Reads from this register when the receive FIFO is not empty return the data from the top of the receive FIFO. Reads from this register when the receive FIFO is empty are ignored.

Reading this register introduces one additional peripheral clock wait state on each read.

14.4.4.1.23.1 Offset

For a = 0 to 7:

Register	Offset
RDRa	A0h + (a × 4h)

14.4.4.1.23.2 Diagram

14.4.4.1.24.3 Fields

Field	Description
31-24 —	Reserved
23-16 WFP	Write FIFO Pointer FIFO write pointer for receive data channel.
15 RCP	Receive Channel Pointer When FIFO Combine mode is enabled for reads, indicates that this data channel is the next FIFO to be read. 0 - No effect. 1 - FIFO combine is enabled for FIFO reads and this FIFO will be read on the next FIFO read.
14-8 —	Reserved
7-0 RFP	Read FIFO Pointer FIFO read pointer for receive data channel.

14.4.4.1.25 Receive Mask (RMR)

This register is double-buffered and updates:

1. When RCSR[RE] is first set
2. At the end of each frame

This allows the masked words in each frame to change from frame to frame.

14.4.4.1.25.1 Offset

Register	Offset
RMR	E0h

14.4.4.1.25.2 Diagram

14.4.4.1.27.3 Fields

Field	Description
31-0 TSC	Timestamp Counter Current value of the timestamp counter.

14.4.4.1.28 Receive Bit Count (RBCR)

Returns the current value of the receive bit counter. The bit counter increments for each bit in a frame when the SAI receiver is enabled. Reading this register causes the Bit Count Timestamp Regsiter to update with the value of the timestamp counter that correponds to the bit count register value.

29-26 —	Reserved
25-24 —	Reserved
23 DIVEN	MCLK Post Divide Enable Enables the post-divider that is output on the MCLK signal pin, the output divider does not impact the audio master clock used by the transmitter or receiver. 0 - Output on MCLK signal pin is the audio master clock. 1 - Output on MCLK signal pin is a post-divided version of audio master clock.
22-8 —	Reserved
7-0 DIV	MCLK Post Divide Post-divide for the audio master clock that only divides the output to the MCLK signal pin. The division value is (DIV + 1) * 2.

14.5 Asynchronous Sample Rate Converter (ASRC)

14.5.1 Overview

The Asynchronous Sample Rate Converter (ASRC) is a digital module that converts audio from a source sample rate to a destination sample rate.

14.5.1.1 Block Diagram

The following diagram gives a high-level overview of the ASRC.

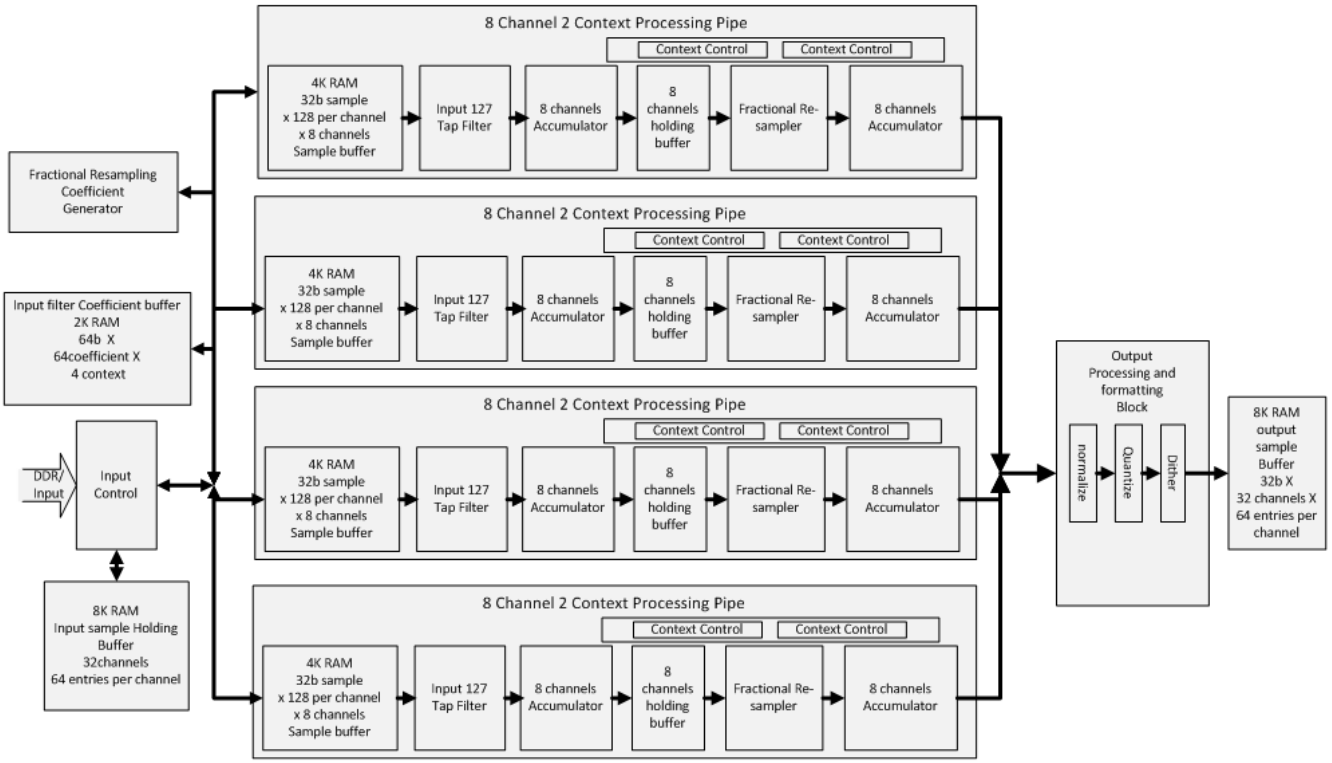

Figure 14-16. ASRC Block Diagram

14.5.1.2 Features

The primary features for the ASRC are as follows:

- 4 Contexts - groups of channels with an independent time base
- Fully independent and concurrent context control
- Simultaneous processing of up to 32 audio channels
- Programmable filter charachteristics for each context
- 32, 24, 20, and 16-bit fixed point audio sample support
- 32-bit floating point audio sample support
- 8kHz to 384 kHz sample rate
- 1/16 to 16x sample rate conversion ratio
- Software control of fine conversion ratio

14.5.2 Functional description

14.5.2.1 ASRC Datapath Overview

The ASRC can process 4 groups of audio channels with an independent time-base simultaneously. A group of channels with the same time-base (or resampling ratio) is referred to as a context. Each context has an independent input/output sample memory, resampling ratio, prefilter coefficient FIFO, number of channels, and assigned datapath resources. A context can be configured to start and stop at any time without affecting the processing of other contexts in flight. The maximum number of channels which can run on the ASRC is 32. These 32 channels can either be associated with a single context or spread across multiple contexts. The ASRC datapath is comprised of 4 independent context processing pipes capable of running the prefilter and resampling algorithms.

The following sections will describe the contents of each major component within the block diagram.

14.5.2.1.1 ASRC Input Control

The input control block acts as the interface between the ASRC and external sources of audio data. This block contains a circular queue to store sample data for each context before it is processed. In addition, each circular queue has interleaving hardware to support fetching data from a variety of sample sources. The circular queues are described in detail throughout section, ASRC FIFO Organization. The ASRC runs all internal calculations on a unified sample format. The input control block can convert a variety of input formats to the internal standard used by the ASRC by utilizing register fields within the ASRC_CTX_CTRL register. Note, all input samples must be written to the ASRC in a 32-bit packed format (1 sample contained within a 32-bit field). The input control block supports 16, 20, 24, and 32-bits per sample (ASRC_CTX_CTRL[BITS_PER_SAMPLE]), fixed point and floating-point data (ASRC_CTX_CTRL[FLOAT_FMT]), bit-reversal of sample data (ASRC_CTX_CTRL[BIT_REV]), and a variable sample position within each packed 32-bit write (ASRC_CTX_CTRL[SAMPLE_POSITION]). The main purpose of the input control block is to format samples and forward them to the context processing pipes when requested.

14.5.2.1.2 ASRC Context Processing Pipe

There are four 8-Channel 2-Context Processing Pipes in the ASRC design. Each processing pipe contains a prefilter and a fractional-resampler which can process a maximum of 8 audio channels at a time. The prefilter configuration is flexible and can be used to implement an FIR or IFIR filter architecture. The number of prefilter taps, stages, and IFIR expansion factor is programmable for each context. The resampler is configurable for 32, 64, or 128 taps. Note, the resampler configuration applies to every

context in the design. The 8 audio channels in each datapath processing pipe can be associated with up to 2 contexts (slots). A single context control within a datapath processing unit it is referred to as a slot. If a single context is configured to contain more than 8 channels then it must be distributed across multiple context processing pipe slots. The resources for a single context processing pipe can be configured through the ASRC_PROC_CTRL_SLOTx_Rxx registers. These registers contain the control fields for both slots in a processor SLOT0 and SLOT1. Each slot has control fields to select the context which will run (SLOTx_CTX_NUM), the number of channels associated with each slot (SLOTx_NUM_CH), which channels from the context will run in this slot (SLOTx_MIN_CH to SLOTx_MAX_CH), and an enable bit (SLOTx_EN). The context processing pipes act as the master control blocks throughout the datapath. They control fetching sample data, coefficients, performing computations, and managing available resources. When a resource is unavailable they will stall processing of samples and insert back pressure to the beginning of the pipeline.

14.5.2.1.3 ASRC Input Filter Coefficient Buffer

The input filter coefficient buffer manages addressing and fetching of the prefilter coefficients. Note, each context supports a programmable length prefilter which can be configured using the registers ASRC_CTX_CTRL_EXT1x[ST1_NUM_TAPS] and ASRC_CTX_CTRL_EXT2x[ST2_NUM_TAPS]. The prefilter can run in a single-stage (ST1 only) or two-stage (ST1 and ST2) mode by controlling the bit ASRC_CTX_CTRL_EXT1x[PF_TWO_STAGE_EN]. Both prefilter stages must be symmetric about the center tap. The coefficient buffer is designed to store one half of the filter coefficients, and it can store up to 192 filter coefficients per context. The number of coefficients places a limit on the maximum number of filter taps which can run per context (192x2=384). The coefficient memory is shared between the ST1 and ST2 filter stages, so the cumulative number of filter taps between these stages must remain below 384. The coefficients are stored in IEEE 64-bit floating point format by writing to the ASRC_PRE_COEFF_FIFO[COEFF_DATA] register. After each write to this register, the coefficient buffer write address will be automatically incremented. Writes to the coefficient buffer should be performed from tap 0 to the center tap in incrementing order. To reset the write pointer back to zero, the register field ASRC_CTX_CTRL_EXT1x[PF_COEFF_MEM_RST] can be toggled from 0x0 to 0x1 to 0x0. Stage1 coefficients are written by default, and stage2 coefficients can be written by setting the register field ASRC_CTX_CTRL_EXT1x[PF_COEFF_STAGE_WR]. When switching between stages, the address pointer should be reset back to 0x0 before performing a write.

14.5.2.1.4 ASRC Fractional Resampling Coefficient Generator

The fractional resampling coefficient generator is responsible for generating the resampling interpolation filters for each context. The resampling coefficient generator will calculate a new coefficient for each request from the context processing datapath. This process is computed on the fly for each sample group in flight. In addition, it will calculate the normalization factor which will be used to cancel out any dc gain incurred throughout the resampling process. Each coefficient represents an interpolated value from the coefficient RAM which is managed by this block. The format of the coefficient RAM is dependent on the number of taps used by the resampling process. Note, there is 1 coefficient RAM in the design. Any resampling filter characteristics will be applied to all contexts in the ASRC; however, each context can have an independent resampling ratio. The resampling filter can be configured to operate in 32, 64, or 128-tap mode by configuring the register field ASRC_CTX_RS_COEFF_CTRL[NUM_RES_TAPS]. In 32-tap mode the resampling coefficient RAM is organized as 16 taps x 128 phases/tap x 4 coefficients/phase x 64-bits/coefficient (64 kB). In 64-tap mode, the resampling coefficient RAM is organized as 32 taps x 64 phases/tap x 4 coefficients/phase x 64-bits/coefficient (64 kB). In 128-tap mode, the resampling coefficient RAM is organized as 64 taps x 32 phases/tap x 4 coefficients/phase x 64-bits/coefficient (64 kB). The coefficient RAM must be configured prior to beginning any context processing within the ASRC, and the RAM can be accessed by writing to ASRC_CTX_RS_COEFF_CTRL[RS_COEFF_WDATA].

14.5.2.1.5 ASRC Output Processing and Formatting

The output processing and formatting block serves the following purposes: fetching data from the context processing datapath, normalizing each sample with data provided by the resampling coefficient generator, implementing the TPDF dither algorithm, formatting samples according to user specifications, and managing the output sample circular queues. When a complete sample group from timestamp N has been processed by the context processing data paths, this block will perform a burst fetch to grab every output sample associated with the given context at time N. Each sample group has an associated normalization coefficient norm[CTX][N] which was generated during the resampling process. This coefficient is computed for every sample group output from the ASRC, and it must be applied to every sample associated with context the CTX at timestamp N. After the normalization procedure has been completed, the samples are then passed through the TPDF dither block. The dither function is enabled using the configuration register ASRC_CTX_OUT_CTRL[DITHER_EN]. Output formatting logic is implemented to allow for the following sample modifications: variable bits-per-sample ASRC_CTX_OUT_CTRL[BITS_PER_SAMPLE], bit-reversal of sample data ASRC_CTX_OUT_CTRL[BIT_REV], floating-point or fixed-point output ASRC_CTX_OUT_CTRL[FLOAT_FMT], and a variable sample position within a 32-bit

packed sample ASRC_CTX_OUT_CTRL[SAMPLE_POSITION]. Each sample group is written to the output circular queue which can be accessed through the ASRC_RDFIFOa registers.

14.5.2.2 Data Formatting and Dither

The ASRC can process signed fixed-point sample data which is represented as 16, 20, 24, or 32-bits per sample, and floating-point sample data formatted in IEEE single-precision floating point format (1 sign, 8 exponent, 23 mantissa). Note, all samples associated with a given context must have the same sample format. The ASRC will re-format all input samples to IEEE double-precision floating point format prior to running any calculations. The ASRC input sample Datapath is represented in the following block diagram. The sample position must be set to 0x0 and bits per sample must be set to 32 when operating on floating point input data.

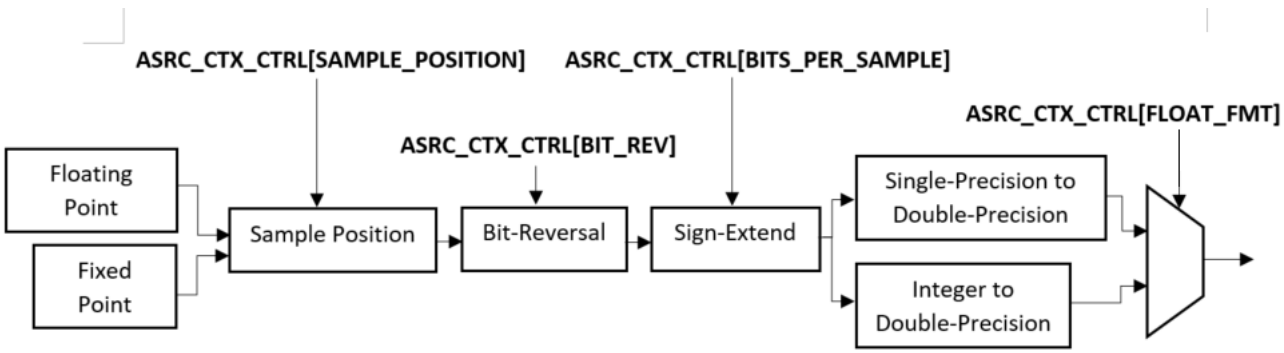

Figure 14-17. Input Sample Formatting Datapath

Samples output from the ASRC can be selected as 16, 20, 24, or 32-bits per sample with fixed or floating-point format. The input and output data formats are completely independent and can be selected in an arbitrary combination. This is due to the unified double-precision sample format which is utilized throughout the ASRC Datapath. There are 3 fixed point cases of interest which should be considered when determining how samples will be conditioned using different input and output bit-widths: up-conversion, down-conversion, and equivalent bit-width. When the input sample data has a lower number of bits per sample than the output data, this case is considered an up-conversion. During an up-conversion, the final output sample data will be multiplied by a constant to scale it up to the output bit width. As an example, if the input sample data is configured to contain 20 bits per sample, and the output data is configured to contain 32 bits per sample, then the ASRC output data will be multiplied by a constant factor of 2^(32-20) = 2^12. Clipping will be performed to ensure that output samples will not overflow beyond the output bit-width after this conversion. Note, any fractional resolution which was tracked throughout the ASRC Datapath will be retained during the up-conversion. When

the input sample data has a higher number of bits per sample than the output data, this case is considered a down-conversion. To perform a down-conversion, the output data LSBs will be truncated and optionally dithered.

TPDF dither can be optionally applied to the output samples of a context. To generate the TPDF dither values, two independent signed pseudo-random numbers are added together to form the final dither value. The dither is then scaled to one-half of the output LSB size and added to the audio sample data. Overflow detection is built into the hardware to ensure that an overflow doesn't occur after adding the TPDF dither to the final sample. A block diagram of the TPDF dither function is provided below. Note, dither is unsupported in 32 bit floating point output format.

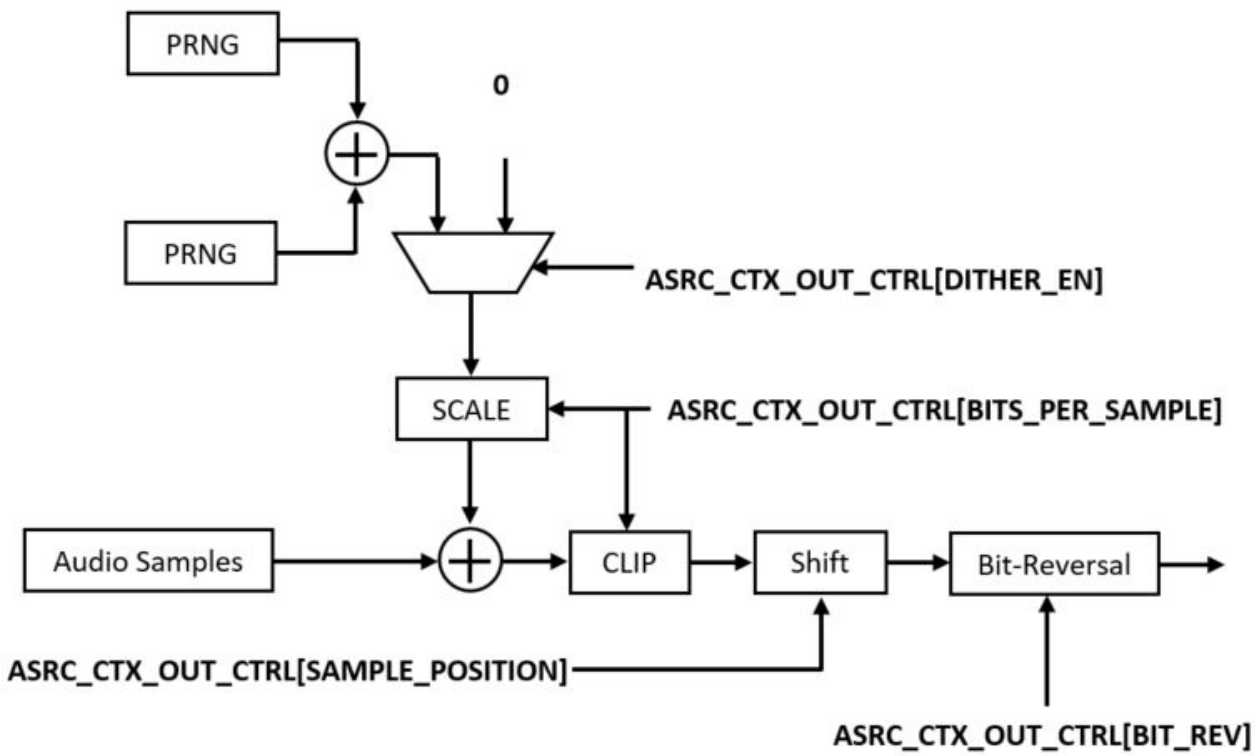

Figure 14-18. TPDF Dither and Output Formatting

14.5.2.3 ASRC FIFO ORGANIZATION

There are independent circular queues for each context in the ASRC. Each context is provided with an input circular queue (accessed through ASRC_WRFIFOa) and an output circular queue (accessed through ASRC_RDFIFOa). When writing data to be processed by the ASRC, each sample will be written to the ASRC_WRFIFOa register corresponding to the context which controls processing for the sample selected. The address for each ASRC_WRFIFO is automatically managed by the ASRC. The ASRC

formats each circular queue using a consistent sample interleaving pattern. This pattern ensures that all samples from a single time stamp for a given context (referred to as a Sample Group) are grouped together in sequential memory locations. This pattern is illustrated in the following figure. Note, this example shows the circular queue for Context0 with 6 channels enabled.

ASRC_WRFIFO0 Memory Organization
ASRC_CTX_CTRL0[NUM_CH_EN] = 0x5

ADDR	DATA	
0x0	CTX0.Channel0.Sample0	
0x1	CTX0.Channel1.Sample0	
0x2	CTX0.Channel2.Sample0	Sample Group 0
0x3	CTX0.Channel3.Sample0	
0x4	CTX0.Channel4.Sample0	
0x5	CTX0.Channel5.Sample0	
0x6	CTX0.Channel0.Sample1	
0x7	CTX0.Channel1.Sample1	
0x8	CTX0.Channel2.Sample1	Sample Group 1
0x9	CTX0.Channel3.Sample1	
0xA	CTX0.Channel4.Sample1	
0xB	CTX0.Channel5.Sample1	
...	...	...

Figure 14-19. ASRC WRFIFO Organization

As shown in the figure above, Context0 is configured to contain 6 channels. Each channel will contain a single sample at time N (denoted CTX0.ChannelX.SampleN). The context circular queues are formatted to ensure that all samples corresponding to time N are contained in sequential memory locations. For example, channel 0-5 sample 0 will be contained in addresses 0x0-0x5 (Sample Group 0), channel 0-5 sample 1 will be contained in address 0x6-0xB (Sample Group 1), and so on in this order.

The ASRC provides interleaving support in hardware to ensure that a variety of sample sources can be internally combined to conform with this format. Interleaving parameters are accessed through the ASRC_CTRL_IN_ACCESSa and ASRC_CTRL_OUT_ACCESSa registers. The interleaving pattern is controlled using 3 register fields: GROUP_LENGTH, ACCESS_LENGTH, and ITERATIONS. This is intended to support hardware configurations which distribute a single context across samples from multiple audio sources. The following figure illustrates a use case where 3 audio sources are combined to be processed using a single ASRC context.

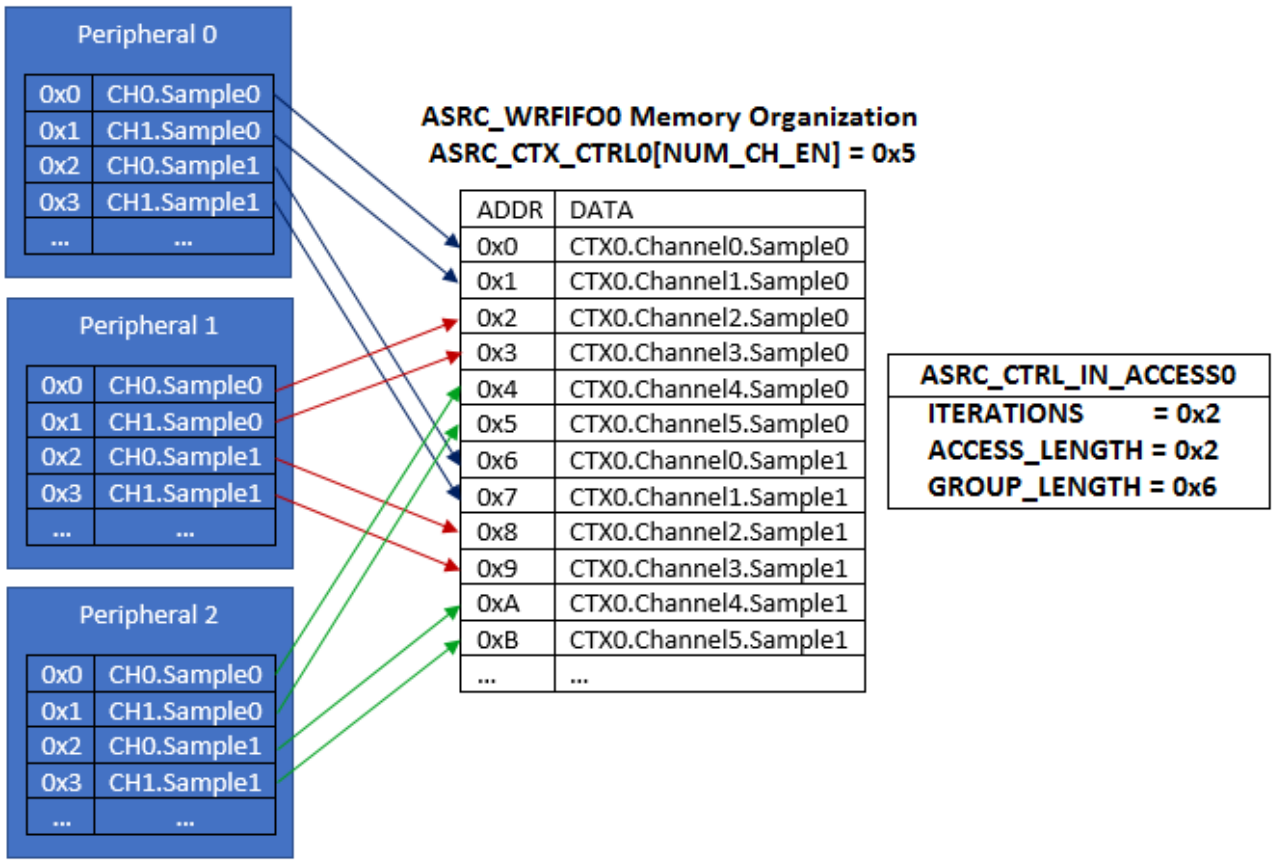

Figure 14-20. ASRC WRFIFO Interleaving Example

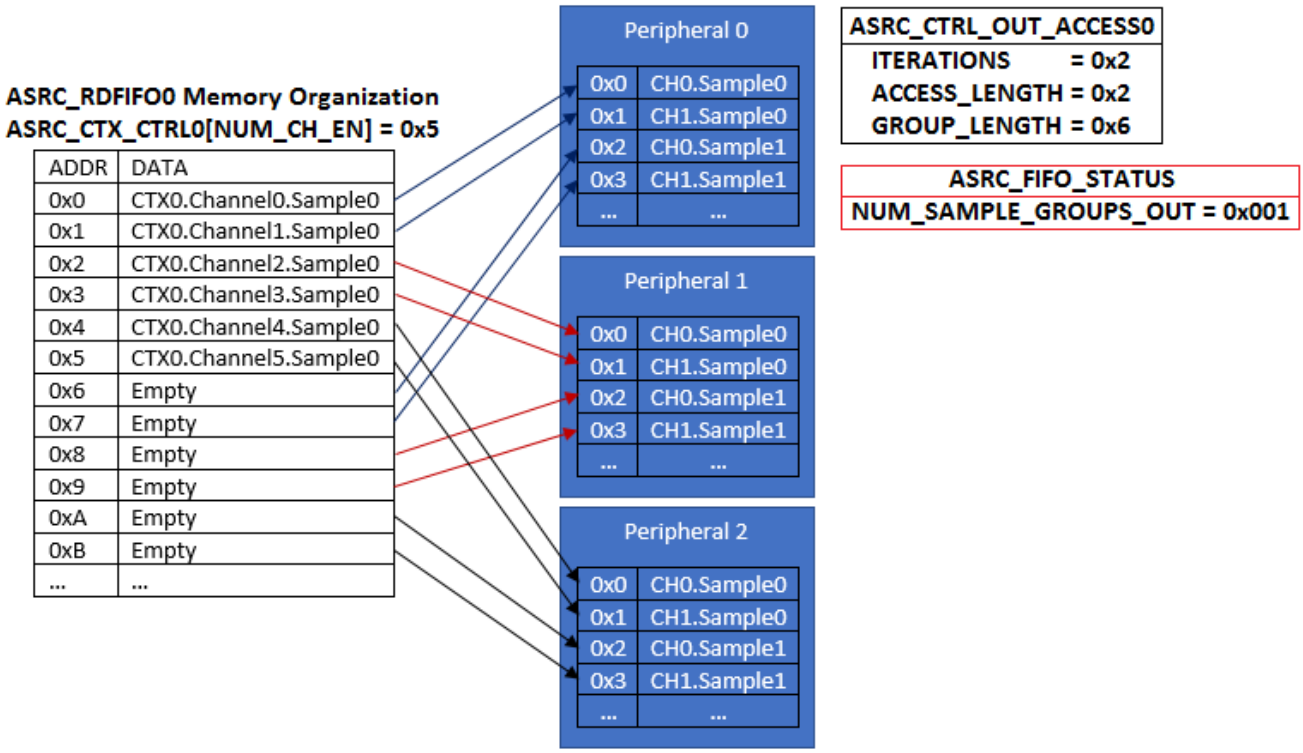
In the figure above, 3 audio sources (Peripheral0-2) will be processed by the ASRC using Context0. Each peripheral contains 2 channels of audio data (ACCESS_LENGTH = 0x2). The total number of channels contained across these 3 sources is 6 ((2 channels/source)*(3 sources); GROUP_LENGTH = 0x6). To make memory accesses more efficient, the burst length was configured to fetch 4 samples per access to a peripheral. This pattern will fetch 2 samples per channel on each peripheral access (ITERATIONS = 0x2). The ASRC input interleaving hardware will control the ASRC_WRFIFO0 memory address to increment in the following order: 0x0, 0x1, 0x6, 0x7, 0x2, 0x3, 0x8, 0x9, 0x4, 0x5, 0xA, 0xB. This will ensure that sample groups are separated sequentially in the WRFIFO memory space.

The ASRC processes data on a sample group granularity. Prior to running any SRC calculations, the ASRC will ensure that a complete sample group has been written to the WRFIFO. The ASRC_FIFO_STATUSa registers provide visibility into how many sample groups are stored in the WRFIFO. This can be read using the field NUM_SAMPLE_GROUPS_IN. Note, this register field will only be incremented once a complete sample group has been written to the FIFO. Utilizing the example above, this would occur after a write to addresses 0x5 and 0xB. As illustrated with this example, the number of writes required to increment the NUM_SAMPLE_GROUPS_IN status is

dependent on the ASRC_CTRL_IN_ACCESS register parameters. Each WRFIFO has a watermark status with dma request support. The watermark is configured with ASRC_CTX_CTRL[FIFO_WTMK], and the dma request can be enabled with ASRC_CTX_CTRL[FWMDE]. If the number of sample groups stored in the WRFIFO is less than the FIFO_WTMK then the ASRC_SAMPLE_FIFO_STATUS[INFIFO_WTMK] will be set, and a dma transfer will be requested (if enabled).

The examples outlined in this section were illustrated for the input WRFIFO; however, the same concepts can be applied to the output RDFIFO. The output RDFIFO contains a sample group count (ASRC_FIFO_STATUSa[NUM_SAMPLE_GROUPS_OUT]), a watermark (ASRC_CTX_OUT_CTRL[FIFO_WTMK]) with associated dma request (ASRC_CTX_OUT_CTRL[FWMDE]) and status flag (ASRC_FIFO_STATUSa[OUTFIFO_WTMK]), and output interleaving parameters (ASRC_CTRL_OUT_ACCESS). The RDFIFO address is automatically managed by the ASRC output interleaving hardware, and the NUM_SAMPLE_GROUPS_OUT is only updated when a complete sample group is written or read. Note, data is written to the RDFIFO one sample group at a time by the ASRC. However, data may be read across sample groups depending on the output interleaving parameters. This makes it possible to request data from an empty RDFIFO element by indexing the read address beyond the number of sample groups stored in the RDFIFO. If a read is requested from an empty element, then the error flag ASRC_FIFO_STATUSa[OUTFIFO_EMPTY_RD] will be triggered. The following example illustrates the case where an empty RDFIFO element is accessed.



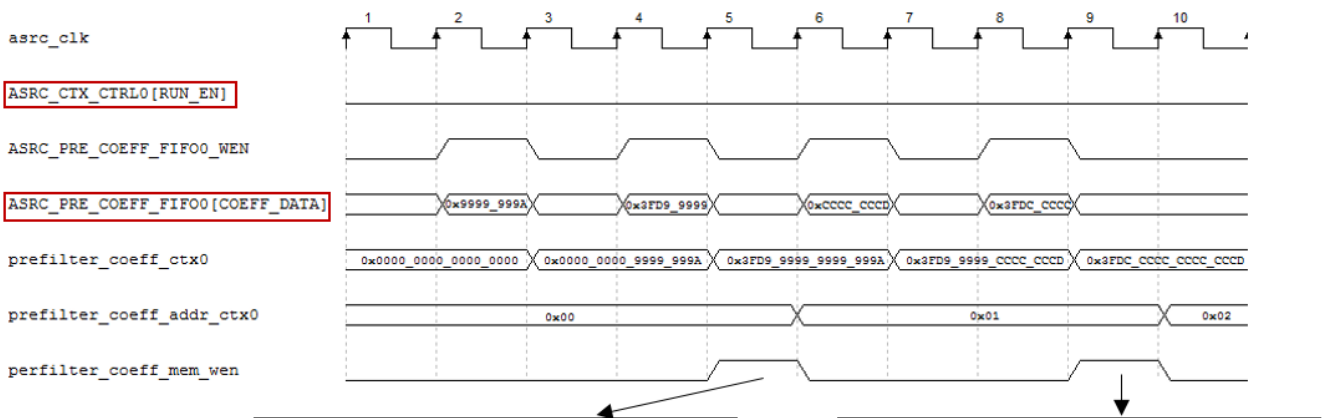


Figure 14-21. ASRC RDFIFO Empty Request

In the above example, the ASRC has completed processing for sample group 0 and has written this data to the RDFIFO in addresses 0x0-0x5. In addition, the ASRC_FIFO_STATUS is updated to indicate that 0x001 sample groups are stored in the RDFIFO. The RDFIFO access parameters are configured with 0x2 ITERATIONS and 0x2 ACCESS_LENGTH. For a complete burst read to be fulfilled, the RDFIFO would need to contain 0x002 sample groups. If a burst access is attempted under these conditions, then the first empty request will be made from address 0x6 after 2 completed reads from 0x0 and 0x1. When the empty read request is made, the OUTFIFO_EMPTY_RD flag will be asserted for Context0, stale data will be read, and the RDFIFO internal read address will remain unmodified. The internal read address will only change when valid data has been read from the RDFIFO. Care should be taken to avoid this scenario by utilizing the RDFIFO watermark and dma request feature.

14.5.2.4 ASRC Coefficient Memory

The ASRC contains memory instances to store coefficients for both the prefilter and resampler. All coefficients within the ASRC are stored in 64-bit IEEE floating point format (1-sign, 11-exponent, 52-mantissa).

The number of prefilter taps is configurable from 1 to 384 taps using the registers ASRC_CTX_CTRL_EXT2x[ST1_NUM_TAPS] and ASRC_CTX_CTRL_EXT2x[ST2_NUM_TAPS]. Both prefilter stages must be symmetric around the center tap, so the prefilter coefficient memory is sized to contain a maximum of 192 entries. The prefilter coefficients can be programmed individually for each context in the design. To modify the value of a prefilter coefficient, the user must perform a write to the register ASRC_PRE_COEFF_FIFOn[COEFF_DATA] while the respective context n RUN_EN bit is set to 0b0. The register bit ASRC_CTX_CTRL_EXT1x[PF_COEFF_STAGE_WR] can be controlled to select which filter stage coefficients will be modified (ST1 or ST2). Two 32-bit writes are required to update a single 64-bit coefficient value. After each coefficient write has been performed, the memory index will be automatically incremented. The following example illustrates 4 writes to the ASRC_PRE_COEFF_FIFO for context 0 ST1 to configure the coefficient values for tap 0 and tap 1. Software controlled signals are outlined in red.

Address	Data
0x00	0x3FD9_9999_9999_999A
0x01	X
...	...
0x3F	X

Address	Data
0x00	0x3FD9_9999_9999_999A
0x01	0x3FDC_CCCC_CCCC_CCCD
...	...
0x3F	X

Figure 14-22. Prefilter Coefficient Access

The above example illustrates the programming sequence required to initialize the first two taps of the ST1 prefilter coefficient FIFO for CTX0 (ASRC_PRE_COEFF_FIFO0[COEFF_DATA]). Note, it is assumed that the write which occurs on asrc_clk cycle 2 is the first write to the context prefilter FIFO out of reset. To indicate this, the prefilter_coeff_addr_ctx0 is initialized to 0x00, which acts as the pointer to the prefilter coefficient for tap 0. After the 4th write has occurred (post clock cycle 9), the context0 prefilter coefficient FIFO will contain the floating-point representation of 0.4 in tap0 and 0.45 in tap1. On clock cycle 10, the coefficient fifo address will be equal to 0x02. This indicates that the next write sequence will be used to modify tap2 of the prefilter. To reset this address back to 0x00, the user must toggle the associated prefilter

pointer reset (this example would use ASRC_CTX_CRTL_EXT10[PF_COEFF_MEM_RST]) or continue performing writes until the address rolls over back to 0x00. By default, the coefficients for prefilter ST1 will be updated. To perform a write for the ST2 coefficients, set the PF_COEFF_STAGE_WR bit to 0x1 for the context to be modified. The prefilter coefficient address pointer should always be reset using PF_COEFF_MEM_RST prior to writing any coefficient values.

There is one resampling coefficient memory within the ASRC design. This memory is designed to store the coefficients used to perform a cubic spline interpolation of a sinc function with NUM_RES_TAPS/2 zero crossings between tap 0 and tap NUM_RES_TAPS/2 inclusive. The organization of this memory is dependent on the number of taps used in the resampling stage (ASRC_CTX_RS_COEFF_CTRL[NUM_RES_TAPS]). The peak of the sinc function should occur at tap NUM_RES_TAPS/2. It should be documented that the center tap of the sinc function lies outside of the coefficient RAM, and it will be programmed directly to the registers ASRC_RS_CT_HIGH and ASRC_RS_CT_LOW. Note, the coefficient RAM is sized to store one half of the full windowed sinc function under the assumption that the sinc function is symmetric around tap NUM_RES_TAPS/2. When the filter is programmed to run in 32-tap mode, the memory will be organized with 16-taps, 128-phases, and 4-coefficients per phase. This organization is illustrated in the image below.

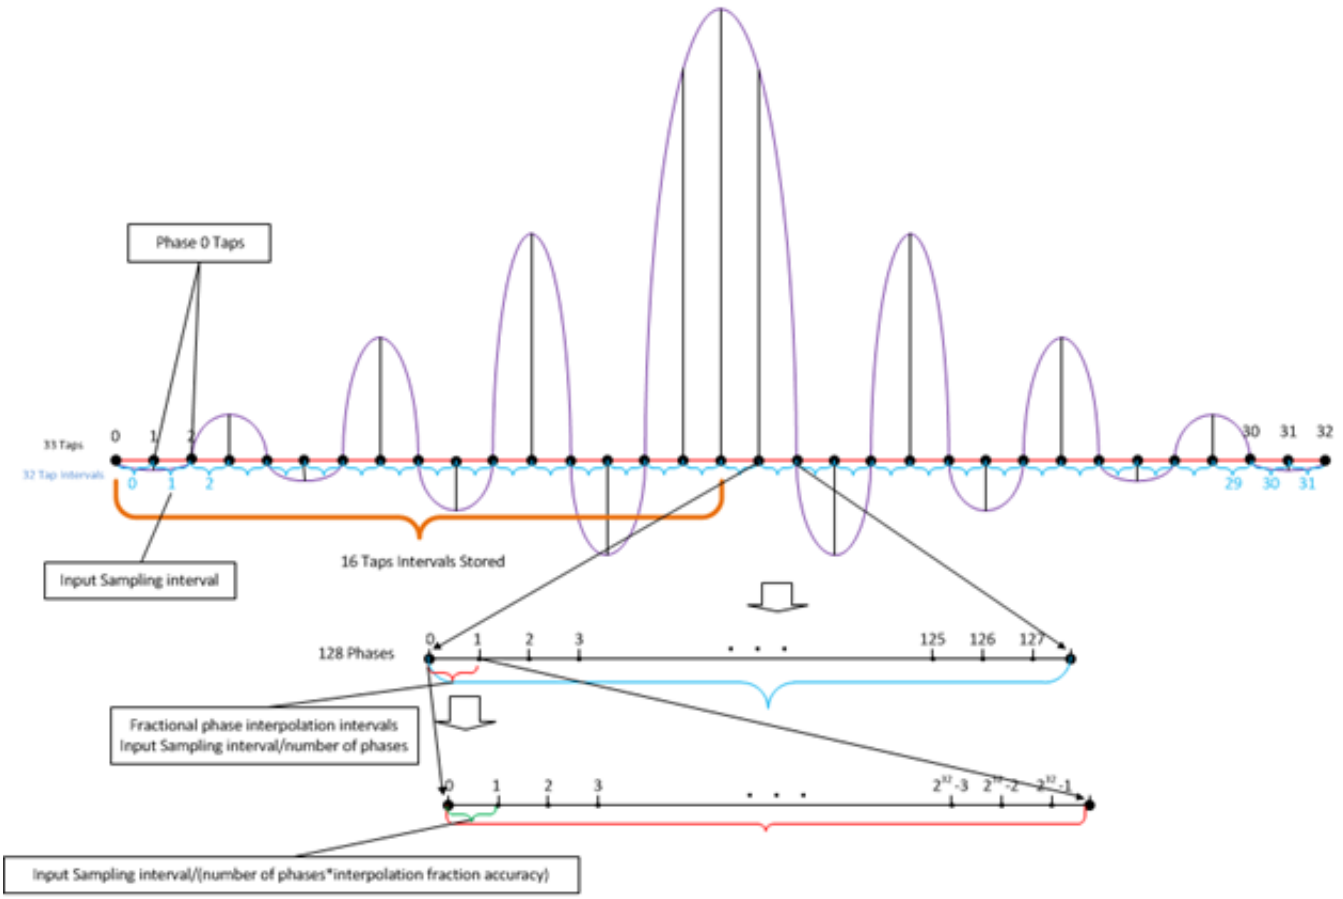

Figure 14-23. Resampling Coefficient Organization

In 32-tap mode, software will need to program 16x128 elements of RAM, where each element contains the 4 64-bit floating point coefficients used to perform the cubic spline interpolation. This requires a total of 16x128x8 writes to the ASRC_CTX_RS_COEFF register. Each element in RAM is organized as follows:

Table 14-10. Resampling Coefficient RAM Element

Address	coeff3[63:0]	coeff2[63:0]	coeff1[63:0]	coeff0[63:0]

The resampling coefficient generator will perform the cubic spline interpolation using the following equation:

resampler_coeff_out(x) = coeff0*x^3 + coeff1*x^2 + coeff2*x + coeff3

In this case, x will be equal to a number between 0 and 2^32-1, where 0 indicates that x lies exactly on the lower interpolation phase and 2^32-1 lies directly to the left of the higher interpolation phase. In this equation, x essentially represents the distance between the two nearest phases in the resampling coefficient RAM. In 64-tap mode, the resampling coefficient ram is organized as 32-taps, 64-phases, and 4-coefficients per phase. In this mode software will need to program 32x64 elements of RAM, and the

coefficient values will be calculated according to the new 64-tap organization. In 128-tap mode, the resampling coefficient ram is organized as 64-taps, 32-phases, and 4-coefficients per phase. The following timing diagram provides an example of programming the first element of the resampling coefficient RAM.

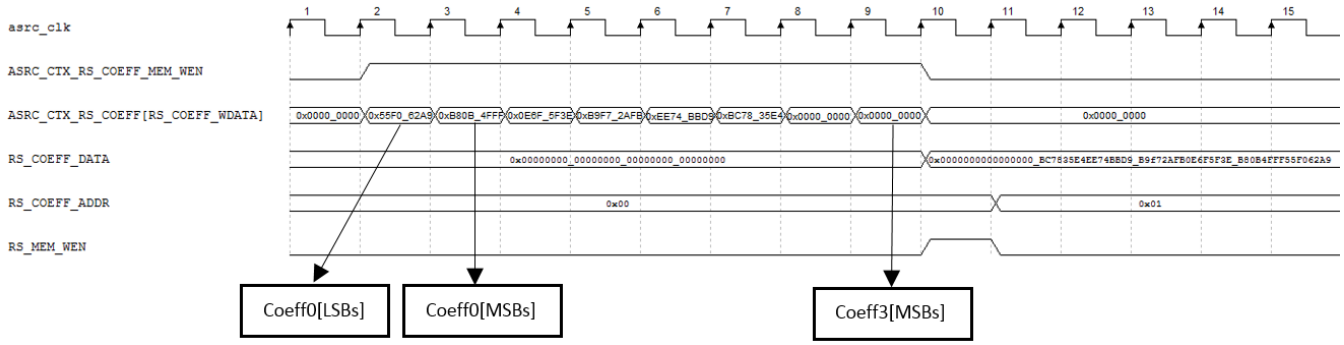

Figure 14-24. ASRC RDFIFO Empty Request

This example shows 8 consecutive writes being performed to the ASRC_CTX_RS_COEFF[RS_COEFF_WDATA] register field. It is assumed that this example shows the first writes to the resampling coefficient memory out of reset. This is illustrated by the RS_COEFF_ADDR being initialized to 0x00. After the 8 writes have been completed, element 0x00 of the resampling coefficient memory will be stored, and the write address will increment to 0x01. The writes are always performed from coeff0 to coeff3 with LSBs leading the MSBs. The RS_COEFF_ADDR can be reset by toggling the state of ASRC_CTX_RS_COEFF_CTRL[RS_COEFF_PTR_RST] or by performing the full 16x128x8 writes to RS_COEFF_WDATA until the address rolls over back to 0x00.

14.5.2.5 Resampling and Normalization

The resampling process works by performing a sinc interpolation of the input samples to generate the output samples. To accomplish this, the fractional resampling coefficient generator computes an interpolation filter for every sample group which is output from the ASRC. The interpolation filter generated is dependent on the following factors: the resampling ratio, the timestamp for the output sample being generated, the cubic spline interpolation coefficients, and the number of taps used in the resampling stage. The resampling ratio is calculated by dividing the input sample frequency Fsin by the output sample frequency Fsout. In 32 tap mode, this ratio is represented as a 44-bit fixed point number with 5 integer bits and 39 fractional bits. The resampling ratio is broken up internally into three component parts:

1. Whole number portion (INT) : rs_ratio[43:39]
2. Integer Phase (IP) : rs_ratio[38:32]

3. Fractional Phase (FP) : rs_ratio[31:0]

To understand how the resampling coefficient generator functions, these three component parts must first be understood. The INT portion of the resampling ratio is used to determine how many input samples need to be shifted into/out of the resampling filter per every output sample generated. For example, if the resampling ratio is selected to be 2.0 (Fsin = 2*Fsout) then the INT will be equal to 2, and the resampler will need to shift in 2 new samples per every output sample generated. The INT is passed from the resampling coefficient generator to the resampler within the context processing datapath for every sample group output to indicate the number of new samples to shift into/out of the buffer.

When the IP portion and FP portion are concatenated {IP,FP}, this value represents the fractional time difference between the output sample being generated and the nearest input sample. This is represented by the following diagram.

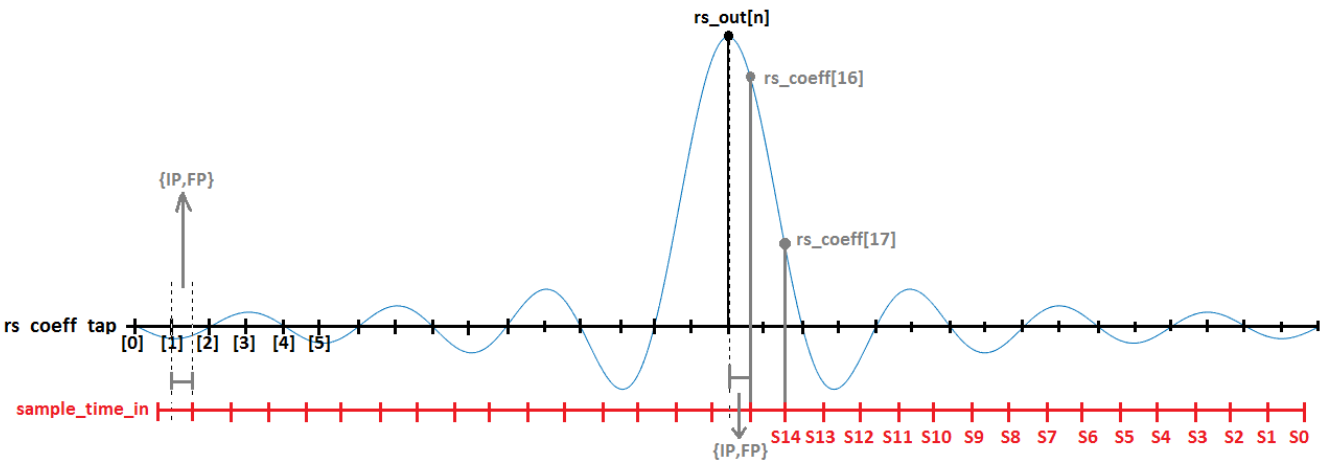

Figure 14-25. Resampling Coefficient Generation

In this example, the resampler is performing an iteration to compute the output sample rs_out[n] (center of the sinc function). This sample lies on a fractional time offset from the input sample time, and this offset is represented by {IP,FP}. Ideally, the resampler would compute the coefficients rs_coeff[x] exactly by sampling the sinc interpolation function at the time offset represented by {IP,FP}. To store all possible samples of the sinc function required for the 39-bit fractional time offset {IP,FP} would require 2^(39) sample points between each of the rs coeff tap points. To implement this practically a coefficient RAM is used to store cubic spline coefficients for the sinc function. Each interval between the rs coeff tap points is divided into 128 sections which are indexed using the IP portion of the fractional time difference. The IP portion is split from this fraction and used to determine which phase of the filter tap is being fetched from the resampling coefficient RAM. Note, the section "ASRC Coefficient Memory" provides an overview of how the RAM is organized. In summary, this RAM is split into the following

component sections when operating in 32-tap mode: 16 taps x 128 phases per tap. The cubic spline coefficients are stored in RAM for each of the 16x128 knots in the sinc function.

Once the IP portion of the fractional time difference is utilized to fetch the proper cubic spline coefficients, the FP portion is used to interpolate the rs_coeff[x] value. There are 4 cubic spline coefficients stored per phase in the resampling coefficient RAM (coeff[3],coeff[2],coeff[1],coeff[0]). The final rs_coeff[x] value is interpolated by the following equation:

rs_coeff[x] = coeff[0] * FP^3 + coeff[1]* FP^2 + coeff[2] * FP + coeff[3]

The IP portion is used to divide the interval between resampling coefficient taps into 128 phases, and the FP portion is used to divide the phases into 2^32 sections by using cubic spline interpolation. This method provides a high degree of accuracy for computing the proper coefficient value at time offset {IP,FP}.

After each output sample is calculated, the internal resampling ratio is accumulated, and the coefficient generation process is repeated. This is equivalent to incrementing the time base of the resampler to the location of the next output sample. If this accumulation results in the INT being greater than 0 then INT sample groups are shifted into/out of the resampling buffer for the next computation. In addition, the fractional time offset {IP,FP} will increase to the fractional location of the next output sample. To prevent the resampling process from generating a dc gain on the output sample data, the resampling coefficients must accumulate to a value which is equal to 1. However, due to minor errors which may be produced in the interpolation process, the accumulated coefficient values could potentially result in a value which is less than or equal to 1. This requires a normalization stage which divides the resampler output data by the sum of all resampling coefficients used to generate each sample. This normalization occurs in the output processing and formatting block.

The initial resampling ratio configured through the ASRC_RS_RATIO_LOWx and ASRC_RS_RATIO_HIGHx registers must be static while the target context is actively processing data. Updates to the internal resampling ratio can be made to an active context through the ASRC_RS_UPDATE_CTRLx registers. Note, any modification to the internal resampling ratio is applied during the next available output sample time. These registers provide software control over the resampling ratio ramp rate and fine adjustment amount. To prevent distortion when making large adjustments to the resampling ratio, an upper limit can be placed on the resampling ratio adjustment amount through the RS_RATIO_RAMP_RATE register field. This will place a cap on the maximum amount of change which can be applied to the resampling ratio per output sample time (this is an absolute value of the maximum change allowed). The desired resampling rate adjustment is programmed to the RS_RATIO_MOD register field. Pending updates are accumulated and applied to the resampling ratio depending on the ramp rate and output sample time.

The following flowcharts illustrate how RS_RATIO_MOD and RS_RATIO_RAMP_RATE are utilized to adjust the internal resampling ratio RS_RATIO. Note RS_RATIO is initialized to the concatenation of {RS_RATIO_HIGH,RA_RATIO_LOW} while the context is in reset. Sample Out RDY is a flag which triggers after every output sample time.

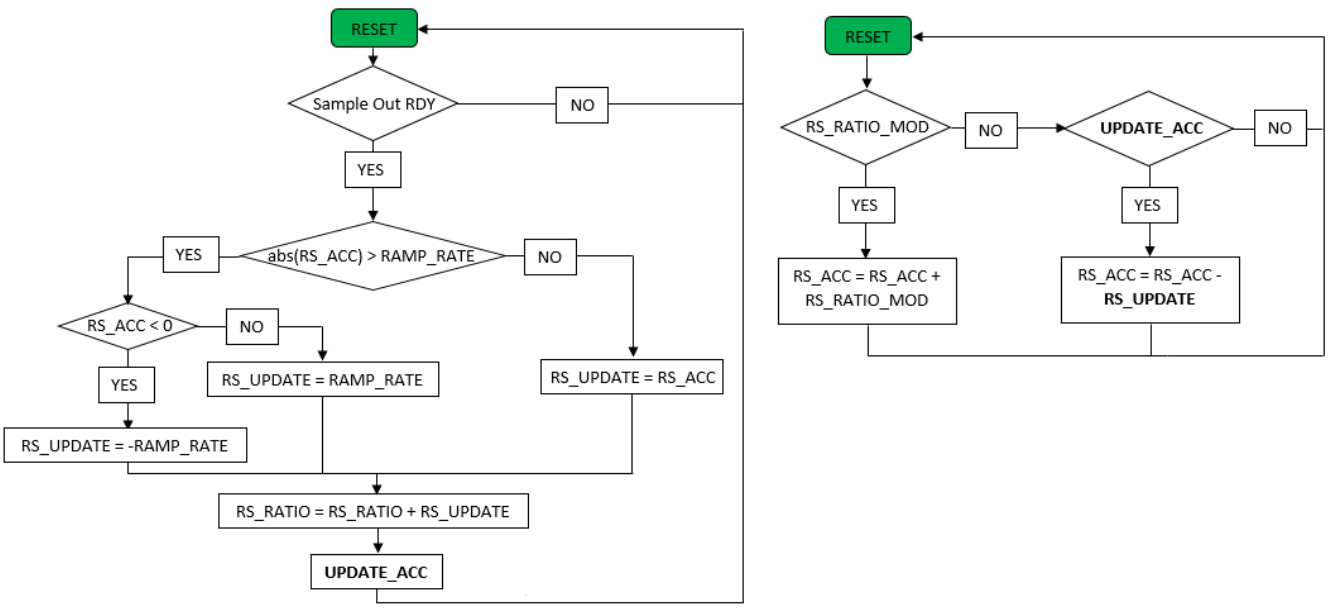

Figure 14-26. Resampling Coefficient Generation

14.5.2.6 ASRC Context Processor Initialization

The following section provides a programming example which initializes 4 contexts to run on the ASRC context processing datapath. The configuration of prefilter and resampling coefficient RAMs will not be included in this example. This configuration step is outlined in section ASRC Coefficient Memory and must be completed prior to running any conversions with the ASRC. The prefilter configuration registers will be outlined in the section ASRC Prefilter Configuration and Performance.

In this example, context 0 (CTX0) will be configured to run 4 channels, CTX1 will be configured to run 6 channels, CTX2 will be configured to run 5 channels, and CTX3 will be configured to run 12 channels

One possible first step to initialize a context is to determine where to distribute the channels within the design. A single context can be split amongst any of the 4 context processing pipes in the design. The user can poll the ASRC_PROC_CTRL_SLOTx_R0x registers to see what is available when determining where to place a context. Two conditions must be met for a context processor to be considered available:

1. At least one of the following two bits must be set to zero: SLOT1_EN or SLOT0_EN, or the context configured in one of the slots is not running. To determine if a slot context is running, first read the ASRC_PROC_CTRL_SLOT1_R0x[SLOT1_CTX_NUM] and ASRC_PROC_CTRL_SLOT0_R0x[SLOT0_CTX_NUM] registers to see which contexts are selected for each slot. Next, read the associated ASRC_CTX_CTRLx[RUN_EN] bits to determine if each context is active.
2. The total number of channels consumed within the context processor must be less than or equal to 8. To determine how many channels are in use, SLOT0_NUM_CH and SLOT1_NUM_CH can be accumulated (note, these are zero indexed). The number of channels consumed by a slot with SLOTx_EN = 0 is always 0.

In this example, the ASRC is unused at the time of configuring context 0. This means that every context processor in the design is available (All SLOTx_EN bits are low and all RUN_EN bits are low). The initial configuration of the ASRC datapath is represented in the following diagram.

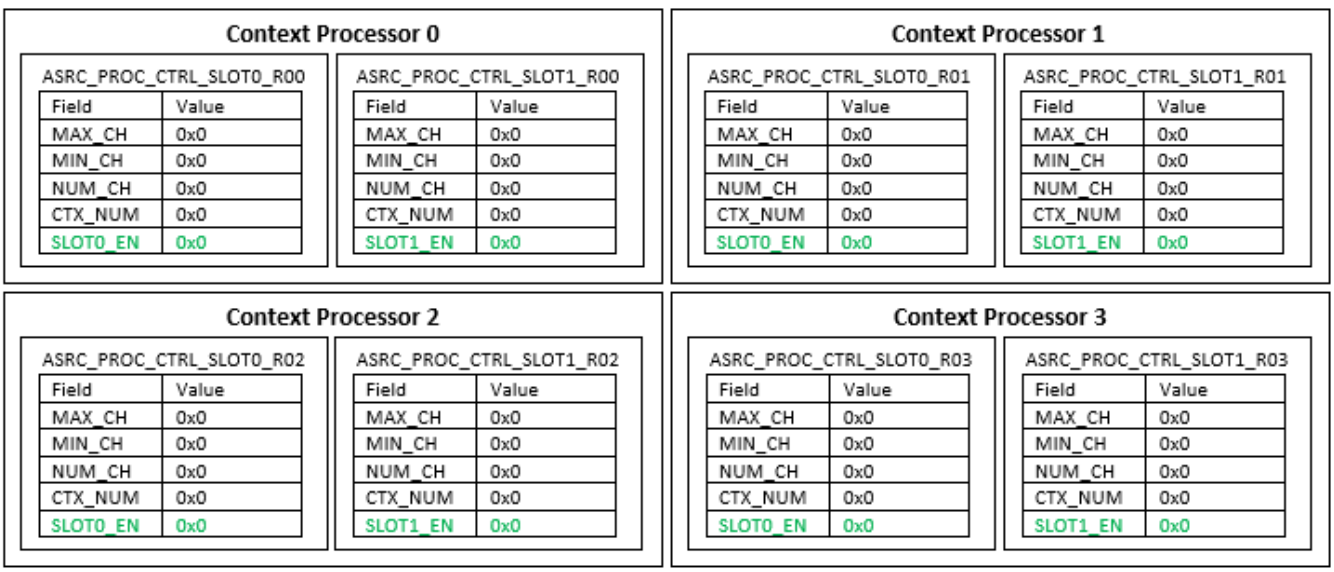

Figure 14-27. Context Processor Initialization State

The placement of a context is arbitrary if the resources are available. However, the minimum number of SLOTs per context should be chosen to ensure maximum utilization of available resources. In this case, context 0 will be placed on datapath processor 3 SLOT0. To program this configuration, the following register settings will be selected:

1. ASRC_PROC_CTRL_SLOT0_R03[SLOT0_EN] = 0x1: This slot is in use
2. ASRC_PROC_CTRL_SLOT0_R03[SLOT0_CTX_NUM] = 0x0 : CTX0 will run here
3. ASRC_PROC_CTRL_SLOT0_R03[SLOT0_NUM_CH] = 0x3 : 4 channels will be used by this slot

4. ASRC_PROC_CTRL_SLOT0_R03[SLOT0_MIN_CH] = 0x0 : CTX0 channel range lower boundary set to 0
5. ASRC_PROC_CTRL_SLOT0_R03[SLOT0_MAX_CH] = 0x3 : CTX0 channel 0 (SLOT0_MIN_CH) to channel 3 will run here

After programming the ASRC_PROC_CTRL_SLOT*_R0* registers, the prefilter memories will need to be allocated for each SLOT in the processor. This allocation is dependent on the number of prefilter stages, the number of taps per stage, and the prefilter ST1 expansion factor selected. A detailed programming example will cover prefilter initialization in the "ASRC Prefilter Initialization" section. Note, the following top-level Context 0 registers will need to be programmed prior to running the context:

1. ASRC_CTX_CTRL_EXT10
2. ASRC_CTX_CTRL_EXT20
3. ASRC_CTRL_IN_ACCESS0
4. ASRC_CTX_OUT_CTRL0
5. ASRC_CTRL_OUT_ACCESS0
6. ASRC_CHANNEL_STATUSx0
7. ASRC_RS_RATIO_LOW0
8. ASRC_RS_RATIO_HIGH0

After each of these registers has been configured, the last step is to configure the register fields within ASRC_CTX_CTRL0, and set the ASRC_CTX_CTRL0[RUN_EN] = 0x1. This will allow CTX0 to begin processing any samples which are written to ASRC_WRFIFO0[CTX_WR_DATA]. This same process should be followed when setting up the remaining channels from CTX1, CTX2, and CTX3. The following diagram illustrates one possible programming for this context set:

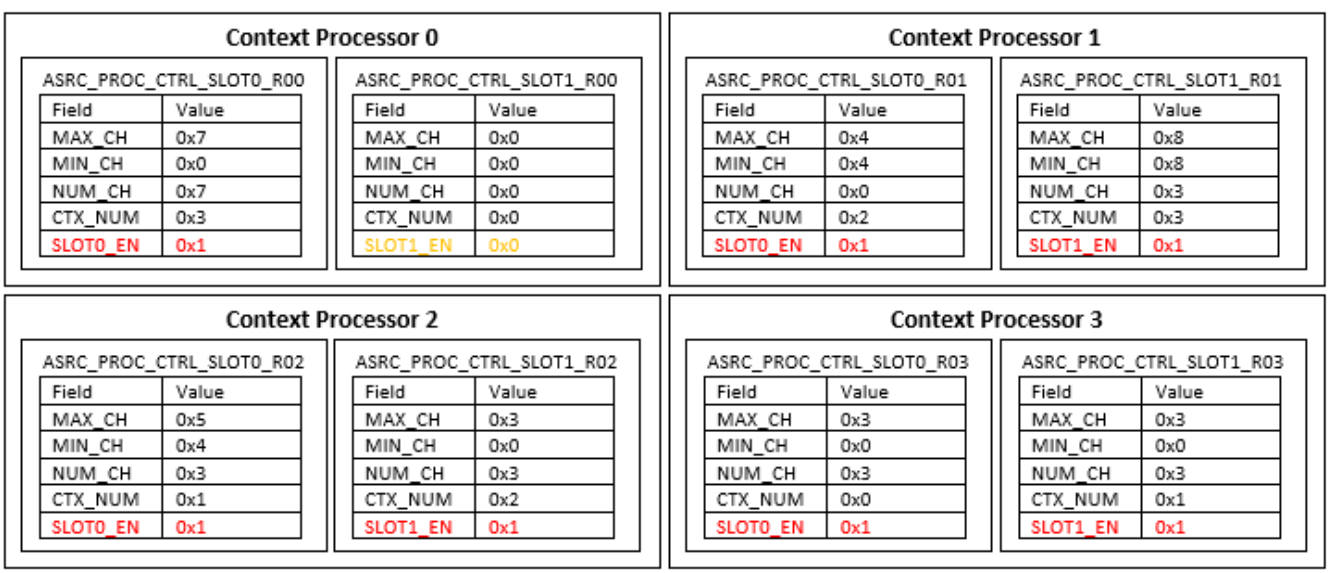

Figure 14-28. Context Processor Configuration Result

To summarize, CTX0 is configured to run 4 channels on processor 3 (PROC3) SLOT0, CTX1 is configured to run 4 channels on PROC3 SLOT1 and 2 channels on PROC2 SLOT0, CTX2 is configured to run 4 channels on PROC2 SLOT1 and 1 channel on PROC1 SLOT0, and CTX3 is configured to run 8 channels on PROC0 SLOT0 and 4 channels on PROC1 SLOT0. As a final note, when a context is shut down, all the context processor slots which were in use must be initialized back to 0x0 to ensure resources are available for the next configuration.

14.5.2.7 ASRC Prefilter Configuration and Performance

Each ASRC context processor contains a prefilter which can be configured to run in a single or double stage mode. The single stage prefilter configuration will be implemented using a FIR structure, and the double stage prefilter configuration will be implemented using an IFIR structure. Both the stage1 (ST1) and stage2 (ST2) prefilter share a single sample memory. This memory structure (PF Sample Memory) contains a total of 6144 elements (1 element = 1 sample).

Samples for the ST1 stage are received directly from the ASRC Input Write FIFO, and samples for the ST2 stage are received from the ST1 Writeback path. The ST1 prefilter has a programmable number of taps (ASRC_CTX_CTRL_EXT2[ST1_NUM_TAPS]), and a programmable expansion factor (ASRC_CTX_CTRL1[PF_EXPANSION_FACTOR]). The ST2 prefilter has a programmable number of taps (ASRC_CTX_CTRL_EXT2[ST2_NUM_TAPS]) with an implied expansion factor of 0. A simplified block diagram for the ASRC Prefilter is shown in the following block diagram. Note, this structure is instantiated one time in each context processor.

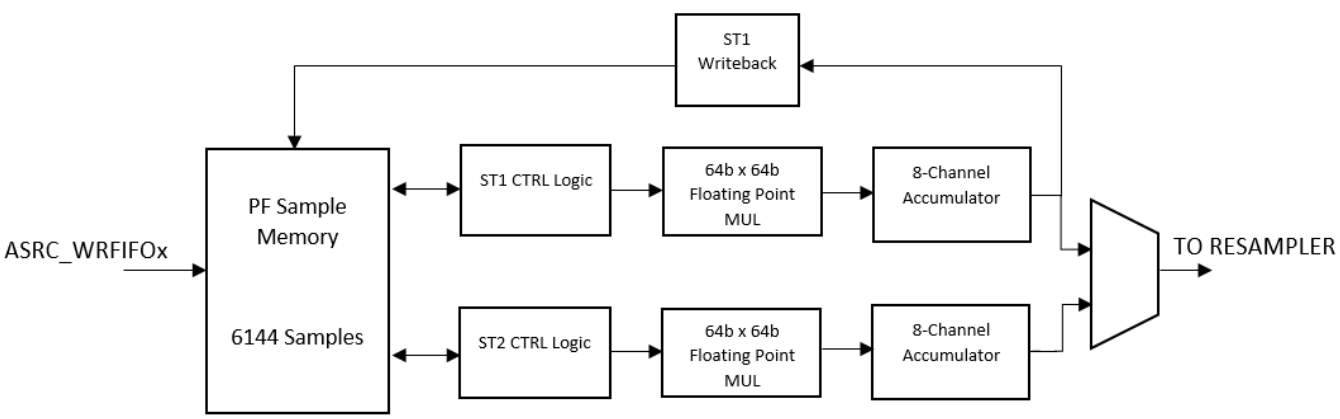

Figure 14-29. Prefilter Block Diagram

The PF Sample Memory partitions must be specified by software using the ASRC_PROC_CTRL registers. The following procedure can be followed to determine the amount of memory which will be used by each filter stage. This example illustrates the case for a two stage prefilter. In addition, it is assumed that the context being programed has already been placed in a context processor. Since there is 1 prefilter per context processor, this procedure must be followed by every processor where the context is running.

1. Program the context to use a two layer prefilter:

   ASRC_CTX_CTRL_EXT1x[PF_TWO_STAGE_EN] = 0x1

2. Select the number of taps used by ST1:

   ASRC_CTX_CTRL_EXT2x[ST1_NUM_TAPS]

3. Select the expansion factor used by ST1:

   ASRC_CTX_CTRL_EXT1x[PF_EXPANSION_FACTOR]

4. Determine the number of channels which will be using the prefilter in each context processor where the selected context will be enabled. If the context is in SLOT0, the number of channels will be equal to:

   NUM_CH = SLOT0_NUM_CH + 1

5. Calculate the amount of prefilter memory which will be used by ST1:

   EXP = ASRC_CTX_CTRL_EXT1x[PF_EXPANSION_FACTOR] + 1

   NUM_S1_TAPS = ASRC_CTX_CTRL_EXT2x[ST1_NUM_TAPS]

   ST1_MEM_ALLOC = NUM_S1_TAPS*NUM_CH*EXP + NUM_CH

   ASRC_PROC_CTRL_SLOTx_R3x[SLOTx_ST1_MEM_ALLOC] = ST1_MEM_ALLOC

6. Compute the CHANxEXP parameter which is used by the prefilter ST1 addressing logic:

   CHANxEXP =NUM_CH * ASRC_CTX_CTRL_EXT1x[PF_EXPANSION_FACTOR]

   ASRC_PROC_CTRL_SLOTx_R2x[SLOTx_ST1_CHANxEXP] = CHANxEXP

7. Calculate the amount of prefilter memory which will be used by ST2:

   NUM_S2_TAPS = ASRC_CTX_CTRL_EXT2x[ST2_NUM_TAPS] + 1

   ST2_MEM_ALLOC = NUM_CH * NUM_S2_TAPS

ASRC_PROC_CTRL_SLOTx_R3x[SLOTx_ST2_MEM_ALLOC] =
ST2_MEM_ALLOC

After SLOTx[ST1_MEM_ALLOC] and SLOTx[ST2_MEM_ALLOC] have been calculated, a base address will need to be specified to determine the location to place each queue in the Prefilter Sample Memory. The base address for each queue is programmed through the ASRC_PROC_CTRL_SLOTx_R2x[SLOTx_ST1_ST_ADDR] and ASRC_PROC_CTRL_SLOTx_R3x[SLOTx_ST2_ST_ADDR] registers. Software must ensure that queues do not overlap within the memory. One method to determine the base address placement is to keep SLOT0 queues incrementing from the min address (0x00) and SLOT1 queues decrementing from the max address (6143). For example, the SLOT0 ST1 base address can be set to 0x0, and the SLOT0 ST2 base address can be set equal to SLOT0[ST1_MEM_ALLOC]. Next, the base address for SLOT1 ST1 can be placed at (6144 - SLOT1[ST1_MEM_ALLOC]), and the base address for SLOT1 ST2 can be placed at (6144 - SLOT1[ST1_MEM_ALLOC] - SLOT1[ST2_MEM_ALLOC]). The following diagram illustrates the one potential Prefilter Sample Memory queue partition.

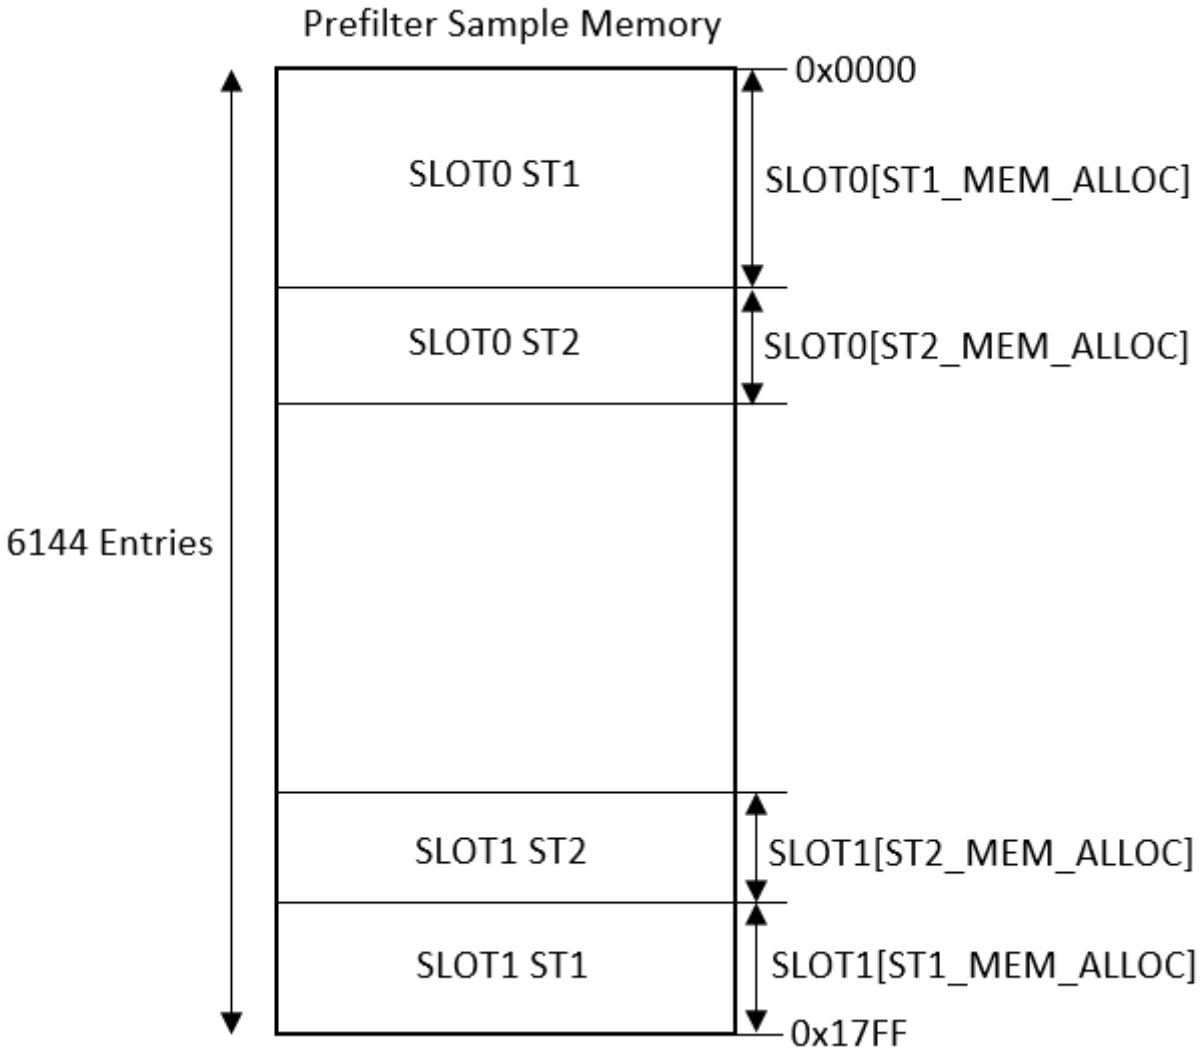

Figure 14-30. ASRC Prefilter Memory Partition

Three factors must be simultaneously optimized when determining how many taps can be ran on the prefilter:

1. The amount of memory available in the prefilter sample memory.
2. The performance limitations of the prefilter (coefficient fetch and MAC rate).
3. The amount of coefficient memory available in ASRC_PRE_COEFF_FIFO.

The Prefilter Sample Memory size places a direct restriction on the number of taps and the max expansion factor for the ST1 and ST2 prefilter. The prefilter coefficient memory places a restriction on the number of taps shared between the ST1 and ST2 prefilter. The cumulative number of taps between ST1 and ST2 must remain below 384 because the prefilter coefficient FIFO is sized to store a maximum of 192 coefficients per context. In addition, the ASRC has a performance requirement which places a limit on the number of filter taps shared between ST1 and ST2 prefilter stages. This performance requirement

exists because the ASRC prefilter can compute a maximum of 786.5*10^6 floating-point multiplications per second. If the prefilter is being utilized by a single context, then the maximum number of filter taps which can run per context processor is equal to:

MAX_TAPS = (786.5*10^6/Fs)/NUM_CH

For example, if the Fs = 384kHz, then the MAX_TAPS will be equal to 2048.17/ NUM_CH. This number of taps represents the total number of multiplies the ASRC can perform for a given number of channels. If the processor from this example is using all 8 channels, then the maximum number of taps per channel will be equal to 2048.17/8 = 256. This performance limitation requires that the ASRC remain under an 8-channel 256-tap prefilter at Fs=384kHz. If the processor from this example if only using 4 channels, then the maximum number of taps will be 512 (Note, this is beyond the coefficient memory boundary of 384). The maximum number of taps can be distributed in any organization across ST1 and ST2 if the cumulative number of taps between ST1 and ST2 remains below the maximum of 384.

All contexts within the design share a single prefilter coefficient memory which is capable of delivering 400*10^6 coefficients per second. The bendiwdh consumed by all prefilters within the ASRC must not exceed this limit. For example, if there are 4 contexts enabled with an Fsin = 384 kHz, then the maximum number of prefilter taps per context is limited to:

MAX_TAPS(384kHz,4-context) = 400*10^6/(4 * 384 kHz) = 260 taps

The number of prefilter taps available to each context is dependent on the sample rate of input data and the number of contexts running within the design. To compute the total bandwidth used by the coefficient memory, the following equation can be used: (Note, fs_in[i] is the input sample rate of context i, and num_pf_taps[i] is the number of prefilter taps used for context i)

int bandwidth = 0; for (int i=0; i<4; i++) { bandwidth = bandwidth + fs_in[i] * num_pf_taps[i]; }

Multiple contexts can run on a single prefilter, and each context can have a different Fs. The maximum number of taps for each context can be calculated by considering each individually. For example, if both CTX0 and CTX1 are sharing Prefilter0, CTX0 Fs=384kHz, CTX1 Fs=48kHz, CTX0 is using 5 channels, CTX1 is using 3 channels, and CTX0 needs to run a 256 tap prefilter. In this case, the number of taps which can run on CTX1 will be calculated as follows:

N = 786.5*10^6 - (384kHz*5*256) = 294.98*10^6

(N/(48kHz))/3 = 2048-taps

From this example, CTX0 can run a 5-channel 256-tap prefilter at 384kHz, while CTX1 can run a 3-channel 2048-tap prefilter at 48kHz on the same processor. Note, however, that this configuration would exceed the available memory in the context processor as well as the coefficient FIFO.

MEM_USED = 5*246+2048*3 =7424 entries

To remain within the limitations of the ASRC prefilter, CTX1 would need to reduce the number of taps to fit within the boundaries of the PF Sample Memory and coefficient FIFO. When determining the capabilities of the prefilter, both the number of taps as well as the performance of the system must be considered.

The prefilter can also be enabled to run in a bypass mode ASRC_CTX_CTRL_EXT1x[PF_BYPASS_MODE]. When bypass mode is enabled, both the prefilter ST1 and ST2 stages will be unused, and input samples will be forwarded directly to the resampling stage. Bypass mode can be used efficiently for resampling options which are performing an up-conversion of the sampling frequency. When a context is placed in prefilter bypass mode, it will not consume any of the PF Sample Memory entries, and will not have a performance impact on the prefilter. If two contexts are sharing a context processor and one of them is in prefilter bypass mode, then the other context can use all the PF Sample Memory entries and max out the performance without impacting the context which is being bypassed. Note, when a context is configured in bypass mode, the ASRC_CTX_CTRL_EXT2x[ST1_NUM_TAPS] and ASRC_CTX_CTRL_EXT1x[PF_EXPANSION_FACTOR] must be set to 0x0.

14.5.2.8 Filter Initialization and Shut Down

When a context is configured to begin processing on the ASRC, the associated prefilter and resampling filters can be initialized to begin in one of 3 possible states. The prefilter and resampling initialization options are selected using the ASRC_CTX_CTRL_EXT1x[RS_INIT_MODE] and ASRC_CTX_CTRL_EXT1x[PF_INIT_MODE]. These options allow the user to select which tap the first sample will be multiplied by and how the ASRC will initialize the remaining filter taps. If ASRC_CTX_CTRL_EXT1x[PF_INIT_MODE] is set to 0x2, then the prefilter will be initialized to run in zero-fill mode. In zero-fill mode, the right half of the prefilter will be filled with zeros, and the first sample written to the ASRC will be multiplied by the center tap of the prefilter. Note, the prefilter initialization mode selected will be applied to both stages ST1 and ST2 of the prefilter. The following diagram represents the zero-fill mode for the case of a 127-tap single stage prefilter. In this diagram S0 represents the sample group written at time 0, S1 represents the sample group written at time 1, or more generally SN is the sample group written at time N.

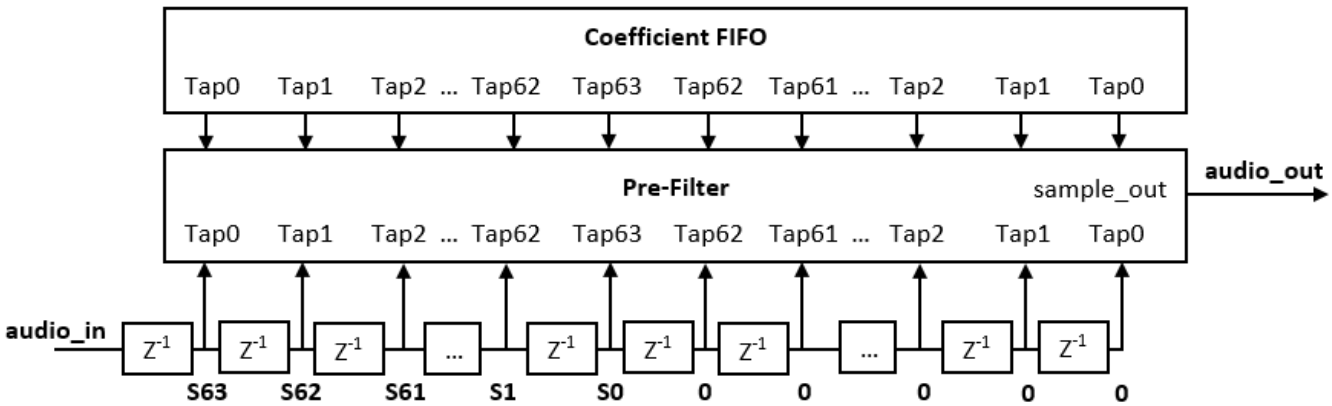

Figure 14-31. Single-Stage Prefilter Zero-Fill Initialization

When operating in zero-fill mode, the first prefilter output sample will be computed after sample data has been written to every tap on the left half of the filter. For the case of a 127 tap prefilter, the first output won't occur until 64 sample groups have been written to the ASRC (S63 to S0). The prefilter output in this mode will be can be represented by the following equation (note pf_tap[n] is the prefilter coefficient at tap n, and audio_in[x] = 0 if x < 0):

$$\text{audio_out}[n] = \sum_{k=0}^{62} \text{audio_in}[n - 63 + k] * \text{pf_tap}[k] + \sum_{k=0}^{63} \text{audio_in}[n + k] * \text{pf_tap}[63 - k]$$

Figure 14-32. Single-Stage Prefilter Zero-Fill Output Equation

If the prefilter is configured to run in a two-stage mode, then the ASRC_CTX_CTRL_EXT1x[PF_INIT_MODE] setting will be applied to both the ST1 and ST2 prefilter. The following image illustrates the zero-fill process for the case of a two-stage prefilter with 127 ST1 taps and 127 ST2 taps. The ST1 prefilter has a programmable expansion factor to place additional delay elements between adjacent filter taps. The expansion factor allows the prefilter to be configured in an IFIR architecture. This will effectively increase the number of samples which must be written to ST1 before an output will be computed. The number of samples needed to calculate the first ST1 output (ST1[0]) is equal to: floor(TAPS/2)*(EXP+1)+1. Note, in this example, S0 corresponds to the first sample group input for this context, S1 corresponds to the sample group input at sample time 1*(EXP+1) (EXP = expansion factor), S2 corresponds to the sample group input at sample time 2*(EXP+1), and more generally SN corresponds to the sample group input at sample time N*(EXP+1).

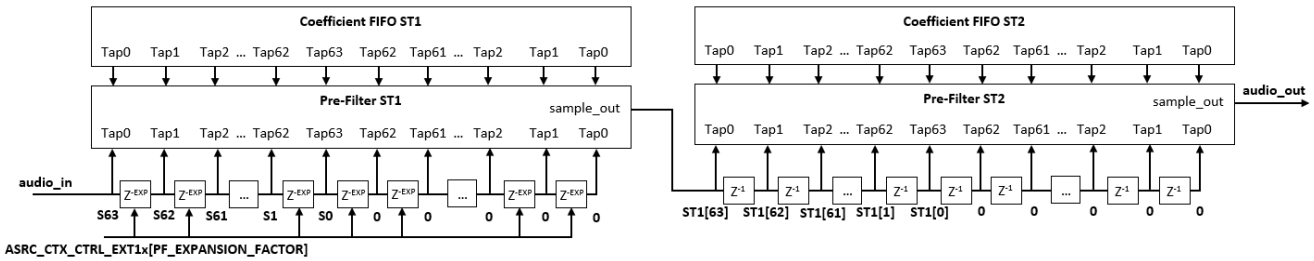

Figure 14-33. Two-Stage Prefilter Zero-Fill Initialization

When ASRC_CTX_CTRL_EXTx[PF_INIT_MODE] is set to 0x1, the prefilter will be initialized in replication mode. In replication mode, the first sample group written to the ASRC will be replicated to fill the right-half of the prefilter taps. In the case of 127 taps, the first output from the prefilter will occur once 64 sample groups have been written to the ASRC. Replication mode is represented in the following diagram.

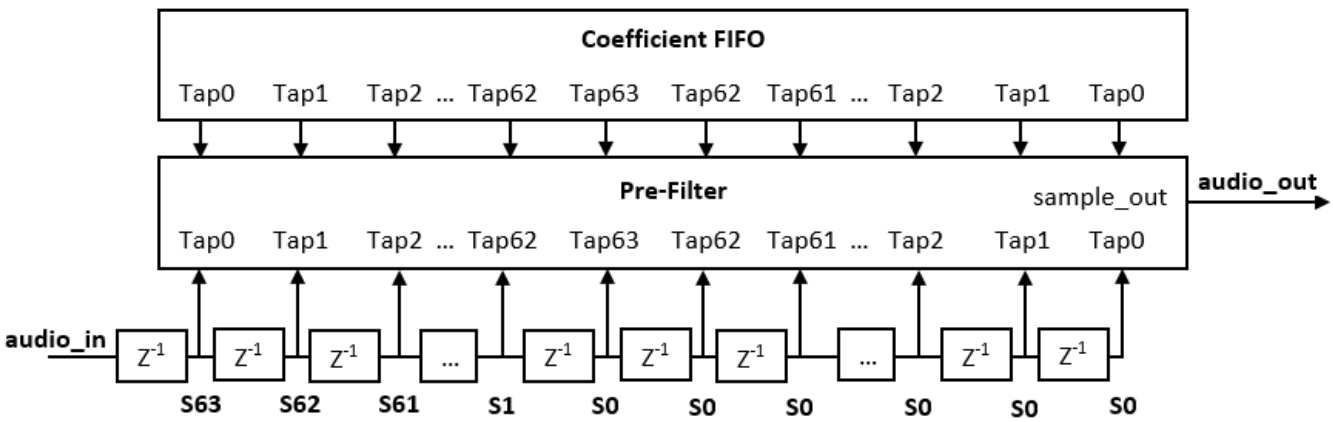

Figure 14-34. Single-Stage Prefilter Replication Initialization

The output data in replication mode can be represented by the same equation as zero-fill mode with the exception that audio_in[x] = S0 if x < 0.

$$\text{audio_out}[n] = \sum_{k=0}^{62} \text{audio_in}[n - 63 + k] * \text{pf_tap}[k] + \sum_{k=0}^{63} \text{audio_in}[n + k] * \text{pf_tap}[63 - k]$$

Figure 14-35. Single-Stage Prefilter Replication Output Equation

If the prefilter is running in a two-stage mode, then the replication initialization mode will be applied to both ST1 and ST2. The ST2 prefilter will replicate the first output from the ST1 prefilter for half of the filter taps enabled. This process is represented in the following image. Note, in this example, S0 corresponds to the first sample group input for this context, S1 corresponds to the sample group input at sample time 1*(EXP+1)

(EXP = expansion factor), S2 corresponds to the sample group input at sample time 2*(EXP+1), and more generally SN corresponds to the sample group input at sample time N*(EXP+1).

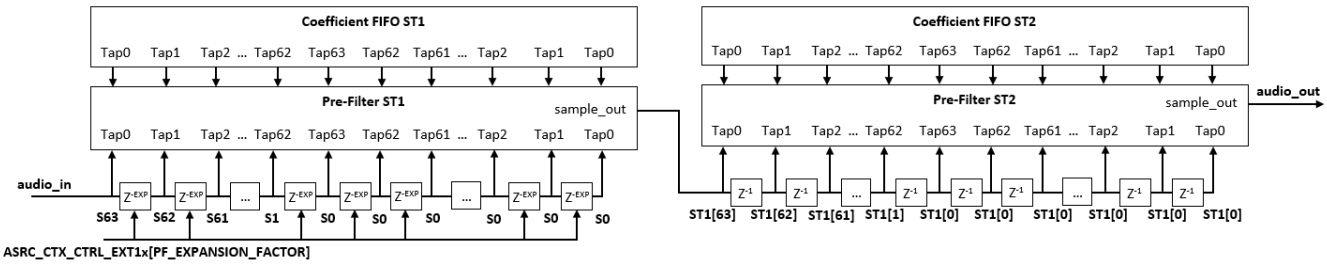

Figure 14-36. Two-Stage Prefilter Replication Initialization

When ASRC_CTX_CTRL_EXTx[PF_INIT_MODE] is set to 0x0, the prefilter initialization will be under software control. There will be no hardware mechanism enabled to fill any of the prefilter taps. The first sample group written to the ASRC will correspond to the rightmost tap of the prefilter, and an output will not be computed until all prefilter taps have been filled with input data. For the case of a 127 tap prefilter, 127 samples must be written to the ASRC before a single prefilter output is computed. This mode is represented in the following diagram.

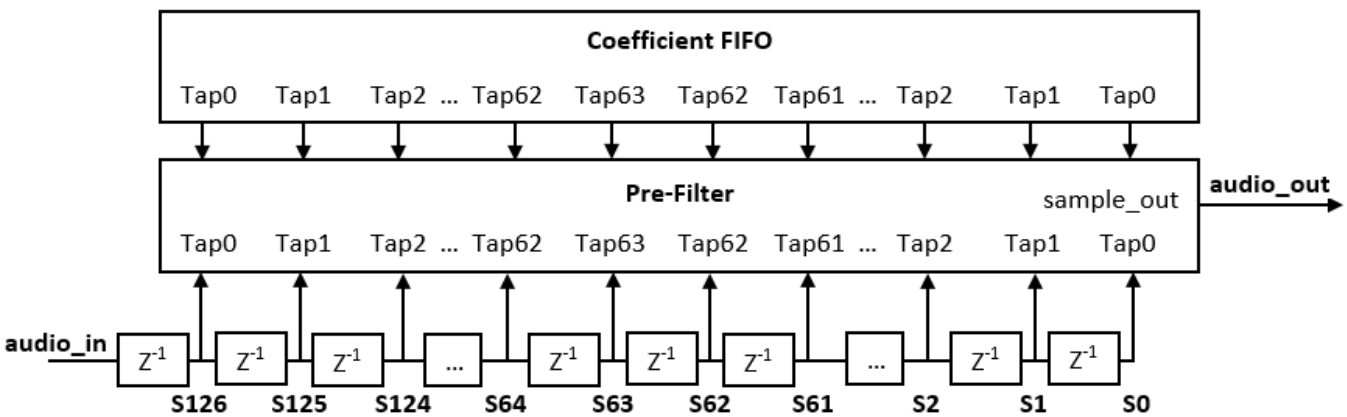

Figure 14-37. Prefilter Software-Initialization Mode

The prefilter output in software control mode is equal to:

$$\text{audio_out}[n] = \sum_{k=0}^{62} \text{audio_in}[n+k] * \text{pf_tap}[k] + \sum_{k=0}^{63} \text{audio_in}[n+k+63] * \text{pf_tap}[63-k]$$

Figure 14-38. Prefilter Software-Initialization Mode

The resampling filter has an equivalent set of initialization modes: software-control, replication, and zero-fill. The resampling initialization mode can be configured using the ASRC_CTX_CTRL_EXTx[RS_INIT_MODE] register field. The only difference to note here is that the initial value written to the resampler is equal to the first output from the prefilter stage.

Each iteration of the prefilter algorithm will fetch 1 new sample from the input audio stream and retire the oldest sample (this is equivalent to a shift by 1 sample operation). If there is no data to fetch then the prefilter will stall until the next sample is received. After the final sample is written to the ASRC, the user must indicate that the audio data is complete to flush the remaining samples from the pipeline. If this stop condition is not indicated to the ASRC, then the remining process will stall under the assumption that there is still more data pending to be received. The bit field ASRC_CTX_CTRLx[RUN_STOP] can be set to indicate that processing for a context will complete, and the pipeline will be flushed. Once the RUN_STOP bit has been triggered, there are two configuration options which can be selected to determine how to flush data from the prefilter and resampling filters. The RS_STOP_MODE and PF_STOP_MODE bit fields in the ASRC_CTX_CTRL_EXTx registers are used to select the RUN_STOP configuration options for the resampler and prefilter respectively. These modes operate similarly to the initialization options. On RUN_STOP, hardware will automatically fill the left-half of the prefilter and resampler with data. This data can either be selected to run in a replication mode or zero-fill mode. In replication mode, the final sample which was written to the ASRC will be replicated for the left-half of the prefilter taps. Also, the final sample from the prefilter will be replicated for the left-half of the resampler taps. In zero fill mode, once all samples have been read from the input WRFIFO, zeros will be written to the prefilter to fill the left-half. Next, zeros will be written to fill the left-half of the resampler once the final calculation has been performed by the prefilter.

14.5.2.9 ASRC IEC60958 Data Insertion

The ASRC contains IEC60958 bit field insertion hardware integrated into the output processing and formatting block. Note, the IEC60958 bit fields are logically ORed with the ASRC output sample data. The user must shift each output sample to the Audio Sample Word boundary defined in the IEC60958 packet specification to ensure data isn't corrupted by this process. This is accomplished using the ASRC_CTX_OUT_CTRLx[SAMPLE_POSITION] bit field. IEC60958 data insertion is only supported when the output is configured to have 16, 20, or 24 bits per sample. To enable IEC60958 data insertion, the ASRC_CTX_OUT_CTRLx[IEC_EN] bit field must

be set on a per-context basis. IEC60958 data is formatted into blocks, frames, and sub-frames. Each sub-frame contains a single sample of audio data along with sample related metadata. The IEC60958 sub-frame is represented in the following diagram.

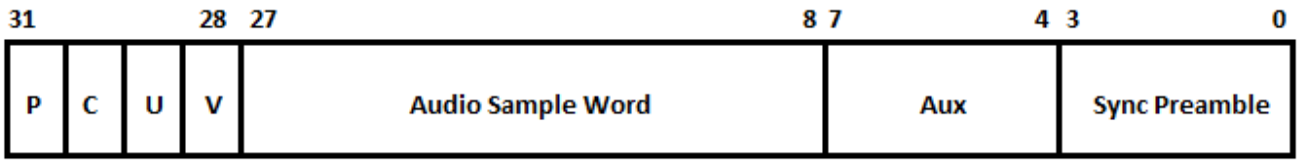

Figure 14-39. IEC60958 Sub-Frame

A sub-frame is composed of the following fields:

1. Parity (P): This is used to give the sub-frame (minus preamble) an even parity
2. Channel Status (C): This contains one bit from a 192-bit channel status packet which is transmitted once per block.
3. User Data (U): The user data field is unsupported by the ASRC and is always set to 0b0.
4. Validity Bit (V): This bit is controlled through the ASRC_CTX_OUT_CTRLx[IEC_V_DATA] register field per context.
5. Audio Sample Word: This field holds the sub-frame sample data (left justified to align the MSB to position 27).
6. Aux: This bit field is unused by the ASRC unless in 24-bits per sample mode. It will contain the lowest 4-bits of the sample data in 24-bit per sample mode.
7. Sync Preamble: This field carries one of the three permitted IEC60958 preambles M, W, or B.

Each frame is comprised of two sub-frames, and each block is comprised of 192 frames (384 sub-frames). If a context contains more than 2 channels, then a single sample group will span across multiple frames. For example, if a context contains 4 channels, then each sample group will span across 2 frames (4 sub-frames). To conform with IEC60958 specifications, the number of channels running on a context with IEC_EN must be an even divisor of 384. This places a limitation to on the number of channels which can run on a context with IEC_EN to: 1, 2, 4, 6, 8, 12, 16, 24, and 32. Each sub-frame contains a preamble which is used for identification and synchronization of blocks, frames, and sub-frames. The preambles are automatically inserted by the ASRC when IEC_EN is set. The B preamble is used for block synchronization, and is only inserted on the first sub-frame of every block. The W preamble is inserted on the second sub-frame of every frame, and the M preamble is inserted on the first sub-frame of every frame, unless it is the first in a block. The preamble insertion pattern is illustrated in the following diagram:

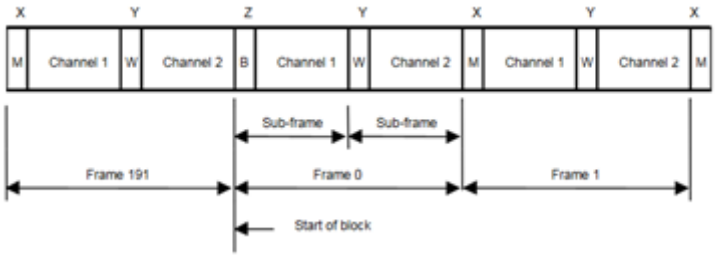

Figure 14-40. ASRC Preamble Insertion

The channel status information is contained in a 192-bit data packet which is transmitted with 1 unique bit per frame (W sub-frames will contain the same channel status as the M sub-frame in the same frame). Channel status data can be configured through the ASRC_CHANNEL_STATUS_xx registers. Each context contains enough storage for a full 192-bit channel status contained within the ASRC. The IEC60958 data insertion logic will cycle through this 192-bit packet starting from the LSB of ASRC_CHANNEL_STATUS0x[CHN_STAT] to the MSB of ASRC_CHANNEL_STATUS_5x[CHN_STAT]. Once the complete packet has been transmitted, the ASRC will start transmitting again repeating from the LSB of ASRC_CHANNEL_STATUS0x[CHN_STAT].

14.5.3 Memory Map and Register Definition

The ASRC Digital memory map and detailed descriptions of all its registers are as follows.

14.5.3.1 D_IP_ASRC_SYN register descriptions

14.5.3.1.1 ASRC_ADDR memory map

d_ip_asrc_syn base address: 30C9_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0 - C	ASRC Input Write FIFO (ASRC_WRFIFO0 - ASRC_WRFIFO3)	32	WO	0000_0000

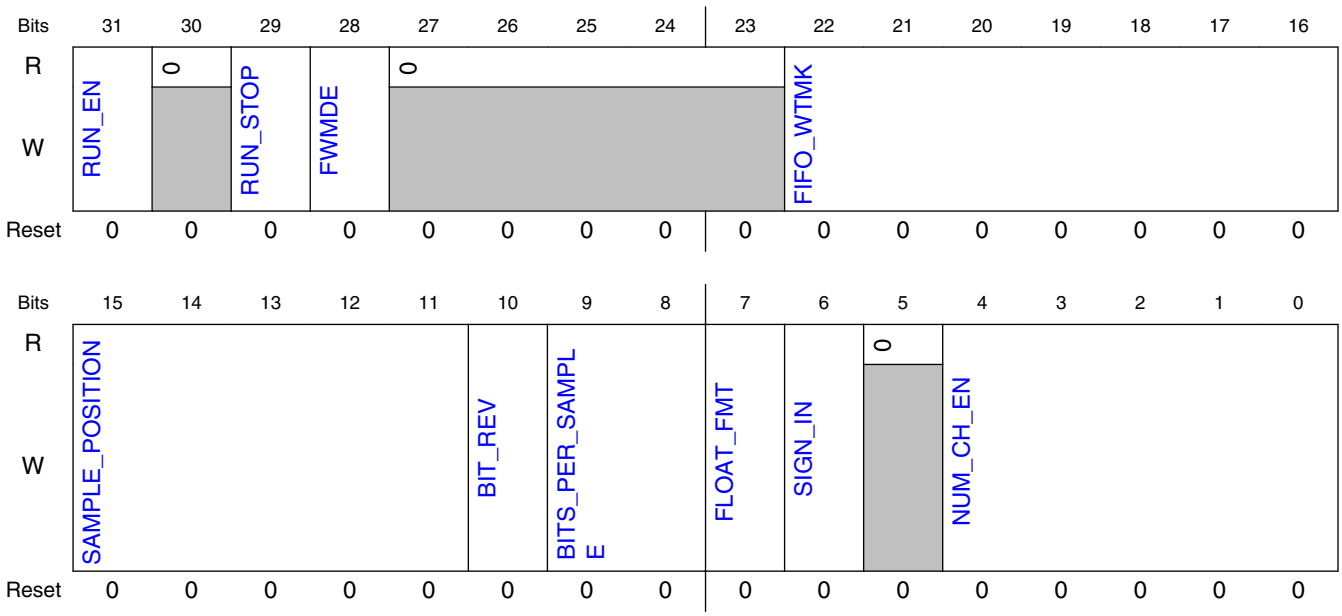
14.5.3.1.3.3 Fields



Field	Description
31-0 CTX_RD_DATA	Read Data For CTX Output FIFO Audio samples for CTX[N] will be stored in this FIFO until read by the user. This FIFO contains the final processed audio data for each context.

14.5.3.1.4 ASRC Context Control (ASRC_CTX_CTRL0 - ASRC_CTX_CTRL3)

14.5.3.1.4.1 Offset

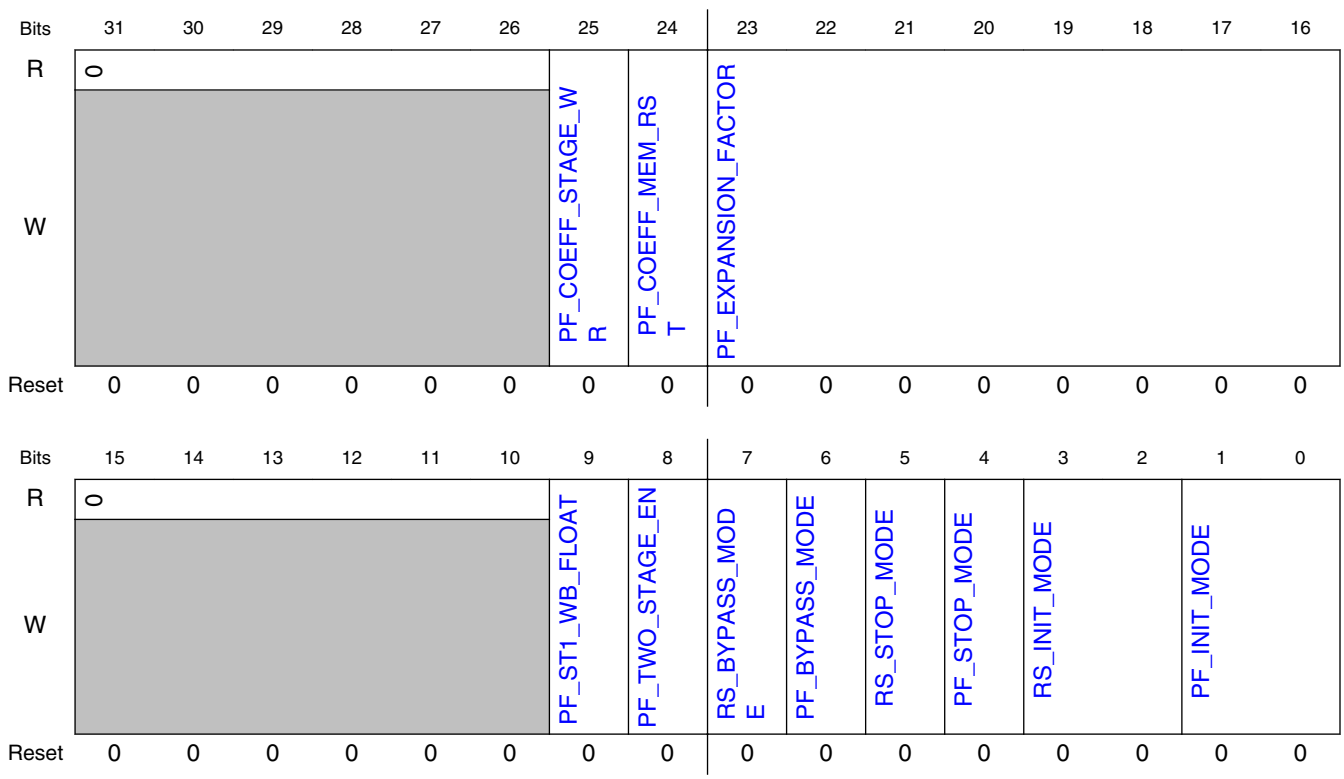
Register	Offset
ASRC_CTX_CTRL0	20h
ASRC_CTX_CTRL1	24h
ASRC_CTX_CTRL2	28h
ASRC_CTX_CTRL3	2Ch

14.5.3.1.4.2 Diagram

14.5.3.1.4.3 Fields

Field	Description
31 RUN_EN	Context Run Enable The RUN_EN bit informs the datapath to begin processing sample data for the context. Note, setting RUN_EN to 1'b0 acts as a soft-reset for the context. Data processing will immediately halt upon de-assertion. All control fields associated with a context must be stable prior to setting RUN_EN.
30 —	Reserved
29 RUN_STOP	Context Run Stop The RUN_STOP bit is used to flush the ASRC pipeline and completely end processing for a context. When this bit is asserted, the ASRC will complete processing of all outstanding sample groups in the input FIFO. Note, partial sample groups will be ignored. If samples are written to the FIFO while this bit is set they will be ignored. The last sample (per channel) will be automatically written to the prefilter for half the number of taps of each filter respectively. Next, the final output from the prefilter will be written to the resampler for half the number of resampling taps enabled. Once all outstanding sample conversions have been written to the output FIFO, the associated ASRC_IRQ_FLAGS[RUN_STOP_DONE] flag will be asserted. Note, the OUTFIFO may still contain samples to read when the ASRC_IRQ_FLAGS[RUN_STOP_DONE] bit is set. The RUN_EN bit must be de-asserted for a full soft-reset of the context.
28 FWMDE	FIFO Watermark DMA Enable This bit is used to enable DMA requests for more sample data in the input FIFO. 0 - Input DMA Requests Not Enabled for This Context 1 - Input DMA Requests Enabled for This Context
27-23 —	Reserved

Table continues on the next page...



Field	Description
22-16 FIFO_WTMK	Context Input FIFO Watermark The FIFO watermark will be used when generating DMA requests. If the number of sample groups in the input FIFO is < the FIFO_WTMK and the DMA request is enabled with FWMDE then a DMA request will be made for more sample data. Note, the maximum number of sample groups per context is limited to 128.
15-11 SAMPLE_POSITION	Sample Position This register field is used to specify the position of the first valid sample bit within a 32 bit boundary. The position is indexed starting from 0. For example, if the input sample is 16-bits wide and left-justified on a 32-bit boundary, then this register should be set to 16. If the input sample is 16-bits wide and right-justified on a 32-bit boundary, then this register should be set to 0. Bit reversal of the sample data should not be considered when programming this field.
10 BIT_REV	Sample Bit Reversal This register field is used to reverse the bit ordering of input sample data. Note, the bit-reversal operation is computed after shifting (SAMPLE_POSITION) is applied. 0 - Keep Input Ordering 1 - Reverse Bit Ordering
9-8 BITS_PER_SAMPLE	Number of Bits Per Audio Sample This register field is used to specify the number of bits per sample within this context. Note, this width doesn't account for metadata associated with a sample. 00 - 16-bits Per Sample 01 - 20-bits Per Sample 10 - 24-bits Per Sample 11 - 32-bits Per Sample
7 FLOAT_FMT	Context Input Floating Point Format This register field is used to select the input sample data format. The ASRC can process signed integer samples or 32-bit floating point samples. Note, if FLOAT_FMT is set to 0b1 then BITS_PER_SAMPLE must be set to 0b11, and SAMPLE_POSITION must be set to 0x00. 0 - Integer Format 1 - Single Precision Floating Point Format
6 SIGN_IN	Input Data Sign This bit is used to select if the input data is in a signed or unsigned format. The ASRC will provide an internal offset to convert unsigned to signed data when SIGN_IN is set. Note, to convert back to unsigned format at the output of the ASRC, the ASRC_CTX_OUT_CTRLx[SIGN_OUT] bit must also be set for the associated context. This field is only active in 32, 24, 20, or 16-bit integer modes. 0 - Signed Format 1 - Unsigned Format
5 —	Reserved
4-0 NUM_CH_EN	Number of Channels In Context This register field is used to specify the number of channels associated with a context. NUM_CH_EN is zero indexed, so the number of channels associated with the context is (NUM_CH_EN + 1). There are 32 total channels in the design. The sum of all NUM_CH_EN registers in the design must not exceed the total number of channels supported in the design.

14.5.3.1.5 ASRC Context Control Extended 1 (ASRC_CTX_CTRL_EXT10 - ASRC_CTX_CTRL_EXT13)

14.5.3.1.5.1 Offset

Register	Offset
ASRC_CTX_CTRL_EXT10	30h
ASRC_CTX_CTRL_EXT11	34h
ASRC_CTX_CTRL_EXT12	38h
ASRC_CTX_CTRL_EXT13	3Ch

14.5.3.1.5.2 Diagram

14.5.3.1.5.3 Fields

Field	Description
31-26 —	Reserved
25 PF_COEFF_STAGE_WR	Prefilter Coefficient Write Select Select which stage to write prefilter coefficients to. 1: Write to S2 coefficient memory. 0: Write to S1 coefficient memory.
24 PF_COEFF_MEM_RST	Prefilter Coefficient Memory Reset If PF_COEFF_MEM_RST is set to 0b1, the coefficient write address will be reset to 0. This should be done before any write operation to the prefilter coefficient memory begins.
23-16 PF_EXPANSION_FACTOR	Prefilter IFIR Expansion Factor When the prefilter is running in a two stage mode, the first stage (ST1) can be configured with an optional expansion factor. This expansion factor selects the number of delay stages placed between adjacent taps of the prefilter. For example, if PF_EXPANSION_FACTOR is set to 0x3 then 3 delay stages will be placed between each filter tap. This means that every 4th sample will be multiplied by a coefficient. If the PF_EXPANSION_FACTOR is set to 0x5, then 5 delay stages will be placed between each filter tap. This means that every 6th sample will be multiplied by a coefficient.
15-10 —	Reserved
9 PF_ST1_WB_FLOAT	Prefilter Stage1 Writeback Floating Point This register bit is used to select the format for prefilter stage 1 results in two stage mode. The prefilter results ftom stage1 are written back to memory prior to being used by stage2. By default, results are written back to memory in 32-bit integer format. If the PF_ST1_WB_FLOAT bit is set, results from stage1 will be written to memroy in a 32-bit floating point format. 0 - The pre-filter stage1 results are stored in 32-bit integer format. 1 - The pre-filter stage1 results are stored in 32-bit floating point format.
8 PF_TWO_STAGE_EN	Prefilter Two-Stage Enable This register bit is used to select the prefilter configuration. The prefilter can run in a single or double stage mode. When operating in a double-stage mode, the prefilter can be configured to perform an IFIR operation. In a single-stage mode, the prefilter can be configured to perform a FIR operation. 0 - The pre-filter will run in single stage mode (ST1 only) 1 - The pre-filter will run in two stage mode (ST1 and ST2)
7 RS_BYPASS_MODE	Resampler Bypass Mode This register field is used to place the resampler in bypass mode. Bypass mode will force all resampling coefficients to zero except for the center tap. When operating in bypass mode, the resampling ratio for the associated context must be set to Fsin/Fsout = 1.0. The center tap coefficient must be set to a non-zero value. Note, the RS_STOP_MODE and RS_INIT_MODE mode fields will still be active. For a true 1-to-1 input vs output, set RS_INIT_MODE to a non-zero value. When a context is placed in resampler bypass mode, the prefilter is still active. 0 - Run the resampler in normal operation. 1 - Run the resampler in bypass mode.
6 PF_BYPASS_MODE	Prefilter Bypass Mode

Table continues on the next page...

Field	Description
	This register field is used to place the prefilter in bypass mode. When operating in bypass mode, samples for this context will be passed directly to the resampler. Both the ST1 and ST2 prefilter stages will be unused for this context. The prefilter sample memory will be unused by this context. The PF_EXPANSION_FACTOR must be set to 0x0 when operating in bypass mode. The ST1_NUM_TAPS must be set to 0x0 when operating in bypass mode. 0 - Run the prefilter in normal operation. 1 - Run the prefilter in bypass mode.
5 RS_STOP_MODE	Resampler Stop Mode This register field selects the shut-down procedure for the resampling sample buffer. When the ASRC_CTX_CTRL[RUN_STOP] bit is set, ASRC will perform a shut-down option to fill the last (NUM_RES_TAPS/2) taps of the resampling filter with the last output from the prefilter (on a per channel basis) or zeros. 0 - Replicate the final prefilter output for the left-half of the resampler on RUN_STOP. 1 - Zero-Fill the left-half of the resampler on RUN_STOP.
4 PF_STOP_MODE	Pre-Filter Stop Mode This register field selects the shut-down procedure for the Pre-Filter sample buffer. When the ASRC_CTX_CTRL[RUN_STOP] bit is set, ASRC will perform a shut-down option to fill the last (NUM_LPF_TAPS/2) taps of the pre-filter with the last sample input to the ASRC_WRFIFO (on a per channel basis) or zeros. 0 - Replicate the last sample input to the ASRC_WRFIFO for the left-half of the pre-filter on RUN_STOP. 1 - Zero-Fill the left-half of the pre-filter on RUN_STOP.
3-2 RS_INIT_MODE	Resampler Initialization Mode This register field selects the initialization procedure for the resampling sample buffer. The ASRC contains an initialization option to fill the first (NUM_RES_TAPS/2) taps of the resampling filter with the first sample output from the prefilter (on a per channel basis) or zeros. Otherwise the ASRC will require NUM_RES_TAPS samples to be written to the resampler prior to running a resampling calculation. 00 - Do not pre-fill any resampler taps. The first sample output from the prefilter corresponds to the highest index resampling filter tap. 01 - Replicate the first prefilter output sample to fill the right half of the resampler. 10 - Fill the right half of the re-sampler with zeros. 11 - N/A
1-0 PF_INIT_MODE	Prefilter Initialization Mode This register field selects the initialization procedure for the prefilter sample buffer. The ASRC contains an initialization option to fill the first (NUM_LPF_TAPS/2) taps of the prefilter with zeros or the first sample written to the input FIFO (on a per channel basis). Otherwise the ASRC will require NUM_LPF_TAPS samples to be written to the input FIFO prior to running a filter calculation. 00 - Do not pre-fill any prefilter taps. The first sample written to the ASRC corresponds to the highest index prefilter filter tap. 01 - Replicate the first sample to fill the right half of the prefilter. 10 - Zero fill the right half of the prefilter. 11 - N/A

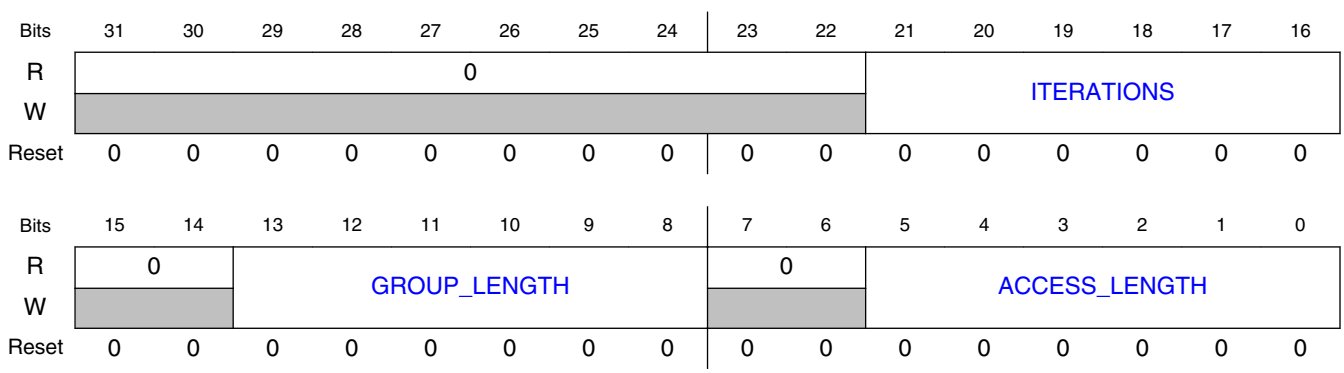
14.5.3.1.6.3 Fields

Field	Description
31-25 —	Reserved
24-16 ST2_NUM_TAPS	Prefilter Stage2 Number of Taps Number of taps used by the prefilter stage 2. This register is zero-indexed. If ST2_NUM_TAPS is set to 0x0 then the number of taps S2_TAPS will be equal to 1.
15-9 —	Reserved
8-0 ST1_NUM_TAPS	Prefilter Stage1 Number of Taps Number of taps used by the prefilter stage 1. This register is zero-indexed. If ST2_NUM_TAPS is set to 0x0 then the number of taps S2_TAPS will be equal to 1.

14.5.3.1.7 ASRC Control Input Access (ASRC_CTRL_IN_ACCESS0 - ASRC_CTRL_IN_ACCESS3)



This register is used to describe how input samples are interleaved when being written to the ASRC. The ASRC has general de-interleaving hardware built into the input stage. This interleaving format supports fetching data from multiple sources per burst, a programmable number of channels per source, and variable length burst accesses.

A single burst transaction will iterate across (GROUP_LENGTH/ACCESS_LENGTH) number of sources. Each source access will consist of a burst transaction which fetches ITERATIONS*ACCESS_LENGTH samples. If all channels associated with a given context are contained within a single source, then the GROUP_LENGTH will be equal to the ACCESS_LENGTH. The total number of samples input to the ASRC in a burst access will be equal to GROUP_LENGTH*ITERATIONS. Note, it is assumed that channels are interleaved within a single source.

14.5.3.1.7.1 Offset

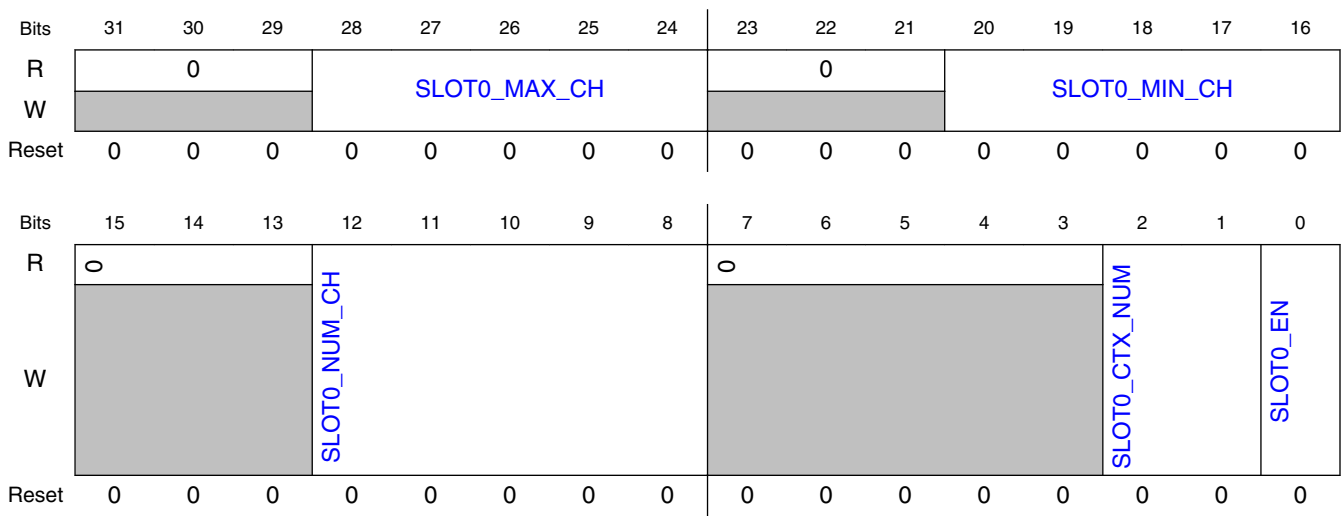
Register	Offset
ASRC_CTRL_IN_ACCESS0	50h
ASRC_CTRL_IN_ACCESS1	54h
ASRC_CTRL_IN_ACCESS2	58h
ASRC_CTRL_IN_ACCESS3	5Ch

14.5.3.1.7.2 Diagram

14.5.3.1.7.3 Fields

Field	Description
31-22 —	Reserved
21-16 ITERATIONS	Number of Sequential Fetches Per Source This register selects the number of sequential ACCESS_LENGTH reads from a single source prior to iterating to the next source. For example, if one audio source contains two channels of data (ACCESS_LENGTH == 0x2), and every access to this source will read 32 samples, then the ITERATIONS parameter should be set to 16. ITERATIONS is indexed from one. If ITERATIONS is set to 0x0 this will result in an invalid configuration.
15-14 —	Reserved
13-8 GROUP_LENGTH	Number of Channels in a Context This register has units of channels/context. When combined with ACCESS_LENGTH, these parameters will inform the ASRC how many independent sources will be combined to provide data in a burst write. The number of sources per burst is (GROUP_LENGTH/ACCESS_LENGTH). This register is indexed from one. If GROUP_LENGTH == 0x0 this will result in an invalid configuration. For example, if the context has 2 channels associated with it then GROUP_LENGTH should be programmed to 0x2. The maximum valid GROUP_LENGTH value is 0x20. GROUP_LENGTH must be programmed to an integer multiple of ACCESS_LENGTH.
7-6 —	Reserved
5-0 ACCESS_LENGTH	Number Of Channels Per Source This register has units of channels/source. When fetching samples from a single source the ASRC will assume data is formatted with ACCESS_LENGTH interleaved samples. The total number of samples fetched from a single source before iterating to the next source is ACCESS_LENGTH*ITERATIONS. For example, if a single audio source contains two channels, then ACCESS_LENGTH should be set to 0x2. Note 0x0 is not a valid ACCESS_LENGTH configuration.

14.5.3.1.8 ASRC Datapath Processor Control Slot0 Register0 (ASRC_PROC_CTRL_SLOT0_R00 - ASRC_PROC_CTRL_SLOT0_R03)



This register contains control fields to configure Slot0 of each datapath processing unit within the design. Each processing unit contains control registers to run up to 2 independent contexts (called slots). There are a total of 8 channels supported per datapath processing unit. If a single context contains more than 8 channels, it must be split between multiple datapath processing units. Note, setting the SLOTx_EN bit will not begin processing for the associated context. To begin processing data, the global ASRC_CTX_CTRLa[RUN_EN] must be set. Prior to setting ASRC_CTX_CTRLa[RUN_EN] for a given context, all of the slots associated with it

must be statically configured in the ASRC_PROCESSOR_CTRLa registers. Each register in the ASRC_PROC_CTRL_SLOT0_R0 register array corresponds to a different context datapath processor.

14.5.3.1.8.1 Offset

Register	Offset
ASRC_PROC_CTRL_SLOT0_R00	60h
ASRC_PROC_CTRL_SLOT0_R01	64h
ASRC_PROC_CTRL_SLOT0_R02	68h

14.5.3.1.8.2 Diagram

14.5.3.1.8.3 Fields

Field	Description
31-29 —	Reserved
28-24 SLOT0_MAX_CH	SLOT0 Maximum Global Channel Number The global ASRC_CTX_CTRLN[NUM_CH_EN] registers are used to select how many global channels correspond to a single context (0 to 32). The SLOT0_MIN_CH and SLOT0_MAX_CH are used to break down this number of channels into the values which will run on SLOT0. For example, if CONTEXT0 owns

Table continues on the next page...

Field	Description
	16 channels (ASRC_CTX_CTRL0[NUM_CH_EN] = 0xF), and SLOT0 is used to process channels 0 through 5, then the SLOT0_MIN_CH will be set to 0x0 and SLOT0_MAX_CH will be set to 0x5. An alternative implementation could have SLOT0 processing channels 7 through 12. In this case, SLOT0_MIN_CH will be set to 0x7 and SLOT0_MAX_CH will be set to 0xC.
23-21 —	Reserved
20-16 SLOT0_MIN_CH	SLOT0 Minimum Global Channel Number The global ASRC_CTX_CTRLN[NUM_CH_EN] registers are used to select how many global channels correspond to a single context (0 to 32). The SLOT0_MIN_CH and SLOT0_MAX_CH are used to break down this number of channels into the values which will run on SLOT0. For example, if CONTEXT0 owns 16 channels (ASRC_CTX_CTRL0[NUM_CH_EN] = 0xF), and SLOT0 is used to process channels 0 through 5, then the SLOT0_MIN_CH will be set to 0x0 and SLOT0_MAX_CH will be set to 0x5. An alternative implementation could have SLOT0 processing channels 7 through 12. In this case, SLOT0_MIN_CH will be set to 0x7 and SLOT0_MAX_CH will be set to 0xC.
15-13 —	Reserved
12-8 SLOT0_NUM_CH	SLOT0 Number of Channels This register field selects the number of context channels used by SLOT0. Note, a single datapath processing unit supports up to 8 channels. One slot can use anywhere from 0 to 8 channels. The total number of channels used by the combination of SLOT0_NUM_CH and SLOT1_NUM_CH must be less than or equal to 8 for valid operation. If SLOT0_EN is set to 0b0, then SLOT0_NUM_CH will use 0 channels. 00000 - Context SLOT0 owns 1 of 8 channels 00001 - Context SLOT0 owns 2 of 8 channels 00010 - Context SLOT0 owns 3 of 8 channels 00011-00111 - Context SLOT0 owns N of 8 channels
7-3 —	Reserved
2-1 SLOT0_CTX_NUM	Context SLOT0 Selection This register selects the context which will run in SLOT0. Note, one context can be enabled to run in multiple slots across multiple datapath processing units. However, SLOT0 and SLOT1 within a single datapath processor should not be set to the same context.
0 SLOT0_EN	SLOT0 Enable Set this bit to 0b1 to enable SLOT0 for data processing. Note, the context running in this slot (SLOT0_CTX_NUM) will not begin processing data until the global ASRC_CTX_CTRL[RUN_EN] bit is set to 0b1. This register field must be static prior to setting the associated ASRC_CTX_CTRL[RUN_EN]. 0 - Context SLOT0 is disabled 1 - Context SLOT0 is enabled

14.5.3.1.9 ASRC Datapath Processor Control Slot0 Register1 (ASRC_PROC_CTRL_SLOT0_R10 - ASRC_PROC_CTRL_SLOT0_R13)

This register contains control fields to configure Slot0 of each datapath processing unit within the design. Each processing unit contains control registers to run up to 2 independent contexts (called slots). There are a total of 8 channels supported per datapath processing unit. If a single context contains more than 8 channels, it must be split between multiple datapath processing units. Note, setting the SLOTx_EN bit will not begin processing for the associated context. To begin processing data, the global ASRC_CTX_CTRLa[RUN_EN] must be set. Prior to setting ASRC_CTX_CTRLa[RUN_EN] for a given context, all of the slots associated with it must be statically configured in the ASRC_PROCESSOR_CTRLa registers. Each register in the ASRC_PROC_CTRL_SLOT0_R1 register array corresponds to a different context datapath processor.

12-0 SLOT0_ST1_CHANxEXP	SLOT0 Stage1 Channels x Expansion Factor When the ASRC prefilter is configured to run in two stage mode, the first stage can be programmed to have an expansion factor ASRC_CTX_CTRL_EXT1x[PF_EXPANSION_FACTOR]. The expansion factor specifies the number of delay units between each filter tap in the Stage1 filter. For example, if the Stage1 expansion factor is set to 1, then 1 unit of delay will be placed between adjacent filter taps. If the Stage1 expansion factor is set to 2, then 2 units of delay will be placed between adjacent filter taps. When the prefilter is running in a 2 stage mode, this register must be programmed with the following value: `SLOT0_ST1_CHANxEXP = (ASRC_PROC_CTRL_S0_R0x[SLOT0_NUM_CH]+1) * (ASRC_CTX_CTRL_EXT1x[PF_EXPANSION_FACTOR])` When the ASRC prefilter is configured to run in a single stage mode, this register must be set to 0x00.

14.5.3.1.10 ASRC Datapath Processor Control Slot0 Register2 (ASRC_PROC_CTRL_SLOT0_R20 - ASRC_PROC_CTRL_SLOT0_R23)

This register contains control fields to configure Slot0 of each datapath processing unit within the design. Each processing unit contains control registers to run up to 2 independent contexts (called slots). There are a total of 8 channels supported per datapath processing unit. If a single context contains more than 8 channels, it must be split between multiple datapath processing units. Note, setting the SLOTx_EN bit will not begin processing for the associated context. To begin processing data, the global ASRC_CTX_CTRLa[RUN_EN] must be set. Prior to setting ASRC_CTX_CTRLa[RUN_EN] for a given context, all of the slots associated with it must be statically configured in the ASRC_PROCESSOR_CTRLa registers. Each register in the ASRC_PROC_CTRL_SLOT0_R2 register array corresponds to a different context datapath processor.

14.5.3.1.10.3 Fields

Field	Description
31-29 —	Reserved

28-16
SLOT0_ST1_MEM_ALLOC
	SLOT0 Stage1 Memory Allocation
	This register will specify the amount of memory to be used by the SLOT0 ST1 prefilter. The amount of memory used here is specific to the ST1 prefilter number of taps (ASRC_CTX_CTRL_EXT2x[ST1_NUM_TAPS]), expansion factor (ASRC_CTX_CTRL_EXT1x[PF_EXPANSION_FACTOR]), and number of channels (ASRC_PROC_CTRL_SLOT0_R0x[SLOT0_NUM_CH]). To compute the amount of memory to use for the ST1 prefilter, the following equation can be used:
	`SLOT0_ST1_MEM_ALLOC = [ ASRC_CTX_CTRL_EXT2x[ST1_NUM_TAPS] * (ASRC_PROC_CTRL_SLOT0_R0x[SLOT0_NUM_CH]+1) * (ASRC_CTX_CTRL_EXT1x[PF_EXPANSION_FACTOR]+1) ] + (ASRC_PROC_CTRL_SLOT0_R0x[SLOT0_NUM_CH]+1)`
	When operating in a single stage prefilter, the amount of memory can be calculated through the following equation:
	`SLOT0_ST1_MEM_ALLOC = (ASRC_PROC_CTRL_SLOT0_R0x[SLOT0_NUM_CH]+1) * (ASRC_CTX_CTRL_EXT2x[ST1_NUM_TAPS]+1)`

15-13 —	Reserved
12-0 SLOT0_ST1_ST_ADDR	SLOT0 Stage1 Start Address This register will specify the prefilter RAM base address for the SLOT0 ST1 prefilter. The value selected here must prevent SLOT0 ST1, SLOT0 ST2, SLOT1 ST1, and SLOT1 ST2 from overlapping in RAM. For example, if SLOT0_ST1_ST_ADDR = 0x0, and SLOT0_ST1_MEM_ALLOC = 0x10, then the address range of 0x0 - 0x0F is consumed by SLOT0 ST1, and no other masters in this context processor can occupy this address range.

14.5.3.1.11 ASRC Datapath Processor Control Slot0 Register3 (ASRC_PROC_CTRL_SLOT0_R30 - ASRC_PROC_CTRL_SLOT0_R33)

This register contains control fields to configure Slot0 of each datapath processing unit within the design. Each processing unit contains control registers to run up to 2 independent contexts (called slots). There are a total of 8 channels supported per datapath processing unit. If a single context contains more than 8 channels, it must be split between multiple datapath processing units. Note, setting the SLOTx_EN bit will not begin processing for the associated context. To begin processing data, the global ASRC_CTX_CTRLa[RUN_EN] must be set. Prior to setting ASRC_CTX_CTRLa[RUN_EN] for a given context, all of the slots associated with it must be statically configured in the ASRC_PROCESSOR_CTRLa registers. Each register in the ASRC_PROC_CTRL_SLOT0_R3 register array corresponds to a different context datapath processor.

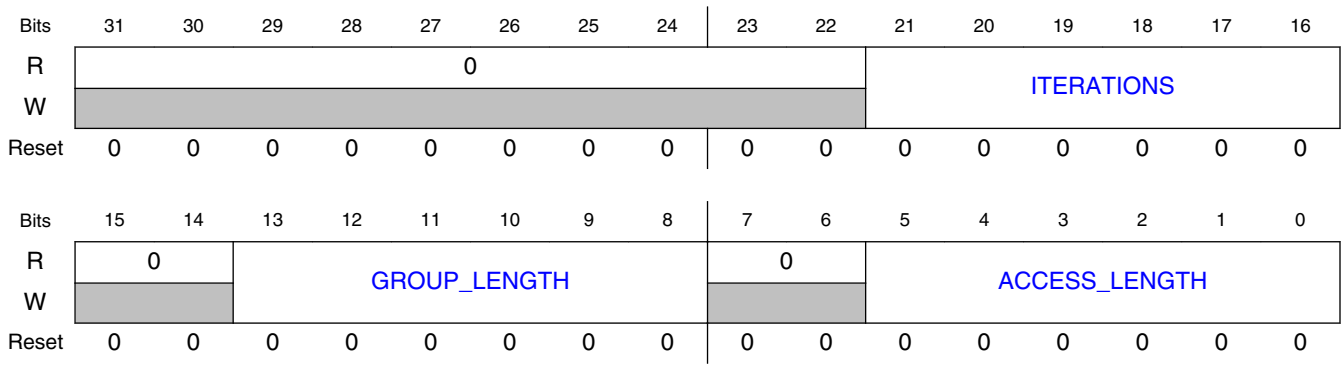
14.5.3.1.16.3 Fields

Field	Description
31-29 —	Reserved
28 FWMDE	Output FIFO Watermark DMA Enable This bit is used to enable DMA requests for FIFO_WTMK. A DMA request will be generated if the number of sample groups stored in the output FIFO is > the FIFO_WTMK and FWMDE is set. 0 - Output DMA Requests Not Enabled for This Context 1 - Output DMA Requests Enabled for This Context
27-23 —	Reserved
22-16 FIFO_WTMK	Context Output FIFO Watermark The FIFO watermark level will be used to generate an output FIFO status signal. This status signal can be utilized when servicing DMA requests for sample data. If the number of sample groups in the output FIFO is > the FIFO_WTMK then the associated ASRC_CTRL_FIFO_STATUSa[OUTFIFO_WTMK] will be flagged as 0b1. Note, the output FIFO is sized to support a maximum of 64 sample groups per context.
15-11 SAMPLE_POSITION	Sample Position This register field is used to specify the position of the first valid sample bit within a 32 bit boundary. The position is indexed starting from 0. For example, if the sample is 16-bits wide and left-justified on a 32-bit boundary, then this register should be set to 16. If the sample is 16-bits wide and right-justified on a 32-bit boundary, then this register should be set to 0. Bit-Reversal of the sample data should not be considered when programming this field.
10 BIT_REV	Sample Bit-Reversal

Table continues on the next page...

Field	Description
	This register field is used to reverse the bit ordering of output sample data. The BIT_REV operation only operates on sample data and will not impact iec60958 bit field insertion. 0 - No change. 1 - Bit-reverse sample data.
9-8 BITS_PER_SAMPLE	Number of Bits Per Audio Sample This register field is used to specify the number of bits per sample within this context. Note, this width doesn't account for meta-data associated with a sample. 00 - 16-bits Per Sample 01 - 20-bits Per Sample 10 - 24-bits Per Sample 11 - 32-bits Per Sample
7 FLOAT_FMT	Context Output Floating Point Format This register field is used to select the output sample data format. The ASRC can output signed integer samples or 32-bit floating point samples. Note, if FLOAT_FMT is set to 0b1 then BITS_PER_SAMPLE must be set to 0b11, and SAMPLE_POSITION must be set to 0x00. 0 - Integer Format 1 - Single Precision Floating Point Format
6 SIGN_OUT	Output Data Sign This bit is used to convert output data to an unsigned format. SIGN_OUT is only active in 32, 24, 20, or 16-bit integer modes. Note, an unsigned conversion should only be made when the ASRC_CTX_CTRLx[SIGN_IN] is set. 0 - Signed Format 1 - Convert to Unsigned
5-3 —	Reserved
2 IEC_V_DATA	IEC60958 Validity Flag This register is used directly as the IEC60958 validity flag for the associated context.
1 IEC_EN	IEC60958 Bit-Field Insertion Enable This register is used to enable IEC60958 field insertion on the output sample data. This mode is only supported when BITS_PER_SAMPLE != 0b11. SAMPLE_POSITION must be adjusted to ensure that output sample data is properly aligned in the sample bit-field defined by IEC60958. SAMPLE_POSITION must be programmed to shift the sample MSB to position 27 of the output sample word. If BITS_PER_SAMPLE = 0b00, SAMPLE_POSITION = 12. If BITS_PER_SAMPLE = 0b01, SAMPLE_POSITION = 8. If BITS_PER_SAMPLE = 0b10, SAMPLE_POSITION = 4. If BITS_PER_SAMPLE = 0b11, IEC60958 data insertion is not supported. 0 - No Data Insertion Enabled. 1 - IEC60958 Bit-Field Insertion Enabled.
0 DITHER_EN	Output Dither Enable The output path contains a TPDF dither function. To enable this function, this bit must be set to 0b1. Dither is supported in all fixed point output modes (16, 20, 24, and 32-bit). Dither is not supported in 32bit floating point output mode.

14.5.3.1.17 ASRC Control Output Access (ASRC_CTRL_OUT_ACCESS0 - ASRC_CTRL_OUT_ACCESS3)



This register is used to describe how output samples are interleaved when being read from the ASRC. The ASRC has general interleaving hardware built into the output stage. This interleaving format supports writing data to multiple sources per burst, a programmable number of channels per source, and variable length burst accesses.

A single burst transaction can be configured to split channels across (GROUP_LENGTH/ ACCESS_LENGTH) number of destinations. Note, the channels output to a single destination will be in an interleaved format. The ASRC can be configured for a burst transaction which fetches ITERATIONS*ACCESS_LENGTH samples to be routed to one destination. The number of channels per destination is ACCESS_LENGTH. If all channels associated with a given context are contained within a single destination, then the GROUP_LENGTH should be set equal to the ACCESS_LENGTH. The total number of samples which need to be read from the ASRC in a complete burst access will be equal to GROUP_LENGTH*ITERATIONS.

14.5.3.1.17.1 Offset

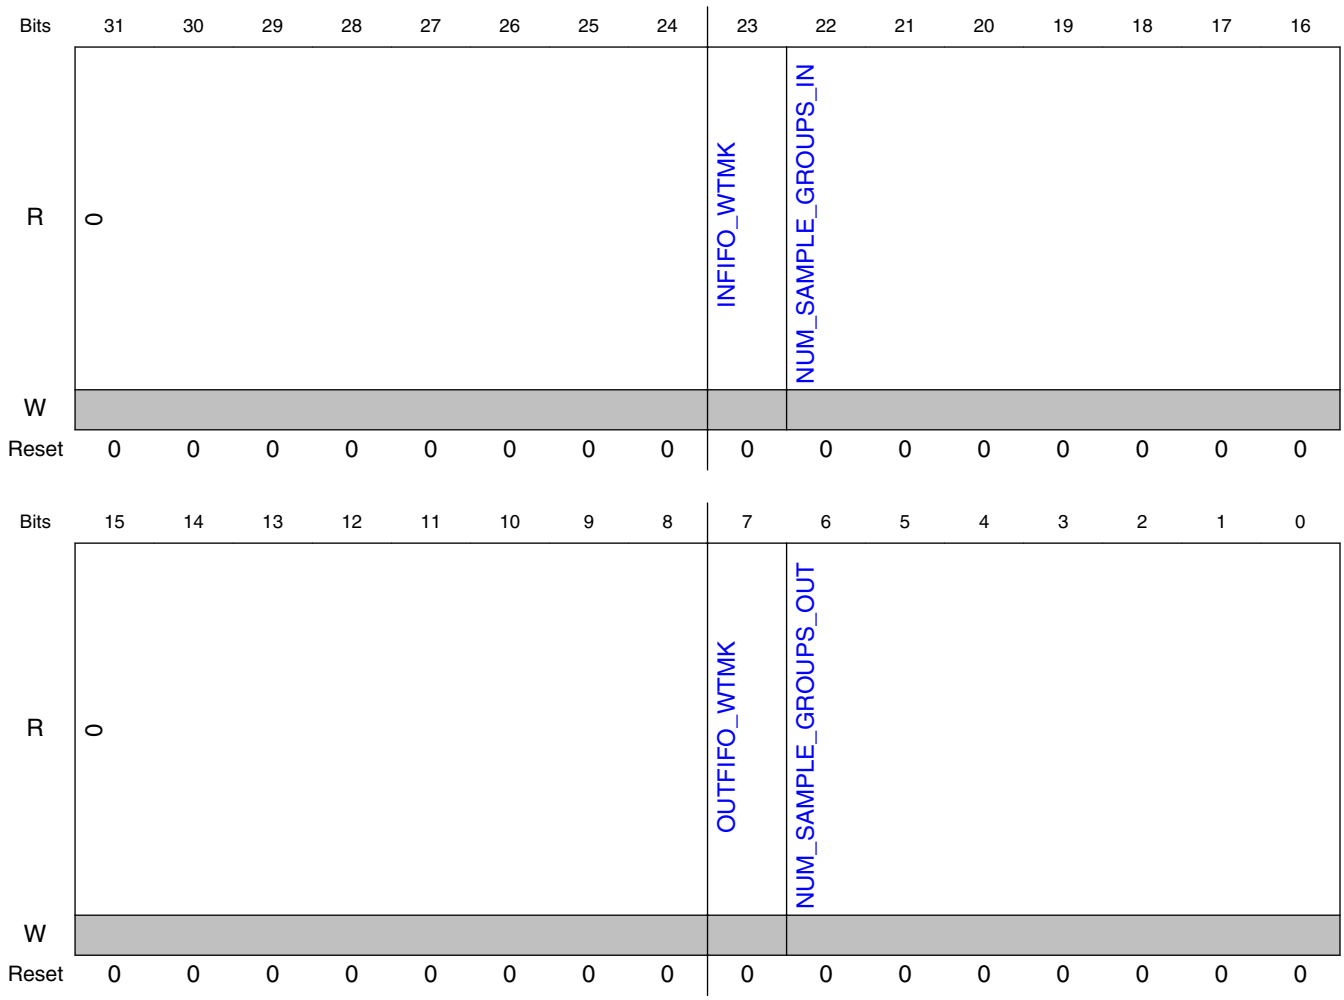
14.5.3.1.17.2 Diagram

14.5.3.1.17.3 Fields

Field	Description
31-22 —	Reserved
21-16 ITERATIONS	Number of Sequential Fetches Per Channel Group This register selects the number of sequential ACCESS_LENGTH reads from a single set of channels prior to iterating to the next set. For example, if one audio source destination will contain two channels of data (ACCESS_LENGTH == 0x2), and every access to this source will write 32 samples, then the ITERATIONS parameter should be set to 0x10. ITERATIONS is indexed from one. If ITERATIONS is set to 0x0 this will result in an invalid configuration.
15-14 —	Reserved
13-8 GROUP_LENGTH	Number of Channels in a Context This register has units of channels/context. When combined with ACCESS_LENGTH, these parameters will inform the ASRC how many independent destinations will be used in a burst read. The number of destinations per burst is (GROUP_LENGTH/ACCESS_LENGTH). This register is indexed from one. If GROUP_LENGTH == 0x0 this will result in an invalid configuration. For example, if the context has 2 channels associated with it then GROUP_LENGTH should be programmed to 0x2. The maximum valid GROUP_LENGTH value is 0x20. GROUP_LENGTH must be programmed to an integer multiple of ACCESS_LENGTH.
7-6 —	Reserved
5-0 ACCESS_LENGTH	Number Of Channels Per Destination This register field allows a context containing many channels to be split into sub-groups of channels to be forwarded to separate destinations. For example, if a single context contains 6 channels, but these results are to be output to 3 independent destinations then the ACCESS_LENGTH parameter can be set to 0x2 (2 channels/destination). This allows sequential reads from a context output FIFO to only fetch channel data associated with one destination at a time. This register has units of channels/destination. The total number of samples output to a single destination before iterating to the next is ACCESS_LENGTH*ITERATIONS. For example, if a single destination will contain audio data for two channels, then ACCESS_LENGTH should be set to 0x2. Note 0x0 is not a valid ACCESS_LENGTH configuration.



14.5.3.1.18 ASRC Sample FIFO Status (ASRC_SAMPLE_FIFO_STATUS0 - ASRC_SAMPLE_FIFO_STATUS3)

This register provides a status for the number of samples stored in the input and output FIFOs. Note, the status fields track the number of sample groups associated with each context. All data is handled on a sample group granularity internal to the ASRC.

14.5.3.1.18.1 Offset

Register	Offset
ASRC_SAMPLE_FIFO_STATUS0	100h
ASRC_SAMPLE_FIFO_STATUS1	104h
ASRC_SAMPLE_FIFO_STATUS2	108h
ASRC_SAMPLE_FIFO_STATUS3	10Ch

14.5.3.1.18.3 Fields

Field	Description
31-24 —	Reserved
23 INFIFO_WTMK	Input FIFO Watermark Flag This flag will be set to 0b1 when the number of sample groups contained within the input FIFO is less than the associated ASRC_CTX_CTRLa[FIFO_WTMK]. Note, the associated context ASRC_CTX_CTRLa[RUN_EN] muse be set to 0b1 for this field to be active.
22-16 NUM_SAMPLE_GROUPS_IN	Number Of Sample Groups Stored in Input FIFO This register holds the number of sample groups per context contained in the input FIFO. Note, when performing a burst write which has non-equivalent ACCESS_LENGTH and GROUP_LENGTH, this pointer will only update once a complete sample group has been written to the FIFO. This could take multiple ITERATIONS*ACCESS_LENGTH cycles until the first sample group has been completely written to the FIFO.

Table continues on the next page...

Field	Description
15-8 —	Reserved
7 OUTFIFO_WTMK	Output FIFO Watermark Flag This flag will be set to 0b1 when the number of sample groups contained within the output FIFO is greater than the associated ASRC_CTX_OUT_CTRLa[FIFO_WTMK]. Note, the associated context ASRC_CTX_CTRLa[RUN_EN] must be set to 0b1 for this field to be active.
6-0 NUM_SAMPLE_GROUPS_OUT	Number Of Sample Groups Stored in the output FIFO This register holds the number of sample groups per context stored in the output FIFO. Note, when performing a burst read which has non-equivalent ACCESS_LENGTH and GROUP_LENGTH, this pointer will only update once a complete sample group has been read from the FIFO. This could take multiple ITERATIONS*ACCESS_LENGTH cycles until the first sample group has been completely read from the FIFO.

14.5.3.1.19 ASRC Resampling Ratio Low (ASRC_RS_RATIO_LOW0 - ASRC_RS_RATIO_LOW3)

The ASRC_RS_RATIO_LOW register can only be modified before a context has began processing data. A write to ASRC_RS_RATIO_LOW will only be accepted if the respective ASRC_CTX_CTRL[RUN_EN] = 0x0, or if the context has not began processing samples yet. Note, when starting up a new context, the ASRC will stall processing of data until an initial write to {ASRC_RS_RATIO_HIGH,ASRC_RS_RATIO_LOW} has occurred. Subsequent writes to this register will be ignored while the context is actively processing data. Updates to the resampling ratio can be made while the a context is active through the ASRC_RS_UPDATE_CTRL register. The order of write operations should always follow ASRC_RS_RATIO_LOW followed by ASRC_RS_RATIO_HIGH. Note, writes to ASRC_RS_RATIO_HIGH without a previous write to ASRC_RS_RATIO_LOW will be considered invalid. In addition, a write to ASRC_RS_RATIO_LOW without a subsequent write to ASRC_RS_RATIO_HIGH will be considered invalid. This register is 32-bit accessible only.

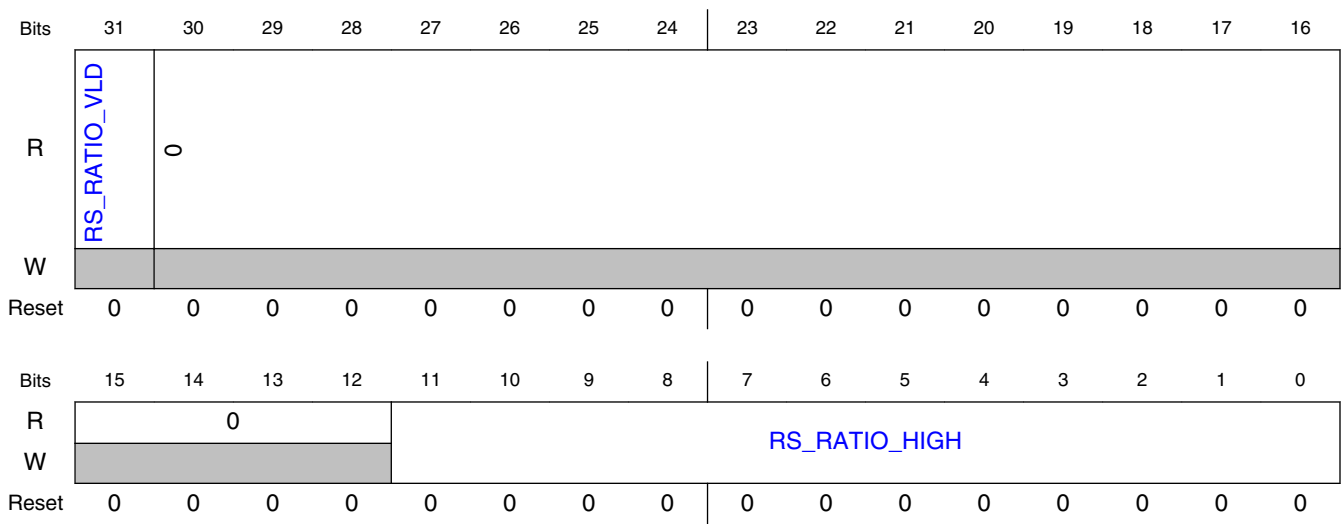
14.5.3.1.19.3 Fields

Field	Description
31-0 RS_RATIO_LOW	Resampling Ratio Low This register contains the lower 32-bits of the 44-bit fixed point resampling ratio between input to output sources. The concatenation of {RS_RATIO_HIGH,RS_RATIO_LOW} represents the 44-bit unsigned integer and fractional phase offset between input samples to output samples. The resampling ratio is calculated by dividing the input sample frequency by the output sample frequency Fs(in)/Fs(out). The format of the resampling ratio is dependent on the number of taps in the resampler (ASRC_CTX_RS_COEFF_CTRL[NUM_RES_TAPS]). If the resampler is in 32-tap mode, the resampling ratio is formatted with with 5 integer bits and 39 fractional bits (5.39 format). If the resampler is in 64-tap mode, the resampling ratio is formatted with 6 integer bits and 38 fractional bits (6.38 format). If the resampler is in 128-tap mode, the resampling ratio is formatted with 7 integer bits and 37 fractional bits (7.37 format). Note, the maximum up-sampling ratio supported is Fs(in)/Fs(out) = 1/8. The maximum down-sampling ratio supported is Fs(in)/Fs(out) = 16.

14.5.3.1.20 ASRC Resampling Ratio High (ASRC_RS_RATIO_HIGH0 - ASRC_RS_RATIO_HIGH3)



The ASRC_RS_RATIO_HIGH register can only be modified before a context has began processing data. A write to ASRC_RS_RATIO_HIGH will only be accepted if the respective ASRC_CTX_CTRL[RUN_EN] = 0x0, or if the respective context has not began processing samples. Note, when starting up a new context, the ASRC will stall processing of data until an initial write to {ASRC_RS_RATIO_HIGH,ASRC_RS_RATIO_LOW} has occurred. Subsequent writes to this register will be ignored while the context is actively processing data. Updates to the resampling ratio can be made while the a context is active through the ASRC_RS_UPDATE_CTRL register. The order of write operations should always follow ASRC_RS_RATIO_LOW followed by ASRC_RS_RATIO_HIGH. Note, writes to ASRC_RS_RATIO_HIGH without a previous write to ASRC_RS_RATIO_LOW will

be considered invalid. In addition, a write to ASRC_RS_RATIO_LOW without a subsequent write to ASRC_RS_RATIO_HIGH will be considered invalid. This register is 32-bit accessible only.

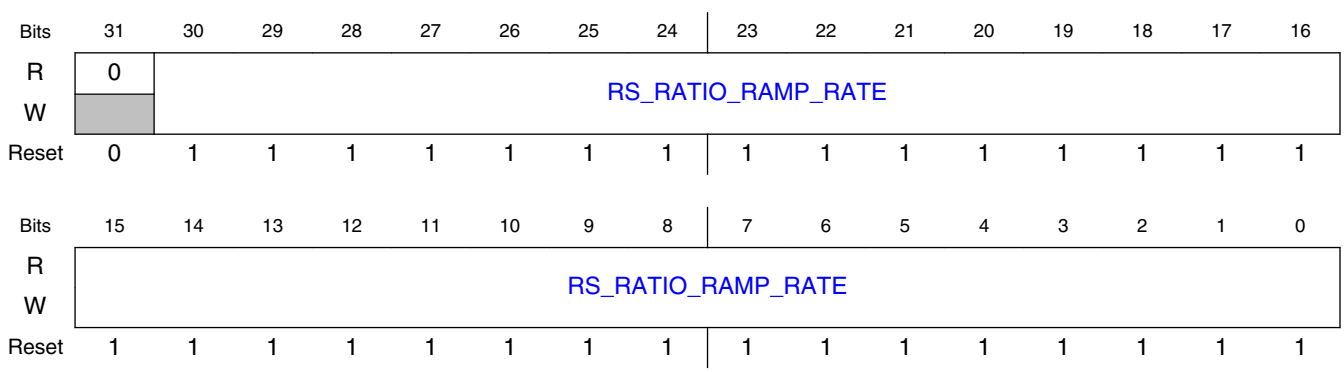
14.5.3.1.21.3 Fields

Field	Description
31-0 RS_RATIO_MOD	Resampling Ratio Modifier The RS_RATIO_MOD register field is a 32-bit two's compliment signed value which is used to adjust the resampling ratio in the ASRC. When a write is performed to this register, the RS_RATIO_MOD will be automatically added to an accumulator containing pending resampling ratio updates. Pending resampling ratio updates are added to the lowest 31-bits of the 44-bit resampling ratio after each output sample time. Note, the rate of change of the resampling ratio is limited by RS_RATIO_RAMP_RATE. If the value programmed in RS_RATIO_MOD is > RS_RATIO_RAMP_RATE then the update will be distributed over RS_RATIO_MOD / RS_RATIO_RAMP_RATE output sample times.



14.5.3.1.22 ASRC Resampling Ratio Update Rate (ASRC_RS_UPDATE_RATE0 - ASRC_RS_UPDATE_RATE3)

The resampling ratio update rate register is used limit the resampling ratio update rate per output sample time.

14.5.3.1.22.1 Offset

Register	Offset

ASRC_RS_UPDATE_RATE1	144h
ASRC_RS_UPDATE_RATE2	148h
ASRC_RS_UPDATE_RATE3	14Ch

14.5.3.1.22.2 Diagram

14.5.3.1.22.3 Fields

Field	Description
31 —	Reserved
30-0 RS_RATIO_RAMP_RATE	Resampling Ratio Ramp Rate The RS_RATIO_RAMP_RATE defines the maximum rate of change for the internal resampling ratio. This is an unsigned value which represents the magnitude of the maximum change to the resampling ratio per output sample time. If the value programmed in RS_RATIO_MOD is > RS_RATIO_RAMP_RATE then the update will be distributed across (RS_RATIO_MOD/RS_RATIO_RAMP_RATE) output sample times. Note, RS_RATIO_RAMP_RATE applies to the lower 31-bits of the 44-bit resampling ratio. This caps the maximum rate of change for the resampling ratio. Note, the specific rate is dependent on the number or taps in the resampler. If there are 128 taps, the max rate of change is max(dFsin/dFsout) = (2^31)/(2^38), in 64 tap mode the limit is (2^31)/(2^39), and in 32-tap mode the limit is (2^31)/(2^40).

14.5.3.1.23 ASRC Resampling Center Tap Coefficient Low (ASRC_RS_CT_LOW)

14.5.3.1.25 ASRC Prefilter Coefficient FIFO (ASRC_PRE_COEFF_FIFO0 - ASRC_PRE_COEFF_FIFO3)

The prefilter coefficient FIFOs store the coefficients used by the ASRC prefilter stage1 (ST1) and stage2 (ST2). Both the ST1 and ST2 filters are designed to be symmetric around the center tap. Each coefficient FIFO contains 192 entries to be shared between the ST1 and ST2 filters. This places a maximum of 394 taps on the number of cumulative filter taps which can be shared between the ST1 and ST2 filter stages. The length of each filter is programmable using the ASRC_CTX_CTRL_EXT2a[STx_NUM_TAPS] register fields. Note, the coefficients are stored in 64-bit floating point format. This requires 2 32-bit register writes to update each coefficient. After a coefficient has been updated, the write pointer will be automatically indexed to the next entry in the FIFO. To reset the FIFO write pointer, toggle the state of ASRC_CTX_CTRL_EXT1a[PF_COEFF_MEM_RST]. By default, a write to this register will update the coefficients for the ST1 filter stage. The ASRC_CTX_CTRL_EXT1a[PF_COEFF_STAGE_WR] bit must be set to 0x1 to write ST2 coefficients for the selected context.

14.5.3.1.25.2 Diagram

14.5.3.1.25.3 Fields

Field	Description
31-0 COEFF_DATA	Coefficient Value For Prefilter Each coefficient FIFO contains up to 192 entries. The coefficients are stored in 64-bit IEEE floating point format. This format contains 1 sign bit, 11 biased exponent bits, and 52 mantissa bits. To modify a single element, two register writes are required starting with the LSBs of the value to be modified. The first access to this register should contain the lower 32-bits of the mantissa, and the second access should contain the sign bit, 11 exponent bits, and upper 20 mantissa bits concatenated. The FIFO pointers are automatically indexed after each access. To reset a FIFO write pointer back to zero, toggle the state of ASRC_CTX_CTRL_EXT1a[PF_COEFF_MEM_RST]. Note, this can also be used to cancel an outstanding 32-bit write operation which isn't complete. The FIFOs can only be written when the associated ASRC_CTX_CTRLa[RUN_EN] is set to 0b0. Writes to this register take lower priority than internal accesses. Wait states will be added on the bus if multiple masters are attempting to access this FIFO at the same time.

14.5.3.1.26 ASRC Context Resampling Coefficient Memory (ASRC_CTX_RS_COEFF_MEM)

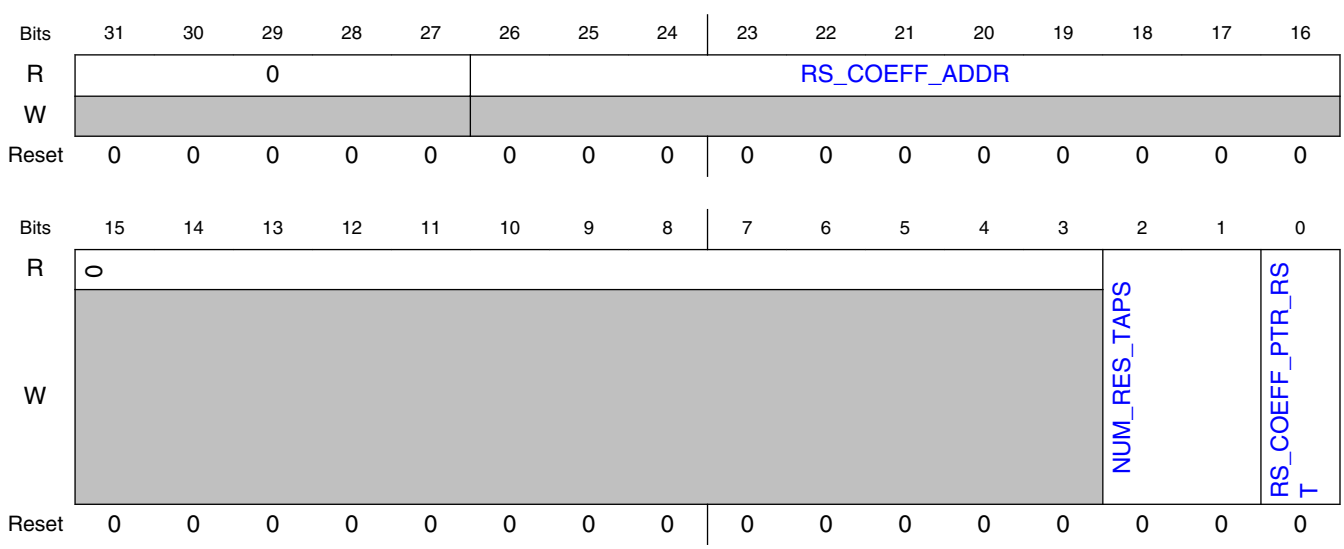
14.5.3.1.26.3 Fields



Field	Description
31-0 RS_COEFF_WDATA	Resampling Coefficient Write Data If NUM_RES_TAPS = 0b00, the resampling coefficient memory contains 16 taps and 128 phase entries per tap. If NUM_RES_TAPS = 0b01, the resampling coefficient memory contains 32 taps and 64 phase entries per tap. If NUM_RES_TAPS = 0b10, the resampling coefficient memory contains 64 taps and 32 phase entries per tap. Each phase entry contains 4 64-bit floating point coefficients. The coefficients can be modified by writing to ASRC_CTX_RS_COEFF_MEM[RS_COEFF_WDATA]. The FIFO pointer (RS_COEFF_ADDR) is automatically indexed after each 256-bit access. To reset the FIFO write pointer back to zero, toggle the state of ASRC_CTX_RS_COEFF_CTRL[RS_COEFF_PTR_RST] from 0b0 to 0b1 and back to 0b0. The FIFO write pointer will be held in reset as long as ASRC_CTX_RS_COEFF_CTRL[RS_COEFF_PTR_RST] is set to 0b1. Note, this can also be used to cancel an outstanding 32-bit write operation which isn't complete. The FIFOs can only be written when all ASRC_CTX_CTRL[RUN_EN] bits in the design are set to 0b0. Each entry in the RAM is 256-bits wide. 8 writes to RS_COEFF_WDATA must be completed prior to a single entry being updated. Writes will be ordered internally from LSB to MSB.

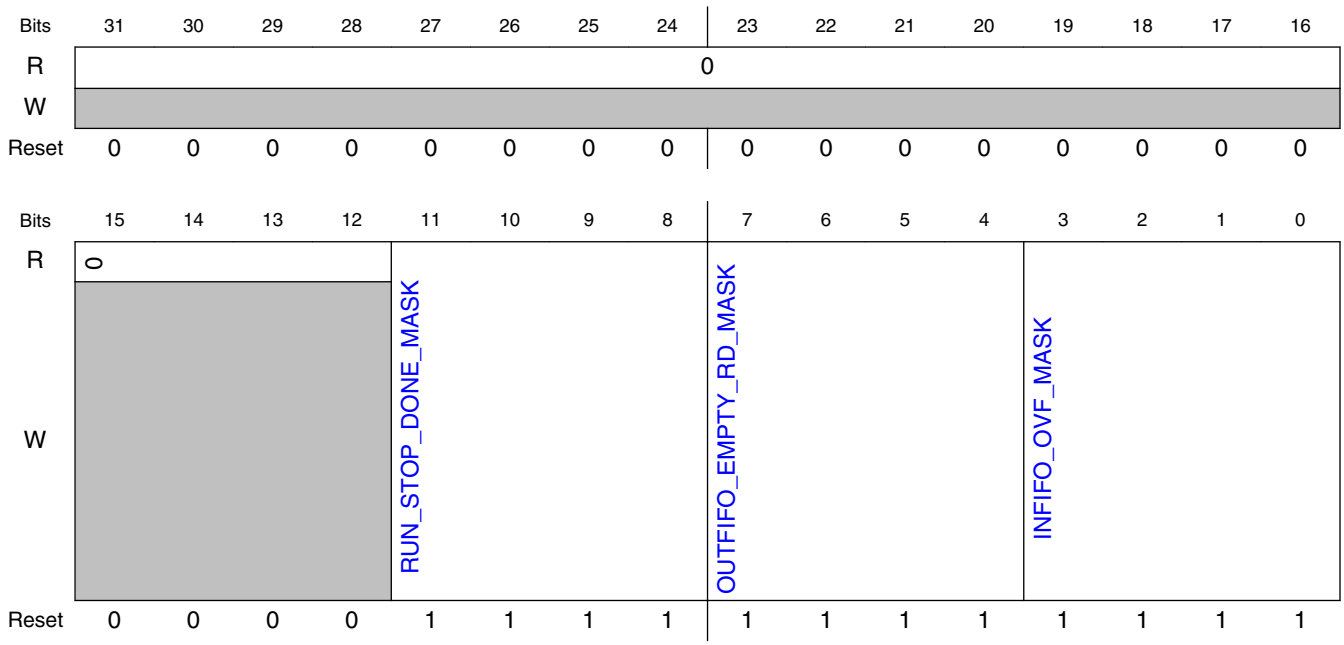
26-16 RS_COEFF_ADDR	Resampling Coefficient Address This is the current resampling coefficient access address being written to with RS_COEFF_WDATA. Note, this address is comprised of two concatenated fields: If NUM_RES_TAPS == 0b00, the address is comprised of {filter_tap[3:0],phase[6:0]} If NUM_RES_TAPS == 0b01, the address is comprised of {filter_tap[4:0],phase[5:0]} If NUM_RES_TAPS == 0b10, the address is comprised of {filter_tap[5:0],phase[4:0]}
15-3 —	Reserved
2-1 NUM_RES_TAPS	Number of Resampling Coefficient Taps The second stage data processing pipeline includes a fractional resampling filter. The number of filter taps and filter coefficients can be selected as 32, 64, or 128. 00 - 32-Tap Resampling Filter 01 - 64-Tap Resampling Filter 10 - 128-Tap Resampling Filter 11 - N/A
0 RS_COEFF_PTR_RST	Resampling Coefficient Write Pointer Reset The FIFO pointers are automatically indexed after each write access to RS_COEFF_WDATA. To reset a FIFO write pointer back to zero, toggle the state of RS_COEFF_PTR_RST. Note, this can also be used to cancel an outstanding 32-bit write operation which isn't complete.



14.5.3.1.28 ASRC Interrupt Control (ASRC_IRQ_CTRL)

The ASRC_IRQ_CTRL register provides the mask bits for all interrupt sources within the ASRC. By default, all interrupt sources are disabled. To enable an interrupt source, the respective mask bit should be clear.

14.5.3.1.28.1 Offset

Register	Offset
ASRC_IRQ_CTRL	178h

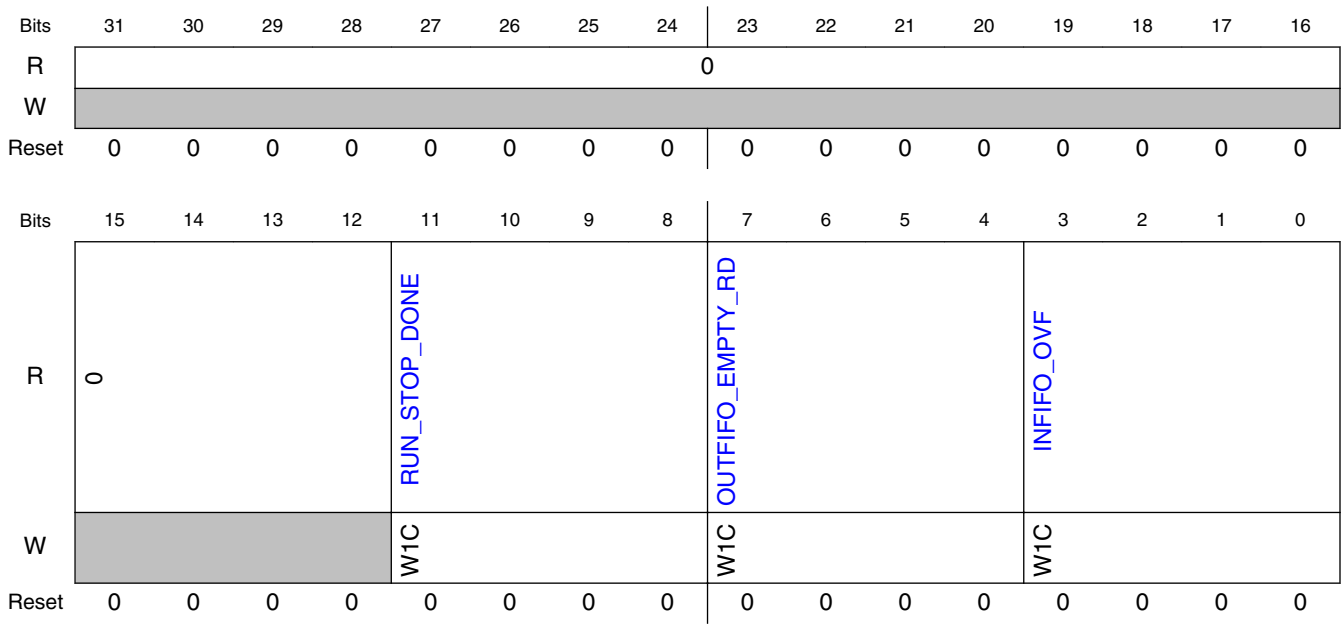
14.5.3.1.28.2 Diagram

14.5.3.1.28.3 Fields

Field	Description
31-12 —	Reserved
11-8 RUN_STOP_DONE_MASK	ASRC RUN STOP DONE MASK The RUN_STOP_DONE flag indicates the previous ASRC_CTX_CTRL[RUN_STOP] operation has been completed. The ASRC context will be IDLE and all output samples will have been written to the output FIFO. Each bit in this register corresponds to a single context. Bit 8 corresponds to Context0, Bit 9 corresponds to Context1, ... The IRQ associated with each context is enabled when it's respective bit position is set to 0b0. 0000 - The RUN_STOP_DONE interrupt is enabled for Context 0 to 3. 0001 - The RUN_STOP_DONE interrupt is disabled for Context 0 and enabled for Context 1 to 3. 0010 - The RUN_STOP_DONE interrupt is disabled for Context 1 and enabled for Context 0, 2, and 3. 0011-1110 - The RUN_STOP_DONE interrupt is enabled for any context with a 1'b0 bit field. 1111 - The RUN_STOP_DONE interrupt is disabled for Context 0 to 3.
7-4 OUTFIFO_EMPTY_RD_MASK	ASRC Output FIFO Empty Read Mask The OUTFIFO_EMPTY_RD flags are triggered if a read is requested from an empty output FIFO. In this case, the return data from the read will be invalid. Note, the ASRC tracks conversions on a sample group granularity. This flag triggers if the sample group being accessed has not been completely written to the FIFO prior to a read being requested. Each bit in this register corresponds to a single context. Bit 4 corresponds to Context0, Bit 5 corresponds to Context1, ... The IRQ associated with each context is enabled when it's respective bit position is set to 0b0. 0000 - The OUTFIFO_EMPTY_RD interrupt is enabled for Context 0 to 3.

Table continues on the next page...

Field	Description
	0001 - The OUTFIFO_EMPTY_RD interrupt is disabled for Context 0 and enabled for Context 1 to 3. 0010 - The OUTFIFO_EMPTY_RD interrupt is disabled for Context 1 and enabled for Context 0, 2, and 3. 0011-1110 - The OUTFIFO_EMPTY_RD interrupt is enabled for any context with a 1'b0 bit field. 1111 - The OUTFIFO_EMPTY_RD interrupt is disabled for Context 0 to 3.
3-0 INFIFO_OVF_MASK	ASRC Input FIFO Overflow Mask The INFIFO_OVF flags are triggered if an input FIFO has overflown. This condition may occur if writes are issued to the ASRC_WRFIFO registers faster then the input samples can be processed by the ASRC internal logic or the ASRC_RDFIFO consumer. Each bit in this register corresponds to a single context. Bit 0 corresponds to Context0, Bit 1 corresponds to Context1, ... The IRQ associated with each context is enabled when it's respective bit position is set to 0b0. 0000 - The INFIFO_OVF interrupt is enabled for Context 0 to 3. 0001 - The INFIFO_OVF interrupt is disabled for Context 0 and enabled for Context 1 to 3. 0010 - The INFIFO_OVF interrupt is disabled for Context 1 and enabled for Context 0, 2, and 3. 0011-1110 - The INFIFO_OVF interrupt is enabled for any context with a 1'b0 bit field. 1111 - The INFIFO_OVF interrupt is disabled for Context 0 to 3.



14.5.3.1.29 ASRC Interrupt Status Flags (ASRC_IRQ_FLAGS)

The ASRC_IRQ_FLAGS register provides the unmasked status flags for all interrupt sources within the ASRC. All status flags are implemented as W1C registers and should be cleared after servicing the interrupt.

14.5.3.1.29.1 Offset

Register	Offset
ASRC_IRQ_FLAGS	17Ch

14.5.3.1.29.2 Diagram

14.5.3.1.29.3 Fields

Field	Description
31-12 —	Reserved
11-8 RUN_STOP_DONE	ASRC RUN STOP DONE FLAG The RUN_STOP_DONE flag indicates the previous RUN_STOP operation has been completed. The ASRC context will be IDLE and all output samples will have been written to the output FIFO. Each bit in this register corresponds to a single context. Bit 8 corresponds to Context0, Bit 9 corresponds to Context1, ... An interrupt will be requested if one of the RUN_STOP_DONE flags are set and the respective RUN_STOP_DONE_MASK bit is cleared. 0000 - No RUN_STOP operations have been completed. 0001 - The RUN_STOP operation for Context 0 has completed. 0010 - The RUN_STOP operation for Context 1 has completed. 0011-1110 - The RUN_STOP operation has completed for any context with a 1'b1 bit field. 1111 - The RUN_STOP operation has completed for Context 0 to 3.
7-4 OUTFIFO_EMPTY_RD	ASRC Output FIFO Empty Read Flag The OUTFIFO_EMPTY_RD flags are triggered if a read is requested from an empty output FIFO. In this case, the return data from the read will be invalid. Note, the ASRC tracks conversions on a sample group granularity. This flag triggers if the sample group being accessed has not been completely written to the FIFO prior to a read being requested. Each bit in this register corresponds to a single context. Bit 4 corresponds to Context0, Bit 5 corresponds to Context1, ... An interrupt will be requested if one of the OUTFIFO_EMPTY_RD flags are set and the respective OUTFIFO_EMPTY_RD_MASK bit is cleared.

Table continues on the next page...

Field	Description
	0000 - No reads have been requested from an empty ASRC_RDFIFO. 0001 - A read has been requested from ASRC_RDFIFO0 when it was empty. 0010 - A read has been requested from ASRC_RDFIFO1 when it was empty. 0011-1110 - A read has been requested from ASRC_RDFIFOn when it was empty. n = any bit position with a 0b1. 1111 - A read has been requested from ASRC_RDFIFO0, ASRC_RDFIFO1, ASRC_RDFIFO2, and ASRC_RDFIFO3 while empty.
3-0 INFIFO_OVF	ASRC Input FIFO Overflow Flag The INFIFO_OVF flags are triggered if an input FIFO has overflown. This condition may occur if writes are issued to the ASRC_WRFIFO registers faster then the input samples can be processed by the ASRC internal logic or the ASRC_RDFIFO consumer. Each bit in this register corresponds to a single context. Bit 0 corresponds to Context0, Bit 1 corresponds to Context1, ... An interrupt will be requested if one of the INFIFO_OVF flags are set and the respective INFIFO_OVF_MASK bit is cleared. 0000 - No INFIFO_OVF errors have been recorded. 0001 - The ASRC_WRFIFO0 has overflown. 0010 - The ASRC_WRFIFO1 has overflown. 0011-1110 - The ASRC_WRFIFOn has overflown. Where n = any bit position set to 0b1. 1111 - ASRC_WRFIFO0, ASRC_WRFIFO1, ASRC_WRFIFO2, and ASRC_WRFIFO3 have overflown.

14.5.3.1.30 ASRC Channel Status 0 (ASRC_CHANNEL_STATUS_00 - ASRC_CHANNEL_STATUS_03)

The ASRC Channel Status registers are used to specify the channel status field used when operating with ASRC_CTX_CTRL[IEC_EN] = 0b1. The channel status registers will be shifted out 1 bit per frame starting from the LSB of ASRC_CHANNEL_STATUS_0 to the MSB of ASRC_CHANNEL_STATUS_5. Note, there is one ASRC_CHANNEL_STATUS_x register per context in the design. ASRC_CHANNEL_STATUS_00 corresponds to context 0, ASRC_CHANNEL_STATUS_01 corresponds to context 1, and so in in this format.

14.6 Enhanced Audio Return Channel (eARC)

14.6.1 Overview

The Audio XCVR module is compliant to the HDMI Specification (version 2.1, dated November 13, 2017). This module supports eARC, ARC and SPDIF modes.

14.6.1.1 Block diagram

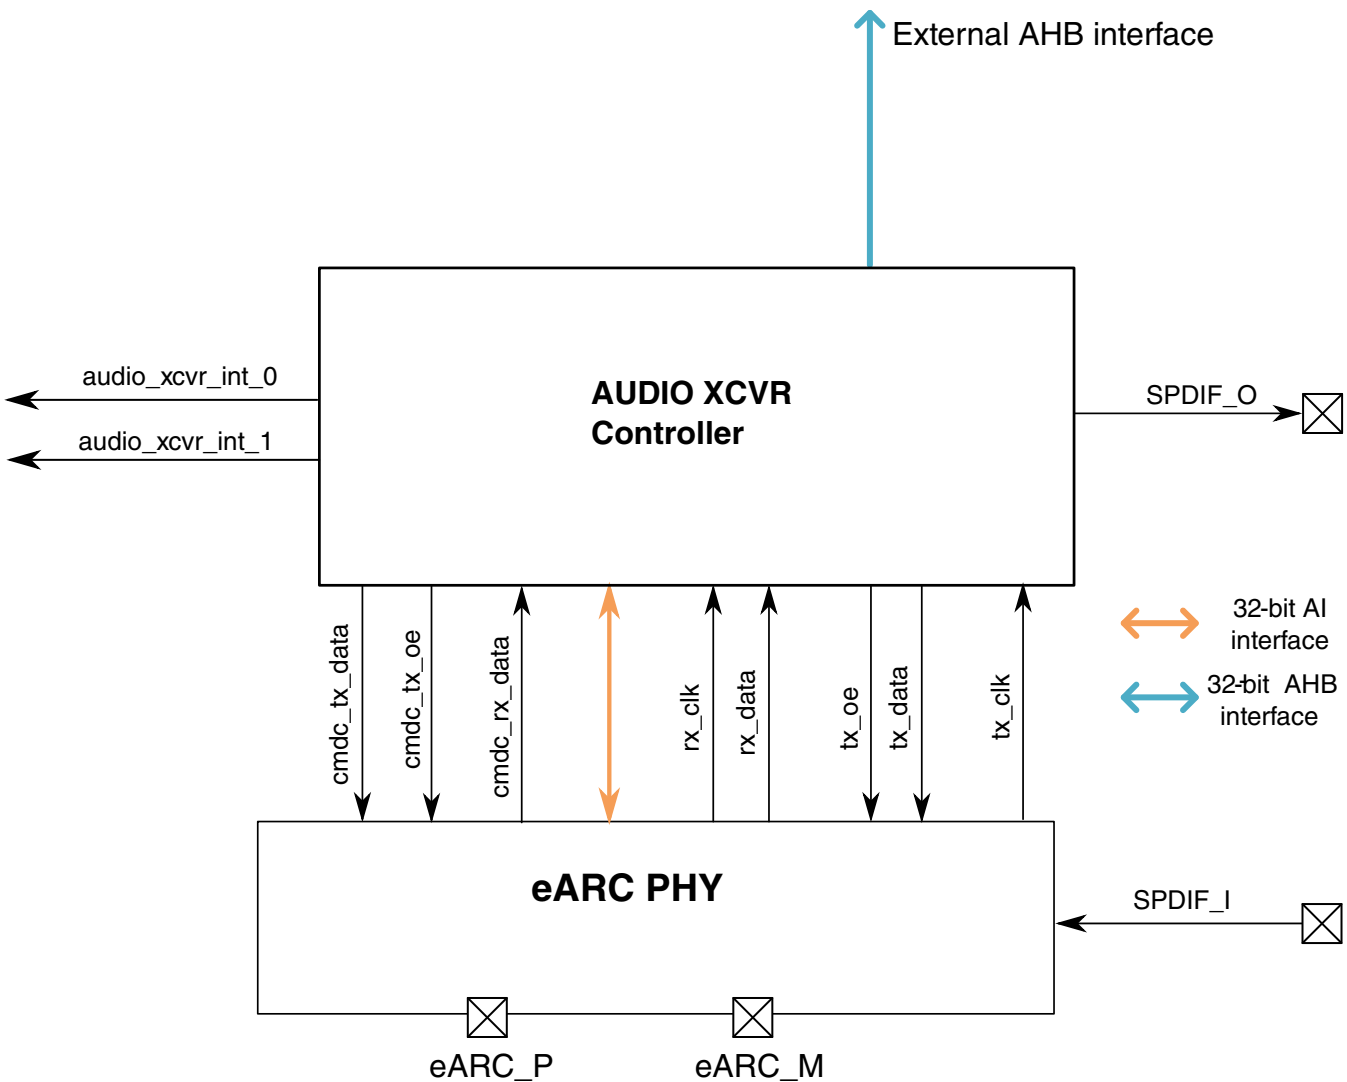

Figure 14-41. EARC block diagram

The main building blocks are:

1. Audio XCVR PHY: Used to receive eARC, SPDIF and ARC data from the +/- eARC pins and from the SPDIF input.

2. Audio XCVR Controller : Used to process the received audio data or the audio data that needs to be transmitted (SPDIF). It also receives and transmits the Common mode data used for establishing an eARC channel.

14.6.1.2 Features

The Audio XCVR module can operate in one of the following modes:

- eARC Receiver:
  - Full support for the eARC specification including all defined audio modes
  - No support for content protection
  - Support for error detection and recovery of audio
- ARC Receiver:
  - Support for up to 192kHz sample rate
  - Support for CEC for ARC backwards compatibility. DDC will be handled by the HDMI TX SS
  - CEC provides a potential system wake-up source
- SPDIF Receiver:
  - Support for 32kHz - 192kHz sample rate
- SPDIF Transmitter:
  - Support for 32kHz - 192kHz data tx rate

14.6.2 Functional description

The following sections describe functional details of the EARC module.

14.6.2.1 Audio data format support

All eARC/ARC/SPDIF message formats use IEC60958 framing. Data is stored in the FIFO in Big endian in 2 possible formats :

1. IEC60958 data that does not need ECC protection.
   - 31:28 - Preamble. For TX, the preamble can be added by HW or stored in the FIFO with the correct value. For RX, the 3rd bit will be replaced by MUTE and 4th bit will be replaced by Parity error if either one is detected.

- 27:4 - TX data
- 3:0 - V,U,C and P. For TX, these bits can be added by HW or stored in the FIFO with the correct value.

Each sub-frame can be stored in memory in the reverse order, bit 31 is stored in position 0 and so on using register bit : FRM_FMT in TX_DATAPATH_CTRL and STORE_FMT in RX_DATAPATH_CTRL.

2. IEC61937 data that requires ECC protection
   - 31:28 - Preamble. For TX, the preamble can be added by HW or stored in the FIFO with the correct value. For RX, the 3rd bit will be replaced by MUTE and 4th bit will be replaced by Parity error.
   - 27:12 - 16 bits of data. (MSB is stored in bit 27)
   - 11:4 - Not used. 8bit's 0.
   - 3:0 - V,U,C and P. For TX, these bits can be added by HW or stored in the FIFO with the correct value.

   Each sub-frame can be stored in memory in the reverse order, bit 31 is stored in position 0 and so on using register bit : FRM_FMT in TX_DATAPATH_CTRL and STORE_FMT in RX_dATAPATH_CTRL.

eARC supports multiple audio formats within the IEC60958-1 framing structure. SPDIF supports L-PCM and compressed audio within the IEC60958-1 framing structure.

Table 14-11. Supported data formats

Interface	Type	Channels	Payload Size	Frame Format
eARC	2-ch LPCM	2	24	IEC60958
	Multi-ch LPCM	2	24	
	Multi-ch LPCM	8	24	
	Multi-ch LPCM	16	24	
	Multi-ch LPCM	32	24	
	One-bit	6	24	
	One-bit	12	24	
	IEC61937 Compressed	Layout A	16 (+8 ECC)	
	IEC61937 Compressed	Layout B	16 (+8 ECC)	
SPDIF	2-ch LPCM	2	16, 20, or 24	IEC60958
	IEC61937 Compressed	Layout A	16 (+8 ECC)	

14.6.2.2 eARC Data Rates

EARC supports high audio bit rates

- Uncompressed audio at 2.048Mbps for 2-ch 32/16

- Uncompressed audio at 36.864Mbps for 8-ch 192/24
- Compressed audio up to 24.576Mbps

In all cases the maximum is 49.152Mbps, or a 768kHz IEC60958-1 Frame rate. Biphase-mark coding and FEM doubles the DMAC frequency to a maximum of 98.304Mbps.

NOTE

- The eARC specification does not specifically identify supported Fs, except for 32, 44.1 and 48kHz 2-ch LPCM.
- The table uses permissible Fs values for HDMI2.1
- L-PCM audio sample rates are maximum 192kHz
- eARC cannot meet the theoretical HDMI support for one-bit (up to 192kHz * 64) due to the 6 or 12-ch grouping

Table 14-12. Supported eARC Data Rates

Type	Channels	Fs (kHz)	Data (Mbps)

14.6.2.3 Functional Operating mode

The AUDIO transceiver hardware can be used without leveraging the M0+ or the code for it. However, the intended use is to use the M0+ to set up the HW and use it to process the data.

The interface is interrupt driven and when the corresponding interrupt is received, FW will release HW from reset and set up the PHY.

The AUDIO XCVR can be operated in eARC RX, ARC RX or SPDIF TX and/or RX. In order to set up the Controller in the various modes, set the following interrupts.

- eARC RX mode: In order to set up the AUDIO_XCVR in eARC_RX mode, load the M0 code and release it from reset. Once HPD is received, FW will enable the PHY and set up the PLL as needed.
- ARC RX mode: In order to set up the PHY and controller in ARC RX mode, assert the ARC single ended mode (IER[23]) or ARC common mode (IER[22]) interrupt. When either of these interrupts are asserted, FW will program the PHY and Controller controller registers.
- SPDIF TX mode: This mode is the same as eARC TX mode. This mode can be set up by asserting IER[21]. Host core will need to program the PHY PLL to output a 2*TX data rate clock.
- SPDIF RX mode: This mode can be set up using IER[20]. This will set up the PHY and Controller registers as needed. SPDIF TX and RX can be operated simultaneously. If this is desired, use IER[19]. The HDMI TX SS PLL will still need to be set up by the host core.

14.6.2.4 Low power modes

The M0+ core can be put on hold / in reset, reducing it's power consumption. Each of the data paths, DATA TX, DATA RX, and CMDC in eARC RX can be put in reset when not being used. This will reduce power consumption from the corresponding data paths.

14.6.2.5 Test modes

The main test modes that are supported by the Audio XCVR controller are the loopback modes for Audio transceiver Data path and eARC CMDC. Loopback tests for all sets of HW can be run separately or a combination of DMAC with CMDC HW. The loopback test is slightly different for CMDC compared to DMAC.

14.6.2.5.1 CMDC Loopback Mode

The below steps indicate how the CMDC can be enabled in loopback mode. Special PHY programming is also required and is listed below.

Start out by enabling the PHY. This is done by programming the PHY using the AI interface. Refer to AI interface for PHY and PLL programming to see how this is done. The PHY can be enabled by first enabling the bandgap in the PLL eARC.PLL - (0x54) = 0x00000001, and then enabling the PHY eARC.PHY (0x4) = 0x00000001. The PHY will take 2 ms to start up. In the meanwhile, program the PLL and the controller using the below steps:

- Release CMDC RX HW from reset. eARC.CTRL (0x18) = 0x60000000 for RX HW
- Set CMDC in loopback mode: EXT_CTRL (0xC4) = 0x80000000 for RX HW

Once the 2 ms are up, program the PHY to TX and RX data simultaneously, and enable data tx in the controller. Read CMDC RX data and compare against data transmitted. If they match, the test passes. Repeat the below steps with different TX_DATA to check for different values

1. Program the PHY to TX and RX CMDC data: eARC.PHY (0x4) = 0x00000012
2. Write CMDC data to be transmit eARC.CTRL (0xE0) = {0x83F0,TX_DATA} for RX datapath and enable the transmit of CMDC data in the controller.
3. Wait for 60 us and read CMDC RX data eARC.CTRL (0xF0) for RX.
4. If the lower 16 bits from step 1 match the received data, the test passes.

Repeat the above steps for a few more patterns. Suggested patterns are: TX_DATA = 0x0000 / 0xFFFF / 0xAAAA

14.6.2.5.2 DMAC loopback mode

DMAC loopback does not need any special modes to be set. The DMAC TX and RX datapaths can be set up as required. The registers don't necessarily need to be set and can be used in the out of reset mode, where the transmitter will insert parity, and preamble before transmitting data. The PHY needs to be programmed to enable receiving data and the HDMI_TX_AVPLL needs to be programmed to send out the max transmit frequency.

Start out by enabling the PHY. This is done by programming the PHY using the AI interface. Refer to AI interface for PHY and PLL programming and follow the steps. The PHY can be enabled by first enabling the bandgap in the PLL eARC.PLL - (0x54) = 0x00000001, and then enabling the PHY eARC.PHY (0x4) = 0x00000001. The PHY will take 2 ms to start up. In the meanwhile, program the PLL and the controller using the below steps:

- Set up the PHY PLL to output Clock 1. Refer to section: Application Information: Programming the PLL

- Set up PLL in HDMI_TX SS to output a frequency of 491.52MHz. The steps for programming the PLL are the same as above. Refer to the HDMI TX SS on registers to write to, to program the PLL. Follow MFI, MFN and MFD values for DMAC TX in PLL programming sequence.
- Do not enable the output clocks until the MUX has been set to select the right clock source
- Once both the PLLs have locked, set the TX clock source in the PHY to use the output of HDMI SS AVPLL eARC.PHY (0x4) = 0x02000000
- Enable the output clocks from the PLL.

Once the 2 ms are up, program the PHY to TX and RX DMAC data simultaneously, (eARC.PHY(0x4) = 0x00000012) and enable data tx in the controller. Once RX data is available, compare against transmit data.

1. Release DMAC TX and RX datapath from reset. eARC.CTRL (0x18) = 0x18000000.
2. Enable DMAC TX and RX datapath in the PHY. eARC.PHY (0x4) = 0x00000012 and eARC.PHY(0x74) = 0x00004000.
3. Load the transmit FIFO with transmit data, by writing to location eARC.CTRL (0xE00). This location will accept upto 128 entries of transmit data. If you wish to transmit more data, dma_wr_req can be used to add more data to the transmit FIFO.
4. Once the data is written to the transmit FIFO, start transmit of data using eARC.CTRL (0x224) = 0x00004000
5. Once 64 entries are available in the receive FIFO, SDMA_RD_REQ will be asserted and the received data can be checked against the transmitted data, by reading it from address 12'hC00. If fewer entries are transmitted, either wait the required amount of time and read entries from the RX FIFO.

At a minimum, test at least 64 entries to make sure enough data is sent and received on the interface.

14.6.2.6 Operating modes

The AUDIO XCVR can be operated in eARC RX, ARC RX or SPDIF TX and/or RX.

In order to set up the Controller in the various modes, set the following interrupts.

- eARC RX mode: In order to set up the AUDIO_XCVR in eARC_RX mode, load the M0 code and release it from reset. Once HPD is received, FW will enable the PHY and set up the PLL as needed.
- ARC RX mode: In order to set up the PHY and controller in ARC RX mode, assert the ARC single ended mode (IER[23]) or ARC common mode (IER[22]) interrupt. When either of these interrupts are asserted, FW will program the PHY and Controller controller registers.

- SPDIF TX mode: Host core will need to program the PHY PLL to output a 2*TX bit rate clock or 10*TX bit rate clock based on selection programmed in TX_DATAPATH_CTRL[10].
- SPDIF RX mode: This mode can be set up using IER[20]. This will set up the PHY and Controller registers as needed. SPDIF TX and RX can be operated simultaneously. If this is desired, use IER[19]. The HDMI TX SS PLL will still need to be set up by the host core.

14.6.2.7 Interrupts

This section describes all the interrupts that the AUDIO XCVR module generates.

1. CMDC interrupts:
   - CMDC_RESP_TO_ERR - This interrupt is asserted if the CMDC response was not sent out in the programmed time frames. Details about which timer expired can be found from EXT_STATUS register bits [26:23]
   - HB_STATE_CHG - Heartbeat state changed. (If heartbeat was first established or if we lose it after it was established)
   - CMDC_STATUS_UPDATE - Set if on read of CMDC STAT reg, status change bit was set (Can be used to read the latency)
   - OHPD - Set if output HPD is set.
2. DMAC Interrupts:
   - RX_NEW_CH_STAT - New channel status was received (Set by M0+)
   - RX_NEW_USR_DATA - New user data was received which passed CRC check. (Set by M0+). EXT_STATUS register holds additional information if it was UD type 4, 5 or 6
   - MUTE_DET - HW Mute detect
   - ECC_ERR - Asserted when an uncorrectable ECC error is received in compressed data mode
   - PREAMBLE_MISMATCH - Asserted when there is an unexpected preamble received / when a preamble was expected but one was not received.
   - FIFO_OFLOW_UFLOW_ERR - This interrupt is asserted if the RX / TX FIFO overflows / underflows.
   - DMAC_NO_DATA_REC - Set after valid frames were received, but then valid data was not received for over 1us.
   - FMT_CHG_DET - No data was received for ~60 ms. Format change is detected.

- PREAMBLE_MATCH_INT - This interrupt is asserted every time a PA PB / CD match is received in compressed data. The information for packet count when this was received and which match occurred can be read from the 4KB data memory location.
- UNEXP_PRE_REC - This interrupt is set if an unexpected preamble is received. If this is received, Host software should reset the RX datapath and wait for the next B preamble to be received.

3. DMA Interrupts:
   - DMA_RD_REQ - Asserted when RX FIFO entries reaches the programmed threshold. (Default = 64 entries, half full)
   - DMA_WR_REQ - Asserted when TX FIFO entries reaches the programmed threshold. (Default = 64 entries, half empty)

14.6.3 Application information

This section describes the applications supported by the Audio XCVR and how to program the registers to support these features.

14.6.3.1 Memory Access

There are 4 sets of memories that can be accessed.

- 16KB of Program Memory
- 4 KB of Data memory
- Register access space and
- TX / RX Data access space.

Since externally only 4 KB of memory space is allocated to the eARC controller, a paging mechanism implemented in the eARC Controller. The first two memories can be accessed as a chunk of 2KB each, while the registers have their own KB of space, and so does the TX/RX data space.

Memory region access can be paged through using the control register EXT_CTRL[19:16]. Bit[19] Separates 16KB memory(= 0) from 4KB memory(= 1). The rest of the bits are used to page through the memories. 16KB memory has 8 pages, while the 2KB memory has 2 pages.

Register access can be achieved when the address to the eARC controller is : 12'b10xx_xxxx_xxxx , where x can be any value.

RX data can be accessed by reading from 12'h110x_xxxx_xxxx. Since the data is read from a FIFO, the actual address does not matter.

TX data can be accessed by reading from 12'h111x_xxxx_xxxx. Since the data is written to a FIFO, the actual address does not matter.

14.6.3.2 Data RAM organization

The 4KB data RAM is allocated for external host access. It stores a range of information listed below:

- CMDC status and latency registers
- Channel status and user data status information
- Double buffered AUDIO channel status
- Double buffered user data information for ACP, ISRC1 and ISRC2 type
- Capability data structure for CMDC
- PA PB preamble match circular FIFO
- Logging

Table 14-13. Data RAM organization

Function	Address	Size (Bytes)	Comment
CMDC Control / Status	0x0	8	Includes CMDC TX and RX status registers along with the Latency and latency request register. Each register occupies a byte in memory. The first 4 bytes are for CMDC in eARC RX mode and the next 4 bytes are for CMDC in eARC TX mode.
Channel Status Control	0x20	8	These two words hold the control register for channel status buffers. These control registers should be set to 0 by host once read. They will only be updated by M0 if cleared. Buffer 0 is always checked first. Only if buffer 0 has not been cleared will buffer 1 be updated. If both buffers are full, the new status will be dropped and an interrupt indicating new channel status value will not be asserted. The non-zero value has 2 fields: • [31] - Update flag • [30:0] - Packet count after the channel status was processed.
User Data (ACP) Control	0x28	8	These two words hold the control register for ACP user data. These control registers should be set to 0 by host once read. They will only be updated by M0 if cleared. Buffer 0 is always checked first. Only if buffer 0 has not been cleared will buffer 1 be updated. If both buffers are full, the new status will be dropped and an interrupt indicating new user data value will not be asserted. The non-zero value has 2 fields: • [31] - Update flag • [30:0] - Packet count after the channel status was processed.
User Data (ISRC1) Control	0x30	8	These two words hold the control register for ISRC1 user data. These control registers should be set to 0 by host once read. They will only be updated by M0 if cleared. Buffer 0 is

Table continues on the next page...

Table 14-13. Data RAM organization (continued)

Function	Address	Size (Bytes)	Comment
			always checked first. Only if buffer 0 has not been cleared will buffer 1 be updated. If both buffers are full, the new status will be dropped and an interrupt indicating new user data value will not be asserted. The non-zero value has 2 fields: • [31] - Update flag • [30:0] - Packet count after the channel status was processed.
User Data (ISRC2) Control	0x38	8	These two words hold the control register for ISRC2 user data. These control registers should be set to 0 by host once read. They will only be updated by M0 if cleared. Buffer 0 is always checked first. Only if buffer 0 has not been cleared will buffer 1 be updated. If both buffers are full, the new status will be dropped and an interrupt indicating new user data value will not be asserted. The non-zero value has 2 fields: • [31] - Update flag • [30:0] - Packet count after the channel status was processed.
Channel Status Buffers	0x80	64	The channel status buffers are aligned to 32-bytes. The last 8 bytes are empty. Each buffer corresponds with the associated channel status control field. When a new block of data has a channel status update, the buffer that is empty is updated and an interrupt is asserted to the host. Buffer 0 is always checked first.
User data (ACP) Buffers	0xC0	64	The user data buffers are aligned to 32 bytes. IU1,2,3 and byte 1 of the remainder of the IUs are not stored. Each buffer corresponds with the associated user data control field. When a new User data message is received, and it passes CRC checks, the buffer that is empty is updated and an interrupt is asserted to the host. Buffer 0 is always checked first.
User data (ISRC1) Buffers	0x100	64	The user data buffers are aligned to 32 bytes. IU1,2,3 and byte 1 of the remainder of the IUs are not stored. Each buffer corresponds with the associated user data control field. When a new User data message is received, and it passes CRC checks, the buffer that is empty is updated and an interrupt is asserted to the host. Buffer 0 is always checked first.
User data (ISRC2) Buffers	0x140	64	The user data buffers are aligned to 32 bytes. IU1,2,3 and byte 1 of the remainder of the IUs are not stored. Each buffer corresponds with the associated user data control field. When a new User data message is received, and it passes CRC checks, the buffer that is empty is updated and an interrupt is asserted to the host. Buffer 0 is always checked first.
Capabilities data structure	0x300	256	Capability data structure is maximum 256 bytes.

14.6.3.3 PLL Programming Sequence

The pll programmed frequency value will be: PLL frequency = 24 * I (Integer) + (N (Numerator) / D (Denominator))

PLL can be programmed using the below sequence. If programming the PLL for eARC PHY, the first step can be skipped as it is included with enabling the PHY.

1. Enable the bandgap: eARC.PLL (0x54) = 0x00000001
2. Wait for at least 50 us to allow for the bandgap to stabilize the voltage and current reference for the PLL. In the meanwhile, program the PLL I, N and D to desired values
   - Numerator can be programmed by writing to eARC.PLL (0x20)
   - Denominator can be programmed by writing to eARC.PLL (0x30)
   - Integer can be programmed by writing to eARC.PLL (0x4)[6:0]. In order to update this field, always clear the 7 bits first and then set them with the desired value.
3. Assert power up in the PLL eARC.PLL (0x4) = 0x00003000.
4. Wait for 25 us to allow the ring oscillator to settle down.
5. Disable hold ring by clearing the hold bit: eARC.PLL (0x8) = 0x00002000.
6. Wait for 75 us for the PLL to lock. In the mean while, set up the post dividers. eARC.PLL (0x40) bits [2:0] - for clk0, bits [6:4] - for clk1, and bits [10:8] - for clk2.
7. Once the PLL s have locked, make sure to select the right clock source in the PHY before enabling the PLL clocks using bits [26:24] in eARC.PLL (0x4) for clock 2,1 and 0 respectively.

Typical PLL programming values for different use cases:

- For TX Datapath - If only SPDIF TX function is desired, select Clock 0. Set the frequency to 10*(data TX rate) or 2*(data TX rate) for SPDIF TX. If Simultaneous SPDIF TX and RX is desired, use an alternate clock source of HDMI TX AVPLL / Audio SS PLL for SPDIF TX. Set eARC.CTRL(0x0) = 0x02000000 for HDMI TX SS and 0x04000000 for AUDIO SS PLL clock source.
- For DMAC RX / Loopback mode - Select Clock 1. The desired frequency is 1.3GHz. I = 0x36, N = 0x1, D = 0x6. Post divider value [6:4] = 0x0.
- For SPDIF RX - Select clock 2. The desired frequency is 175 MHz. I = 0x1D, N = 0x1, D = 0x6. post Divider value [10:8] = 0x2.

14.6.3.4 Common Mode Data Channel (CMDC)

CMDC is a bi-directional protocol that is used to establish the earc channel, transmit and receive capabilities data structure and exchange latency information. CMDC functions are different for source / sink modes. CMDC in source mode can be brought out of reset using EXT_CTRL.CMDC_RX_REST. The clock to 1us ratio needs to be programmed into the CLK_CTRL register. The default value is for a 400MHz clock. This value is used as a reference for various timers needed by CMDC protocol.

When CMDC is used as the source, host core should update the value in CAP_CHG every time it updates the capabilities data structure. If host core has an update in the RX latency value, it should update the value of STAT_CHG in 4KB memory to let the sink know there is a new value that should be read.

14.6.3.5 Audio Receiver Overview

The Audio RX datapath is held in reset until host core decides to release the HW out of reset to start receiving IEC60958 data. This feature helps save power when specific datapaths are not being used. The PHY transmits DMAC clock and DMAC data over to the controller. SPDIF and ARC data is muxed over on the same signals along with an enable strobe. The data sent over is Bipphase Mark Encoded (BME) and needs to be decoded into subframes.

CMDC interface sees the HPD asserted and responds by sending out the comma pattern. Once heartbeat is achieved, data can be received. There are no HW gates for this. As soon as the RX datapath is released from reset, it is capable of receiving data. The RX datapath can be controled by RX_DATAPATH_CTRL register. Configurations are listed below:

- FSM: The input data stream can be received when aligned to either the B preamble, M preamble, or the M/W preambles. By default, the input stream is set to sync to the B preamble. Change this register setting to align to M/W input preamble.
- COMP and PRC: Compressed data mode can either be detected by HW or enabled by SW. COMP bit selects between HW / SW control of PRC bit HW detection of compressed mode is selected. In this mode, compressed data is detected by matching the first 3 Channel status bits with CBITE and mask CBITM. Once a match is detected, PRC bit is set by HW. If SW mode is selected, SW can set PRC to enable ECC correction and de-interleaving of data frames once the corresponding channel status bits match compressed mode.
- STORE_FMT: Format to store the received data in memory. If this bit is 0, the first bit received in a sub frame is stored in bit position 31. Else, it is stored in bit position 0. The rest of the bits follow the first bit.
- EN_PARITY_CALC: This bit enables parity evaluation. If Parity evaluation fails, bit 4 of the preamble is replaced with 1.
- MUTE_MODE: Mute mode selects between HW detection of MUTE mode and FW enabling Mute. By default, HW mode is set. In this mode, mute is detected by looking at channel status of frame number programmed in MBIT. If SW control is enabled, mute is asserted using MUTE_CTRL. Preamble bit 1 is replaced by

- BLKS: This bit enables blocking audio data that is in compressed mode. Compressed data output can be blocked if Audio XCVR is connected to ASRC and processing L-PCM. If this bit is set, compressed data is blocked and RX audio data sent to the RX fifo is all 0's. Preamble and VUCP bits are preserved.
- LAYB: Layout B handler. This bit is set by HW when compressed data is indicated by PRC. When layout B is detected by parsing the Channel Status registers, only %4 frames are stored starting from the next block of data.
- PABS and DTS_CDS: Pa Pb and DTS CD 14 search can be enabled using these register bits. When enabled, compressed mode data is parsed for a frame match of the values programmed in DMAC_PRE_MATCH_VAL and DMAC_DTS_PRE_MATCH_VAL. The match reference values can be found in registers DMAC_PRE_MATCH_VAL and DMAC_DTS_PRE_MATCH_VAL respectively. When a match is detected, the packet count along with the match type is committed to a FIFO and can be read from DMAC_PRE_MATCH_OFFSET.
- Performance counter: The Audio Receiver path supports a performance/progress counter. This is essentially 2 counters, one running at the highest clock speed available to the block and the other at the audio bit rate. The high speed counter is latched twice, once on every bit clock transition and again when the bit clock counter is read to guarantee a synchronized read.
- Packet counter: The packet counter keeps track of all the sub-frames written to the output FIFO. It is a rolling counter used to keep a reference of the number of frames received.

Channel status and user data buffers are stored per block. Once the data is processed, an interrupt to the host core is asserted if the Channel status does not match the last channel status value. For user data, the type of user data is compared against the previously received user data of that type. If a difference is noticed, CRC is calculated and if the user data chunk of 47 IUs passes CRC, the host core is interrupted. The host core can read this channel status / user data from the 4KB memory with the offsets listed below.

- Channel Status : Offset 0x80
- User Data type 4 : Offset 0xC0
- User Data type 5 : Offset 0x100
- User Data type 6 : Offset 0x140

Channel status and user data values can be reset by FW using RX_DATAPATH_CTRL.CSR and RX_DATAPATH_CTRL.UDR.

14.6.3.6 Audio Transmitter Overview

The Audio transmitter can output data in the SPDIF format. In order to transmit data, the PLL Frequency for clk root 0, needs to be programmed to 5* data TX rate or 1* data TX rate, depending on the mode selected. If transmit datapath needs to be enabled, it should be released from reset using EXT_CTRL.TX_DPATH_RESET. If TX datapath is not released from reset, data entries should not be written to the TX FIFO. TX can now be enabled using TX_DATAPATH_CTRL.STRT_DATA_TX. Once this bit is set, HW will start transmitting data in the TX FIFO. If the FIFO does not have watermark number of entries, HW will assert a dma_wr_req. Care should be taken to make sure the FIFO does not underrun.

The Audio transmitter consists of the following features that can be enabled in TX_DATAPATH_CTRL register.

- EN_PREAMBLE: If this bit is set, preamble matching the frame count is inserted in the TX sub-frame. TX always starts with a B preamble.
- CS_MOD and UD_MOD: These register bits are used to modify the channel status and user data values programmed in the TX FIFO. The channel status and user data replacement values should be programmed in TX_CS_DATA_BITS and TX_USER_DATA_BITS buffers on a block boundary. These registers have an ACK value in UD_ACK and CS_ACK. FW should not write to the data buffers if the ACK bits are not 0. Once FW writes to the registers, the ACK bits should be set so HW can read the new values when it starts transmitting the next block of data. These bits will be cleared by HW when the value in TX_CS_DATA_BITS and TX_USER_DATA_BITS have been moved to a secondary register.
- VLD_MOD and FRM_VLD: These register bits are used to modify the valid field programmed in the TX FIFO. If VLD_MOD is set, Valid bit in the TX frames is replaced by the value in FRM_VLD.
- EN_PARITY: This bit is used to calculate the parity over the data and VUC bits and replace the parity bit of the frame.
- EN_ECC_INTER: If this bit is set, Error correction bits are inserted into the TX frame and then a pair of sub-frames are interleaved.
- TX_CLK_RATE: If this bit is set, output data will be generated by using a clock that is 2* BME bit rate. If this bit is not set, output data will be generated by using a clock that is 10* BME bit rate.
- FRM_FMT: This bit indicates if the preamble is stored in bits 3:0 or 31:28

14.6.4 Memory Map and register definition

This section includes the EARC module memory map and detailed descriptions of all registers.

14.6.4.1 EARC register descriptions

14.6.4.1.1 EARC memory map

eARC base address: 30CC_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)

1D8	Receive datapath Bit count timestamp register. (RX_DPATH_BCTR)	32	RO	0000_0000
1DC	Receive datapath Bit read timestamp register. (RX_DPATH_BCRR)	32	RO	0000_0000
1E0	Preamble match value register (DMAC_PRE_MATCH_VAL)	32	RW	4E1F_F872
1E4	Preamble match value register (DMAC_PRE_MATCH_VAL_SET)	32	RW	4E1F_F872
1E8	Preamble match value register (DMAC_PRE_MATCH_VAL_CLR)	32	RW	4E1F_F872
1EC	Preamble match value register (DMAC_PRE_MATCH_VAL_TOG)	32	RW	4E1F_F872
1F0	Preamble match value register (DMAC_DTS_PRE_MATCH_VAL)	32	RW	1387_FE1C
1F4	Preamble match value register (DMAC_DTS_PRE_MATCH_VAL_SET)	32	RW	1387_FE1C
1F8	Preamble match value register (DMAC_DTS_PRE_MATCH_VAL_CLR)	32	RW	1387_FE1C
1FC	Preamble match value register (DMAC_DTS_PRE_MATCH_VAL_TOG)	32	RW	1387_FE1C
200	Error count for IEC60958-1 Block Synchronization. (RX_DPATH_PRE_ERR)	32	RW	0000_0000
204	Parity Error count for IEC60958-1 Blocks. (RX_DPATH_PARITY_ERR)	32	RW	0000_0000
210	Receive Data packet count. (RX_DPATH_PKT_CNT)	32	RO	0000_0000
214	Receive Data packet Corrected error count. (RX_DPATH_ONE_BIT_ERR_CNT)	32	RO	0000_0000
218	Preamble match offset value register (DMAC_PRE_MATCH_OFFSET)	32	RO	0000_0000
220	Transmit Data path control register (TX_DATAPATH_CTRL)	32	RW	0000_0000
224	Transmit Data path control register (TX_DATAPATH_CTRL_SET)	32	RW	0000_0000
228	Transmit Data path control register (TX_DATAPATH_CTRL_CLR)	32	RW	0000_0000
22C	Transmit Data path control register (TX_DATAPATH_CTRL_TOG)	32	RW	0000_0000

Table continues on the next page...

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
230 - 244	Channel staus bits (TX_CS_DATA_BITS_0 - TX_CS_DATA_BITS_5)	32	RW	0000_0000
248 - 25C	User data bits (TX_USER_DATA_BITS_0 - TX_USER_DATA_BITS_5)	32	RW	0000_0000
260	DMAC counter control register (TX_DPATH_CNTR_CTRL)	32	RW	0000_0000
264	DMAC counter control register (TX_DPATH_CNTR_CTRL_SET)	32	RW	0000_0000
268	DMAC counter control register (TX_DPATH_CNTR_CTRL_CLR)	32	RW	0000_0000
26C	DMAC counter control register (TX_DPATH_CNTR_CTRL_TOG)	32	RW	0000_0000
270	Transmit Datapath Timestamp Counter Register (TX_DPATH_TSCR)	32	RO	0000_0000
274	Transmit Datapath Bit counter register (TX_DPATH_BCR)	32	RO	0000_0000
278	Transmit datapath Bit count timestamp register. (TX_DPATH_BCTR)	32	RO	0000_0000
27C	Transmmit datapath Bit read timestamp register. (TX_DPATH_BCRR)	32	RO	0000_0000
2A0	HPD Debounce Control Register (HPD_DBNC_CTRL)	32	RW	0003_0D40
2A4	HPD Debounce Control Register (HPD_DBNC_CTRL_SET)	32	RW	0003_0D40
2A8	HPD Debounce Control Register (HPD_DBNC_CTRL_CLR)	32	RW	0003_0D40
2AC	HPD Debounce Control Register (HPD_DBNC_CTRL_TOG)	32	RW	0003_0D40

14.6.4.1.2 Version control register (VERSION)

Indicates the version of Audio XCVR

14.6.4.1.2.1 Offset

Register	Offset
VERSION	0h

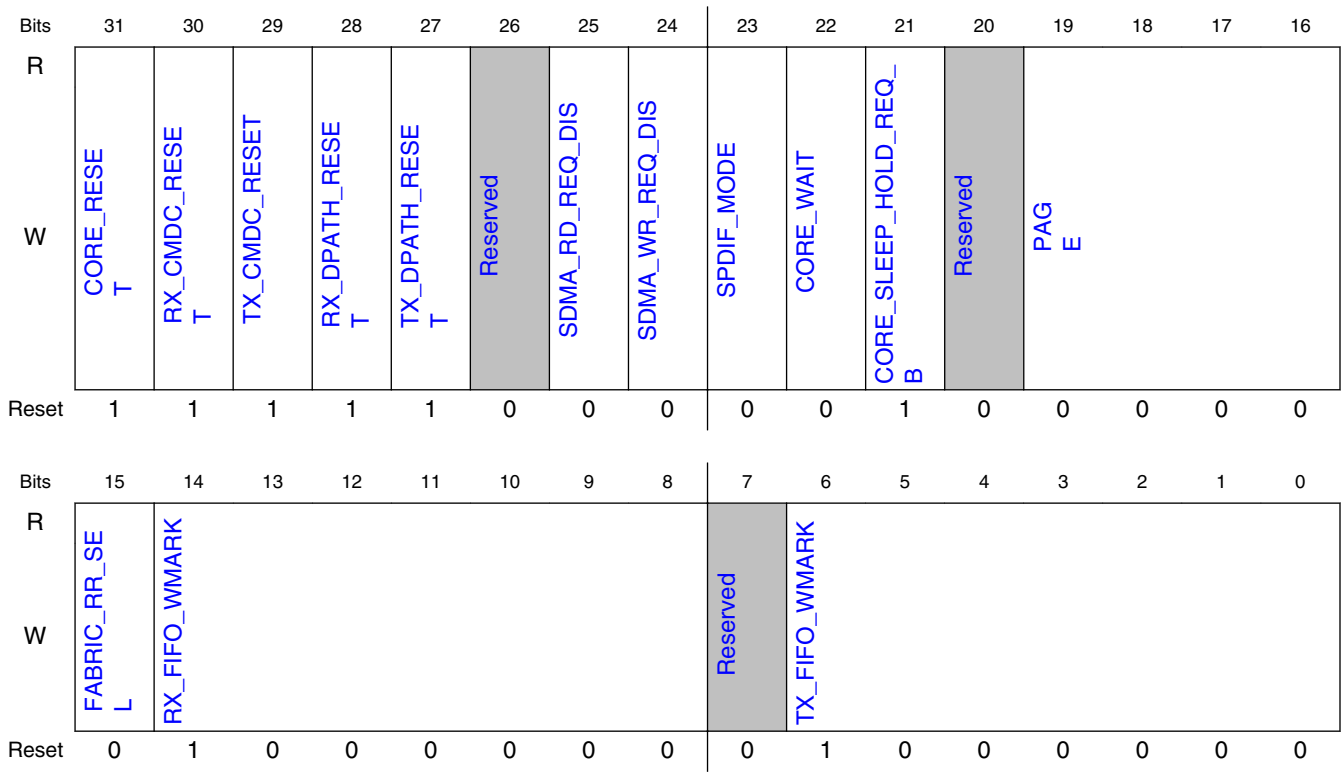
14.6.4.1.2.3 Fields

Field	Description
31-0 VERID	Version ID Indicates the version of Audio XCVR



14.6.4.1.3 External control register (EXT_CTRL)

This register provides host control registers for the Audio XCVR

14.6.4.1.3.1 Offset

Register	Offset	Description
EXT_CTRL	10h	External control register
EXT_CTRL_SET	14h	Writing a 1 to a bit in this register sets the corresponding bit in EXT_CTRL
EXT_CTRL_CLR	18h	Writing a 1 to a bit in this register clears the corresponding bit in EXT_CTRL
EXT_CTRL_TOG	1Ch	Writing a 1 to a bit in this register toggles the corresponding bit in EXT_CTRL

14.6.4.1.3.2 Diagram

14.6.4.1.3.3 Fields

Field	Description
31 CORE_RESET	M0+ Reset Controls the reset to the M0+ core. Allows external host to keep M0+ under reset until memory and control registers are configured. Reset is asserted when '1' is written to this bit. Software must allow 8 or more clock cycles before clearing this bit to allow for reset synchronization and propagation.
30 RX_CMDC_RESET	Soft reset to the eARC Common mode Receiver Receive datapath is reset when '1' is written to this bit. Software must allow 8 or more clock cycles before writing a '0' to this bit to allow for reset synchronization and propagation. In SPDIF and ARC modes, this reset can be asserted to save some power.
29 TX_CMDC_RESET	Soft reset to the eARC Common mode Transmitter Transmit datapath is reset when '1' is written to this bit. Software must allow 16 or more clock cycles before writing a '0' to this bit to allow for reset synchronization and propagation. In SPDIF and ARC modes, this reset can be asserted to save some power.
28 RX_DPATH_RESET	Soft reset to the eARC Differential data Receiver Receive datapath is reset when '1' is written to this bit. Software must allow 8 or more clock cycles before writing a '0' to this bit to allow for reset synchronization and propagation.
27 TX_DPATH_RESET	Soft reset to the Datapath for Transmit Transmit datapath is reset when '1' is written to this bit. Software must allow 8 or more clock cycles before writing a '0' to this bit to allow for reset synchronization and propagation.

Table continues on the next page...

Field	Description
26 —	Reserved
25 SDMA_RD_REQ_DIS	SDMA RD REQ disable This bit field is used to disable SDMA read requests.
24 SDMA_WR_REQ_DIS	SDMA WR REQ disable This bit field is used to disable SDMA write requests.
23 SPDIF_MODE	Indicates SPDIF output mode. If Set, SPDIF data is transmitted.
22 CORE_WAIT	Stop executing code If Set, the core will not execute code, but rather go into WAIT mode.
21 CORE_SLEEP_HOLD_REQ_B	Hold core from going to sleep mode when 0. If not set, the core will not go into sleep mode.
20 —	Reserved
19-16 PAGE	Page Select. Selects 2KB memory that can be accessed by the external interface. Bit 19 is used to pick between the 16KB memory VS the 4KB memory. • 0000 - 16 KB memory, where the 1st 2 KBs are accessible • 0001 - 16 KB memory, where the 2nd 2 KBs are accessible • ... • 0111 - 16 KB memory, where the 8th 2 KBs are accessible • 1000 - 4 KB memory, where the 1st 2 KBs are accessible • 1001 - 4 KB memory, where the 2nd 2 KBs are accessible • 1010 - 1111 - Reserved
15 FABRIC_RR_SEL	Selects Arbitration mode of crossbar switch. This bit selects the Arbitration mode of the cross bar switch. • 0 - M0 core has priority over external core. • 1 - Round Robin Arbitration between M0 core and external master
14-8 RX_FIFO_WMARK	Audio Receive FIFO Watermark Level Indicates the watermark level (number of 32-bit words) at and above which a FIFO read request will be generated Reset to 1/2 the FIFO size. • 0 - Not Applicable • 1 - 127 - Valid values
7 —	Reserved
6-0 TX_FIFO_WMARK	Audio Transmit FIFO Watermark Level Indicates the watermark level (number of 32-bit words) at and below which a FIFO write request will be generated. Reset to 1/2 the FIFO size. • 0 - Not Applicable • 1 - 127 - Valid values

14.6.4.1.4 External Status register (EXT_STATUS)

This register provides status to the host controller

14.6.4.1.4.1 Offset

Register	Offset	Description
EXT_STATUS	20h	External Status register
EXT_STATUS_SET	24h	Writing a 1 to a bit in this register sets the corresponding bit in EXT_STATUS
EXT_STATUS_CLR	28h	Writing a 1 to a bit in this register clears the corresponding bit in EXT_STATUS
EXT_STATUS_TOG	2Ch	Writing a 1 to a bit in this register toggles the corresponding bit in EXT_STATUS

14.6.4.1.4.2 Diagram

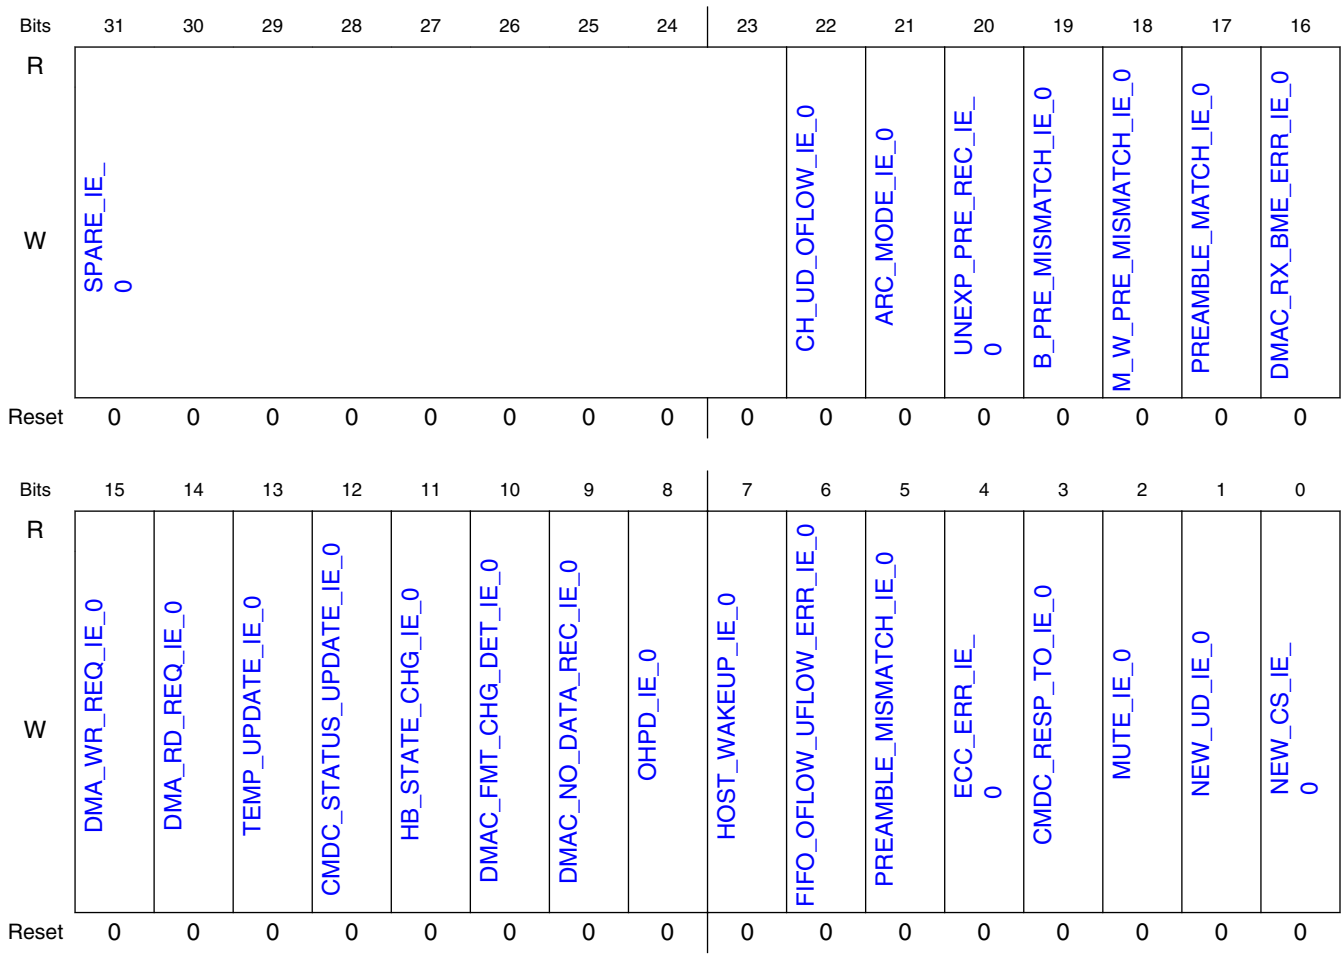
14.6.4.1.4.3 Fields

Field	Description
31 HPD_I	HPD Input status This status provides the read of the HPD input.

Table continues on the next page...

Field	Description
30 NEW_UD6_REC	New user data This bit indicates new user data of type 6
29 NEW_UD5_REC	New user data This bit indicates new user data of type 5
28 NEW_UD4_REC	New user data This bit indicates new user data of type 4
27 HEARTBEAT_STATUS	Earc Connection Status This bit indicates a heartbeat was successfully exchanged within the given timeframe. If this bit is not set, check DEBUG register for CMDC state.
26 —	Reserved
25 RX_CMDC_COMMA_TO	Receiver CMDC comma timeout Interrupt This interrupt indicates the receiver CMDC comma sequence did not result in a successful heartbeat. This interrupt is sent to the host core on CMDC_TO_ERR.
24 —	Reserved
23 RX_CMDC_RESP_TO	CMDC Response not sent in programmed time This bit indicates RX CMDC respose could not be sent out by M0 core in the required timeframe. This interrupt is sent to the host core on CMDC_TO_ERR.
22 —	Reserved
21 TX_PIPE_EMPTY	Indicates TX pipe status. This status bit is used to indicate TX pipeline is empty. This can be used to determine if new block of data can be sent / Frequency can be updated.
20-19 —	Reserved
18 CM0_SLEEP_HOLD_ACK_B	Sleep extension acknowledge.
17 CM0_DEEP_SLEEP	CM0 is in deep sleep mode. Using this bit, the eARC clock into the core can be gated for power savings.
16 CM0_SLEEPING	CM0 is in Sleep mode. Using this bit, the eARC clock into the core can be gated for power savings.
15-8 NO_RX_FIFO_ENTRIES	RX FIFO entries This status provides the number of entries in the receiver FIFO
7-0	TX FIFO entries This status provides the number of entries in the transmit FIFO

Field	Description
NO_TX_FIFO_ENTRIES	



14.6.4.1.5 Interrupt enables for interrupt 0 (EXT_IER0)

Provides enable bits to enable interrupt 0 generation. All enables are active high. Interrupt enables for bits 22 - 31 are reserved for future use

14.6.4.1.5.1 Offset

Register	Offset	Description
EXT_IER0	30h	Interrupt enables for interrupt 0
EXT_IER0_SET	34h	Writing a 1 to a bit in this register sets the corresponding bit in EXT_IER0
EXT_IER0_CLR	38h	Writing a 1 to a bit in this register clears the corresponding bit in EXT_IER0
EXT_IER0_TOG	3Ch	Writing a 1 to a bit in this register toggles the corresponding bit in EXT_IER0

14.6.4.1.5.2 Diagram

14.6.4.1.5.3 Fields

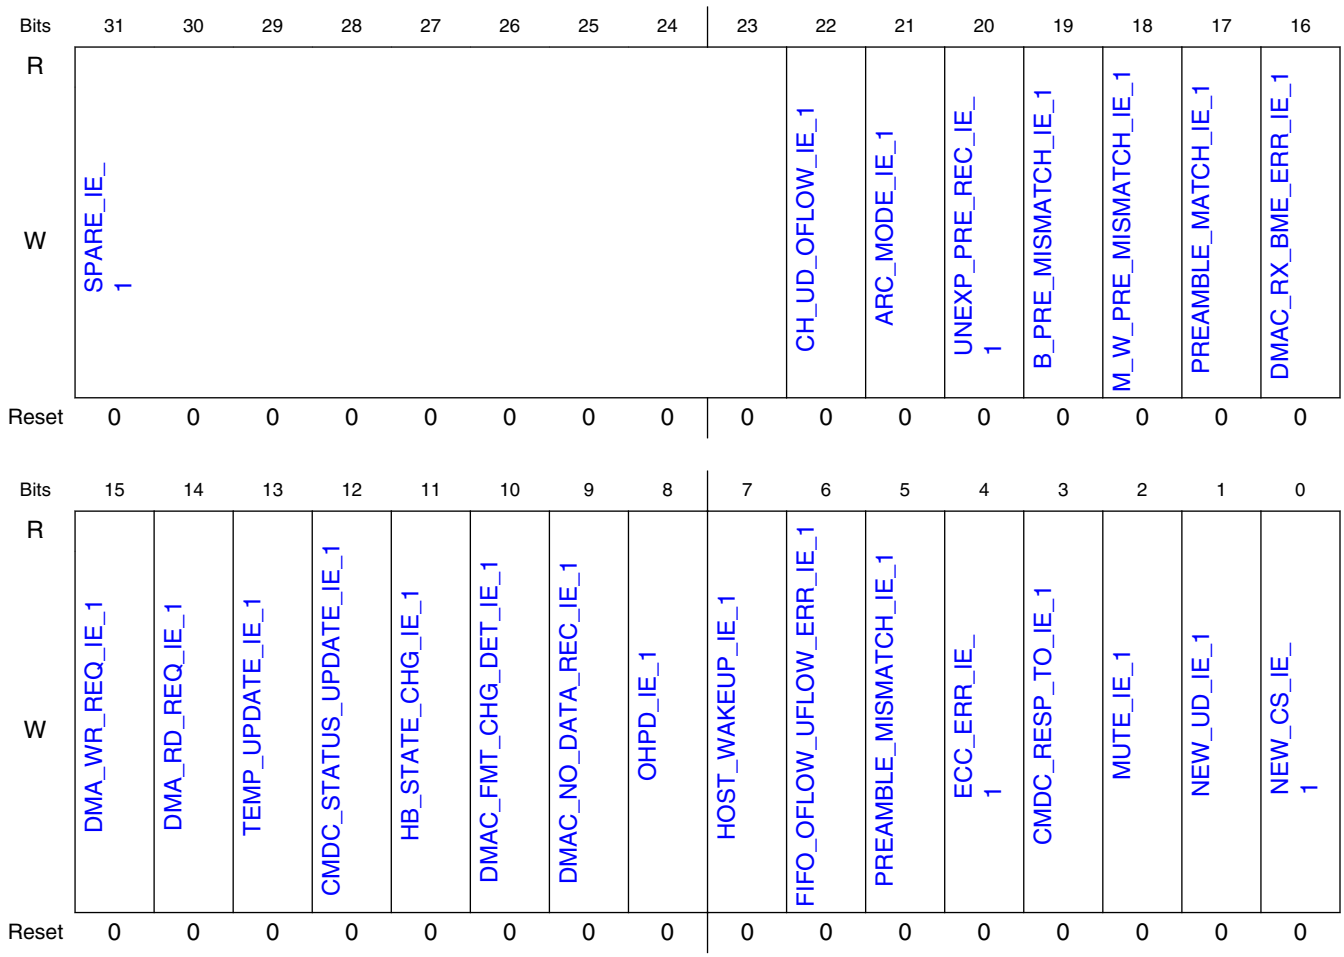
Field	Description
31-23 SPARE_IE_0	Spare interrupts These spare interrupts can be set by M0+.
22 CH_UD_OFLOW_IE_0	Channel status or used data could not be stored. This interrupt enables channel status or user data overflow interrupt. This interrupt is asserted when FW is unable to store user data or channel status because the previous entries were not cleared.
21 ARC_MODE_IE_0	Interrupt to indicate ARC mode setup. This interrupt enables SEL_ARC_MODE interrupt indicating eARC RX state machine could not establish a heartbeat. Check to see if ARC mode needs to be set up.
20 UNEXP_PRE_REC_IE_0	Interrupt enable for Unexpected preamble received. This enables the interrupt to be asserted everytime HW detects a preamble was not received when expected or more than 8 bits were received before a preamble was detected.
19	Interrupt enable for sub-frame B preamble mismatch received.

Table continues on the next page...

Field	Description
B_PRE_MISMATCH_IE_0	This enables the interrupt to be asserted everytime HW detects a B sub-frame preamble mismatch.
18	Interrupt enable for sub-frame M/W preamble mismatch received.
M_W_PRE_MISMATCH_IE_0	This enables the interrupt to be asserted everytime HW detects a M/W sub-frame preamble mismatch.
17	Interrupt enable for preamble match received.
PREAMBLE_MATCH_IE_0	This enables the interrupt to be asserted everytime HW detects a preamble match and FW moves the data to memory and asserts the interrupt.
16	Bi-phase mark encoding error
DMAC_RX_BME_ERR_IE_0	This enables the interrupt to be asserted everytime Bi-phase mark encoded data received has an error. i.e. No toggle after 2 bits.
15	Request to write data to FIFO.
DMA_WR_REQ_IE_0	This enables the interrupt to be asserted everytime Watermark number of entries are available to be filled with tx sub-frames.
14	Request to read data from FIFO.
DMA_RD_REQ_IE_0	This enables the interrupt to be asserted everytime Watermark number of entries are available to be read.
13	Update request for chip temperature value.
TEMP_UPDATE_IE_0	This enables the interrupt to be asserted every 5s, requesting an update in the temperature value for PHY settings.
12	Interrupt enable for CMDC status register update.
CMDC_STATUS_UPDATE_IE_0	This enables the interrupt to be asserted when there is a change in Capabilities data structure / Latency request of the CMDC Status register.
11	Interrupt enable for Heartbeat status change
HB_STATE_CHG_IE_0	This enables the interrupt to be asserted when there is a change in heartbeat status. If heartbeat is either achieved for the first time / heartbeat is lost after the channel was established.
10	Indicates DMAC format change was detected
DMAC_FMT_CHG_DET_IE_0	No DMAC input data for over 65 ms. This interrupt can be set by HW / FW.
9	Indicates no DMAC data is received.
DMAC_NO_DATA_REC_IE_0	No DMAC input data for over 2 ms.
8	Output HPD interrupt enable.
OHPD_IE_0	Enables assertion of interrupt when the output HPD is set.
7	Host wakeup on CEC match interrupt enable.
HOST_WAKEUP_IE_0	Enables wakeup interrupt to the host from CEC commands.
6	Receive FIFO overflow error interrupt enable.
FIFO_OFLOW_UFLOW_ERR_IE_0	Enables assertion of interrupt when FIFO underflows (in TX mode) / overflows (in RX mode).
5	Preamble mismatch interrupt enable.
PREAMBLE_MISMATCH_IE_0	Enables assertion of interrupt when the expected preamble is not received. Usually when a W does not follow an M / an unexpected B preamble is received. Once an unexpected preamble is received, the curent block of data is dropped and sub-frame data is synced to the next input B preamble.

Table continues on the next page...

Field	Description
4 ECC_ERR_IE_0	60958 Compressed data uncorrectable error interrupt enable Enables assertion of interrupt when 60958 compressed data is received with uncorrectable error.
3 CMDC_RESP_TO_IE_0	Receiver CMDC data response timeout interrupt enable Enables assertion of an interrupt to indicate response in the programmed CMDC window was missed.
2 MUTE_IE_0	Enable for Mute detected interrupt Enables assertion of interrupt when HW / FW mute bit is set for receive data.
1 NEW_UD_IE_0	Enable for new user data received interrupt Enables assertion of interrupt when a new user data block is received.
0 NEW_CS_IE_0	Enable for New channel status block received interrupt Enables assertion of interrupt when a new channel status block is received.



14.6.4.1.6 Interrupt enables for interrupt 1 (EXT_IER1)

Provides enable bits to enable interrupt 1 generation. All enables are active high. Interrupt enables 22 - 31 are reserved for future use

14.6.4.1.6.1 Offset

Register	Offset	Description
EXT_IER1	40h	Interrupt enables for interrupt 1
EXT_IER1_SET	44h	Writing a 1 to a bit in this register sets the corresponding bit in EXT_IER1
EXT_IER1_CLR	48h	Writing a 1 to a bit in this register clears the corresponding bit in EXT_IER1
EXT_IER1_TOG	4Ch	Writing a 1 to a bit in this register toggles the corresponding bit in EXT_IER1

14.6.4.1.6.2 Diagram

14.6.4.1.6.3 Fields

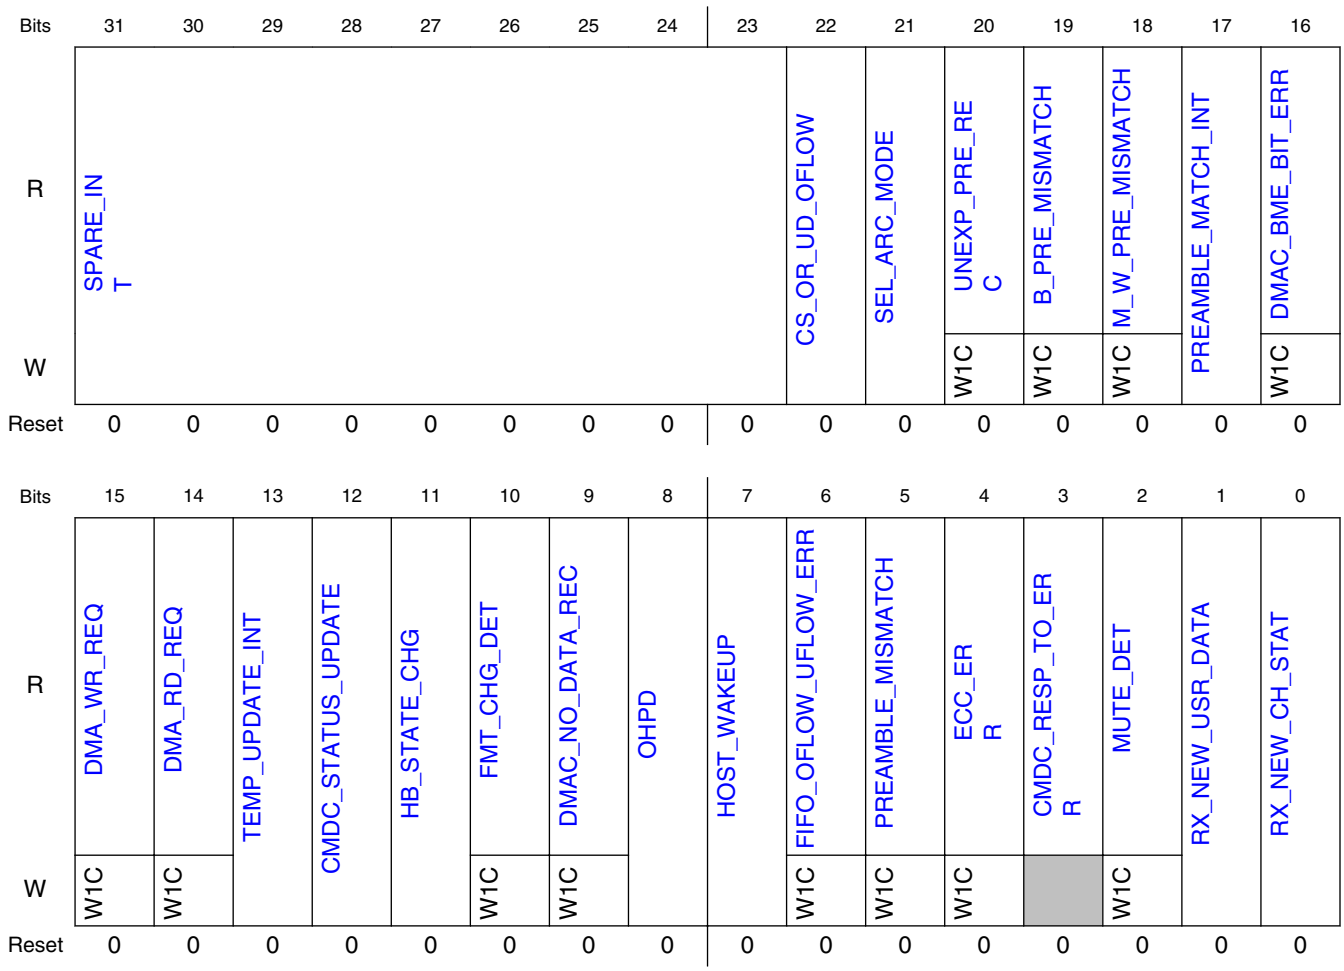
Field	Description
31-23 SPARE_IE_1	Spare interrupt enables. Enables assertion of spare interrupts that cna be set by M0+.
22 CH_UD_OFLOW_IE_1	Channel status or used data could not be stored. This interrupt enables channel status or user data overflow interrupt. This interrupt is asserted when FW is unable to store user data or channel status because the previous entries were not cleared.
21 ARC_MODE_IE_1	Interrupt to indicate ARC mode setup. This interrupt enables SEL_ARC_MODE interrupt indicating eARC RX state machine could not establish a heartbeat. Check to see if ARC mode needs to be set up.
20 UNEXP_PRE_REC_IE_1	Interrupt enable for Unexpected preamble received. This enables the interrupt to be asserted everytime HW detects a preamble was not received when expected or more than 8 bits were received before a preamble was detected.
19	Interrupt enable for sub-frame B preamble mismatch received.

Table continues on the next page...

Field	Description
B_PRE_MISMATCH_IE_1	This enables the interrupt to be asserted everytime HW detects a B sub-frame preamble mismatch.
18	Interrupt enable for sub-frame M/W preamble mismatch received.
M_W_PRE_MISMATCH_IE_1	This enables the interrupt to be asserted everytime HW detects a M/W sub-frame preamble mismatch.
17	Interrupt enable for preamble match received.
PREAMBLE_MATCH_IE_1	This enables the interrupt to be asserted everytime HW detects a preamble match and FW moves the data to memory and asserts the interrupt.
16	Bi-phase mark encoding error
DMAC_RX_BME_ERR_IE_1	This enables the interrupt to be asserted everytime Bi-phase mark encoded data received has an error. i.e. No toggle after 2 bits.
15	Request to write data to FIFO.
DMA_WR_REQ_IE_1	This enables the interrupt to be asserted everytime Watermark number of entries are available to be filled with tx sub-frames.
14	Request to read data from FIFO.
DMA_RD_REQ_IE_1	This enables the interrupt to be asserted everytime Watermark number of entries are available to be read.
13	Update request for chip temperature value.
TEMP_UPDATE_IE_1	This enables the interrupt to be asserted every 5s, requesting an update in the temperature value for PHY settings.
12	Interrupt enable for CMDC status register update.
CMDC_STATUS_UPDATE_IE_1	This enables the interrupt to be asserted when there is a change in Capabilities data structure / Latency request of the CMDC Status register.
11	Interrupt enable for Heartbeat status change
HB_STATE_CHG_IE_1	This enables the interrupt to be asserted when there is a change in heartbeat status. If heartbeat is either achieved for the first time / heartbeat is lost after the channel was established.
10	Indicates DMAC format change was detected
DMAC_FMT_CHG_DET_IE_1	No DMAC input data for over 65 ms. This interrupt can be set by HW / FW.
9	Indicates no DMAC data is received.
DMAC_NO_DATA_REC_IE_1	No DMAC input data for over 2 ms.
8	Output HPD interrupt enable.
OHPD_IE_1	Enables assertion of interrupt when the output HPD is set.
7	Host wakeup on CEC match interrupt enable.
HOST_WAKEUP_IE_1	Enables wakeup interrupt to the host from CEC commands.
6	Receive FIFO overflow error interrupt enable.
FIFO_OFLOW_UFLOW_ERR_IE_1	Enables assertion of interrupt when FIFO underflows (in TX mode) / overflows (in RX mode).
5	Preamble mismatch interrupt enable.
PREAMBLE_MISMATCH_IE_1	Enables assertion of interrupt when the expected preamble is not received. Usually when a W does not follow an M / an unexpected B preamble is received. Once an unexpected preamble is received, the curent block of data is dropped and sub-frame data is synced to the next input B preamble.

Table continues on the next page...

Field	Description
4 ECC_ERR_IE_1	60958 Compressed data uncorrectable error interrupt enable Enables assertion of interrupt when 60958 compressed data is received with uncorrectable error.
3 CMDC_RESP_TO_IE_1	Receiver CMDC data response timeout interrupt enable Enables assertion of an interrupt to indicate response in the programmed CMDC window was missed.
2 MUTE_IE_1	Enable for Mute detected interrupt Enables assertion of interrupt when HW / FW mute bit is set for receive data.
1 NEW_UD_IE_1	Enable for new user data received interrupt Enables assertion of interrupt when a new user data block is received.
0 NEW_CS_IE_1	Enable for New channel status block received interrupt Enables assertion of interrupt when a new channel status block is received.



14.6.4.1.7 External Interrupt Status register (EXT_ISR)

Interrupt status for the host core

14.6.4.1.7.1 Offset

Register	Offset	Description
EXT_ISR	50h	External Interrupt Status register
EXT_ISR_SET	54h	Writing a 1 to a bit in this register sets the corresponding bit in EXT_ISR
EXT_ISR_CLR	58h	Writing a 1 to a bit in this register clears the corresponding bit in EXT_ISR
EXT_ISR_TOG	5Ch	Writing a 1 to a bit in this register toggles the corresponding bit in EXT_ISR

14.6.4.1.7.2 Diagram

14.6.4.1.7.3 Fields

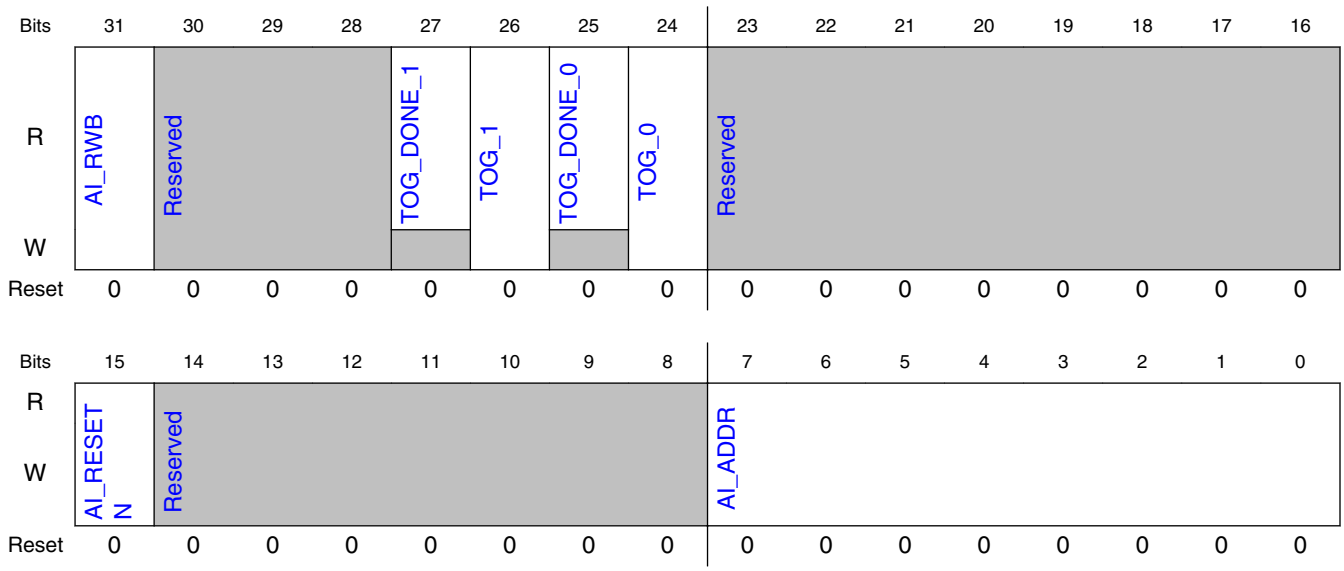
Field	Description
31-23 SPARE_INT	Extra interrupt. Currently not driven. Can be set by M0
22 CS_OR_UD_OFLOW	Channel status or used data could not be stored. This interrupt indicates channel status or user data should have been stored in data ram, but since the previous entries were not cleared, FW was unable to store it.
21 SEL_ARC_MODE	Set when CMDC SM falls out of eARC mode. This interrupt indicates eARC RX state machine could not establish a heartbeat. Check to see if ARC mode needs to be set up.
20 UNEXP_PRE_REC	Set when DMAC preamble was received after unexpected number of input bits. This interrupt indicates DMAC subframe received has a B preamble error. i.e, B preamble expected and was not received / B preamble received and was not expected.
19	Set when DMAC preamble of B has an error.

Table continues on the next page...

Field	Description
B_PRE_MISMATCH	This interrupt indicates DMAC subframe received has a B preamble error. i.e, B preamble expected and was not received / B preamble received and was not expected.
18	Set when DMAC preamble of M/W has an error.
M_W_PRE_MISMATCH	This interrupt indicates DMAC subframe received has a preamble error.
17	Interrupt to indicate PA PB / DTC CD preamble match was detected.
PREAMBLE_MATCH_INT	This interrupt is asserted every time a PA PB match is detected by HW. Host core will neeed to go read the Circular buffer in 4KB memory.
16	Set when DMAC BME data has an error.
DMAC_BME_BIT_ERR	This interrupt indicates BME data received has an error. After a preamble was received, the input data did not toggle after every 2 bits. This interrupt will have to be cleared.
15	Set when DMA write request is asserted.
DMA_WR_REQ	This interrupt indicates Watermark number of entries are free to be filled with new sub-frames. This interrupt will have to be cleared.
14	Set when DMA read request is asserted.
DMA_RD_REQ	This interrupt indicates Watermark number of entries are avaialble to be read. This interrupt will have to be cleared.
13	Interrupt to get the new temperature value.
TEMP_UPDATE_INT	This interrupt is asserted every 5s for an update of the temperature reading.
12	Interrupt enable for CMDC status register update.
CMDC_STATUS_UPDATE	This interrupt is asserted when eARC in TX mode and new capabilities data structure or latency information is available. This should be read from the data RAM at offset 0x300 for the capabilities data structure and byte at offset 0x6 for the latency update.
11	Interrupt enable for Heartbeat status change
HB_STATE_CHG	This interrupt indicates a change in heartbeat status. The link was either established for the first time or an established link lost heartbeat.
10	Format change detect interrupt
FMT_CHG_DET	This interrupt indicates no input DMAC data is received for over 65ms. This interrupt can be set by HW / FW.
9	No DMAC data is received for 1us.
DMAC_NO_DATA_REC	This interrupt indicates input DMAC hasn't toggled in 1us. This is 4* the slowest data rate. This can either indicate a format change / so other issue in the data pipe.
8	HPD output driver
OHPD	This register drives the output HPD value. It should not be cleared by the external host. If the host core does not want to see this interrupt, it should mask the interrupt in IE0 / IE1 registers.
7	Host wakeup on CEC OPCODE match interrupt.
HOST_WAKEUP	This interrupt indicates a wakeup source to the host core.
6	Receive FIFO overflow error interrupt
FIFO_OFLOW_UFLOW_ERR	This interrupt indicates the data receive FIFO is full, or the TX fifo is empty. In RX mode, the new frames will be dropped until the fifo has room for more sub-frames. In TX mode, no data will be sent out on the TX path.
5	Preamble mismatch interrupt

Table continues on the next page...

Field	Description
PREAMBLE_MISMATCH	This interrupt indicates an unexpected preamble is received. When this interrupt is set, HW clears the RX pipe and waits for a new B preamble to start receiving a fresh block of data.
4 ECC_ERR	60958 Compressed data uncorrectable error interrupt This bit indicates there was an uncorrectable error in received compressed data.
3 CMDC_RESP_TO_ERR	CMDC response timeout interrupt This interrupt indicates no CMDC response or comma was received / sent in the CMDC response window. Refer to EXT_STATUS register to see which protocol failed. This interrupt can be cleared in the EXT_STATUS register.
2 MUTE_DET	Interrupt to indicate HW mute bit was detected. This interrupt indicates mute bit was detected in HW or set by FW.
1 RX_NEW_USR_DATA	Received new User data Information This interrupt indicates a unique user data type was received. Refer to the External status register to see if it was IU type 4/5/6.
0 RX_NEW_CH_STAT	Received new channel status block This interrupt indicates a unique channel status block was received.



14.6.4.1.8 AI interface control register (PHY_AI_CTRL)

Provides address and toggle bit controls for the AI interface to the PHY.

14.6.4.1.8.1 Offset

Register	Offset	Description
PHY_AI_CTRL	90h	AI interface control register
PHY_AI_CTRL_SET	94h	Writing a 1 to a bit in this register sets the corresponding bit in PHY_AI_CTRL
PHY_AI_CTRL_CLR	98h	Writing a 1 to a bit in this register clears the corresponding bit in PHY_AI_CTRL
PHY_AI_CTRL_TOG	9Ch	Writing a 1 to a bit in this register toggles the corresponding bit in PHY_AI_CTRL

14.6.4.1.8.2 Diagram

14.6.4.1.8.3 Fields

Field	Description
31 AI_RWB	AI Read / write control bit This register field holds the control to read / write the AI interface.
30-28 —	Reserved
27 TOG_DONE_1	AI toggle done bit This register field holds the Toggle done value for the audio XVCR PHY. When this bit matches TOG_0 the read / write operation has successfully completed.
26 TOG_1	AI toggle bit This register field holds the Toggle value for the audio XVCR PHY. When this bit is set, the AI_ADDR filed and AI_RWB take effect. This bit should not be toggled unless it matches TOG_DONE_1. and TOG_0 matches TOG_DONE_0
25 TOG_DONE_0	AI toggle done bit This register field holds the Toggle done value for the audio PLL in the XCVR PHY. When this bit matches TOG_0 the read / write operation has successfully completed.
24 TOG_0	AI toggle bit This register field holds the Toggle value for the audio PLL in the PHY. When this bit is set, the AI_ADDR filed and AI_RWB take effect. This bit should not be toggled unless it matches TOG_DONE_0 and TOG_1 matches TOG_DONE_1
23-16 —	Reserved
15 AI_RESETN	AI reset bit This register field controls the reset of the AI interface in the eARC controller.
14-8	Reserved

Table continues on the next page...

Field	Description
—	
7-0 AI_ADDR	AI ADDR value This register field holds the ADDR value to be sent out on the AI bus. This value can correspond to the PLL or the Audio XVCR registers. The toggle bit decides where the address will be accepted.

14.6.4.1.9 AI interface WDATA register (PHY_AI_WDATA)

Provides the data to be written using the AI interface to the PHY.

14.6.4.1.9.1 Offset

Register	Offset
PHY_AI_WDATA	A0h

14.6.4.1.9.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

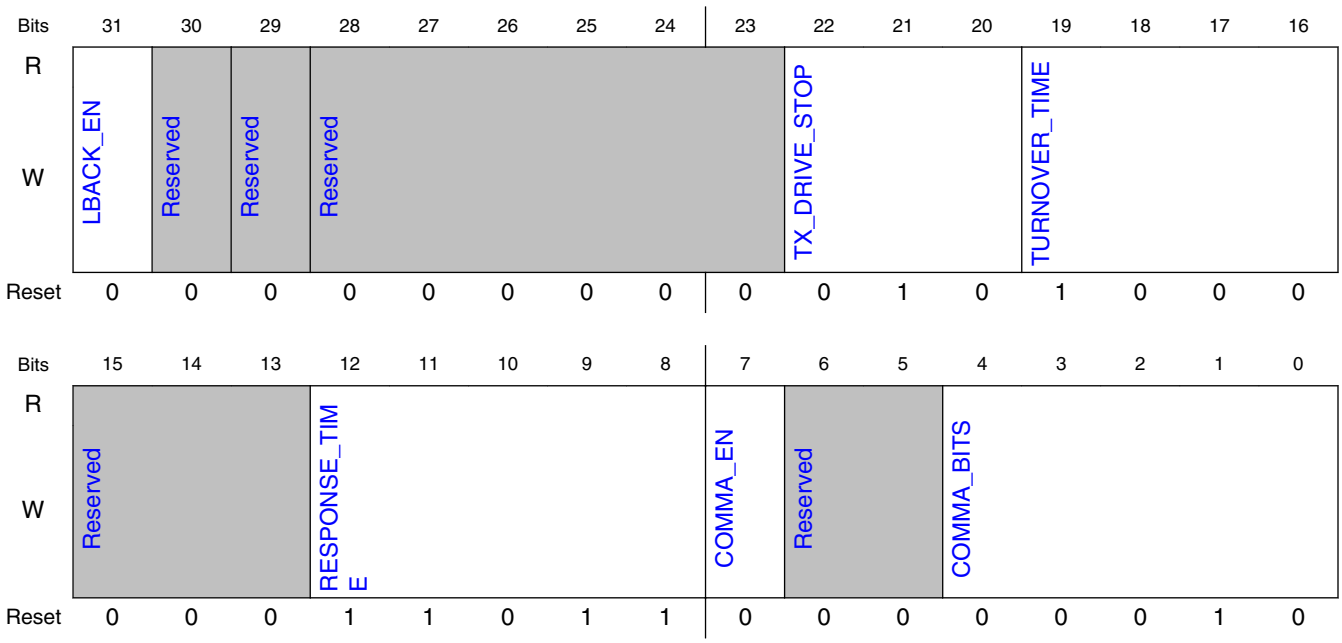
14.6.4.1.11.3 Fields

Field	Description
31-16 —	Reserved
15-8 TX_FRM_CNT	Count of transmitted frames in a block This register holds the count of transmitted frames in a block of data.
7-0 RX_FRM_CNT	Count of received frames in a block This register holds the count of received frames in a block of data.



14.6.4.1.12 CMDC receiver control register (RX_CMDC_CTRL)

Configures and controls operations for the RX CMDC block.

14.6.4.1.12.1 Offset

Register	Offset	Description
RX_CMDC_CTRL	C0h	CMDC receiver control register
RX_CMDC_CTRL_SET	C4h	Writing a 1 to a bit in this register sets the corresponding bit in RX_CMDC_CTRL
RX_CMDC_CTRL_CLR	C8h	Writing a 1 to a bit in this register clears the corresponding bit in RX_CMDC_CTRL
RX_CMDC_CTRL_TOG	CCh	Writing a 1 to a bit in this register toggles the corresponding bit in RX_CMDC_CTRL

14.6.4.1.12.2 Diagram

14.6.4.1.12.3 Fields

Field	Description
31 LBACK_EN	Loopback enable If set, enables loopback between CMDC_TX and CDMC_RX blocks. For test purposes only.
30 —	reserved
29 —	Reserved
28-23 —	reserved
22-20 TX_DRIVE_STOP	Transmitter bus release time This is the time in "us" measured from end of transmission of message (i.e. transmission of parity bit), during which the transmitter shall drive the bus low before releasing it. This field is programmed in steps of 0.5 us. A value of 3 represents 1.5 us time. • 0 - This implies bypass drive stop timer. Transmitter will stop driving the output immediately after the last bit is sent. • 1 - 7 Valid values. Default is 3.
19-16 TURNOVER_TIME	Minimum time before a response is generated Time in "us" - microseconds, which is measured from the end of a received message (i.e. reception of parity bit). M0+ core or external host can provide a response before this time has expired but the message will be ignored until turnover time has expired. • 0 - This implies bypass mode for turnover timer. Response will be sent / accepted when ready depending on response time. • 1 - 15 Valid values. Default is 7.

Table continues on the next page...

Field	Description
15-13 —	Reserved
12-8 RESPONSE_TIME	Transmitter response timeout to a received message This field defines the timeout time in "us" - microseconds, which is measured from the end of a received message (i.e. reception of parity bit). If a message response from M0+ or external host is not available within this window, the response is dropped. • 0 - This implies bypass mode for response timer. Response will be accepted whenever it is available • 1 - 31 Valid values. Default is 27.
7 COMMA_EN	Enables COMMA pattern generation Enables generation of the COMMA pattern as defined in the CMDC_TX_DATA register, and COMMA_BITS bit field (Default: 2 bits = 0x2). The combination of CMDC_TX_DATA register and CMDC_CTRL[COMMA_BITS] determines the comma pattern. • 0 - Disable Comma transmission • 1 - Enable comma transmission.
6-5 —	Reserved
4-0 COMMA_BITS	Number of repeating bits in COMMA pattern Determines the number of bits (LSBs) of the CMDC_TX_DATA register that will be used as the repeating COMMA pattern. This field takes effect only when COMMA_EN = '1'. • 0, 27-31 - Invalid value.. • 1 - 26 Valid values. Default is 2.

14.6.4.1.13 eARC receiver CMDC status (RX_CMDC_STATUS)

Provides the status for CMDC in receiver mode.

14.6.4.1.13.1 Offset

Register	Offset
RX_CMDC_STATUS	D0h

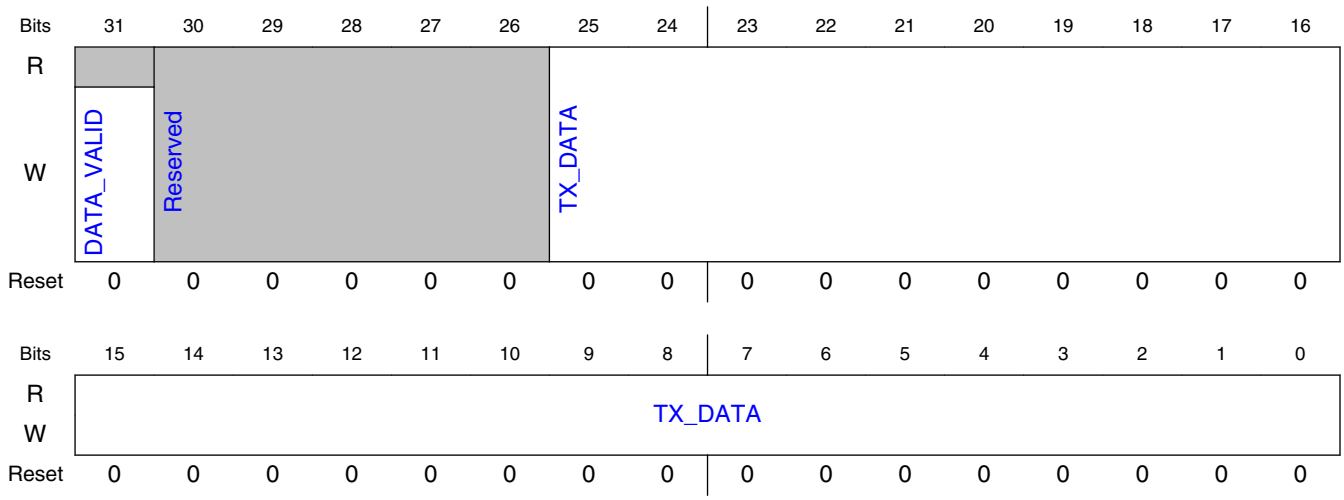
14.6.4.1.13.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved												CMDC_STATE			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

14.6.4.1.13.3 Fields

Field	Description
31-20 —	Reserved
19-16 CMDC_STATE	Current state of the RX CDMC control state machine Provides the current state of CMDC control state machine for M0+ or external host. If M0+ writes to this field, the field will be cleared. • 0 - Idle state. No transactions in flight • 1 - Pending state. Data is received, waiting for M0+ to respond. • 2 - Ready state. M0+ has responded. Waiting for turnover time to expore. • 3 - Send state. Response message is being transmitted • 4 - Send state. Response message is being transmitted • 5 - Timeout state. M0+ did not respond within the required time. • 6 - Compplete. Response sent / received.
15-0 —	Reserved



14.6.4.1.14 CMDC transmit data register (RX_CMDC_TX_DATA)

Provides the data for tranmission and control to indicate a new valid data.

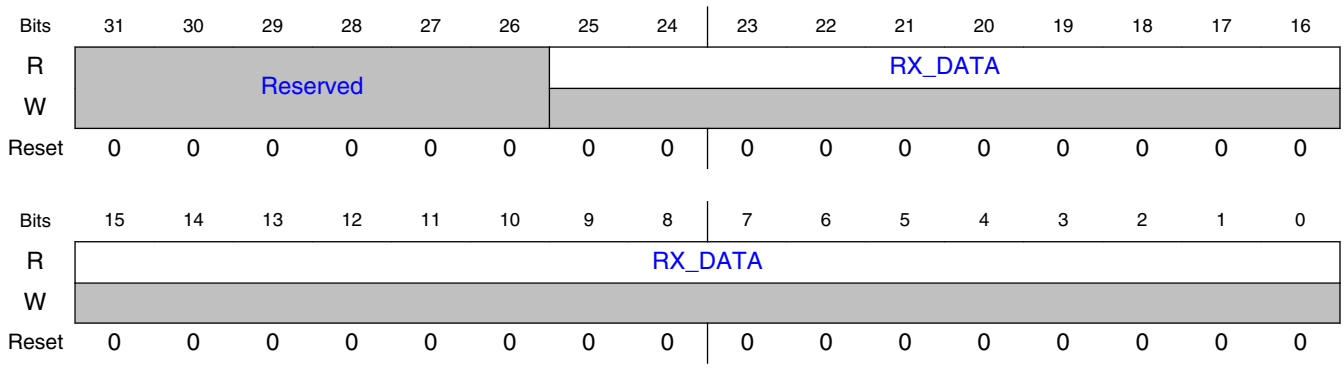
14.6.4.1.14.1 Offset

Register	Offset
RX_CMDC_TX_DATA	E0h

14.6.4.1.14.2 Diagram

14.6.4.1.14.3 Fields

Field	Description
31 DATA_VALID	Transmit Data Valid Write only bit. Read will return zeros. User must write '1' to this bit to indicate new valid data for transmission. **NOTE:** Writing a '1' to this bit causes the bit to toggle internally which is used as an indication for new data available for transmission.
30-26 —	Reserved
25-0 TX_DATA	Transmit data This register is used to provide the COMMA pattern (when CMDC_CTRL[COMMA_EN] ='1') and data message during normal data transfer operation.



14.6.4.1.15 CMDC receive data register (RX_CMDC_RX_DATA)

Provides the recevied data packet for processing by software.

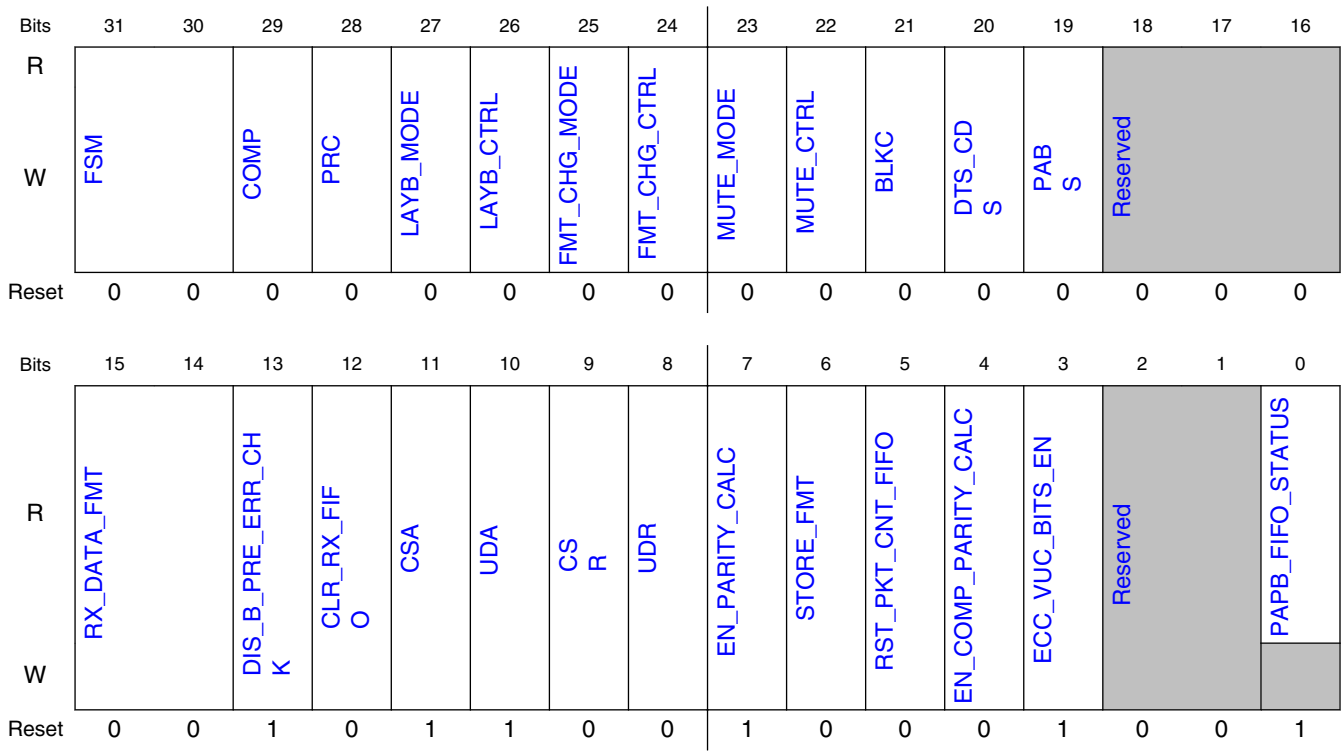
14.6.4.1.15.1 Offset

Register	Offset
RX_CMDC_RX_DATA	F0h

14.6.4.1.15.2 Diagram

14.6.4.1.15.3 Fields

Field	Description
31-26 —	Reserved
25-0 RX_DATA	Receive data Receive data after being qualified with CMDC_RX_MASK and CMDC_RX_MATCH registers is stored in this register.



14.6.4.1.16 Data path control register (RX_DATAPATH_CTRL)

Configuration and control bist for the Receive audio block.

14.6.4.1.16.1 Offset

Register	Offset	Description
RX_DATAPATH_CTRL	180h	Data path control register
RX_DATAPATH_CTRL_SET	184h	Writing a 1 to a bit in this register sets the corresponding bit in RX_DATAPATH_CTRL
RX_DATAPATH_CTRL_CLR	188h	Writing a 1 to a bit in this register clears the corresponding bit in RX_DATAPATH_CTRL
RX_DATAPATH_CTRL_TOG	18Ch	Writing a 1 to a bit in this register toggles the corresponding bit in RX_DATAPATH_CTRL

14.6.4.1.16.2 Diagram

14.6.4.1.16.3 Fields

Field	Description
31-30 FSM	IEC60958-1 Frame Synchronization Mode Selects between frame sync or immediate capture of data. • 00 - Normal, Sync to block using B preamble • 01 - Reserved • 10 - Sync to B or M preamble • 11 - Start with the first received preamble.
29 COMP	Compressed data search mode Selects between M0+ control or hardware control for enabling compressed data search. • 0 - Compressed format autodetect • 1 - M0+ control
28 PRC	Process Compressed Selects between De-interleaving, and ECC correcting compressed data and passing through the data as received to the FIFO. COMP value selects if this bit is set by FW / HW. • 1 - Process interleved, ECC protected IEC61937 data • 0 - pass though data to FIFO
27 LAYB_MODE	Layout B Indicates compressed data layout B is being used • 0 - Not Layout B • 1 - Layout B
26	Layout B mode control

Table continues on the next page...

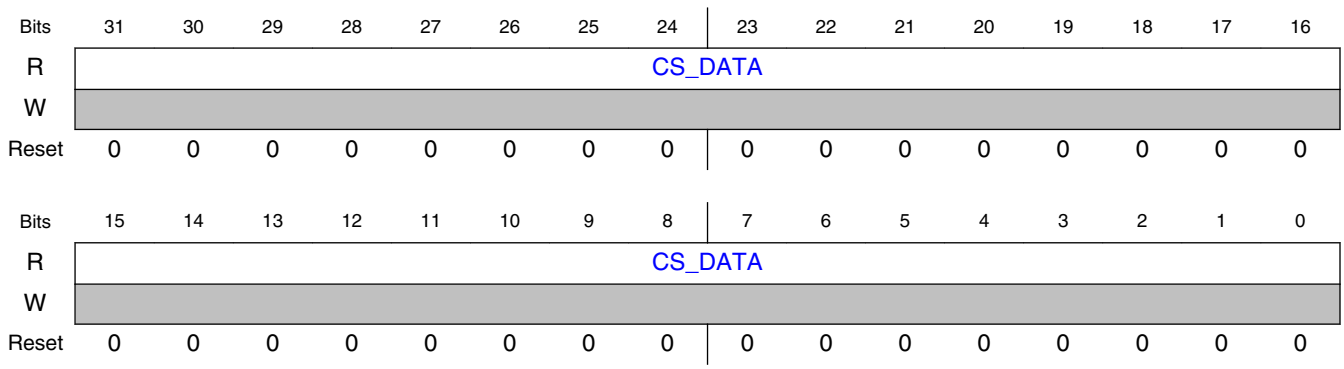
Field	Description
LAYB_CTRL	Selects between M0+ control or hardware control for enabling Layout B mode. • 0 - HW control. Layout B is detected using CS bits 47:44 • 1 - M0+ Control
25 FMT_CHG_MODE	Format change detected. Reset HW for next frame Set by M0+ to indicate format change detected. It is cleared by HW to indicate format information was reset.
24 FMT_CHG_CTRL	Format Change detection control. Selects between M0+ control or hardware control for detecting format change. • 0 - HW control. When no input data is received for 65 ms, format change register is set. • 1 - M0+ Control
23 MUTE_MODE	Mute mode control Selects between M0+ control or hardware control for enabling Mute detection. • 0 - Channel Status control. MBIT field is used to select the bit that will control the mute request • 1 - M0+ Control
22 MUTE_CTRL	M0+ mute request If M0+ is used to control MUTE assertion, this bit is used to set mute mode. • 0 - Normal operation • 1 - Assert mute request
21 BLKC	Block Compressed data If this bit is set, compressed data is blocked. It won't be stored in the FIFO and CS and UD won't be processed.
20 DTS_CDS	Enable DTS CD 14 preamble search Enable Preamble Pa Pb search which matches DTS CD 14 format.
19 PABS	Enable preamble search Enable Preamble Pa,Pb search
18-16 —	reserved
15-14 RX_DATA_FMT	Indicates format of data stored in memory. • 00 - Store complete sub frame • 01 - Store 24 audio data bits of sub-frame. • 10 - Store 20 audio data bits of sub-frame. • 11 - Store 16 audio data bits of sub-frame.
13 DIS_B_PRE_ERR_CHK	RX_DATAPATH: Disable B preamble error check. This bit when enabled, disables dropping frames of data once a bad B preamble is received, • 0 - A new B preamble will clear the pipe and wait for the following B preamble. • 1 - A new B preamble will start receiving a new block of data.
12 CLR_RX_FIFO	Clear Receive FIFO Clear receive FIFO. This is a self clear register bit.
11 CSA	Channel Status Acknowledge channel status acknowledge that should be set once channel status is processed.
10 UDA	User Data Acknowledge User data acknowledge that should be set once user data is processed.
9 CSR	Channel Status reset Reset channel status gathering and storage. This is an active high reset.

Table continues on the next page...

Field	Description
8 UDR	User data reset Reset user data gathering and storage. This is an active high reset.
7 EN_PARITY_CALC	Enable Parity calculation. This bit enables parity calculation. • 0 - Do not calculate Parity for un-compressed data • 1 - Calculate Parity for un-compressed data
6 STORE_FMT	Receive Data store format. This bit describes the format to store the received data in memory. • 0 - Store data with bit 0 of subframe at bit position 31 in sub-frame. • 1 - Store data with bit 0 of subframe at bit position 0 in sub-frame.
5 RST_PKT_CNT_FIFO	Resets the packet count fifo. This bit when enabled, resets the preamble match packet number FIFO • 0 - Do not reset the FIFO • 1 - Reset FIFO.
4 EN_COMP_PARITY_CALC	RX_DATAPATH: Enable Compressed mode Parity calculation. This bit enables parity calculation for compressed mode. • 0 - Do not calculate Parity for compressed data • 1 - Calculate Parity for compressed data
3 ECC_VUC_BITS_EN	RX_DATAPATH: Enable VUC bit replacement after ECC correction. This bit enables VUC replacement for compressed mode with ECC corrected data • 0 - Do not replace VUC bits after ECC correction • 1 - Repalce VUC bits after ECC correction
2-1 —	reserved
0 PAPB_FIFO_STATUS	This bit is an empty fifo indicator for PaPb match.

14.6.4.1.17 Channel staus bits (RX_CS_DATA_BITS_0 - RX_CS_DATA_BITS_5)

Holds the 192 bit channel status for the last received block. It is only updated if M0+ acknowledges reading these registers using RX_DATAPATH_CTRL.CSA.



14.6.4.1.17.1 Offset

Register	Offset
RX_CS_DATA_BITS_0	190h
RX_CS_DATA_BITS_1	194h
RX_CS_DATA_BITS_2	198h
RX_CS_DATA_BITS_3	19Ch
RX_CS_DATA_BITS_4	1A0h

Table continues on the next page...

Register	Offset
RX_CS_DATA_BITS_5	1A4h

14.6.4.1.17.2 Diagram

14.6.4.1.17.3 Fields

Field	Description
31-0 CS_DATA	Channel Status bits 192 bit channel status / block

14.6.4.1.18 User data bits (RX_USER_DATA_BITS_0 - RX_USER_DATA_BITS_5)

Holds the 192 bit user data for the last received block. It is only updated if M0+ acknowledges reading these registers using RX_DATAPATH_CTRL.UDA.

14.6.4.1.18.1 Offset

Register	Offset
RX_USER_DATA_BITS_0	1A8h
RX_USER_DATA_BITS_1	1ACh
RX_USER_DATA_BITS_2	1B0h
RX_USER_DATA_BITS_3	1B4h

14.6.4.1.19 DMAC counter control register (RX_DPATH_CNTR_CTRL)

Controls the functioning of the DMAC internal counters for time stamp and bit count.

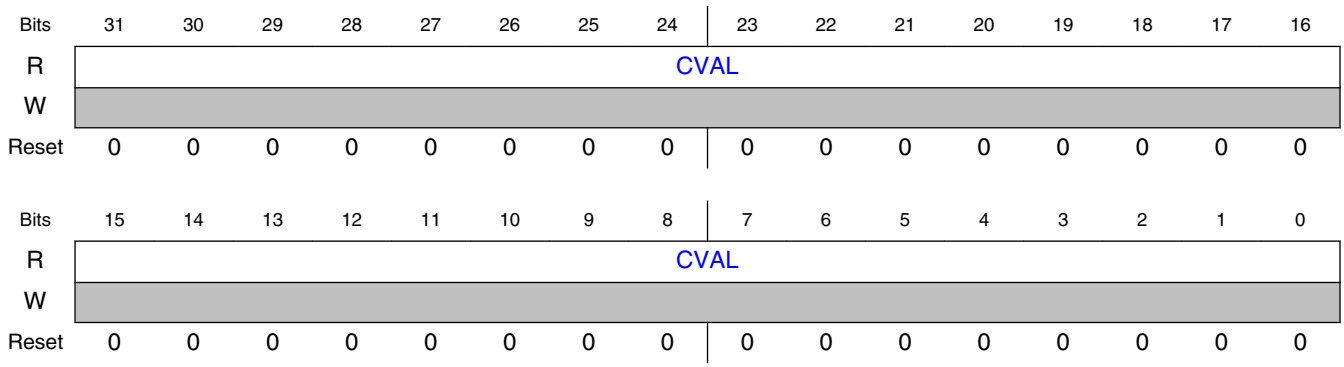
14.6.4.1.19.1 Offset

Register	Offset	Description
RX_DPATH_CNTR_CTRL	1C0h	DMAC counter control register
RX_DPATH_CNTR_CTRL_SET	1C4h	Writing a 1 to a bit in this register sets the corresponding bit in RX_DPATH_CNTR_CTRL
RX_DPATH_CNTR_CTRL_CLR	1C8h	Writing a 1 to a bit in this register clears the corresponding bit in RX_DPATH_CNTR_CTRL
RX_DPATH_CNTR_CTRL_TOG	1CCh	Writing a 1 to a bit in this register toggles the corresponding bit in RX_DPATH_CNTR_CTRL

14.6.4.1.19.2 Diagram

14.6.4.1.19.3 Fields

Field	Description
31-10 —	reserved
9 RST_TS_CNTR	Reset timestamp counter. • 0 - Timestamp counter is not reset. • 1 - Timestamp counter is reset.
8 RST_BIT_CNTR	Reset bit counter. • 0 - Bit counter is not reset. • 1 - Bit counter is reset.
7-2 —	reserved
1 TS_INC	Timestamp Increment • 0 - Timestamp counter starts to increment when enabled and the bit counter has incremented. • 1 - Timestamp counter increments when enabled.
0 TS_EN	Timestamp counter enable • 0 - Timestamp counter is disabled • 1 - Timestamp counter is enabled.



14.6.4.1.20 Receive Datapath Timestamp Counter Register (RX_DPATH_TSCR)

Current value of the timestamp counter.

14.6.4.1.20.1 Offset

Register	Offset
RX_DPATH_TSCR	1D0h

14.6.4.1.20.2 Diagram

14.6.4.1.20.3 Fields

Field	Description
31-0 CVAL	Timestamp counter value This counter is incremented based on the timestamp control register

14.6.4.1.21 Receive Datapath Bit counter register (RX_DPATH_BCR)

This register returns the current value of the bit counter.

14.6.4.1.21.1 Offset

Register	Offset
RX_DPATH_BCR	1D4h

14.6.4.1.21.2 Diagram

Field	Description
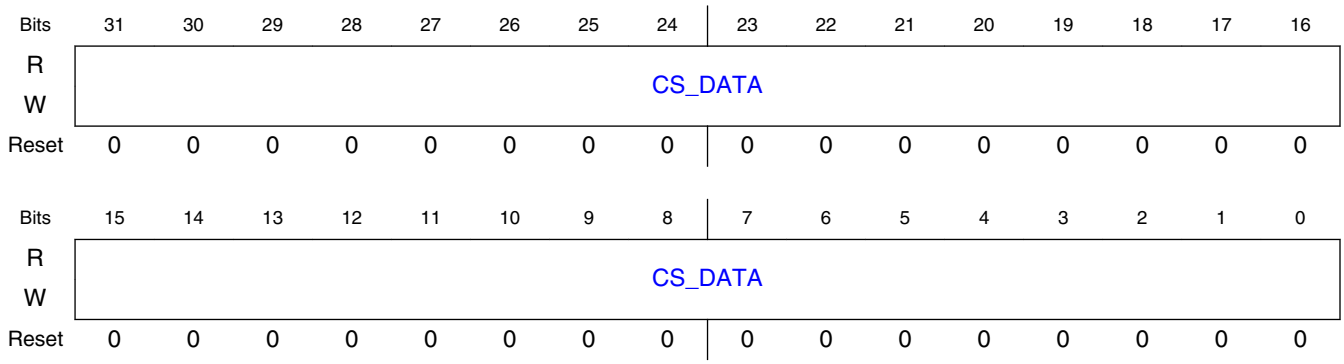
31-30 —	reserved
29 —	Reserved
28-17 —	reserved
16-15 —	reserved
14 STRT_DATA_TX	Once Comma pattern is successively received, and heartbeat is detected, start TX of DMAC data. • 0 - Even though TX FIFO has data, do not transmit it right now. • 1 - As soon as TX_FIFO has data, enable DMAC TX datapath.
13-12 TX_FORMAT	Transmit data format This field describes the number of bits to be transmitted / audio sub-frame. Each FIFO entry only represents one sub-frame worth of data. Bit reversal is indicated by TX_DATAPATH_CTRL.FRM_FMT • 0 - 32 bit data format. The audio data will be positioned within the subframe by SW. • 1 - 24 bit input data stored in bits 23:0 of TX FIFO • 2 - 20 bit input data stored in bits 19:0 of TX FIFO • 3 - 16 bit input data stored in bits 15:0 of TX FIFO
11 FRM_FMT	Frame format of input data • 0 - Frame data will be considered to be aligned to the MSB. i.e, 60958 frame bit 0 is at bit position 31 of the TX data FIFO. • 1 - Output 60958 frame format data will be considered to be aligned to the LSB. i.e, 60958 frame bit 0 is at bit position 0 of the TX data FIFO.
10	This bit controls the TX clock rate.

Table continues on the next page...

Field	Description
TX_CLK_RATE	If this bit is set, TX datapath clock should be = 2* TX bit rate. If this bit is not set, TX datapath clock should be 10* TX bit rate.
9 —	reserved
8 —	Reserved
7 EN_PREAMBLE	Enable preamble insertion If this bit is set, Preamble matching the frame count will be inserted in the TX data path.
6 EN_PARITY	Enable parity insertion If this bit is set, parity will be calculaed and inserted in the TX data path.
5 FRM_VLD	Valid bit value If VLD_MOD bit is set, Valid bit will be replaced in the TX data path with the value in this bit.
4 VLD_MOD	Enable Valid bit insertion If this bit is set, Valid bit will be inserted in the TX data path from the FRM_VLD register bit.
3 UD_MOD	Enable User Data insertion If this bit is set, User data will be inserted in the TX data path from the UD buffer.
2 CS_MOD	Enable Channel Status insertion If this bit is set, Channel status will be inserted in the TX data path from the CS buffer.
1 UD_ACK	User Data ACK Once the user data registers are double buffered, set this ack to let the host know that new values can be written in the UD buffer. Once the Buffer is updated, host should clear this value.
0 CS_ACK	Channel Status ACK Once the Channel status registers are double buffered, set this ack to let the host know that new values can be written in the CS buffer. Once the Buffer is updated, host should clear this value.

14.6.4.1.32 Channel staus bits (TX_CS_DATA_BITS_0 - TX_CS_DATA_BITS_5)

Holds the 192 bit channel status for the current block to transmit. It is updated only when format change needs to be communicated. It can be updated in the time when no data sub-frames will be added to the TX fifo.



14.6.4.1.32.1 Offset

14.6.4.1.39.3 Fields

Field	Description
31-0 VAL	HDP pin debounce interval Specifies the decounce interval on the HPD pin. If set, HW will wait until the timer is up before asserting HPD toggle interrupt to the core. If set to 0, this counter will be ignored. Reset value of the counter is used to support the PHY requirement of waiting for 500 us after HPD before it is enabled.

14.7 Audio DSP (HiFi 4 DSP)

14.7.1 Overview

The HiFi 4 Audio Engine is a highly optimized audio processor geared for efficient execution of audio and voice codecs and pre- and post-processing modules.

The HiFi 4 Audio Engine consists of three main components: a DSP subsystem, floating point unit, and a subsystem to assist with bit stream access and variable-length (Huffman) encoding and decoding.

The HiFi 4 Audio Engine, a SIMD (single-instruction/multiple-data) processor, has the ability to work in parallel on two 32-bit data items or four 16-bit data items. For example, it allows for one operation to perform two 32-bit additions in parallel, with each addition occupying half of a 64-bit AE_DR register.

The HiFi 4 multipliers support multiplication of four, 32-bit operands per cycle. There are operations for single, dual, and quad multiplication. Single or dual multiply operations can be dual issued using VLIW instructions. Special 32x16 and 16x16-bit dot-

product instructions can be dual issued, allowing for a peak of eight multiply operations per cycle. Quad multiply operations cannot otherwise be issued together with other multiplies.

The HiFi 4 Audio Engine can only be configured to use a little-endian byte ordering.

In general, 16-bit support is geared towards efficient support of the ITU-T/ETSI intrinsic model, while 32x16-bit and 32-bit support is provided for both integer and fixed-point computation.

HiFi 4 is a Very-Long Instruction Word (VLIW) architecture, supporting the execution of four operations in parallel. DSP loads, bit-stream and Huffman operations, and core operations are available in slot 0 and 1 of a VLIW instruction. Stores are available only in slot 0. DSP MAC (multiplier–accumulator), ALU, and optional floating point operations are typically available in slots 2 and 3.

HiFi 4 supports either caches or local memories.

14.7.1.1 Block Diagram

The following diagram illustrates the main custom state, register file, and execution units added by the HiFi 4 Audio Engine.

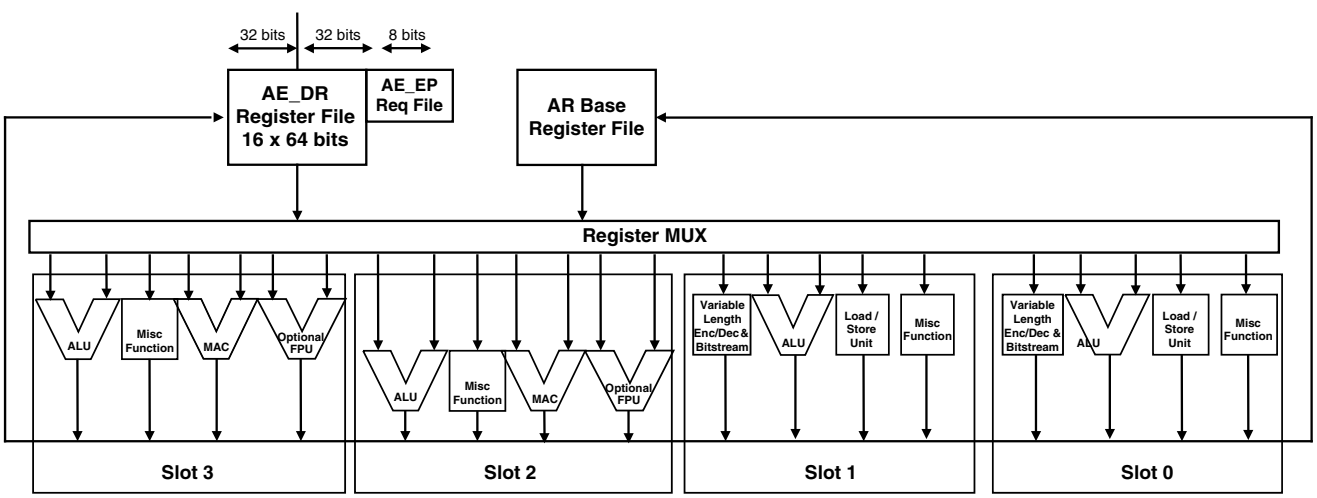

Figure 14-42. HiFi 4 Components

The main hardware resources in the DSP subsystem are two 2/4-multiplier multiply/ accumulate units, an option for two copies of a 2-way SIMD single-precision IEEE floating point unit, a 16-entry register file AE_DR to hold 64-bit, pairs of 32-bit, or quads

of 16-bit data items, an arithmetic/logic unit, an 8-entry register file, AE_EP, to hold eight extra guard bits for AE_DR registers and a shift unit to operate on the AE_DR values.

The multiplier units support four 32x32, up to eight 16x32 or 16x16-bit MACs per cycle. The multiplies are supported through single-instruction quad multiplies or through parallel-issued dual, single, or quad multiply instructions.

The load/store unit is capable of loading or storing up to two 24-bit or 32-bit SIMD elements, four 16-bit SIMD elements, or single elements up to 64 bits in size. 24-bit data can either be contained inside 32-bit envelopes, or can be packed together into 24 bits of memory. Eight packed elements can be loaded or stored in three instructions. The load/store unit supports unaligned accesses, whereby a stream is first primed and afterwards 64 unaligned bits can be loaded or stored in every cycle.

The DSP subsystem can be issued in several VLIW formats. A few formats are encoded in 88 bits and support up to four slots. A few formats are encoded in 48 bits and can support up to two slots in each execution cycle, zero or one operation from each slot can be executed independently according to the static bundling expressed in the machine code.

14.7.1.2 Features

The HiFi 4 Audio Engine includes the following features:

- Four 32x32-bit MAC per cycle (2.7 GMACs)
- Instruction cache, Data cache and prefetching supported
- Instruction and Data Tightly Coupled Memories
- Access to external SDRAM
- 128-bit local AXI bus
- Local access to audio interfaces (eSAI, SAI, SPDIF) to reduce latency
- Support for EC/NR, Audio Codecs, Audio/Voice enhancements algorithms

14.7.2 Functional Description

The sections below describe the HiFi 4 functionality and architecture.

14.7.2.1 HiFi 4 Configuration

The table below provides the configuration details for HiFi 4:

Table 14-14. HiFi 4 Configuration Details

Feature	Value
DSP Frequency	800 MHz at overdrive voltage 600 MHz at nominal voltage
Instruction Cache size	32 KB
Data Cache size	48 KB
Prefetch supported	Yes
Instruction RAM TCM	2 KB
Data RAM TCM	64 KB
AXI Bus width	128-bit
On-Chip RAM (OCRAM)	256 KB

14.7.2.2 Instruction Set Architecture (ISA)

The table below provides the ISA details for HiFi 4:

Table 14-15. HiFi 4 Instruction Set Architecture Details

	HiFi 4
Instruction Set Architecture (ISA)	V32 (vf)
VLIW Slots	4
VLIW bundle Instruction Sizes	48 / 88-bit
Fixed Point MACs per Cycle – 32x32	4
Fixed Point MACs per Cycle – 24x24	4
Fixed Point MACs per Cycle – 16x16	8
Accumulator	64 / 72-bit
Circular buffer support	2
Load/store units	2

14.7.2.3 HiFi 4 Instruction Set Overview

A wide variety of load/store operations support multiple addressing modes, with support for 16/24/32-bit scalar and vector data types together with 56/64-bit scalar. Vector data management is supported with select operations and shifting.

Multiply operations include 32x32-bit, 32x16-bit, and 16x16-bit. Multiply operations come in fixed-point and integer variants. They come in high precision and low precision variants. High-precision multiplies utilize a 64-bit accumulator and in some cases an additional 8-bit extended precision accumulator. Since an accumulator can only hold one result, HiFi 4 supports dual multiplies where the results of two multiplies are added or subtracted together before being added into the accumulator.

Low-precision multiplies accumulate in 32bits or 16 bits. Since each register can hold two, 32-bit accumulators (or four 16-bit accumulators), these instructions can perform two or four independent SIMD multiplies.

A set of bit-stream and variable length instructions allow for efficient access of serial bit streams, including Huffman encode and decode.

The optional floating point unit supports two 2-way SIMD units of IEEE-754 single-precision floating point operations.

14.7.2.4 AE_DR Register

The HiFi 4 Audio Engine contains a 16-entry, 64-bit register file, AE_DR. Each register can hold one or two, 24- or 32-bit operands, one or four 16-bit operands or one 56- or 64-bit operand as shown in Figure 2-1. 24-bit and 56-bit operands are sign extended to fill their 32- or 64-bit container. The separate halves or quarters of the register are always separate data items. For example, if you shift a 32-bit element to the left, the L element does not spill over into the high element.

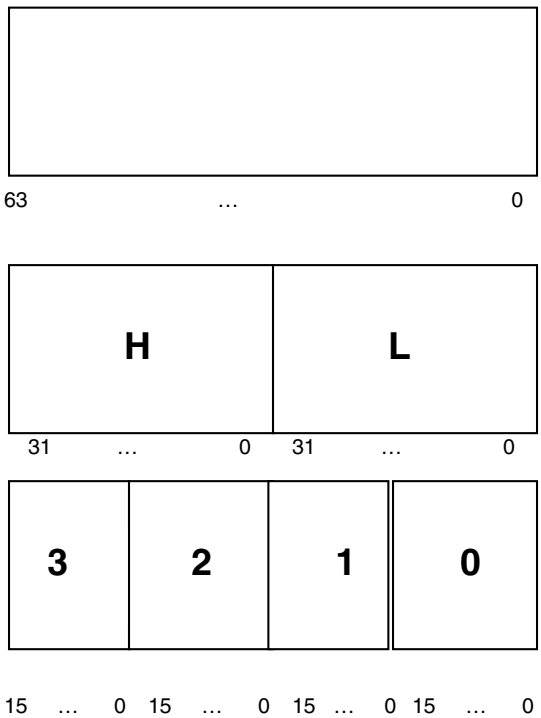

Figure 14-43. AE_DR Register

When a register is stored to memory, the high half of the register is always stored in the lower memory address. Operations that access individual 24- or 32-bit elements of AE_DR registers refer to the elements with selectors L and H in the mnemonics. Operations that access individual 16-bit elements refer to the elements with sectors 3, 2, 1 and 0 in the mnemonics.

14.7.2.5 AE_EP Register

HiFi 4 supports an 8-entry, 8-bit extra precision register, AE_EP. This register is used in conjunction with some multiply, add, shift, and saturate instructions to provide a total of 72 bits of precision. This register is accessed one cycle later than the AE_DR register. Accumulations can still happen every cycle, but there is an extra cycle of delay when trying to shift or saturate the extra accumulator back down to 64 bits.

14.7.2.6 Prefetching

HiFi 4 includes a prefetch option geared for systems with long memory latency. When the HiFi 4 processor detects a positive stride-1 stream of cache misses (either data or instruction), it can speculatively prefetch ahead up to four cache lines and place them in a

buffer close to the processor, or on the data side optionally into the L1 data cache (there is no support for prefetching directly into the L1 instruction cache). In addition, prefetch instructions can be manually issued.

Hardware prefetching is enabled by default. By default, on configurations that support it, data prefetches are placed into the L1 data cache. HAL calls can be used to explicitly disable prefetching or to increase its aggressiveness in different sections of the code. With more aggressive prefetching, the hardware will prefetch earlier when detecting a stream and will prefetch more lines ahead. With aggressive prefetch, the system will require more bandwidth. Prefetching instructions and data can be controlled separately.

14.7.2.7 VLIW Slots and Formats

HiFi 4 can issue up to four operations in a single 88-bit instruction bundle or two operations in a 48-bit bundle. HiFi 4 supports several different formats with different slotting constraints. Every instruction belongs to one format but different formats may pack different numbers of operations in a single instruction.

In general, the first slot supports loads and stores and core operations, the second slot supports loads and core operations and the last two slots support ALU and multiply operations. One of the 48-bit formats uses a dummy second slot to allow multiply operations in the third nominal slot.

For the optional floating point unit, most floating point operations are available in the third and fourth slot, allowing the machine to issue, for example, two SIMD floating point loads in parallel with two, SIMD (2-way), multiply-accumulation operations, allowing for an aggregate of four multiply-accumulation operations per cycle.

A subset of the operations as well as all the bit-stream operations are available in a single issue, 24-bit format called Inst. The compiler will automatically use the 24-bit format when it is not possible (or beneficial) to bundle a relevant operation together with an operation that can go in another slot. Core instructions are all available in Inst or an even smaller 16-bit format.

14.7.2.8 Load and Store Operations

HiFi 4 supports loading and storing scalars or vectors of 16, 24, 32 and 64 bits. Each scalar load/store accesses 16, 24, 32, or 64 bits. Each vector accesses 64 bits or 48 bits for packed 24-bit data. For vector loads and stores, the high address in memory is always stored in the least significant bits in the register. This enables the same source code to work on both little and big endian systems.

Reverse vector loads and stores reverse the elements in a register so that the low address in memory is stored in the least significant bits in the register. This way, whether accessing data in a stride one or stride negative one fashion, the earliest data to be accessed is always in the same position in the register.

HiFi 4 also supports two circular buffers that can be used with either aligned or unaligned data.

14.7.2.9 Multiply and Accumulate Operations

The HiFi 4 ISA supports a rich collection of single, dual, and quad multiply/accumulate operations with different input and output precision, scaling, rounding and saturation modes. HiFi 4 supports four 32-bit or 16-bit multiplies per cycle. Eight 32x16-bit multiplies per cycle are supported but only using four way, dot-product instructions that can only be scheduled together with loads. Otherwise, four 32x16-bit multiplies can be performed per cycle. Individual operations perform one, two, or four multiplies. Single or dual-multiply operations can typically be dual-issued in a VLIW bundle.

Chapter 15
Graphics Processing Unit (GPU)

15.1 GPU Overview

15.1.1 Overview

This section provides a high-level overview of the Graphics Processing Unit (GPU) subsystem in the chip. This chip uses two GPU cores, one for 3D processing and the other to provide 2D and Composition acceleration.

15.1.1.1 Block Diagram

The high level block diagram for the GPU subsystem is shown below:

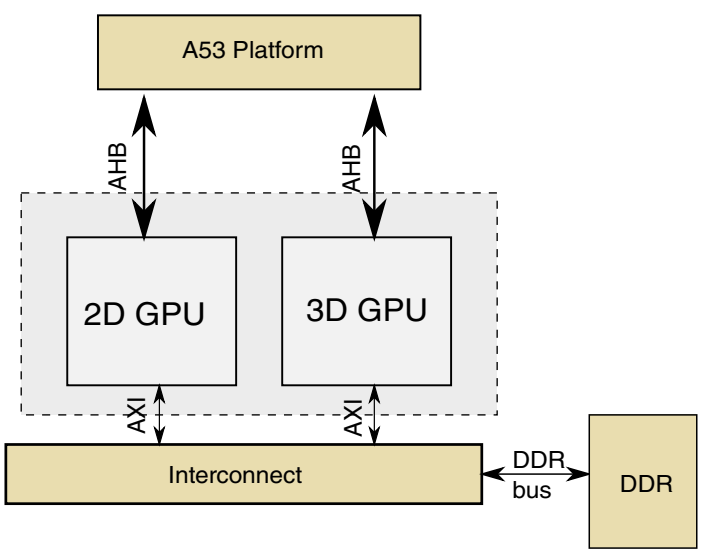

Figure 15-1. GPU Subsystem High Level Block Diagram

The 3D GPU and 2D GPU are designed in such a way that if only one core is required, the other can be gated off.

15.1.2 Features

The key features of the GPUs are described below:

- 3D GPU Core:
  - Two Shader Execution Units
  - Supports OpenGL ES 1.1, 2.0, 3.0, 3.1
  - Supports OpenCL 3.0
  - Supports OpenVG 1.1
  - Supports OpenGL 4.0
  - Supports EGL 1.5
  - Supports Vulkan 1.1
  - Supports tile format
- 2D GPU Core:
  - Supports multi-source composition
  - Supports one-pass filter
  - Supports tile format from 3D GPU

15.2 2D Graphics Processing Unit (GPU2D)

15.2.1 Overview

This 2D Graphics Processing Unit (GPU) is a high-performance, multi-pipe 2D raster graphics core that accelerates the 2D graphics display and provides advanced composition capabilities.

15.2.1.1 Block Diagram

The block diagram of the 2D GPU and the description of the functional blocks is provided below.

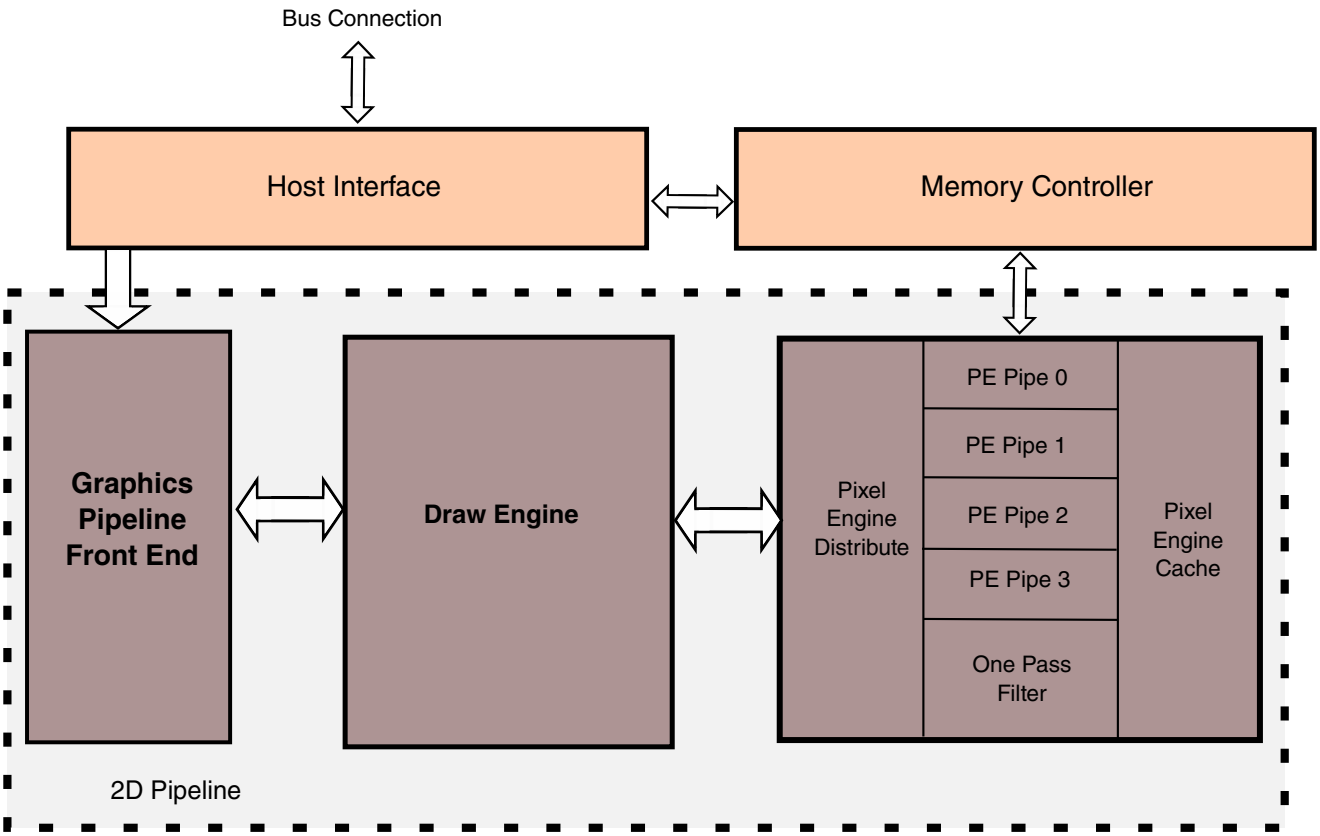

Figure 15-2. 2D GPU Block Diagram

- **Host Interface** - Allows the core to communicate with external memory and the CPU through the AXI or the AHB bus. In this block, data crosses clock domain boundaries.
- **Memory Controller** - Internal memory management unit that controls the block-to-host memory requests.
- **Graphics Pipeline Front End** - Inserts high level primitives and commands into the graphics pipeline.
- **2D Drawing and Scaling Engine** - Draws 2D graphics primitives and rasterizes 2D images.
- **Pixel Engine** - Pixel manipulation and filtering on rendered images. The GPU has four pixel pipes.

15.2.1.2 Features

The features of the GPU include:

- API Support:
  - NXP G2D API
- 2D GPU Unit:
  - Bit Blit

    - Stretch Blit
    - Rectangle fill and clear
    - Line drawing
    - Filter Blit
    - Mono expansion for text rendering
    - ROP2, ROP3 and ROP4
    - Alpha blending, including Java 2 Porter-Duff compositing blending rules
    - 32K x 32K coordinate system
    - 90 / 180 / 270 degree rotation
    - Transparency by monochrome mask, chroma key, or pattern mask
    - Support 2x2 in 4x4 tile format
    - A8 output with rotation in filter Blit and bit Blit
    - Src/Dest color key full bypass support
- Multi Source Blending:
    - Full support for Multi source blending with variable block size to improve BW and reduce SW overhead
    - Up to 8 sources are supported
    - Programmable block size guarantees cache efficiency so each source is read once and each destination is written once
    - Supports 90, 180, 270 degree rotation with different block size for higher cache efficiency
- YUV Support:
    - Full Multi destination support for converting non-planar YUV formats to planar YUV. It is used in extracting various components from input color into different destination planes
    - YUV422 output with alpha blending supported
- Clock disabling:
    - The core clock enters the frequency scaling block, and a clock with missing pulses is output, buffered, and sent to clock gating logic. The clock gate output will be used by the 2D GPU blocks. The core clock can be shut down through software by setting the proper register bits
- AXI Bus:
    - AXI 4-bit ID, such that all Read and Write transactions have a unique AXI ID
    - AXI out of order read return supported
- Additional Enhancements:
    - Full functional MMU with variable page size support
- Rotation:
    - 90° / 180° / 270° / Mirror rotation is supported for all primitives
    - Independent source rotation
- Transparency Mode:
    - For Monochrome Expansion:

    - Opaque
    - Conditional transparency - Transparent if the current pixel matches the specified value
  - For blits:
    - Opaque
    - Masked transparency - Transparent if the mask for the current pixel or pattern is zero
    - Source Conditional transparency - Transparent if the source pixel is within the specified value range
    - Destination Conditional transparency - Transparent if the destination pixel is not within the specified value range
- Clipping:
  - One clipping rectangle is supported for all bit blit primitives

15.2.1.2.1 GPU Host and Memory Interface Features

Table 15-1. Host and memory interface features

Feature	GPU Support
AHB interface	32-bit
Interface for External memory access	one 128-bit AXI
Virtual memory support	Yes
Out of order return support	Yes, supports out of order return for different clients
Code and data memory location restrictions	Unrestricted; arbitrary memory reads and writes
System address space	256 Kbytes (64K 32-bit words); however, the range of addresses used is only 4 Kbytes
Physical address	32 bits
Resource locks with CPU	Semaphore lock
Read write request size support	Memory controller supports 16, 32, 64, 128 byte read and write requests
MMU with variable page size support	MMU supports variable page sizes (4KB, 64KB, 1MB, 16MB)
GPU Cache Flush	Auto-flush at programmable intervals

15.2.1.2.2 GPU Power Management Features

Table 15-2. Power management features

Feature	Support
Low power CMOS technology compatible	Yes
Dynamic clock scaling	Yes
Automatic clock gating of flip flops and rams	Yes
Global clock gating of unused macro blocks	Yes
Active(ON), Idle, Standby and Sleep(OFF) Programmable Power Modes	Yes

15.2.1.2.3 Composition and 2D Hardware Features

This following table provides additional details on the hardware features supported by 2D GPU.

Table 15-3. Composition and 2D Hardware Features

Feature	Support
Programmable OPs	ROP2, ROP3, ROP4 full alpha blending and transparency
Fixed function	Line draw,Rectangle fill, Rectangle Clear, Bit blit, Stretch blit, Filter blit
Blit support	Copy (Bit), Filter, Monochrome Mask, Stretch/Shrink
Alpha blending modes	Java2 Porter-Duff, Chroma Key, Pattern Mask
Alpha blending during filter blit	Not supported
Transparency	Supported by monochrome mask, chroma key or pattern mask
Dithering	2D dither support
Image scaling	Filter Blit FIR resampling filter with up to 9 taps, One Pass Filter with 3/5 taps
Rotation	90 / 180 / 270 degrees with mirror
Clipping	one clipping rectangle supported for all bit blit primitives.
Text rendering	Monochrome expansion
Rendering size	32k x 32k raster 2D coordinate system
Compression	Lossless, tiled compression support

15.2.1.2.3.1 Source and Destination formats

The graphics engine supports the following source and destination formats for data, bit blits and filter blits. In addition to these source and destination RGB formats, their swizzle formats (ARGB, RGBA, ABGR, BGRA) are also supported. For YUV formats, the GPU supports their U/V swap formats.

Table key:

- Y = Yes
- N = No

- MD = Multi-Destinatin Support
- Yv = Only possible when vertical filter blit is done on YUV input

Table 15-4. Supported Source (Src) and Destination (Dest) formats

Format	Bit Blit Src	Bit Blit Dest	Stretch Blit Src	Stretch Blit Dest	Filter Blit Src	Filter Blit Dest	OPF Src	OPF Dest	Multi-Source Src	Multi-Source Dest
A1R5G5B5	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
A4R4G4B4	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
A8R8G8B8	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
X1R5G5B5	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
X4R4G4B4	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
X8R8G8B8	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
R5G6B5	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
A8	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
YUY2 (packed YUV422)	Y	Y	Y	N	Y	Yv	Y	Yv	Y	Y
UYVY (packed YUV422)	Y	Y	Y	N	Y	N	Y	Y	Y	Y

NV12 (semi-planar YUV420)	Y	MD	Y	N	Y	N	Y	N	Y	N
NV16 (semi-planar YUV422)	Y	MD	Y	N	Y	N	Y	N	Y	N
8-bit color index	N	N	Y	N	Y	N	N	N	Y	N
1-bit monochrome	Y	N	N	N	N	N	N	N	N	N

15.2.2 Functional description

15.2.2.1 Composition and 2D Operations

15.2.2.1.1 Line

The LINE operation draws a line. The coordinates for two points are given - start point and end point and the end point is not drawn.

Lines are rendered using the Bresenham algorithm. The Bresenham algorithm has the advantage of using integer arithmetic and has no accumulation of rounding errors.

In the case of line, only ROP2 and ROP4 are supported. It operates on pattern and destination. The pattern should have a transparency mask in order to use ROP4.

Clipping is supported for lines on a per pixel basis.

the figure below shows the operation in more detail.

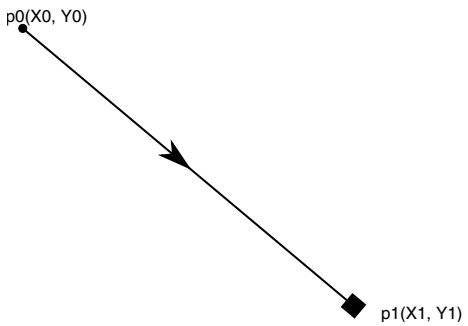

Figure 15-3. Line

15.2.2.1.2 Rectangle Fill and Clear

Rectangle fill suffuses a rectangle area with a given color. Essentially rectangle fill is a pattern fill, where an 8x8 pattern is initialized with the specified color. It supports ROP2 and ROP4 with the pattern and destination as its inputs. If ROP4 is used, the pattern should have a transparency mask.

Clear is similar to rectangle fill except that it does not use a pattern. A 32-bit clear value with 4-bit byte mask is used to fill the entire rectangle area.

Both rectangle fill and clear support clipping, which is performed on a per primitive basis.

15.2.2.1.3 Bit Blit

Bit blit transfers data from one area of a memory (source) to another area of the memory (destination). The source and destination can be from the same or from different memory locations. Both source and destination must be described by a rectangular area. The source and destination rectangles can be the same size (most bit blits are of this nature) or they can be different sizes, in which case the operation becomes a stretch or shrink blit.

Bit blit supports ROP2, ROP3, and ROP4 which includes source, destination and pattern, and an optional transparency color.

Clipping can be performed on a primitive basis.

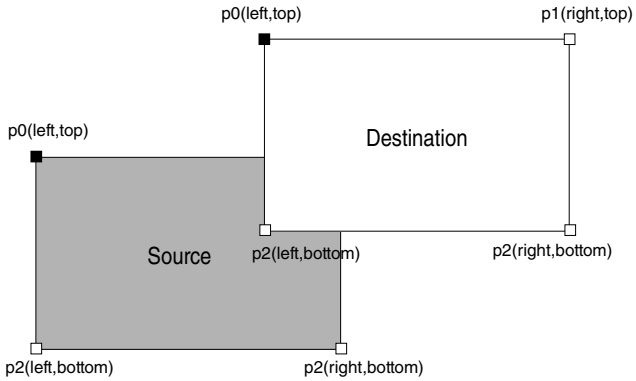

Figure 15-4. Bit Blit

15.2.2.1.4 Stretch Blit

The stretch blit primitive performs a bit blit operation with stretch or shrink. The modified Bresenham algorithm is used to generate corresponding coordinates for fast stretching. The stretch factor is specified in a 15.0 fixed-point format. Stretch blit is not allowed to overlap, that is, no part of source and destination can share any piece of memory. Non-stretch blits can overlap. For stretch blit clipping is performed on a per pixel basis.

15.2.2.1.5 Monochrome Expansion and Mask Blit

Monochrome expansion and mask blit are different operations, although both use the bit stream from the command buffer. And both can be the source for ROP4 source selection. This means that each output pixel can be a combination of source, pattern, monochrome mask (for masked blits) and destination.

Monochrome expansion

For monochrome expansion, the bit from the stream is used to switch on/off a solid color that is defined in a register. This mechanism enables the use of just one bit per pixel to represent colors. In effect, the MONO EXPANSION primitive increases color representation from one bit per pixel to multiple bits per pixel. A typical application for mono color is font drawing.

Monochrome expansion does not support overlapping of the source and destination. It is the responsibility of the driver to make sure that the command will never be executed on overlapping source and destination.

Mask Blit

For mask blit, the bit from the stream is used to toggle on/off a color in the source frame buffer. Mask blit takes its color source from memory and its monochrome mask from the command stream. Clipping is supported and is performed on a per pixel basis.

15.2.2.1.6 YUV Output for 2D Operations

YUV output is available for packed or planar YUV input formats per the following table.

Table 15-5. YUV Output Support for Packed or Planar YUV Source per 2D Operation

2D Operation	Destination
Bit blit	Packed YUV
One Pass Filter	Packed YUV
Multi-source	Packed YUV (no scaling)
Multi-destination	Planar YUV
Stretch blit	NO
Two Pass Filter	NO

15.2.2.1.7 ARGB Data Conversion

The pixels read from source or destination will be expanded into A8R8G8B8 format to maintain lossless pixel operations. The resulting pixels will be converted into the destination format.

15.2.2.1.8 YUV to RGB Conversion

YUV data can be converted into 8-bit per component RGB format at the output of the cache only. Once converted, there is no way back to YUV format. GPU supports BT.601 and BT.709 YUV to RGB color conversion standards.

In BT.601, the YUV to RGB conversion is done using the following approximation:

$$16 \le Y \le 235$$
$$16 \le U \le 240$$
$$16 \le V \le 240$$

$$A = Y - 16 \quad B = U - 128 \quad C = V - 128$$
$$R = clip((298*A + 410*C + 128) >> 8)$$
$$G = clip((298*A - 101*B - 209*C + 128) >> 8)$$
$$B = clip((298*A + 519*B + 128) >> 8)$$

The Y, U and V components are clamped prior to the conversion. Y is clamped between 16 and 235, inclusively. U and V are clamped between 16 and 240, inclusively.

In BT.709, the R, G, B equations are slightly changed to:

R = clip((298*A + 461*C + 128) >> 8)
G = clip((298*A – 55*B – 137*C + 128) >> 8)
B = clip((298*A + 543*B + 128) >> 8)

15.2.2.1.9 Color Index Input Conversion Support

Color index is supported for source data only. A look-up table with 256 entries is provided for indexing the data. The table is fully programmable. The conversion is done when pixels are read out of the cache.

15.2.2.1.10 Source/Destination Pre-multiply Support

The GPU supports pre-multiply source alpha or global alpha, or source global color for global colorizing.

On destination, the GPU supports destination pre-multiply and destination alpha.

On destination, the GPU supports destination pre-multiply destination alpha, destination de-multiply alpha.

Table 15-6. Pre-multiplied modes

Microsoft Alpha Blending	Equation
S:Fix Alpha	D.C=A*S.C+(1-A)*D.C
	D.A=A*S.A+(1-A)*D.A
S:Per-Pixel	D.C=S.C+(1-S.A)*D.C
	D.A=S.A+(1-S.A)*D.A
S:Fix+Per-Pixel	D.C=A*S.C+(1-S.A)*D.C
	D.A=A*S.A+(1-S.A)*D.A
S:Per-Pixel	D.C=S.A*S.C+(1-S.A)*D.C
	D.A=S.A+(1-S.A)*D.A
S:Fix+Per-Pixel	D.C=A*S.A*S.C+(1-S.A)*D.C
	D.A=A*S.A+(1-S.A)*D.A

NOTE

D: Destination

S: Source

A: Alpha

C: Color

15.2.2.1.11 Source/Destination Pre-multiply Support

The GPU supports alpha blending together with ROP. Alpha blending function is performed on ROP function result source.

The general alpha blending equations are:

$$Cd = Fs * Cs' + Fd * Cd'$$
$$Ad = Fs * As'' + Fd * Ad''$$

Where, Cs' is the source color component (adjusted for NPM if necessary)

Cd' is the destination color component (adjusted for NPM if necessary)

As'' is the modified source alpha component

Ad'' is the modified destination alpha component

Fs is fraction of the source that contributes to the final value

Fd is fraction of the destination that contributes to the final value

The blending is done in four logical stages:

1. Transparent/opaque conversion - In this stage, the incoming alpha (source or destination independently) can be inverted if needed to match the internal alpha rule. Internally, an alpha of 0 means transparent, while an alpha of "0xFF" means opaque. External content might follow the opposite rule. The output of the block is either As (Ad for destination) or 1-As (1-Ad for destination).
2. Global value substitution - A global alpha value from a register can be used to substitute or scaled the incoming alpha. An incoming alpha As can pass-through, be directly substituted by Ags (global alpha) or scaled by the global alpha value (As * Ags). The source and destination have distinct global alpha values.
3. Blending factor generation - At this stages, the blending factors are generated (refer to table below). Each alpha can take the values 0, 1, A or 1-A depending on the blending mode.
4. Final blending - This is the final stage which implements the operations described by equations.
5.

The stages are shown in the figure below:

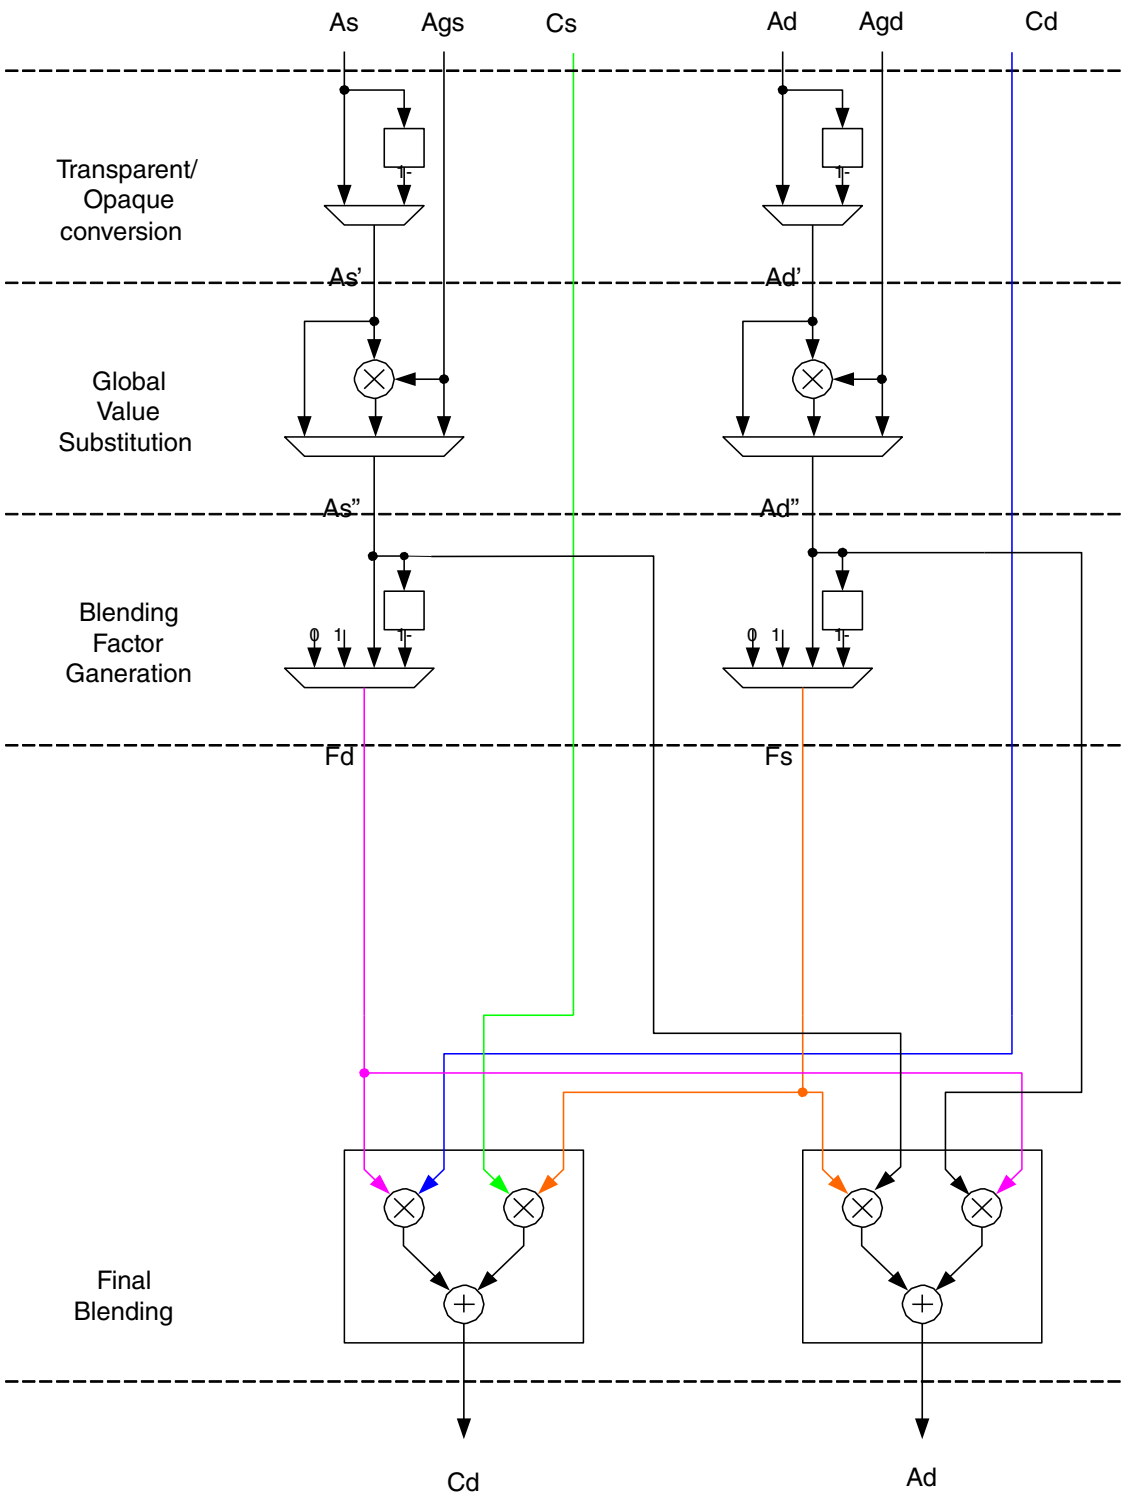

Figure 15-5. Alpha Blender for One Pixel

The fractions take the values described in the following table, depending on the blending mode:

Table 15-7. Blending Modes Fractions Description

Blending Mode	Fs	Fd
Clear	0	0
SRC	1	0
DST	0	1
SRC_OVER	1	1 – As”
DST_OVER	1 – Ad”	1
SRC_IN	Ad”	0
DST_IN	0	As”
SRC_OUT	1 – Ad”	0
DST_OUT	0	1 – As”
SRC_ATOP	Ad”	1 – As”
DST_ATOP	1 – Ad”	As”
XOR	1 – Ad”	1 – As”

15.2.2.1.12 Dither

Color intensity at any point of an image can be thought of as a real number between 0.0 and 1.0 at each location. However, in reality only a discrete number of intensity levels can be represented. This discretization leads to a total error in the color intensities of an image equal to the square root of the sum of the squares from each point.

This error results in contouring. In an image where intensities change slowly, this will cause noticeable jumps. Dithering can be used to diffuse the intensity across neighboring pixels.

In dithering mode pixels are scanned in order, and errors in calculating a pixel's intensity are distributed (i.e., diffused) to neighboring pixels to keep the overall intensity of the image closer to the input intensity.

Dithering is supported for 16-bit color destination formats. The dither table is programmable by software.

15.2.2.1.13 Multi-Source Blending

Up to 8 sources are supported. Programmable block size guarantees cache efficiency so each source is read once and each destination is written once. It supports 90, 180, 270 degree destination and source rotation and mirror with different block size to have high

cache efficiency. It also supports ROP2, ROP3, and ROP4 which includes source, destination and pattern, and an optional transparency color. Alpha blending between every source is supported.

15.2.2.1.14 GPU Cache Management

SW cache flush is supported to flush the GPU cache to memory. Auto-flush of GPU cache is also supported. SW sets up the auto-flush interval, and HW will do the cache flush automatically at programmable intervals.

15.2.2.2 Clocks

The following table describes the clock sources for the 2D GPU. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 15-8. 2D GPU Clocks

Clock name	Description
clk2x	GPU core clock
HCLK	AHB interface clock
ACLK	AXI interface clock

15.2.3 External Signals

There are no external signals pinned out for this module.

15.2.4 Initialization and Application Information

The GPU should be programmed through the NXP provided driver. NXP does not provide support for software that directly programs the GPU registers. APIs for programming the GPU through the software driver are described in separate driver documentation.

15.3 3D Graphics Processing Unit (GPU3D)

15.3.1 Overview

The 3D Graphics Processing Unit (GPU) provides high performance, high quality graphics, and low power consumption.

The 3D GPU supports modern API features and full support for Android, Linux, and a variety of other embedded development platforms.

15.3.1.1 Block Diagram

The block diagram of the GPU and description of the functional blocks is provided below.

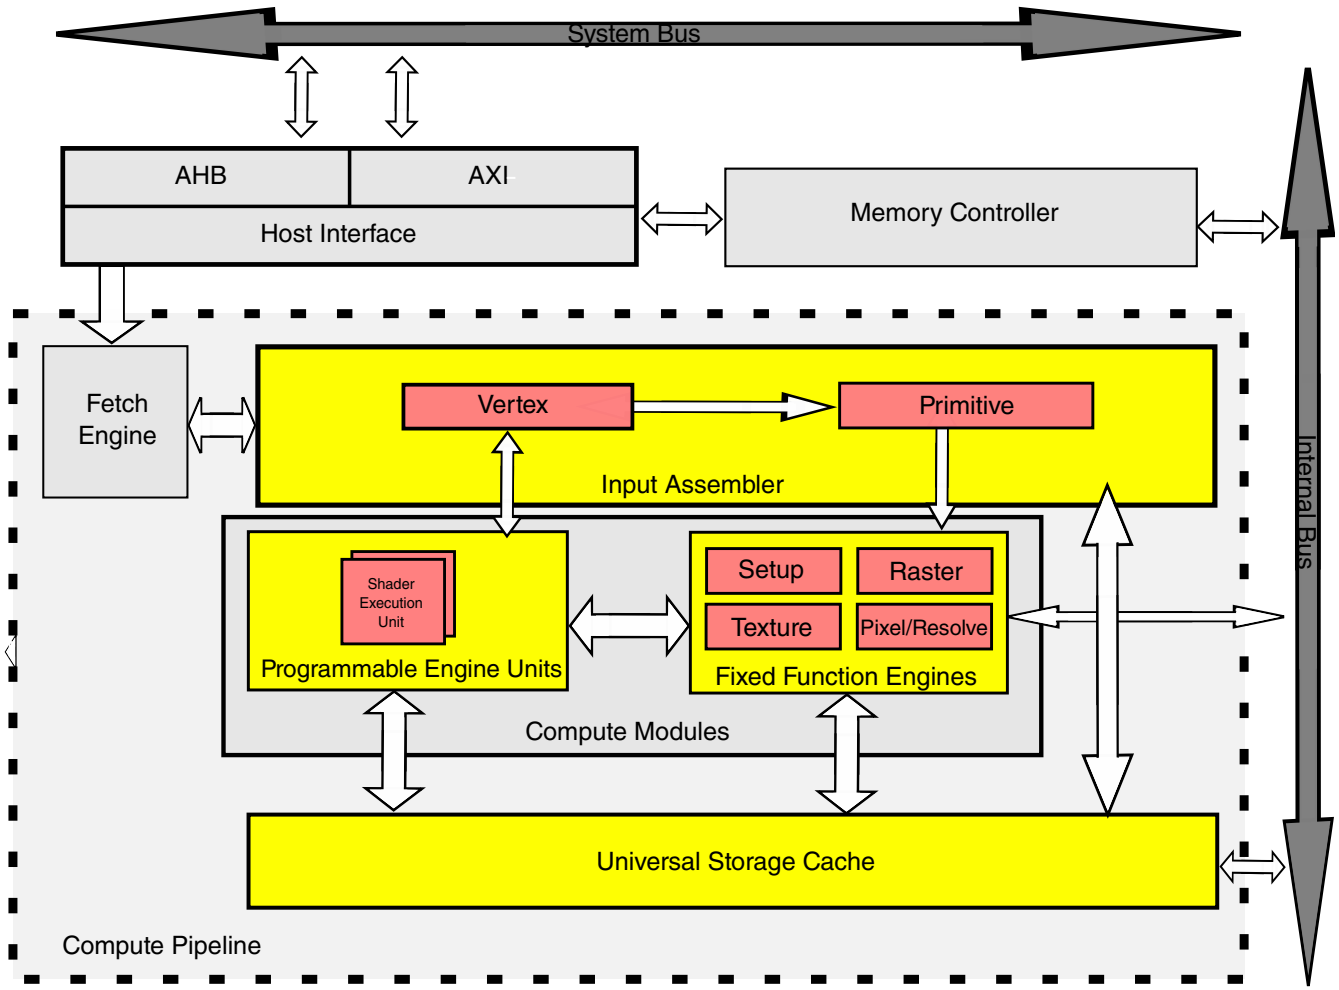

Figure 15-6. GPU Block Diagram

- Host Interface - Allows GCCORE to communicate with external memory and the CPU through AXI or AHB bus. In this block data crosses clock domain boundaries.
- Memory Controller - Internal memory management unit that controls the block-to-host memory request interface.
- Fetch Engine - Inserts high level primitives and commands into the graphics pipeline.
- Input Assembly - Assembles vertices and primitives for further processing.
- Compute Modules:
  - Fixed Function 3D Rendering Engine Units:
    - Setup/Raster - Converts triangles and lines into pixels. Computes slopes of color attributes and texture coordinates. Performs clipping.

- Texture Engine - Retrieves texture information from memory upon request by the vertex shader or fragment shader. Performs interpolation and filtering, and transfers the computed value to the fragment shader or the vertex shader. The texture unit can process one pixel or one vertice/cycle.
- Pixel Engine/Resolve - The Pixel Engine does alpha blending and visible surface determination. Resolve does resolve, clear, tiling and de-tiling as well as FSAA filtering. The Pixel Engine can process one pixel/cycle.

- Programmable Engine Units:
  - Shader Execution Units - SIMD processor that performs as vertex shader and fragment shader. When used as a vertex shader, it performs geometry transformations and lighting computations. When used as a fragment shader it applies texture data and computes color values for each pixel. The shaders also act as Compute Units for OpenCL. The GPU has 2 such vec4 shaders.
- Universal Storage Cache - Cache shared between the Fetch Engine and the Compute Modules. A portion of this cache can be locked to stay on-chip.

15.3.1.2 Features

The features of the GPU 3D unit include:

- IEEE 32-bit floating-point pipeline
- Ultra-threaded, unified vertex and fragment (pixel) shaders
- Low bandwidth at both high and low data rates
- Low CPU loading
- Up to 16 programmable elements per vertex
- Dependent texture operation with high-performance
- Alpha blending
- Depth and stencil compare
- Point sampling, bi-linear sampling, tri-linear filtering, and cubic textures
- Resolve and fast clear
- 8k x 8k texture size and 8k x 8k rendering target
- 8 Vertex DMA streams
- Generates 1 texel and 1 pixel per cycle.
- Supports YUV formats for display output (YUV422, YUYV 4:2:2)
- MMU functionality supported
- Wide AA line support
- Primitive restart support

15.3.1.2.1 API Support

The following table describes API support and select architectural features of the GPU:

Table 15-9. GPU Architecture Features

Feature	GPU Support
Primary API	OpenGL ES 3.1 / 3.0 / 2.0 / 1.1 OpenCL 1.1 / 1.2 / 3.0
Additional APIs	OpenVG 1.1 DirectX 11 (9_3) OpenGL 4.0 Vulkan 1.1
Other graphics support	EGL 1.5
Drivers	OpenGL ES 3.1 / 3.0 / 2.0 / 1.1 OpenVG 1.1 EGL 1.5 DirectX 11 (9_3) OpenGL 4.0 OpenCL 1.1 / 1.2 / 3.0
Operating systems	Windows Embedded Compact / Embedded CE 6 Embedded Linux Android 8.0/7.x / 6.0 /5.1 / 4.x
Z (depth)	Early Z support included
Stencil	Early stencil support included
GLSL ES Shader languages	3.1 / 3.0 / 1.0
DirectX Shader model compatibility	SM3.0
Shader types and execution units	Two programmable Scalable Ultra-threaded Unified Shaders (SIMD4:transcendental,ctl-flow,tx-load) one instruction issue per shader per clock; IEEE 32-bit floating-point pipeline supports long shader instructions
FSAA anti-aliasing mechanisms	High quality MSAA 4x

15.3.1.2.2 GPU Host and Memory Interface Features

Table 15-10. GPU host and memory interface features

Feature	GPU Support
AHB interface	32-bit
AXI interface	1 128-bit AXI / ACE-Lite interfaces for external memory access
Virtual memory support	Yes
Code and data memory location restrictions	Unrestricted; arbitrary memory reads and writes
Physical address	32 bits
Resource locks with CPU	Semaphore lock

15.3.1.2.3 GPU Power Management Features

Table 15-11. Power management features

Feature	GPU Support
Low power CMOS technology compatible	Yes
Dynamic frequency scaling based on current load	Yes
Automatic clock gating of flip flops and rams	Yes
Global clock gating of unused macro blocks	Yes
Independent clock gating for the shader core	Yes
Software controlled effective clock frequency without changing the PLL	Yes

15.3.1.2.4 GPU Command Processor Features

Table 15-12. GPU command processor features

Feature	GPU Support
Counters	Variety of hardware counters for performance profiling

15.3.1.2.5 OpenCL Support

Support for OpenCL includes the following capabilities in a full memory configuration:

Table 15-13. OpenCL Support

OpenCL Support	GPU Support
Profile	Full Profile with Global memory
Compute Devices (GPGPU cores)	1
Compute Units per device	1
Processing Elements per compute unit (vec4 sh cores)	2
Preferred work-group/ thread group size	8
Max count global work-items each dim	64KB
Max count work-items each dim per work-group	1 KB
Instruction Cache Size	512

15.3.1.2.6 Texture processing

Table 15-14. Texture Processing Features

Feature	GPU Support
Fixed-point input texture formats	A8, L8, A8L8, ARGB4, XRGB4, ARGB8, XRGB8, ABGR8, XBGR8, R5G6B5, A1RGB5, X1RGB5, YUY2, UYVY, D16, D24X8, A8_OES, DXT1, DXT2, DXT3, DXT4, DXT5, HDR7E3, HDR6E4, HDR5E5,

Table 15-14. Texture Processing Features (continued)

Feature	GPU Support
Dependent texture operation	High performance; unlimited dependent texture reads
Dependent tx per fragment max, relative sampling	No Limit
Texture repeat max	256
Texture types	2D, seamless cube map, 1D, projected, depth, bump map, displacement map, PCF, 3D, texture array
Texture filters	Point sample, bi-linear, fast tri-linear (1 pixel/cycle), quad-linear, Anisotropic
Texture component mapping: D3D, OGL ES options	Supports both D3D and OES options
Texture size types	Power-of-2, Non-square, Non-power-of-2
Texture swizzle	Yes
OES3 half-float support	Yes

15.3.1.2.7 Fragment Processing and Render Targets

Table 15-15. Fragment Processing and Render Target Features (continued)

Feature	GPU Support
	Render Target no blend formats: A8, R8G8, RI8, RI16, RI32, RI8GI8, RI16GI16, RI32GI32, RI8GI8BI8AI8, RI16GI16BI16AI16, RI10GI10BI10AI2, RF11GF11BF10
Fragment storage / Render Target formats	16-bit color and z, 32-bit color and z for each fragment. Lossless compression, no storage reduction.
Individual fragment alpha masking	Yes
Two sided stencil support	Yes
Compressed formats	Yes, 30% - 70%
Fast clear and initialization options	Yes
Multiple Render Target support	Yes, 4 Targets

15.3.1.2.8 Destination / Alpha Blending

Table 15-16. Destination / Alpha Blending Features

Feature	GPU Support					
Destination / Resolve color formats	Bits	Format	Alpha	R	B	G
	16	ARGB4444	4	4	4	4
	16	ARGB1555	1	5	5	5
	16	RGB565	0	5	6	5
	32	ARGB8888	8	8	8	8
	32	ABGR8888	8	8	8	8
	32	RGB10_a2ui	2	10	10	10

15.3.2 Clocks

The following table describes the clock sources for the GPU. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 15-17. GPU Clocks

Clock name	Description
clkCore	GPU core clock for modules except Shader
clkSh	Core clock for Shader and Universal Storage Cache (USC)
HCLK	AHB interface clock
ACLK	AXI interface clock

15.3.3 External Signals

There are no external signals pinned out for this module.

15.3.4 Initialization and Application Information

The GPU should be programmed through the NXP provided driver. NXP does not provide support for software that directly programs the GPU registers. APIs for programming the GPU through the software driver are described in separate driver documentation.

Chapter 16
Video Processing Unit (VPU)

16.1 VPU G1 Decoder

16.1.1 Overview

The Video Processing Unit (VPU) G1 hardware-based decoder decodes H.264, and VP8 formats. The decoder conforms to the H.264 Baseline, Main and High profile, and VP8 Main Profile

16.1.1.1 Block Diagram

The block diagram of the VPU G1 decoder is shown below.

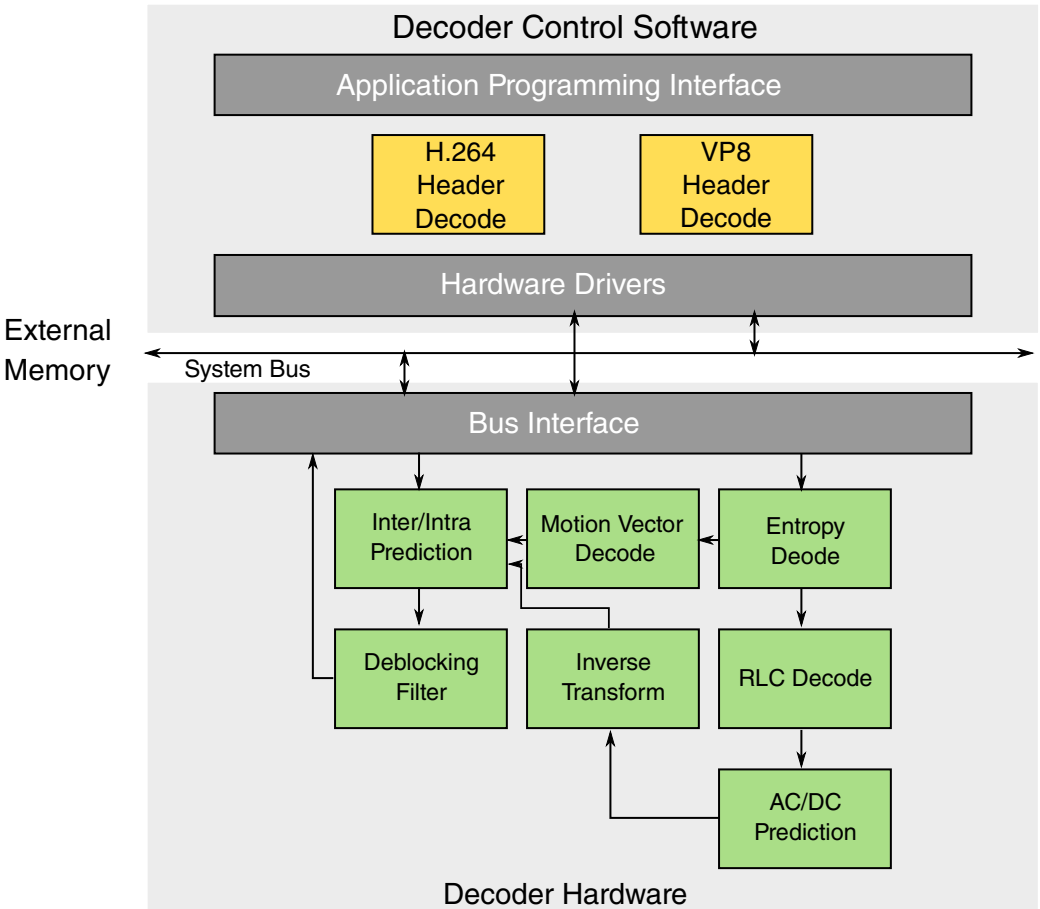

Figure 16-1. VPU G1 Decoder Block Diagram

16.1.1.2 Features

The VPU G1 decoder includes the following features:

- H.264 baseline profile, levels 1-4.2 decoding
  - Byte stream input
  - NAL unit input
- H.264 main and high profile, levels 1-4.2 decoding
- VP8 decoding

16.1.2 Functional description

16.1.2.1 Video Frame Storage Format

The following sections describe the different input and output picture storage formats supported by the decoder.

Table 16-1. Input and output picture storage formats

Input data format	Output data format
H.264 byte or NAL unit stream	YCbCr 4:2:0 semi-planar raster-scan YCbCr 4:2:0 semi-planar 8x4 tiled YCbCr 4:0:0 (monochrome)
VP8 stream	YCbCr 4:2:0 semi-planar raster-scan YCbCr 4:2:0 semi-planar 8x4 tiled

16.1.2.1.1 Raster-scan format

The output picture of the decoder is in semi-planar YCbCr 4:2:0 format, i.e. luminance data forms one plane in memory, and chrominance data forms another. The output picture has to be stored linearly and contiguously in the memory. The interleaved chrominance block has to be stored right after the luminance block in external memory as shown in the following figure. The number of luminance pixels in one row must be divisible by 16.

The interleaved chrominance is stored raster-scanned in memory in Cb0Cr0Cb1Cr1Cb2Cr2Cb3… format.

The decoder output picture for interlaced sequence is always stored as an interlaced frame where even lines belongs to top field and odd lines belongs to bottom field of the frame.

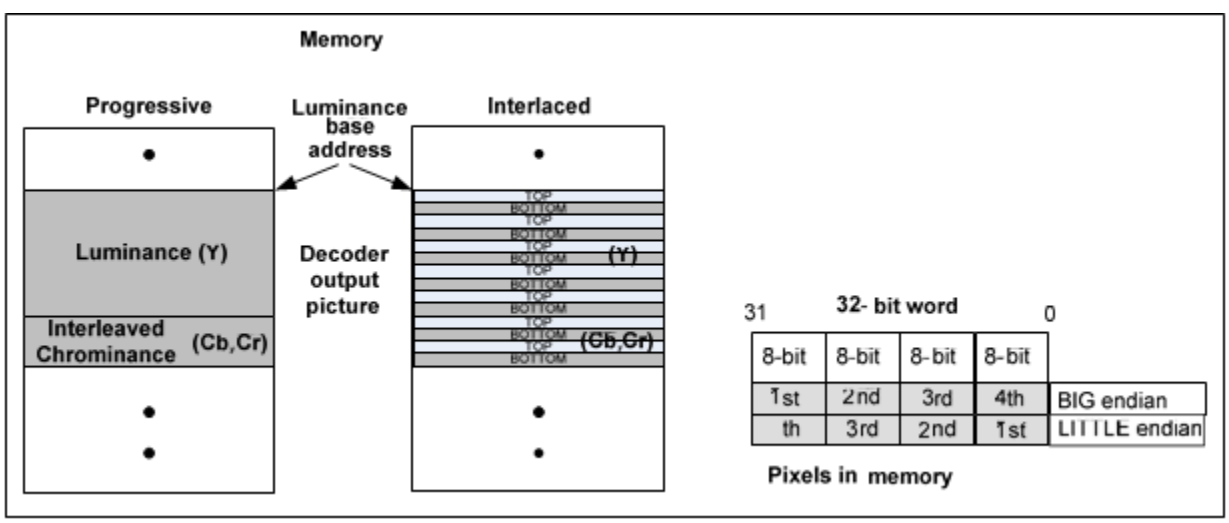

Figure 16-2. Raster-scan Format External Memory Usage

16.1.2.1.2 Tiled format

The output picture of the decoder is in semi-planar YCbCr 4:2:0 format, i.e. luminance data forms one plane in memory, and chrominance data forms another. The distinction from raster scan format is that the output picture is grouped into tiles, which are then stored linearly and contiguously in the memory. The chrominance tiles have to be stored right after the luminance tiles in external memory as shown in Figure 16-3. The number of luminance pixels in one row must be divisible by 16.

The chrominance is stored into tiles in interleaved Cb0Cr0Cb1Cr1Cb2Cr2Cb3… format.

The following figure is an example of external memory usage when using 8x4 tiles.

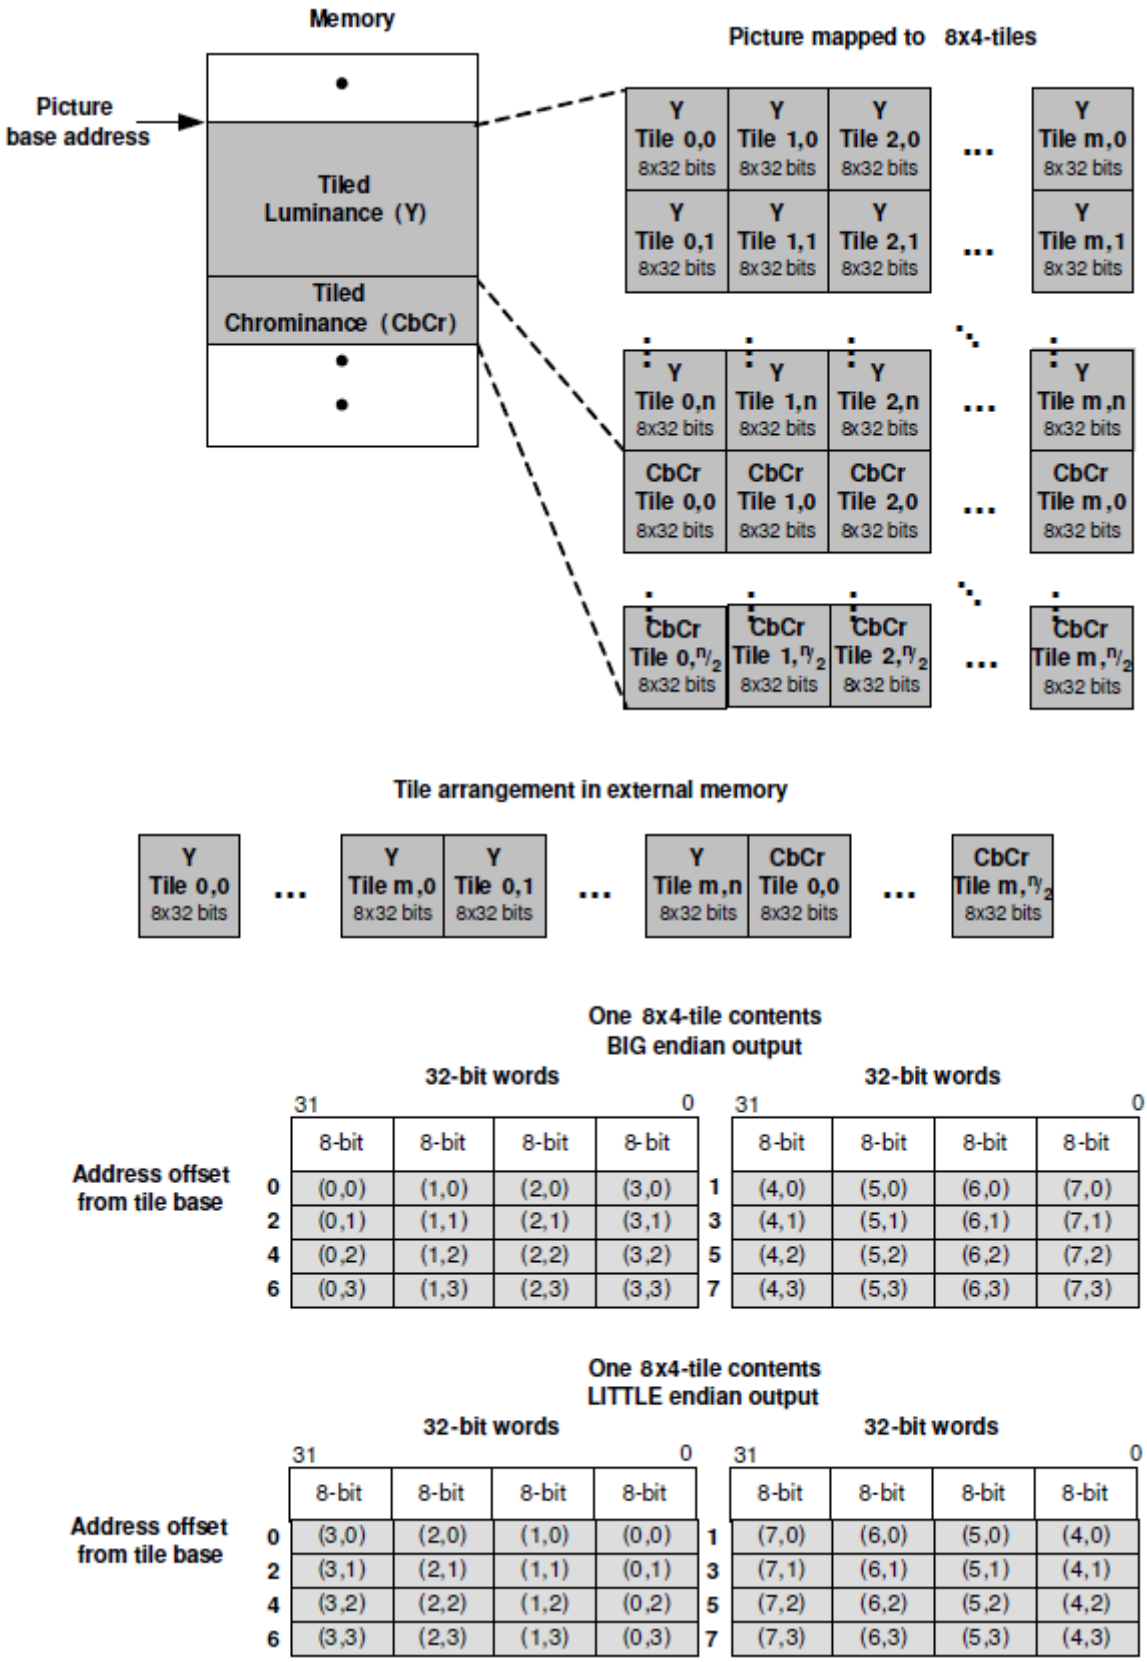

Figure 16-3. External Memory Usage in 8x4 Tiled Reference Picture Mode

16.1.2.2 Clocks

The following table describes the clock sources for the VPU G1 decoder. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 16-2. VPU G1 Clocks

Clock name	Description
core_clk	VPU G1 core clock

16.1.2.3 Reset

The VPU G1 decoder has one software reset (g1_sft_rstn).

16.1.3 External Signals

There are no external signals pinned out for this module.

16.1.4 Initialization and Application Information

The VPU G1 decoder is operated via the VPU Application Programming Interface (API). Details are provided in separate API documentation.

16.1.5 VPU G1 Register Decoder

The definition/function of a register's bit field(s) may differ depending on the decoder mode. The following table maps the bit fields in a register that are applicable for each decoder mode.

NOTE

The VPU G1 decoder supports H.264 and VP8 decoding only.

Bit	Name	Dec Modes

16.1.6 VPU G1 Memory Map/Register Definition

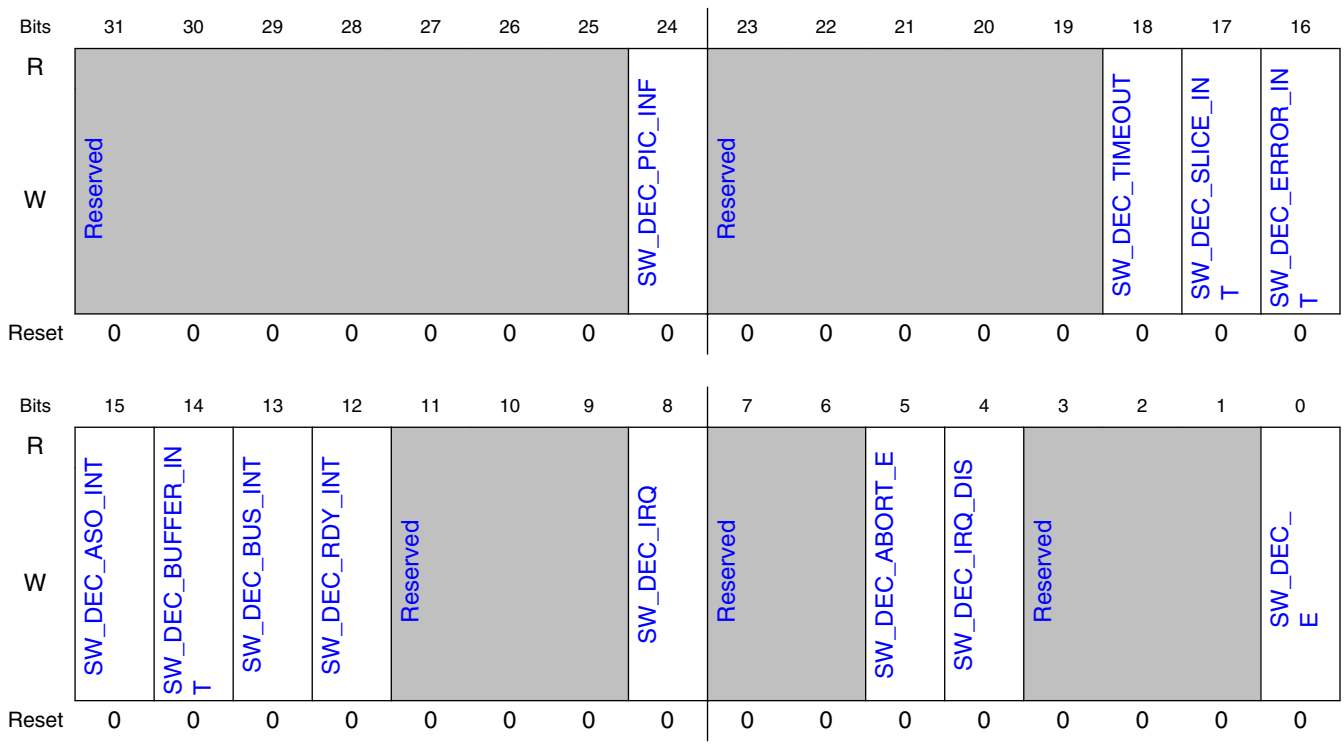
16.1.6.1 VPU_G1 common registers descriptions

16.1.6.1.1 VPU_G1 common registers memory map

VPU_G1 base address: 3830_0000h

Offset	Register	Width (In bits)	Access	Reset value
4h	Interrupt register decoder (SWREG1)	32	RW	0000_0000h
8h	Device configuration register decoder (SWREG2)	32	RW	0000_0000h

Table continues on the next page...



Offset	Register	Width (In bits)	Access	Reset value
Ch	Decoder control register 0 (decmode,picture type etc) (SWREG3)	32	RW	0000_0000h
30h	Base address for RLC data (RLC) / stream start address/decoded end addr register (VLC) (SWREG12)	32	RW	0000_0000h
34h	Base address for decoded picture (SWREG13)	32	RW	0000_0000h
A0h	Base address for standard dependent tables (SWREG40)	32	RW	0000_0000h
A4h	Base address for direct mode motion vectors (SWREG41)	32	RW	0000_0000h
C0h	Error concealment register (SWREG48)	32	RW	0000_0000h
C4h	Prediction filter tap register for H264 (SWREG49)	32	RW	0000_0000h
C8h	Synthesis configuration register decoder 0 (SWREG50)	32	RO	Table 16-2
CCh	Reference picture buffer control register (SWREG51)	32	RW	0000_0000h
D0h	Reference picture buffer information register 1 (SWREG52)	32	RO	0000_0000h
D4h	Reference picture buffer information register 2 (SWREG53)	32	RO	0000_0000h
D8h	Synthesis configuration register decoder 1 (SWREG54)	32	RO	0000_0000h
DCh	Reference picture buffer 2 / Advanced prefetch control register (SWREG55)	32	RW	0000_0000h
E0h	Reference buffer information register 3 (SWREG56)	32	RO	0000_0000h
E4h	Decoder fuse register (SWREG57)	32	RO	Table 16-2
E8h	Device configuration register decoder 2 + Multi core control register (SWREG58)	32	RW	0000_0000h
ECh	H264 Chrominance 8 pixel interleaved data base (SWREG59)	32	RW	0000_0000h
198h	Base address for H264 decoded chroma picture (SWREG102)	32	RW	0000_0000h
19Ch	Base address for reference chroma picture index 0 (SWREG103)	32	RW	0000_0000h
1A0h	Base address for reference chroma picture index 1 (SWREG104)	32	RW	0000_0000h
1A4h	Base address for reference chroma picture index 2 (SWREG105)	32	RW	0000_0000h
1A8h	Base address for reference chroma picture index 3 (SWREG106)	32	RW	0000_0000h
1ACh	Base address for reference chroma picture index 4 (SWREG107)	32	RW	0000_0000h
1B0h	Base address for reference chroma picture index 5 (SWREG108)	32	RW	0000_0000h
1B4h	Base address for reference chroma picture index 6 (SWREG109)	32	RW	0000_0000h
1B8h	Base address for reference chroma picture index 7 (SWREG110)	32	RW	0000_0000h
1BCh	Base address for reference chroma picture index 8 (SWREG111)	32	RW	0000_0000h
1C0h	Base address for reference chroma picture index 9 (SWREG112)	32	RW	0000_0000h
1C4h	Base address for reference chroma picture index 10 (SWREG113)	32	RW	0000_0000h
1C8h	Base address for reference chroma picture index 11 (SWREG114)	32	RW	0000_0000h
1CCh	Base address for reference chroma picture index 12 (SWREG115)	32	RW	0000_0000h
1D0h	Base address for reference chroma picture index 13 (SWREG116)	32	RW	0000_0000h
1D4h	Base address for reference chroma picture index 14 (SWREG117)	32	RW	0000_0000h
1D8h	Base address for reference chroma picture index 15 (SWREG118)	32	RW	0000_0000h

16.1.6.1.2 Interrupt register decoder (SWREG1)

16.1.6.1.2.1 Offset

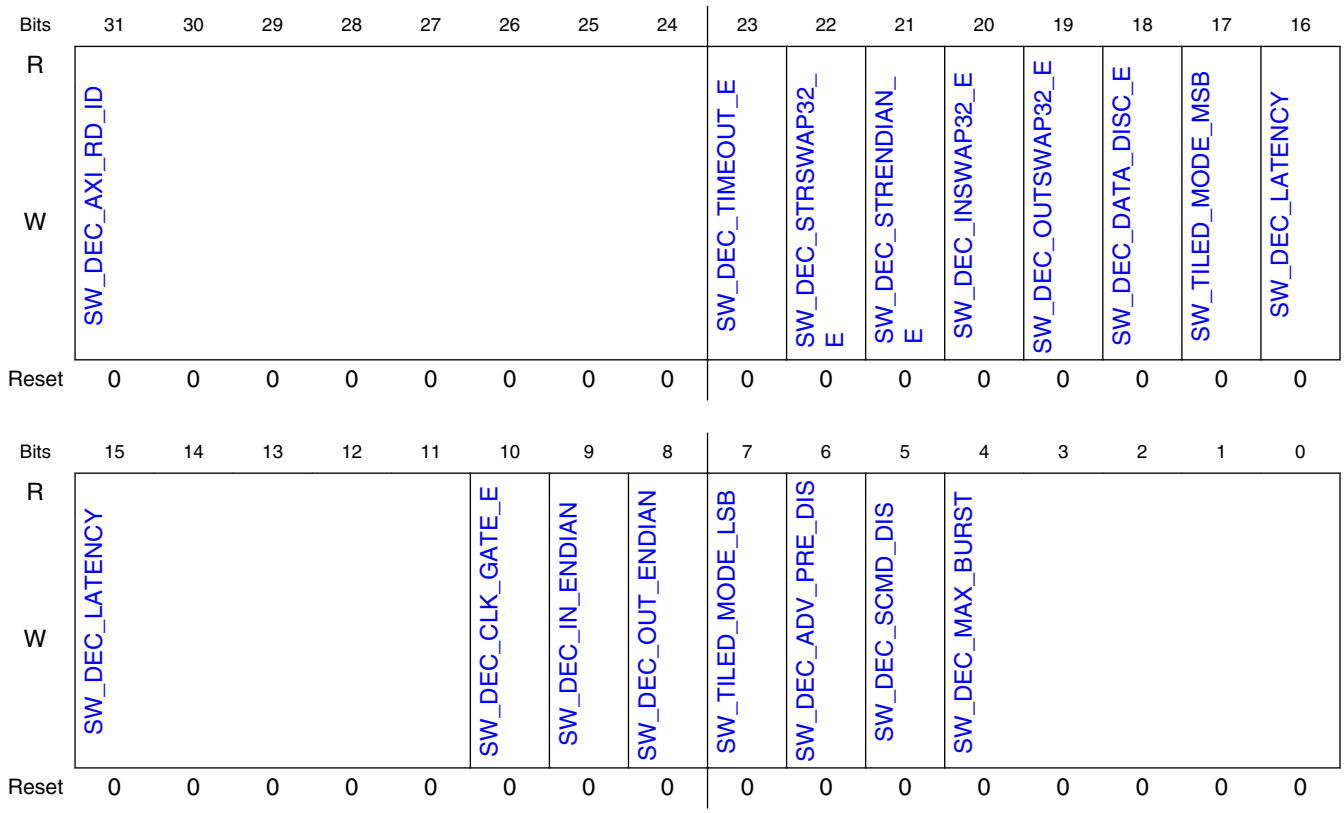
Register	Offset
SWREG1	4h

16.1.6.1.2.2 Diagram

16.1.6.1.2.3 Fields

Field	Function
31-25 —	Reserved.
24 SW_DEC_PIC_INF	B slice detected. This signal is driven high during picture ready interrupt if B-type slice is found. This bit does not launch interrupt but is used to inform SW about h264 tools.
23-19 —	Reserved.

Table continues on the next page...



Field	Function
18 SW_DEC_TIMEOUT	Interrupt status bit decoder timeout. When high the decoder has been idling for too long. HW will self reset. Possible only if timeout interrupt is enabled
17 SW_DEC_SLICE_INT	Interrupt status bit dec_slice_decoded. When high SW must set new base addresses for sw_dec_out_base and sw_jpg_ch_out_base before resetting this status bit. Used for VP8 web-p modes
16 SW_DEC_ERROR_INT	Interrupt status bit input stream error. When high, an error is found in input data stream decoding. HW will self reset.
15 SW_DEC_ASO_INT	H264: Interrupt status bit ASO (Arbitrary Slice Ordering) detected. When high, ASO detected in input data stream decoding. HW will self reset. VP8: Error detected in Residual data. HW returns MB number in error concealment register for MB it detected it
14 SW_DEC_BUFFER_INT	Interrupt status bit input buffer empty. When high, input stream buffer is empty but picture is not ready. HW will not self reset.
13 SW_DEC_BUS_INT	Interrupt status bit bus. Error response from bus.
12 SW_DEC_RDY_INT	Interrupt status bit decoder. When this bit is high decoder has decoded a picture. HW will self reset.
11-9 —	Reserved.
8 SW_DEC_IRQ	Decoder IRQ. When high, decoder requests an interrupt. SW will reset this after interrupt is handled.
7-6 —	Reserved.
5 SW_DEC_ABORT_E	Abort decoding enable. Setting this bit high will cause HW to abort decoding and safely to reset itself down. After abort is complete the corresponding interrupt status is set and this bit is set low as well as the decoder enable.
4 SW_DEC_IRQ_DIS	Decoder IRQ disable. When high, there are no interrupts concerning decoder from HW. Polling must be used to see the interrupt statuses.
3-1 —	Reserved.
0 SW_DEC_E	Decoder enable. Setting this bit high will start the decoding operation. HW will reset this when picture is processed or ASO or stream error is detected or bus error or timeout interrupt is given.

16.1.6.1.3 Device configuration register decoder (SWREG2)

16.1.6.1.3.1 Offset

Register	Offset
SWREG2	8h

16.1.6.1.3.2 Diagram

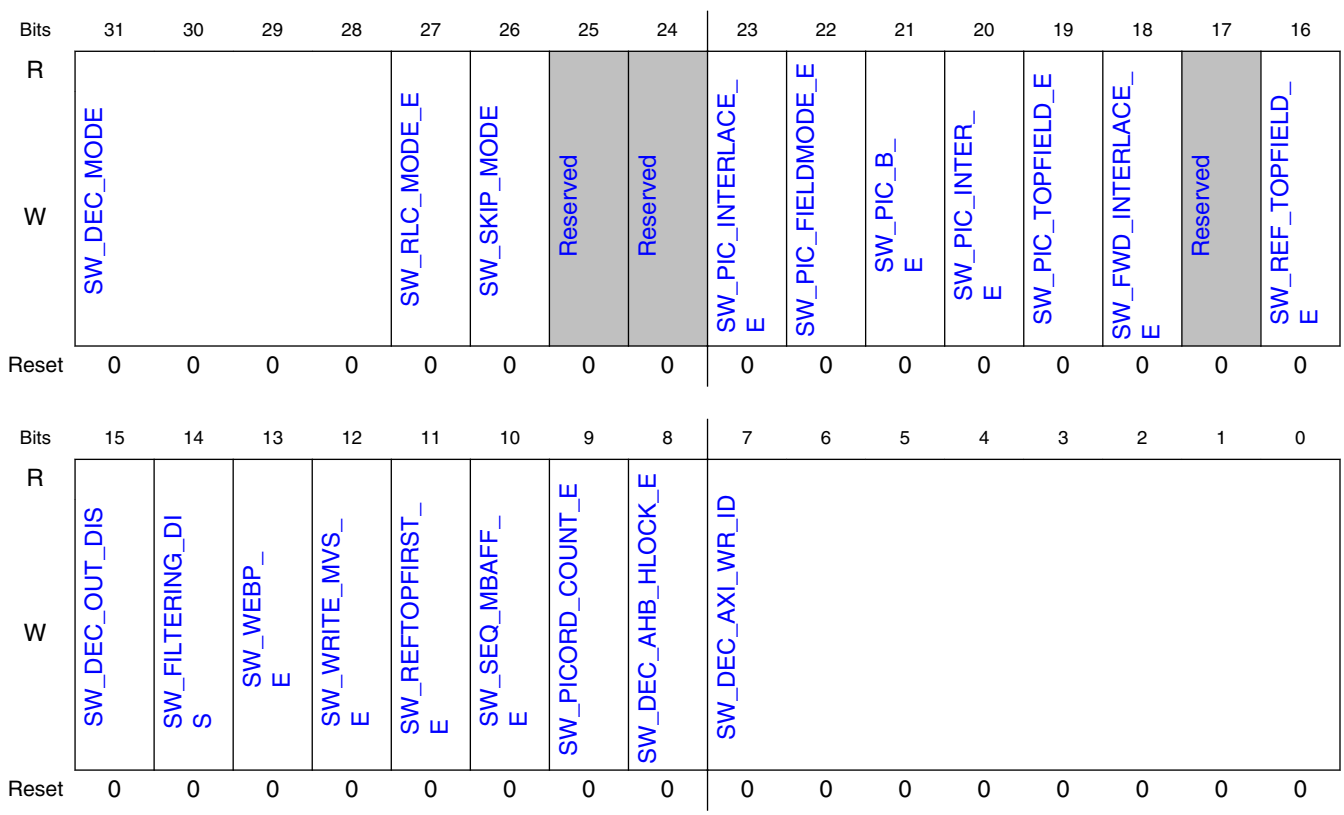
16.1.6.1.3.3 Fields

Field	Function
31-24 SW_DEC_AXI_RD_ID	Read ID used for decoder reading services in AXI bus (if connected to AXI).
23 SW_DEC_TIMEOUT_E	Timeout interrupt enable. If enabled HW may return timeout interrupt in case HW gets stuck while decoding picture.
22 SW_DEC_STRSWAP32_E	Decoder input 32bit data swap for stream data (may be used for 64 bit environment): 0b - no swapping of 32 bit words 1b - 32 bit data words are swapped (needed in 64 bit environment to achieve 7-6-5-4-3-2-1-0 byte order(also little endian should be enabled))

Table continues on the next page...

Field	Function
21 SW_DEC_STR ENDIAN_E	Decoder input endian mode for stream data: 0b - Big endian (0-1-2-3 order) 1b - Little endian (3-2-1-0 order)
20 SW_DEC_INSW AP32_E	Decoder input 32bit data swap for other than stream data (may be used for 64 bit environment): 0b - no swapping of 32 bit words 1b - 32 bit data words are swapped (needed in 64 bit environment to achieve 7-6-5-4-3-2-1-0 byte order(also little endian should be enabled))
19 SW_DEC_OUT SWAP32_E	Decoder output 32bit data swap (may be used for 64 bit environment): 0b - no swapping of 32 bit words 1b - 32 bit data words are swapped (needed in 64 bit environment to achieve 7-6-5-4-3-2-1-0 byte order(also little endian should be enabled))
18 SW_DEC_DAT A_DISC_E	Data discard enable. Precise burst lengths are used with reading services. Extra data is discarded internally. Note. If AHB maxburst 17 is used data discard cannot be enabled (causes conflict)
17 SW_TILED_MO DE_MSB	Tiled mode msb. Concatenated to Tiled mode lsb which form 2 bit tiled mode. 0b - Tiled mode not enabled 1b - Tiled mode enabled for 8x4 tile size
16-11 SW_DEC_LATE NCY	Decoder master interface additional latency. Can be used to slow down decoder HW between services in steps of 8 clock cycles: 0 = no latency 1 = minimum 8 cycles of IDLE between services 2 = minimum 16 cycles of IDLE between services . . . 63 = minimum latency of 504 cycles of IDLE between services
10 SW_DEC_CLK_ GATE_E	Decoder dynamic clock gating enable: 0b - Clock is running for all structures 1b - Clock is gated for decoder structures that are not used. Note: Clock gating value can be changed only when decoder is disabled.
9 SW_DEC_IN_E NDIAN	Decoder input endian mode for other than stream data: 0b - Big endian (0-1-2-3 order) 1b - Little endian (3-2-1-0 order)
8 SW_DEC_OUT _ENDIAN	Decoder output endian mode: 0b - Big endian (0-1-2-3 order) 1b - Little endian (3-2-1-0 order)
7 SW_TILED_MO DE_LSB	Tiled mode lsb. Concatenated to Tiled mode msb which form 2 bit tiled mode. Defined in tiled_mode_msb
6 SW_DEC_ADV_ PRE_DIS	Advanced PREFETCH mode disable (advanced reference picture reading mode for video)
5 SW_DEC_SCM D_DIS	9170 decoder and later->: AXI Single Command Multiple Data disable. 9170 axi wrapper supports this mode by default (where only the first addresses of the burst are given from address generator). This bit is used to disable the feature (possible SW workaround if something is not working correctly)

Table continues on the next page...



Field	Function
4-0 SW_DEC_MAX_BURST	Maximum burst length for decoder bus transactions. Valid values: AHB: 1, 4, 8, 16 and 17. Other values will result in INCR type (undefined length) for all transfers. INCR used for lengths 2 and 3. 17 = fixed bursts are used when possible. INCR bursts are used for lengths 2, 3, 5, 6, 7, 9, 10, 11, 12, 13, 14 and 15. OCP: 16-31 AXI: 1-16

16.1.6.1.4 Decoder control register 0 (decmode,picture type etc) (SWREG3)

16.1.6.1.4.1 Offset

Register	Offset
SWREG3	Ch

16.1.6.1.4.2 Diagram

16.1.6.1.4.3 Fields

Field	Function
31-28 SW_DEC_MODE	Decoding mode: 0000b - H.264 0001b - Reserved 0010b - Reserved 0011b - Reserved 0100b - Reserved 0101b - Reserved 0110b - Reserved 0111b - Reserved 1000b - Reserved 1001b - Reserved 1010b - VP8 1011b - Reserved 1100b - Reserved 1101b - Reserved 1110b - Reserved 1111b - Reserved
27 SW_RLC_MODE_E	RLC mode enable: 0b - HW decodes video from bit stream (VLC mode) + side information 1b - HW decodes video from RLC input data + side information (Differential MV's, separate DC coeffs, Intra 4x4 modes, MB control). Valid only for H.264 Baseline.
26 SW_SKIP_MODE	VP8: • 0 : HW decodes mb_coeff_skip -flag • 1 : HW does not decode mb_coeff_skip -flag
25 —	Reserved.
24 —	Reserved.
23 SW_PIC_INTERLACE_E	Coding mode of the current picture: 0b - progressive 1b - interlaced
22 SW_PIC_FIELDMODE_E	Structure of the current picture (residual structure) 0b - Frame structure. For H264, this means MBAFF structured picture for interlaced sequence 1b - Field structure
21 SW_PIC_B_E	B picture enable for current picture: 0b - picture type is I or P depending on sw_pic_inter_e 1b - picture type is B depending on sw_pic_inter_e (not valid for H264 since it is slice based information)
20 SW_PIC_INTER_E	Picture type. Please also see SW_PIC_B_E. 0b - Intra type (I) 1b - Inter type (P)
19 SW_PIC_TOPFIELD_E	If field structure is enabled, this bit informs which one of the fields is being decoded: 0b - bottom field 1b - top field
18	Coding mode of forward reference picture

Table continues on the next page...

Field	Function
SW_FWD_INTERLACE_E	**NOTE:** For backward reference picture, the coding mode is always the same as for current picture. 0b - progressive 1b - interlaced
17 —	Reserved.
16 SW_REF_TOPFIELD_E	Indicates which field should be used as reference if sw_ref_frames = '0': 0b - bottom field 1b - top field
15 SW_DEC_OUT_DIS	Disable decoder output picture writing: 0b - Decoder output picture is written to external memory 1b - Decoder output picture is not written to external memory
14 SW_FILTERING_DIS	De-block filtering disable: 0b - filtering is enabled for current picture 1b - filtering is disabled for current picture
13 SW_WEBP_E	SW_WEBP_E: Webp enable for VP8: • '0' = Normal VP8 • '1' = WEBP picture SW_MVC_E: Multi View Coding enable. Possible for H264 only.
12 SW_WRITE_MVS_E	Direct mode motion vector write enable for current picture / VPX motion vector write enable for error concealment purposes: 0b - Writing disabled for current picture 1b - The direct mode motion vectors are written to external memory. H264 direct mode motion vectors are written to DPB aside with the corresponding reference picture. Other decoding mode dir mode mvs are written to external memory starting from sw_dir_mv_base.
11 SW_REFTOPFIRST_E	Indicates which FWD reference field has been decoded first. 0b - FWD reference bottom field 1b - FWD reference top field
10 SW_SEQ_MBAFF_E	Sequence includes MBAFF coded pictures
9 SW_PICORD_COUNT_E	h264_high config: Picture order count table read enable. If enabled HW will read picture order counts from memory in the beginning of picture
8 SW_DEC_AHB_HLOCK_E	AHB master HLOCK enable. When high the service is locked to decoder as long as it needs the bus (whenever decoder requests the bus it will be granted)
7-0 SW_DEC_AXI_WR_ID	Write ID used for decoder writing services in AXI bus (if connected to AXI)

16.1.6.1.5 Base address for RLC data (RLC) / stream start address/ decoded end addr register (VLC) (SWREG12)

16.1.6.1.5.1 Offset

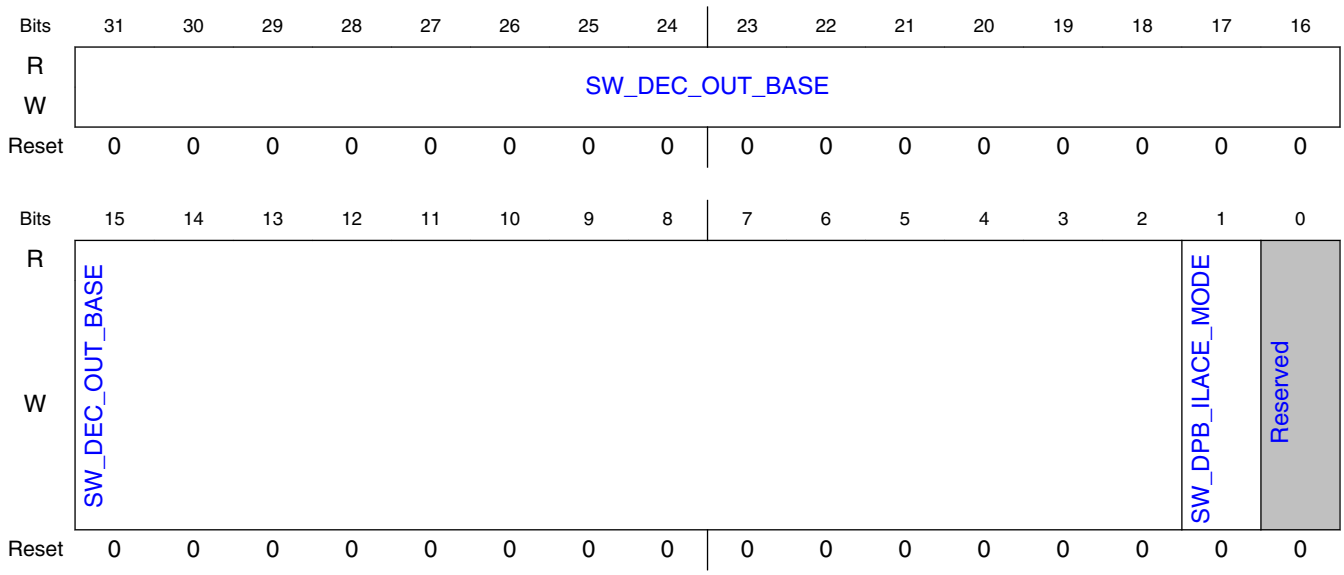
Register	Offset
SWREG12	30h

16.1.6.1.5.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	SW_RLC_VLC_BASE															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	SW_RLC_VLC_BASE															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

16.1.6.1.5.3 Fields



Field	Function
31-0 SW_RLC_VLC_BASE	RLC mode: Base address for RLC data (swreg3.sw_rlc_mode_e = 1). VLC mode: Stream start address / end addr+I288ess with byte precision (swreg4.rlc_mode_en = 0), start bit number in swreg5.stream_start_bit. When sw_dec_buffer_int is high or sw_dec_e is low this register contains HW return value of last_byte_address where stream has been read (and used) in accuracy of byte. For debug purposes the last_byte_address is also written when stream error/ASO is detected even though it may not be accurate. VP8: This base address is used as sw_dct_strm0_base including DCT stream for MB rows 0,2n.

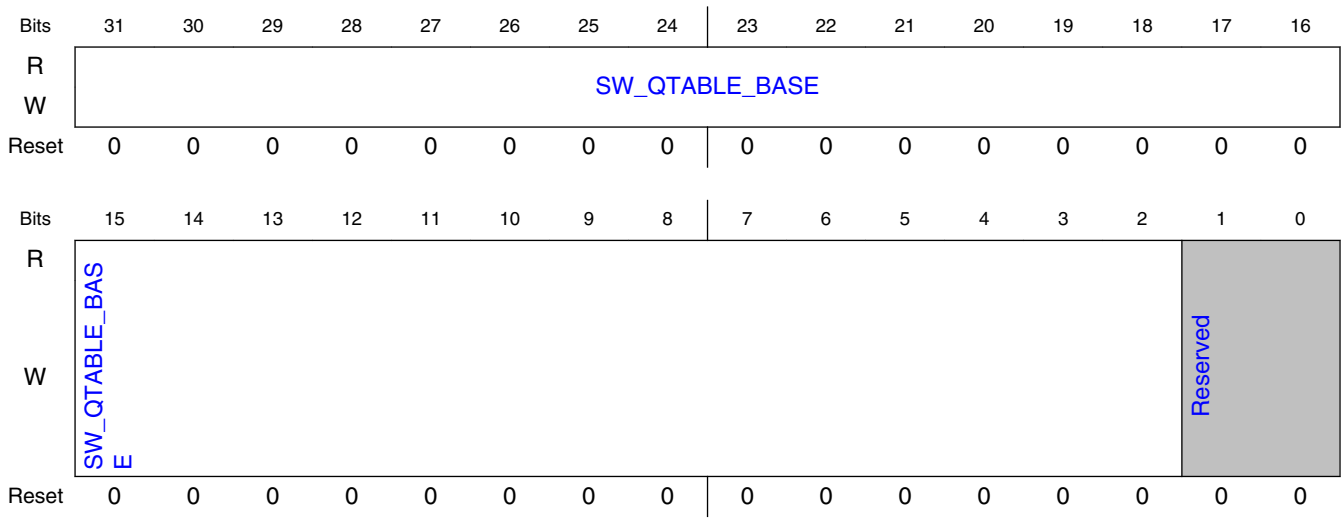
16.1.6.1.6 Base address for decoded picture (SWREG13)

16.1.6.1.6.1 Offset

Register	Offset
SWREG13	34h

16.1.6.1.6.2 Diagram

16.1.6.1.6.3 Fields



Field	Function
31-2 SW_DEC_OUT_BASE	Video: Base address for decoder output picture. Points directly to start of decoder output picture or field.
1 SW_DPB_ILACE_MODE	DPB ilaced mode: '0' : DPB consist of ilaced/progressive frames '1' : DPB consist of progressive frames / separate fields. This mode requires config support from HW
0 —	Reserved.

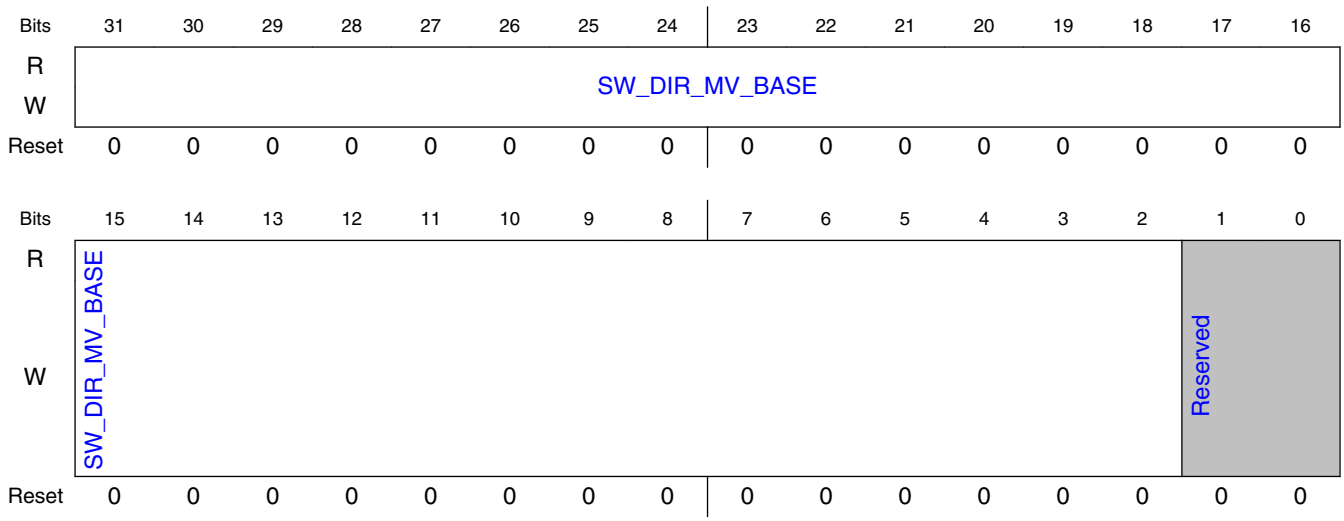
16.1.6.1.7 Base address for standard dependent tables (SWREG40)

16.1.6.1.7.1 Offset

Register	Offset
SWREG40	A0h

16.1.6.1.7.2 Diagram

16.1.6.1.7.3 Fields



Field	Function
31-2 SW_QTABLE_BASE	Base address for standard dependent tables: H.264: base address for various tables VP8: base address for stream decoding tables
1-0 —	Reserved.

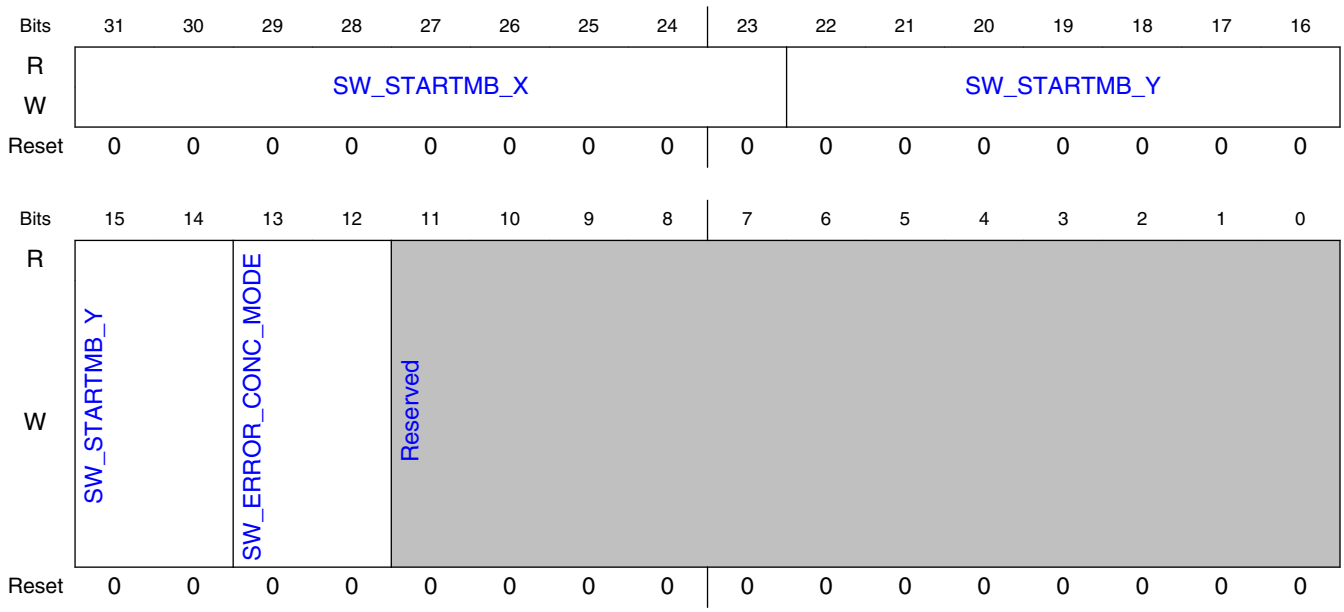
16.1.6.1.8 Base address for direct mode motion vectors (SWREG41)

16.1.6.1.8.1 Offset

Register	Offset
SWREG41	A4h

16.1.6.1.8.2 Diagram

16.1.6.1.8.3 Fields



Field	Function
31-2 SW_DIR_MV_BASE	Direct mode motion vector write/read base address. For H264 this is used only for direct mode motion vector write base. VP8: Motion vectors are written for error concealment purposes if sw_write_mvs is high. In error concealment mode motion vectors are read from this base address
1-0 —	Reserved.

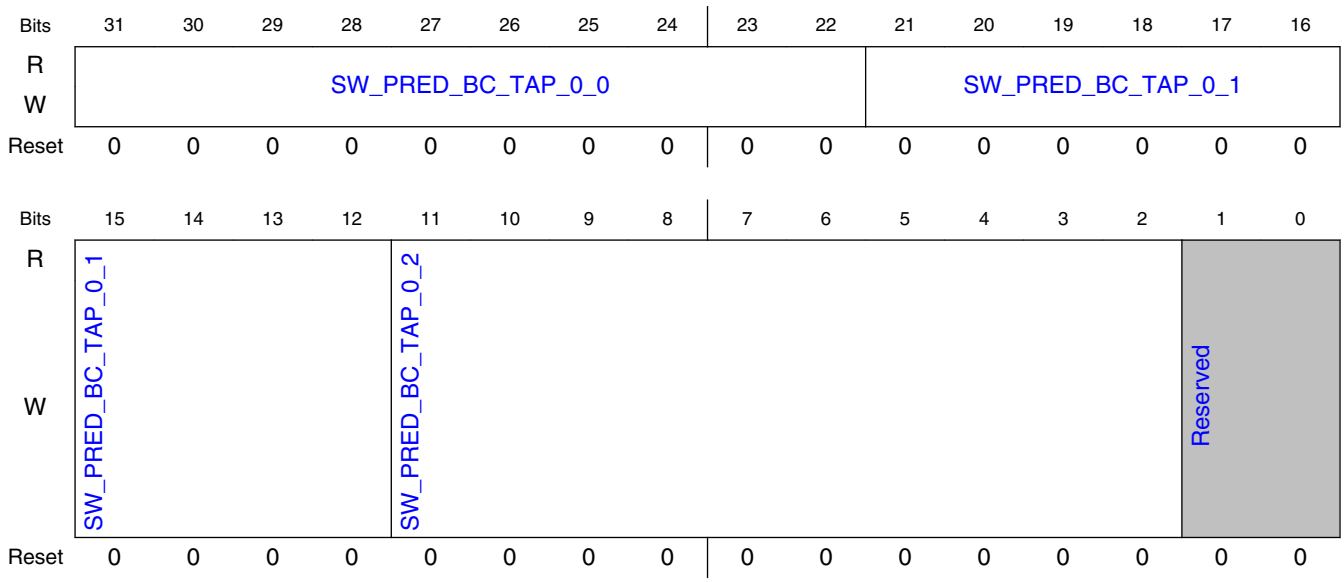
16.1.6.1.9 Error concealment register (SWREG48)

16.1.6.1.9.1 Offset

Register	Offset
SWREG48	C0h

16.1.6.1.9.2 Diagram

16.1.6.1.9.3 Fields



Field	Function
31-23 SW_STARTMB_X	Start MB from SW for X dimension. Used in error concealment case as HW return value if HW founds an error or in HW init mb for error concealment if SW enables error concealment
22-14 SW_STARTMB_Y	Start MB from SW for Y dimension. Used in error concealment case as HW return value if HW founds an error or in HW init mb for error concealment if SW enables error concealment
13-12 SW_ERROR_CONC_MODE	Error concealment mode: 00b - disabled (normal decoding mode) 01b - enabled for direct mode MV usage starting from MB defined by sw_startmb_x, sw_startmb_y
11-0 —	Reserved.

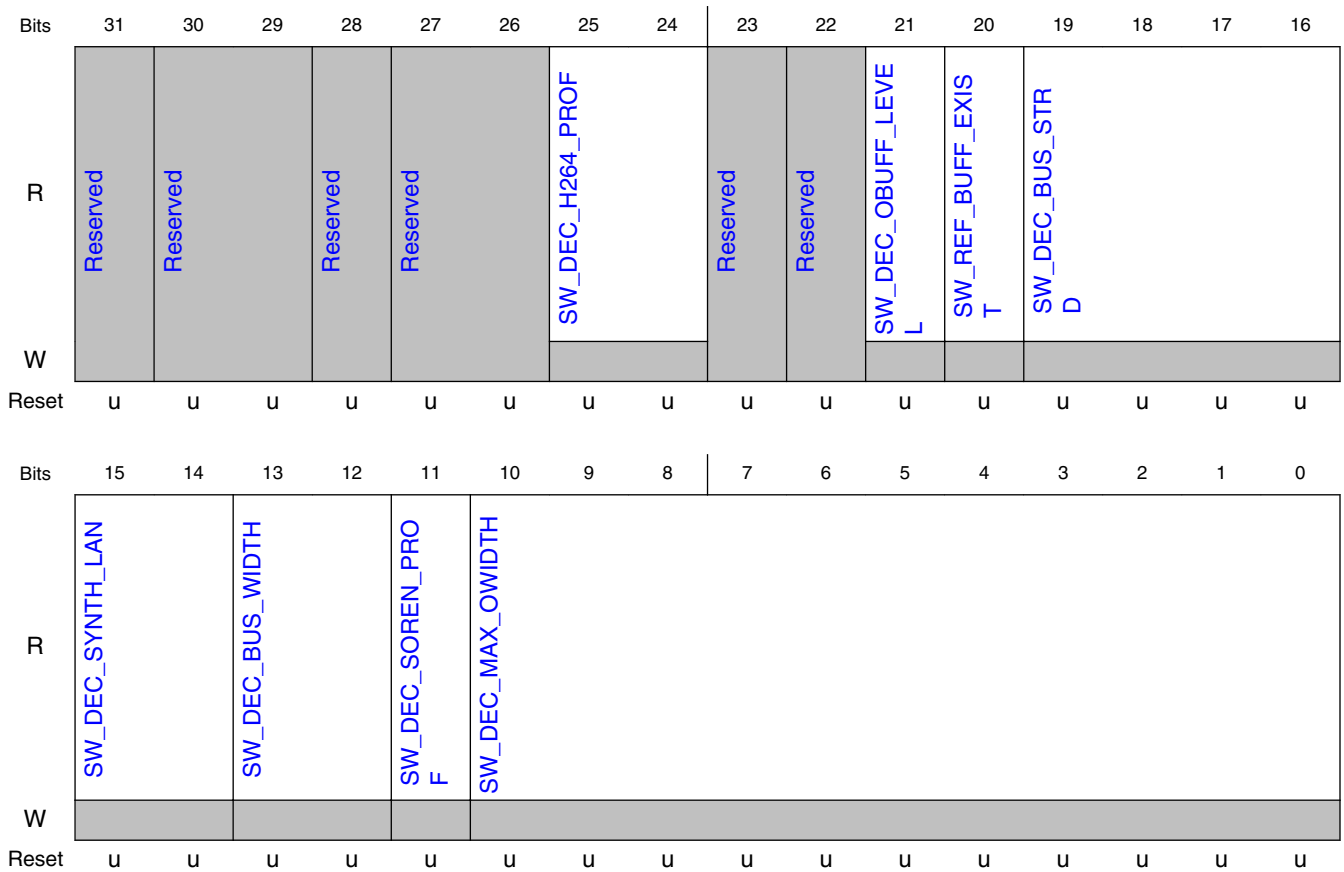
16.1.6.1.10 Prediction filter tap register for H264 (SWREG49)

16.1.6.1.10.1 Offset

Register	Offset
SWREG49	C4h

16.1.6.1.10.2 Diagram

16.1.6.1.10.3 Fields



Field	Function
31-22 SW_PRED_BC_TAP_0_0	Prediction filter set 0, tap 0
21-12 SW_PRED_BC_TAP_0_1	Prediction filter set 0, tap 1
11-2 SW_PRED_BC_TAP_0_2	Prediction filter set 0, tap 2
1-0 —	Reserved.

16.1.6.1.11 Synthesis configuration register decoder 0 (SWREG50)

16.1.6.1.11.1 Offset

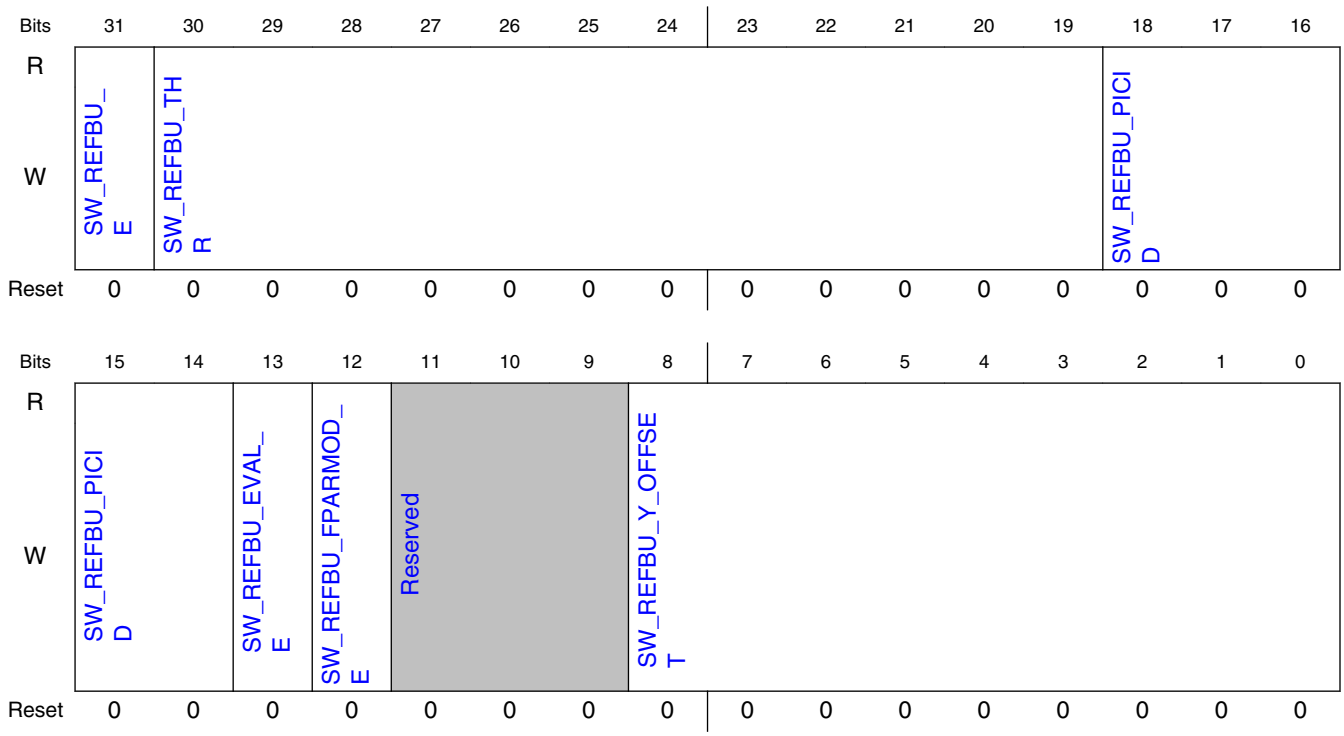
Register	Offset
SWREG50	C8h

16.1.6.1.11.2 Diagram

16.1.6.1.11.3 Fields

Field	Function
31 —	Reserved.
30-29 —	Reserved.
28 —	Reserved.
27-26 —	Reserved.
25-24 SW_DEC_H264_PROF	Decoding format support, H.264 00b - not supported 01b - supported up to baseline profile 10b - supported up to high profile labeled stream with restricted high profile tools (Tools that are used in Hantro 7280, 8270 encoder) 11b - supported up to high profile

Table continues on the next page...



Field	Function
23 —	Reserved.
22 —	Reserved.
21 SW_DEC_OBUFF_LEVEL	Decoder output buffer level: 0b - 1 MB buffering is used 1b - 4 MB buffering is used
20 SW_REF_BUFF_EXIST	Reference picture buffer usage: 0b - not supported 1b - reference buffer is used
19-16 SW_DEC_BUS_STRD	Connected to standard bus: 0000b - error 0001b - AHB master, AHB slave 0010b - OCP master, OCP slave 0011b - AXI master, AXI slave 0100b - AXI master, APB slave 0101b - AXI master, AHB slave
15-14 SW_DEC_SYNTH_LAN	00b - error 01b - vhdl 10b - verilog
13-12 SW_DEC_BUS_WIDTH	00b - error 01b - 32 bit bus 10b - 64 bit bus 11b - 128 bit bus
11 SW_DEC_SOREN_PROF	Decoding format support, Sorenson 0b - not supported 1b - supported
10-0 SW_DEC_MAX_OWIDTH	Max configured decoder video resolution that can be decoded. Informed as width of the picture in pixels.

16.1.6.1.12 Reference picture buffer control register (SWREG51)

16.1.6.1.12.1 Offset

Register	Offset
SWREG51	CCh

16.1.6.1.12.2 Diagram

16.1.6.1.12.3 Fields

Field	Function
31 SW_REFBU_E	Refer picture buffer enable: 0b - refer picture buffer disabled 1b - refer picture buffer enabled. Valid if picture size is QVGA or more.
30-19 SW_REFBU_THR	Reference buffer disable threshold value (cache miss amount). Used to buffer shut down (if more misses than allowed)
18-14 SW_REFBU_PICID	The used reference picture ID for reference buffer usage
13 SW_REFBU_EVAL_E	Enable for HW internal reference ID calculation. If given threshold level is reached by any picture_id after first MB row, that picture_id is used for reference buffer fill for rest of the picture
12 SW_REFBU_FPARMOD_E	Field parity mode enable. Used in refbufferd evaluation mode. 0b - use the result field of the evaluation 1b - use the parity mode field
11-9 —	Reserved.
8-0 SW_REFBU_Y_OFFSET	Y offset for refbufferd. This coordinate is used to compensate the global motion of the video for better buffer hit rate

16.1.6.1.13 Reference picture buffer information register 1 (SWREG52)

16.1.6.1.13.1 Offset

Register	Offset
SWREG52	D0h

16.1.6.1.13.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

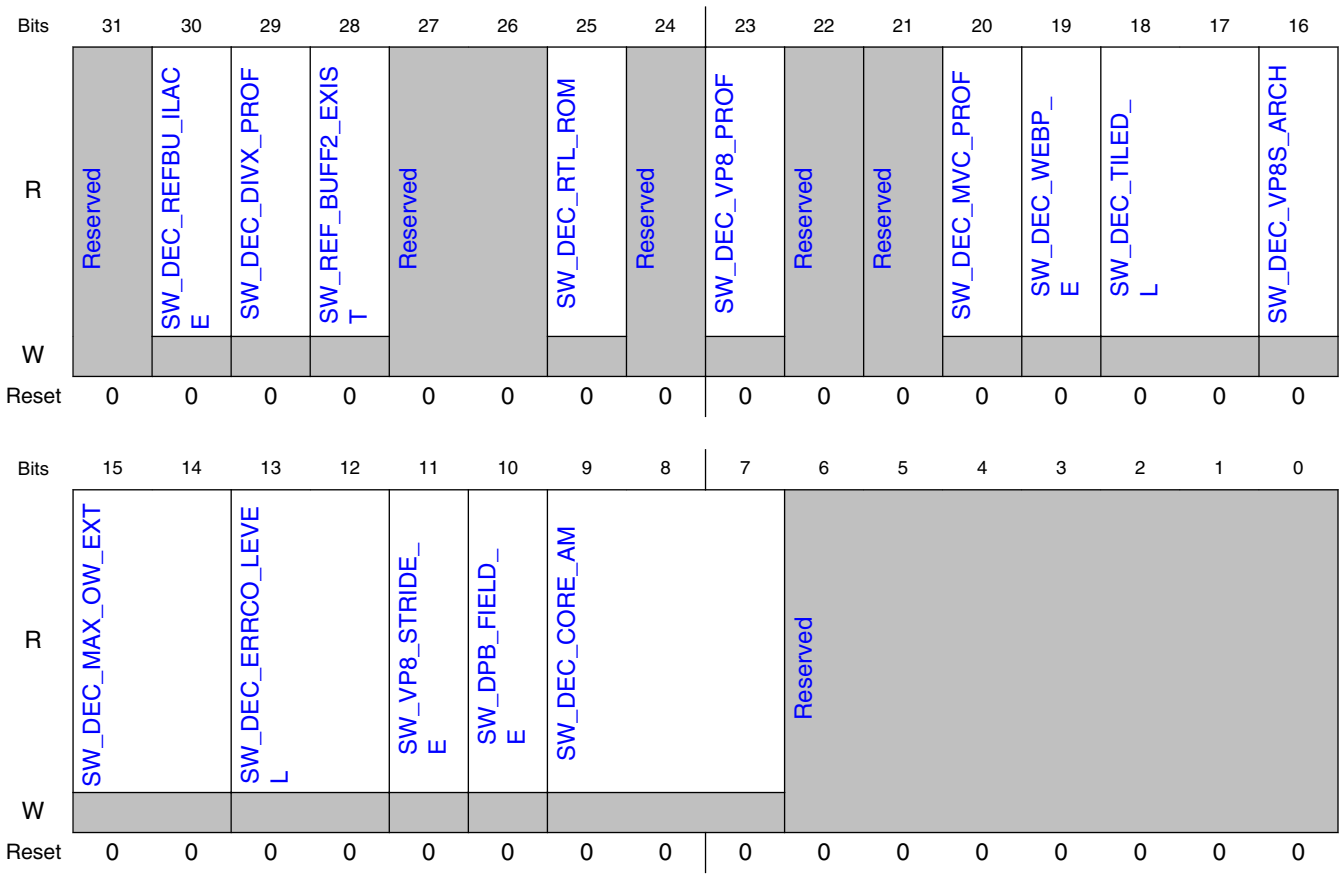
16.1.6.1.14.3 Fields



Field	Function
31-22 —	Reserved.
21-0 SW_REFBU_Y_MV_SUM	The sum of the decoded motion vector y-components of the picture. The first luminance motion vector of each MB is used in calculation. Other motion vectors of the MB are discarded. Each motion vector is saturated between -256 - 255 before calculation. The proceeding of the HW calculation can be read during HW decoding.

16.1.6.1.15 Synthesis configuration register decoder 1 (SWREG54)

16.1.6.1.15.1 Offset

Register	Offset
SWREG54	D8h

16.1.6.1.15.2 Diagram

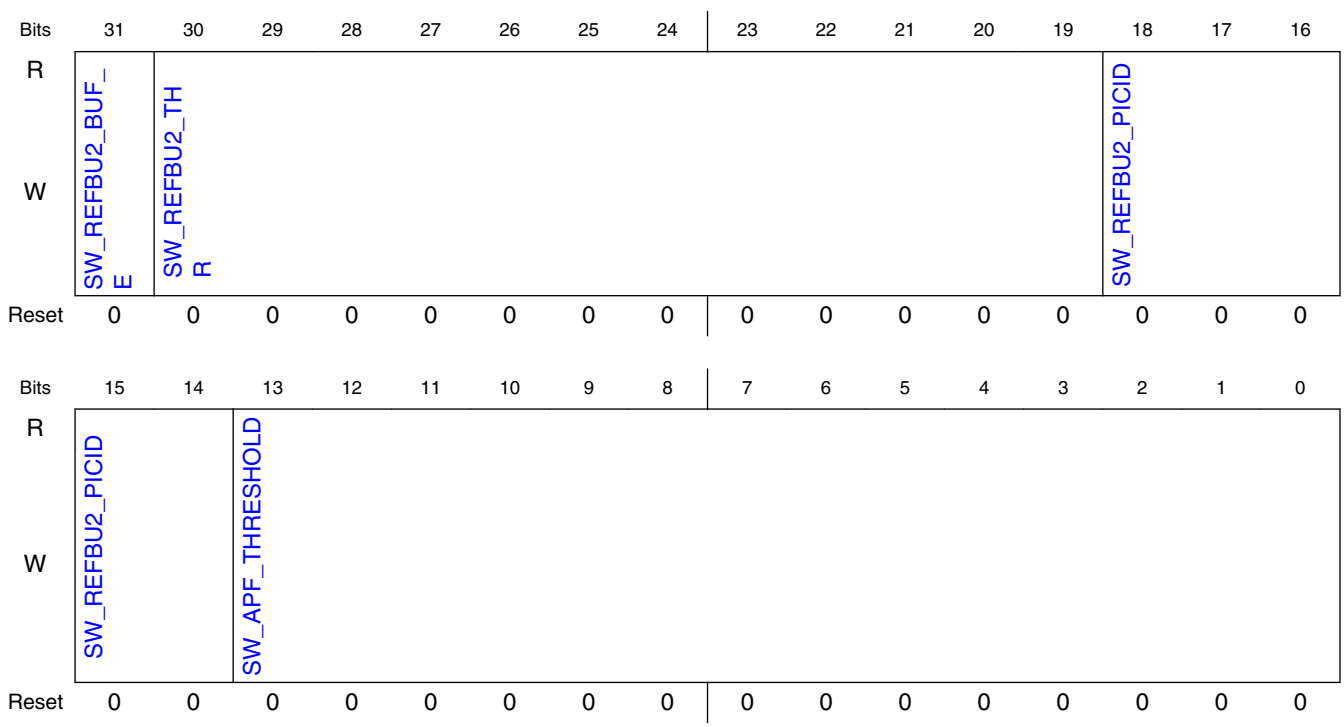
16.1.6.1.15.3 Fields

Field	Function
31 —	Reserved.
30 SW_DEC_REFBU_ILACE	Refbufferd support for interlaced content: 0b - not supported 1b - supported
29 SW_DEC_DIVX_PROF	DIVX Support: 0b - not supported 1b - supported
28 SW_REF_BUFF2_EXIST	Reference picture buffer 2 usage: 0b - not supported 1b - reference buffer 2 is used
27-26 —	Reserved.
25	ROM implementation type (If design includes ROMs) 0b - ROMs are implemented from actual ROM units

Table continues on the next page...

Field	Function
SW_DEC_RTL_ROM	1b - ROMs are implemented from RTL
24 —	Reserved.
23 SW_DEC_VP8_PROF	Decoding format support, VP8 0b - not supported 1b - supported
22 —	Reserved.
21 —	Reserved.
20 SW_DEC_MVC_PROF	Decoding format support, MVC 0b - not supported 1b - supported
19 SW_DEC_WEBP_E	Decoding format support, Web-p 0b - not supported bigger than 1080p resolution 1b - supported upto 16kx16k pixel resolution (defined max)
18-17 SW_DEC_TILED_L	Tiled mode support level 00b - not supported 01b - supported with 8x4 tile size for progressive content 10b - supported with 8x4 tile size for progressive/ilaced content
16 SW_DEC_VP8S_ARCH	VP8 Architecture type (for prediction) 0b - Same prediction architecture as for other decoding formats 1b - Dedicated small architecture for VP8 (refbuffer cannot be used either)
15-14 SW_DEC_MAX_OW_EXT	Max configured decoder video resolution that can be decoded. This is the MSB part of the configuration signal
13-12 SW_DEC_ERRCO_LEVEL	Decoder error concealment support level: 00b - Error concealment not supported (only error detection) 01b - VP8 direct mode motion vector error concealment supported
11 SW_VP8_STRIDE_E	Decoder output stride support for VP8. Separate base addresses for Y/C data and possibility to set scanline bigger than picture width: 0b - not supported, Y and C tables attached. 1b - supported, Y and C tables can be set freely.
10 SW_DPB_FIELD_E	DPB field separate mode support for ilaced content: 0b - Not supported. For ilaced content, DPB is ilaced frame order. 1b - Supported. For ilaced content, DPB can consist of ilaced frames or separate fields (TOP/BOT).
9-7 SW_DEC_CORE_AM	Decoder core amount. If other than 0, the multicore can be used. Each individual cores can be identified from corresponding core ID register: 000b - single core decoder 001b - dual core decoder 010b - 3 core decoder 011b - 4 core decoder 100b - 5 core decoder 101b - 6 core decoder 110b - 7 core decoder 111b - 8 core decoder

Table continues on the next page...



Field	Function
6-0 —	Reserved.

16.1.6.1.16 Reference picture buffer 2 / Advanced prefetch control register (SWREG55)

16.1.6.1.16.1 Offset

Register	Offset
SWREG55	DCh

6-0 —	Reserved.

16.1.6.1.19 Device configuration register decoder 2 + Multi core control register (SWREG58)

16.1.6.1.19.1 Offset

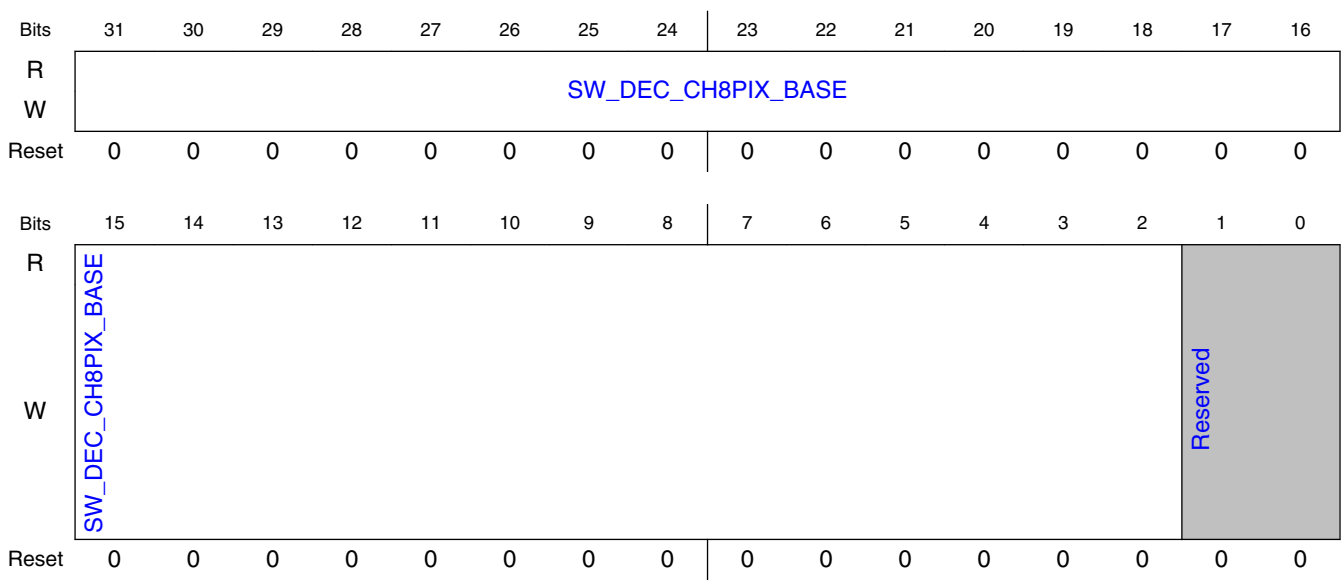
Register	Offset
SWREG58	E8h

16.1.6.1.19.2 Diagram

16.1.6.1.19.3 Fields

Field	Function
31 SW_SERV_MERGE_DIS	Decoder service merge disable: 0b - HW merges simultaneous sub-block requests internally if they are same type (read or write). 1b - decoder serves one sub-block per service and merging is disabled.
30 SW_DEC_MULTICORE_E	Decoder multi core enable: 0b - Multi core disabled or only one core exists in design. 1b - Multi core enable. Each reference picture status must be verified from external memory status field before usage. 128 bits status word exists after each reference picture and include picture proceeding coordinates Y and X.
29 SW_DEC_WRITESTAT_E	Decoder write statusword enable. Must be high if multi core decoding enabled. HW writes output picture data proceeding to external memory after picture data (and after H264 direct mode MVS if they exist)
28-27 SW_DEC_MC_POLLMODE	Decoder multicore status reading mode: 00b - HW internal status polling mechanism is used. Status of reference picture is read only when required coordinate for the reference picture is not big enough. If the status is still not big enough after reading it the HW waits N clock cycles per pixel from the coordinate difference. The N is defined by the sw_dec_mc_polltime (range 0...4). 01b - Dummy status polling mechanism is used for all reference pictures. HW reads status of all reference pictures at frequency defined by sw_dec_mc_polltime.
26-17 SW_DEC_MC_POLLTIME	sw_dec_mc_polltime definition depends on sw_dec_mc_mode. if mode is 0 (HW internal mechanism) the sw_dec_mc_polltime: • 0 = 1/4 cycles per pixel • 1 = wait 1/2 cycles per pixel • 2 = wait one cycle per pixel • 3 = wait 2 cycles per pixel • 4=wait 4 cycles per pixel

Table continues on the next page...



Field	Function
	For dummy polling mechanism the sw_dec_mc_polltime defines the amount cycles between status reads x1024: • 0 = wait 1024 cycles between status reading • 1 = wait 2048 cycles between status reading • 2 = wait 3072 cycles between status reading • N = wait (N+1)x1024 cycles
16-0 —	Reserved.

16.1.6.1.20 H264 Chrominance 8 pixel interleaved data base (SWREG59)

16.1.6.1.20.1 Offset

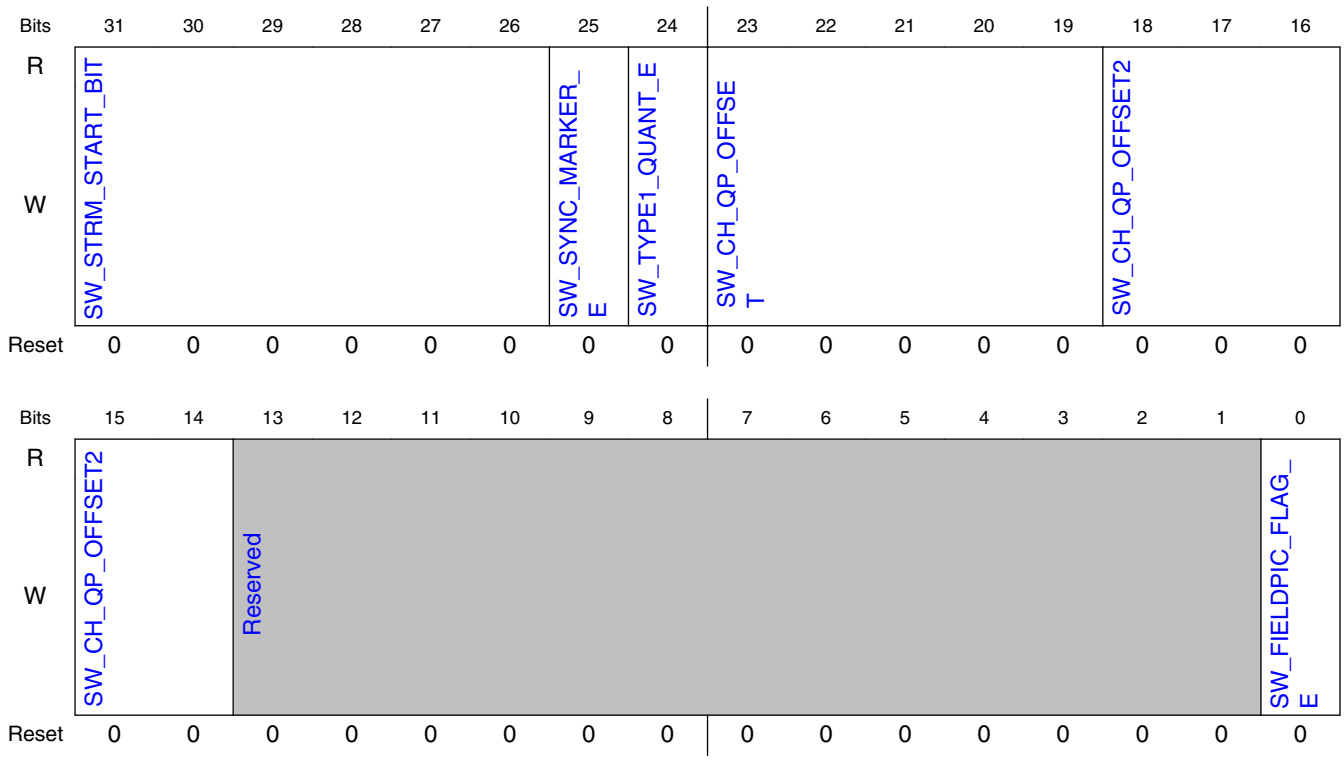
SWREG4	10h

16.1.6.2.2.2 Diagram

16.1.6.2.2.3 Fields

Field	Function
31-23 SW_PIC_MB_WIDTH	Picture width in macroblocks = ((width in pixels + 15) /16)
22-19 SW_MB_WIDTH_OFF	The amount of meaningfull horizontal pixels in last MB (width offset) 0 if exactly 16 pixels multiple picture and all the horizontal pixels in last MB are meaningfull
18-11	Picture height in macroblocks =((height in pixels+15)/16). Picture height is informed as size of the (progressive) frame also for single field (of interlaced content) is being decoded

Table continues on the next page...



Field	Function
SW_PIC_MB_HEIGHT_P	
10-7 SW_MB_HEIGHT_OFF	The amount of meaningful vertical pixels in last MB (height offset 0 if exactly 16 pixels multiple picture and all the vertical pixels in last MB are meaningfull
6 SW_ALT_SCAN_E	indicates alternative vertical scan method used for interlaced frames
5 —	Reserved.
4-0 SW_REF_FRAMES	H.264: num_ref_frames, maximum number of short and long term reference frames in decoded picture buffer VC-1: num_ref semantics

16.1.6.2.3 Decoder control register 2 (stream decoding table selects) (SWREG5)

16.1.6.2.3.1 Offset

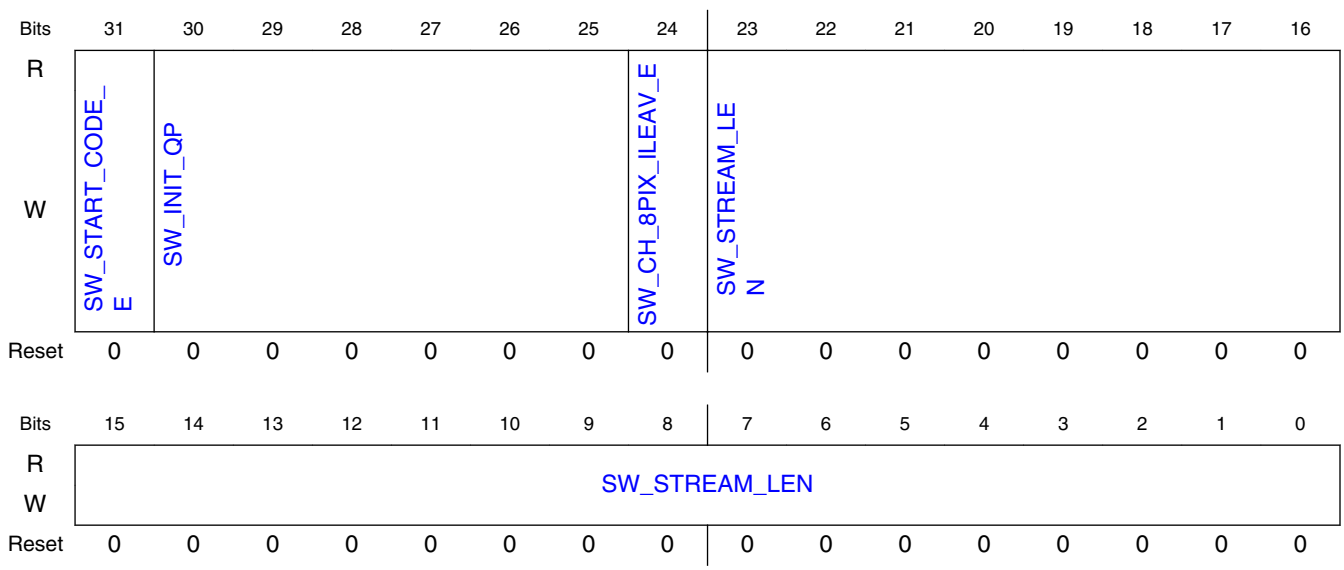
Register	Offset
SWREG5	14h

16.1.6.2.3.2 Diagram

16.1.6.2.3.3 Fields

Field	Function
31-26 SW_STRM_START_BIT	Exact bit of stream start word where decoding can be started (assosiates with sw_rlc_vlc_base)
25 SW_SYNC_MARKER_E	Sync markers enable For progressive JPEG, this indicates that there are restart markers in the stream after restart interval steps. 0b - synch markers are not used 1b - synch markers are used.
24 SW_TYPE1_QUANT_E	MPEG4: Type 1 quantization enable • '0' = type 2 inverse Q method • '1' = type 1 inverse Q method (Q-tables used) H264 (h264_high config): scaling matrix enable • '0' = normal transform • '1' = use scaling matrix for transform (read from external memory)
23-19 SW_CH_QP_OFFSET	Chroma Qp filter offset. (For H.264 this offset concerns Cb only)
18-14	Chroma Qp filter offset for cr type

Table continues on the next page...



Field	Function
SW_CH_QP_OFFSET2	
13-1 —	Reserved.
0 SW_FIELDPIC_FLAG_E	Flag for streamd that field_pic_flag exists in stream

16.1.6.2.4 Decoder control register 3 (stream buffer information) (SWREG6)

16.1.6.2.4.1 Offset

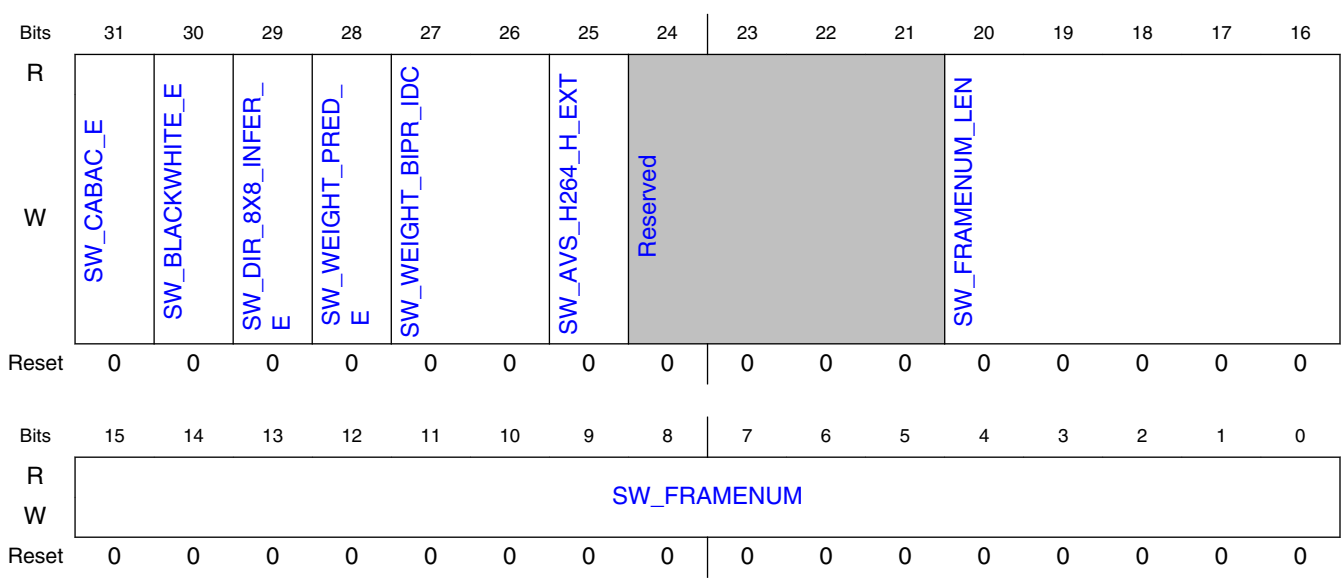
Register	Offset
SWREG6	18h

16.1.6.2.4.2 Diagram

16.1.6.2.4.3 Fields

Field	Function
31	Bit for indicating stream start code existence: 0b - stream doesn't contain start codes

Table continues on the next page...



Field	Function
SW_START_CODE_E	1b - stream contains start codes
30-25 SW_INIT_QP	Initial value for quantization parameter (picture quantizer).
24 SW_CH_8PIX_ILEAV_E	Enable for additional chrominance data format writing where decoder writes chrominance in group of 8 pixels of Cb and then corresponding 8 pixels of Cr. Data is written to sw_dec_ch8pix_base. Cannot be used if tiled mode is enabled
23-0 SW_STREAM_LEN	Amount of stream data bytes in input buffer. If the given buffer size is not enough for finishing the picture the corresponding interrupt is given and new stream buffer base address and stream buffer size information should be given (assosiates with sw_rlc_vlc_base). For VC-1/VP6 the buffer must include data for one picture/slice of the picture For H264/MPEG4/H263/MPEG2/MPEG1 the buffer must include at least data for one slice/VP of the picture For JPEG the buffer size must be a multiple of 256 bytes or the amount of data for one picture.

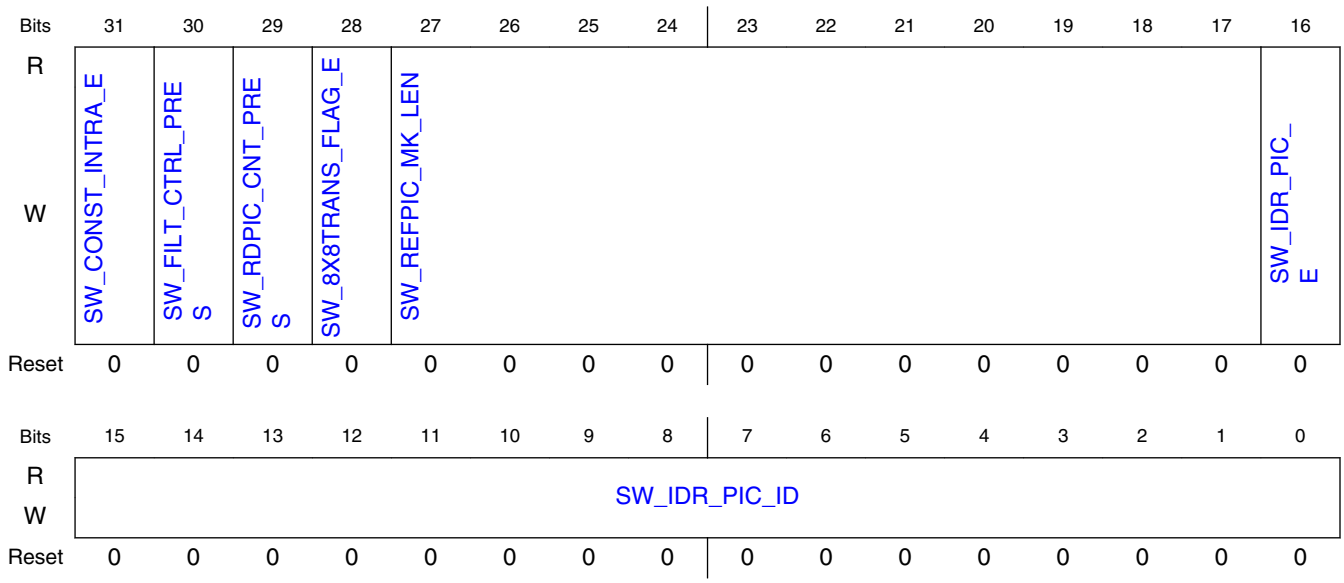
16.1.6.2.5 Decoder control register 4 (H264, VC-1, VP6 and progressive JPEG control) (SWREG7)

16.1.6.2.5.1 Offset

Register	Offset
SWREG7	1Ch

16.1.6.2.5.2 Diagram

16.1.6.2.5.3 Fields



Field	Function
31 SW_CABAC_E	CABAC enable
30 SW_BLACKWHITE_E	0b - 4:2:0 sampling format 1b - 4:0:0 sampling format (H264 monochroma)
29 SW_DIR_8X8_INFER_E	Specifies the method to use to derive luma motion vectors in B_skip, B_Direct_16x16 and B_direct_8x8_inference_flag (see direct_8x8_inference flag)
28 SW_WEIGHT_PRED_E	Weighted prediction enable for P slices
27-26 SW_WEIGHT_BIPR_IDC	weighted prediction specification for B slices: 00b - default weighted prediction is applied to B slices 01b - explicit weighted prediction shall be applied to B slices 10b - implicit weighted prediction shall be applied to B slices
25 SW_AVS_H264_H_EXT	Resolution extension to support 4k resolution for AVS/H264. Used as MSB of sw_pic_mb_height
24-21 —	Reserved.
20-16 SW_FRAMENUM_LEN	H.264: Bit length of frame_num in data stream RV: frame size length. Informs how many bits in stream are used for frame size (HW discards these bits)
15-0 SW_FRAMENUM	current frame_num, used to identify short-term reference frames. Used in reference picture reordering

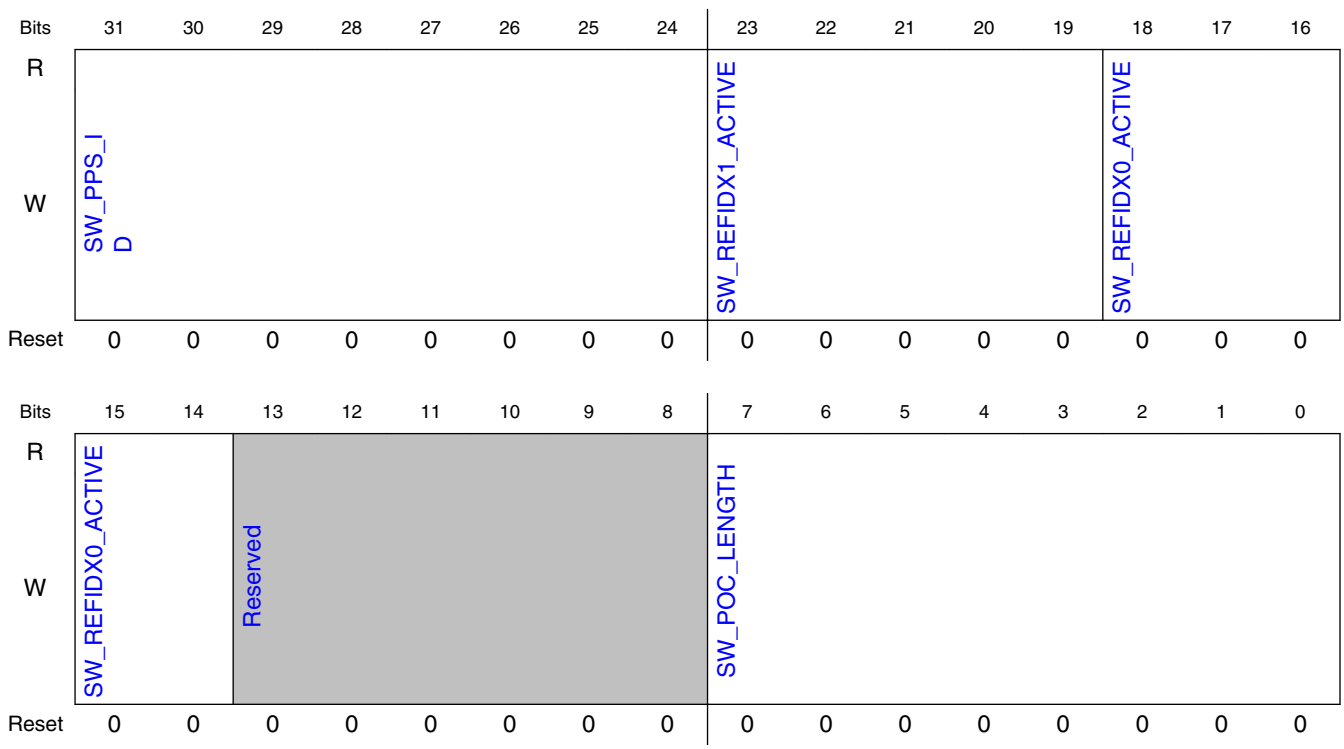
16.1.6.2.6 Decoder control register 5 (H264, VC-1, VP6, Progressive JPEG and RV control) (SWREG8)

16.1.6.2.6.1 Offset

Register	Offset
SWREG8	20h

16.1.6.2.6.2 Diagram

16.1.6.2.6.3 Fields



Field	Function
31 SW_CONST_INTRA_E	constrained_intra_pred_flag equal to 1 specifies that intra prediction uses only neighbouring intra macroblocks in prediction. When equal to 0 also neighbouring inter macroblocks are used in intra prediction process.
30 SW_FILT_CTRL_PRES	deblocking_filter_control_present_flag indicates whether extra variables controlling characteristics of the deblocking filter are present in the slice header.
29 SW_RDPIC_CNT_PRES	redundant_pic_cnt_present_flag specifies whether redundant_pic_cnt syntax elements are present in the slice header.
28 SW_8X8TRANS_FLAG_E	8x8 transform flag enable for stream decoding
27-17 SW_REFPIC_MK_LEN	Length of decoded reference picture marking bits
16 SW_IDR_PIC_E	IDR (instantaneous decoding refresh) picture flag.
15-0 SW_IDR_PIC_ID	idr_pic_id, identifies IDR (instantaneous decoding refresh) picture

16.1.6.2.7 Decoder control register 6 / base address for MB-control (RLC) / VC-1 intensity control 0/ VP6,VP7,VP8 ctrl-stream length/ RV pic slice amount (SWREG9)

16.1.6.2.7.1 Offset

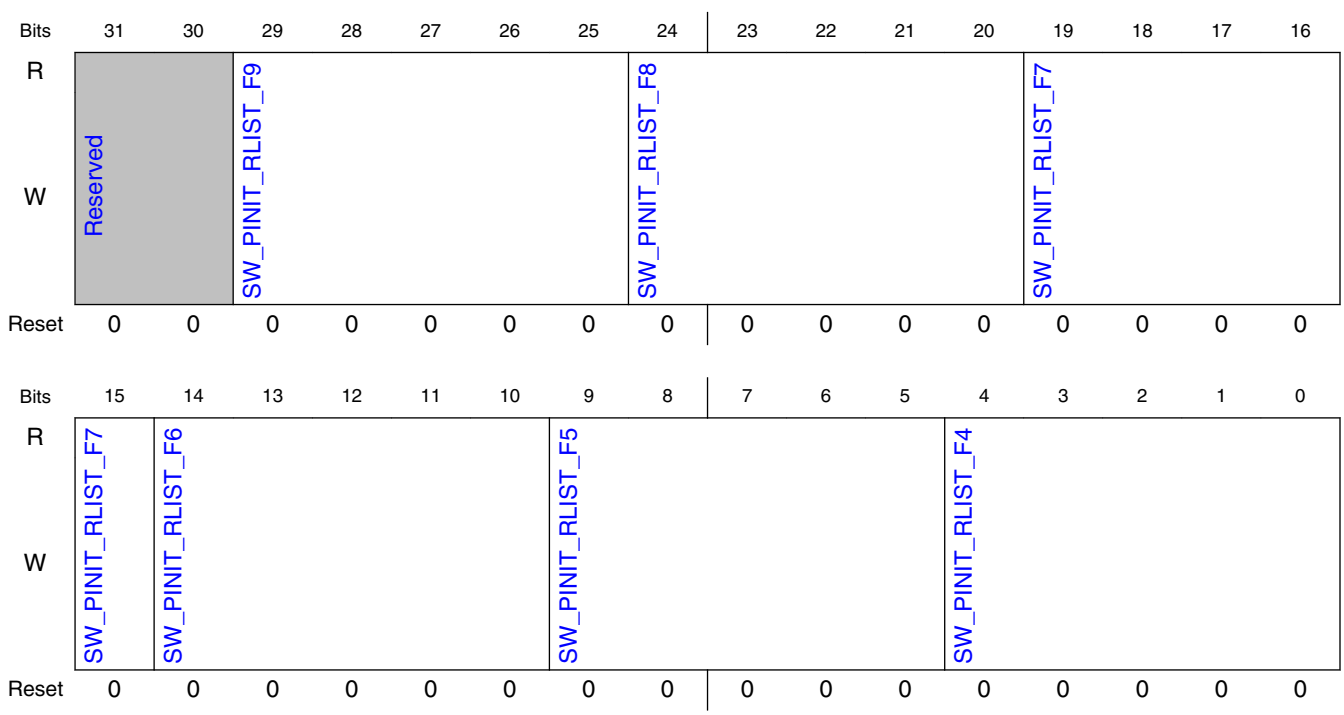
Register	Offset
SWREG9	24h

16.1.6.2.7.2 Diagram

16.1.6.2.7.3 Fields

Field	Function
31-24 SW_PPS_ID	pic_parameter_set_id, identifies the picture parameter set that is referred to in the slice header.
23-19 SW_REFIDX1_ACTIVE	Specifies the maximum reference index that can be used while decoding inter predicted macro blocks.

Table continues on the next page...



Field	Function
18-14 SW_REFIDX0_ACTIVE	Specifies the maximum reference index that can be used while decoding inter predicted macro blocks. This is same as in previous decoders (width increased with q bit)
13-8 —	Reserved.
7-0 SW_POC_LENGTH	Length of picture order count field in stream

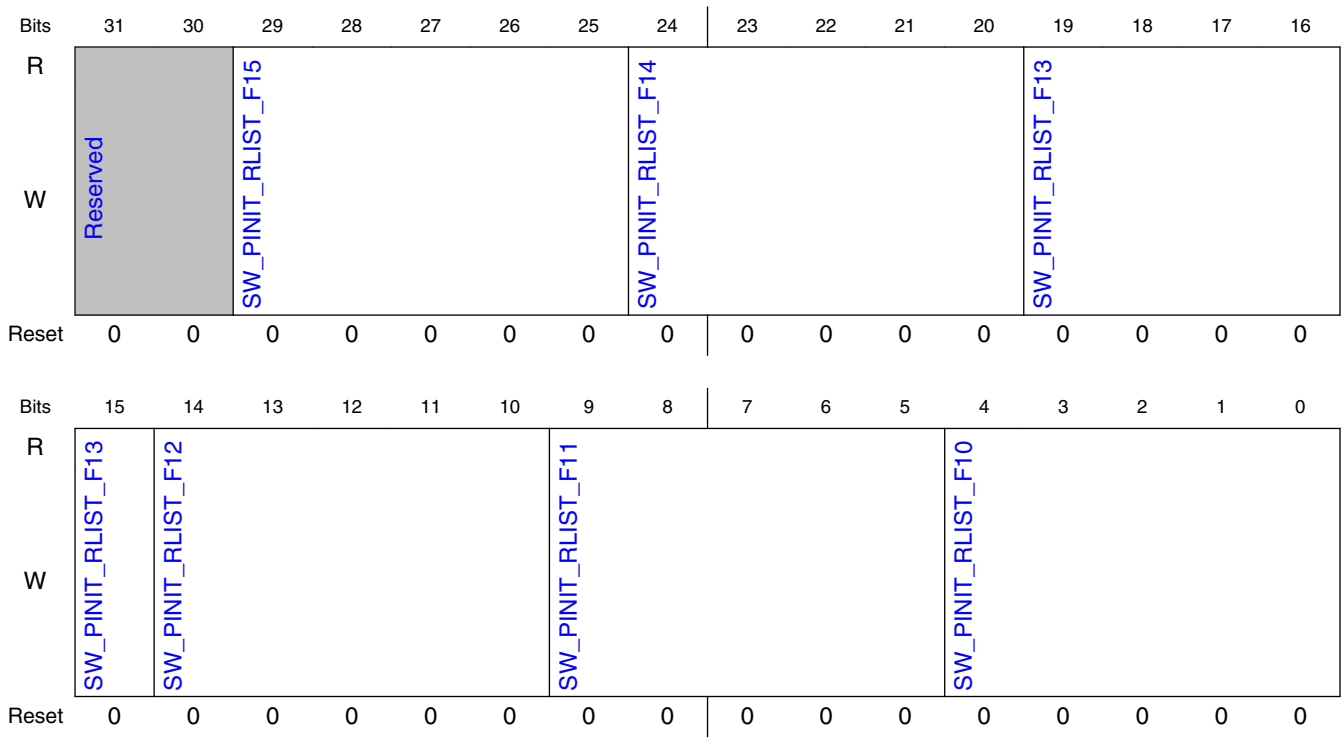
16.1.6.2.8 Base address for differential motion vector base address (RLC-mode) /H264 P initial fwd ref pic list register (4-9)/ VC-1 intensity control 1/ VP7 and VP8 segmentation base register (SWREG10)

16.1.6.2.8.1 Offset

Register	Offset
SWREG10	28h

16.1.6.2.8.2 Diagram

16.1.6.2.8.3 Fields



Field	Function
31-30 —	Reserved.
29-25 SW_PINIT_RLIST_F9	Initial reference picture list for P forward picid 9
24-20 SW_PINIT_RLIST_F8	Initial reference picture list for P forward picid 8
19-15 SW_PINIT_RLIST_F7	Initial reference picture list for P forward picid 7
14-10 SW_PINIT_RLIST_F6	Initial reference picture list for P forward picid 6
9-5 SW_PINIT_RLIST_F5	Initial reference picture list for P forward picid 5
4-0 SW_PINIT_RLIST_F4	Initial reference picture list for P forward picid 4

16.1.6.2.9 Decoder control register 7 (VLC) / base address for H.264 intra prediction 4x4 / base address for MPEG-4 DC component (RLC) / H264 P initial fwd ref pic list register (10-15) / VC-1 intensity control 2 (SWREG11)

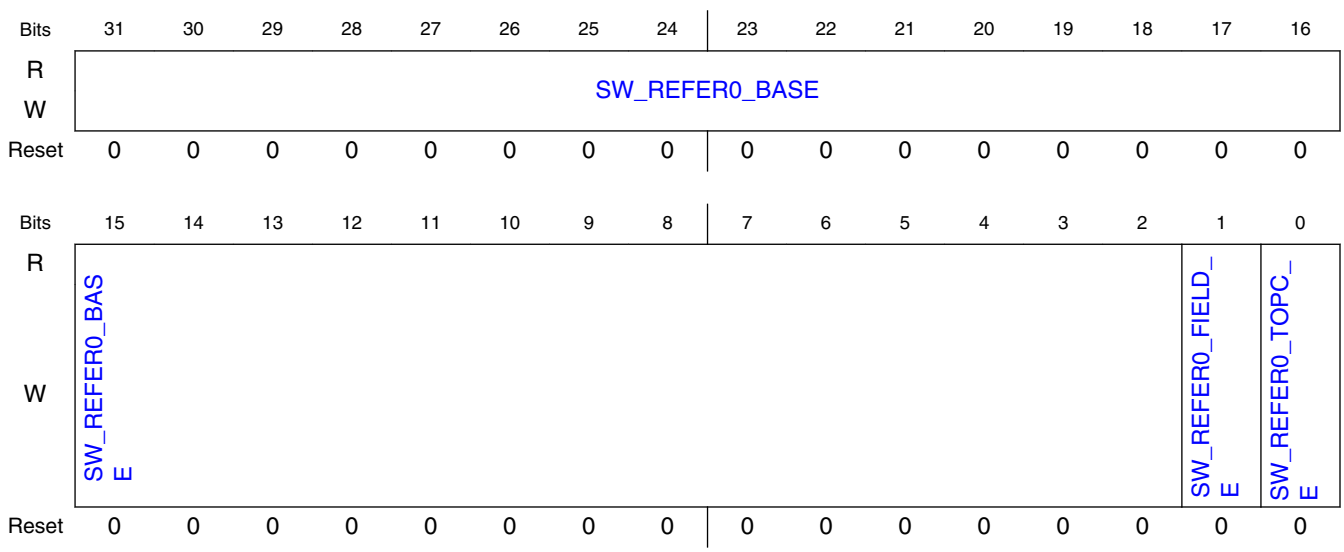
16.1.6.2.9.1 Offset

Register	Offset
SWREG11	2Ch

16.1.6.2.9.2 Diagram

16.1.6.2.9.3 Fields

Field	Function
31-30 —	Reserved.
29-25 SW_PINIT_RLIST_F15	Initial reference picture list for P forward picid 15
24-20 SW_PINIT_RLIST_F14	Initial reference picture list for P forward picid 14
19-15 SW_PINIT_RLIST_F13	Initial reference picture list for P forward picid 13
14-10 SW_PINIT_RLIST_F12	Initial reference picture list for P forward picid 12
9-5 SW_PINIT_RLIST_F11	Initial reference picture list for P forward picid 11
4-0	Initial reference picture list for P forward picid 10



Field	Function
SW_PINIT_RLIST_F10	

16.1.6.2.10 Base address for reference picture index 0 / base address for JPEG decoder output chrominance picture (SWREG14)

16.1.6.2.10.1 Offset

Register	Offset
SWREG14	38h

16.1.6.2.10.2 Diagram

16.1.6.2.10.3 Fields

Field	Function
31-2 SW_REFER0_BASE	Base address for reference picture index 0. See picture index definition from toplevel_sp
1 SW_REFER0_FIELD_E	Refer picture consist of single fields or frame: 0b - reference picture consists of frame 1b - reference picture consists of fields
0	Which field of reference picture is closer to current picture:

Field	Function
SW_REFER0_TOPC_E	0b - Bottom field is closer to current picture 1b - Top field is closer to current picture

16.1.6.2.11 Base address for reference picture index 1 / JPEG control (SWREG15)

16.1.6.4.2 Decoder control register 1 (picture parameters) (SWREG4_JPEG_VP7_VP8)

16.1.6.4.2.1 Offset

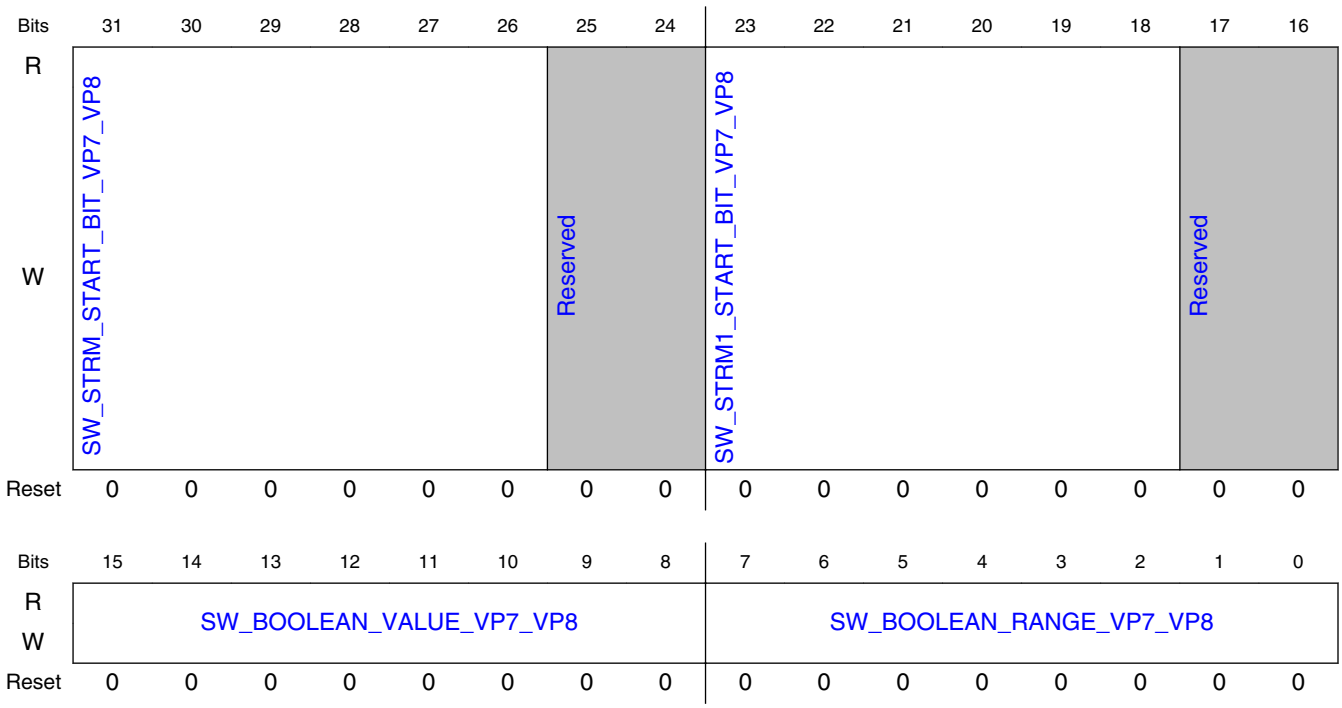
Register	Offset
SWREG4_JPEG_VP7_VP8	10h

16.1.6.4.2.2 Diagram

16.1.6.4.2.3 Fields

Field	Function
31-23 SW_PIC_MB_WIDTH_JPEG_VP7_VP6	Picture width in macroblocks = ((width in pixels + 15) /16)
22-19	The amount of meaningfull horizontal pixels in last MB (width offset) 0 if exactly 16 pixels multiple picture and all the horizontal pixels in last MB are meaningfull

Table continues on the next page...



Field	Function
SW_MB_WIDTH_OFF_JPEG_VP7_VP6	
18-11 SW_PIC_MB_HEIGHT_P_JPEG_VP7_VP6	Picture height in macroblocks =((height in pixels+15)/16). Picture height is informed as size of the (progressive) frame also for single field (of interlaced content) is being decoded
10-7 SW_MB_HEIGHT_OFF_JPEG_VP7_VP6	The amount of meaningful vertical pixels in last MB (height offset 0 if exactly 16 pixels multiple picture and all the vertical pixels in last MB are meaningfull
6 SW_ALT_SCAN_E_JPEG_VP7_VP6	indicates alternative vertical scan method used for interlaced frames
5-3 SW_PIC_MB_W_EXT_JPEG_VP7_VP6	Picture mb width extension. If sw_pic_mb_width does not fit to 9 bits then these bits are used to increase the range upto 11 bits (used as 3 msb)
2-0 SW_PIC_MB_H_EXT_JPEG_VP7_VP6	Picture mb height extension. If sw_pic_mb_height_p does not fit to 9 bits then these bits are used to increase the range upto 11 bits (used as 3 msb). For 4k video one bit is used for extension (bit 0)

16.1.6.4.3 Decoder control register 2 (stream decoding table selects) (SWREG5_VP7_VP8)

16.1.6.4.3.1 Offset

Register	Offset
SWREG5_VP7_VP8	14h

16.1.6.4.3.2 Diagram

16.1.6.4.3.3 Fields

Field	Function
31-26 SW_STRM_START_BIT_VP7_VP8	Exact bit of stream start word where decoding can be started (assosiates with sw_rlc_vlc_base)
25-24 —	Reserved.
23-18 SW_STRM1_START_BIT_VP7_VP8	Start bit for ctrl-stream (needed if multistream is enabled, assosiates with sw_bitpl_ctrl_base)
17-16 —	Reserved.
15-8 SW_BOOLEAN_VALUE_VP7_VP8	Initial value for boolean dec
7-0 SW_BOOLEAN_RANGE_VP7_VP8	Initial range for boolean dec

16.1.6.4.4 Decoder control register 3 (stream buffer information) (SWREG6_VP7_VP8)

16.1.6.4.4.1 Offset

Register	Offset
SWREG6_VP7_VP8	18h

16.1.6.4.4.2 Diagram

16.2 VPU G2 Decoder

16.2.1 Overview

The Video Processing Unit (VPU) G2 hardware-based decoder decodes HEVC and VP9 compatible video streams.

16.2.1.1 Block Diagram

The block diagram of the VPU G2 decoder is shown below.

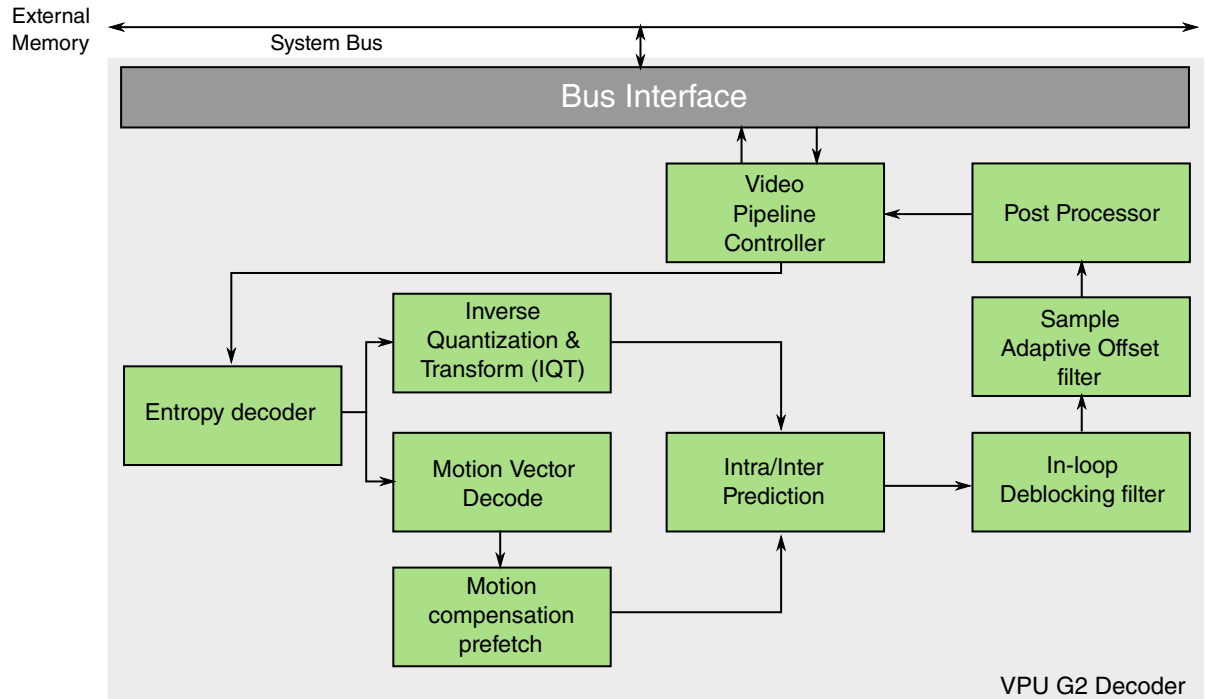

Figure 16-4. VPU G2 Decoder Block Diagram

16.2.1.2 Features

The VPU G2 decoder includes the following features:

- HEVC standard Main/Main 10 profile (up to level 5.1) decoding
- VP9 Profile 0 decoding
- Tiled to raster scan conversion

16.2.2 Functional description

16.2.2.1 Video Frame Storage Format

The decoder supports two storage formats for frames, raster-scan, tiled without being compressed and compressed output. The application using the decoder may specify upon initialization which format is preferred

16.2.2.1.1 Raster-scan format

The output picture of the decoder is in semi-planar YCbCr 4:2:0 format, i.e. luminance data forms one plane in memory, and chrominance data forms the other. The output picture has to be stored linearly and contiguously in the memory. The interleaved

chrominance block has to be stored right after the luminance block in external memory as shown in Figure 16-5 . The number of bytes in one luminance row must be divisible by 16, which means there will be padded 0 in the right edge when necessary.

The interleaved chrominance is stored raster-scanned in memory in Cb0Cr0Cb1Cr1Cb2Cr2Cb3… format.

The decoder output picture for interlaced sequence is always stored as an interlaced frame where even lines belongs to top field and odd lines belongs to bottom field of the frame.

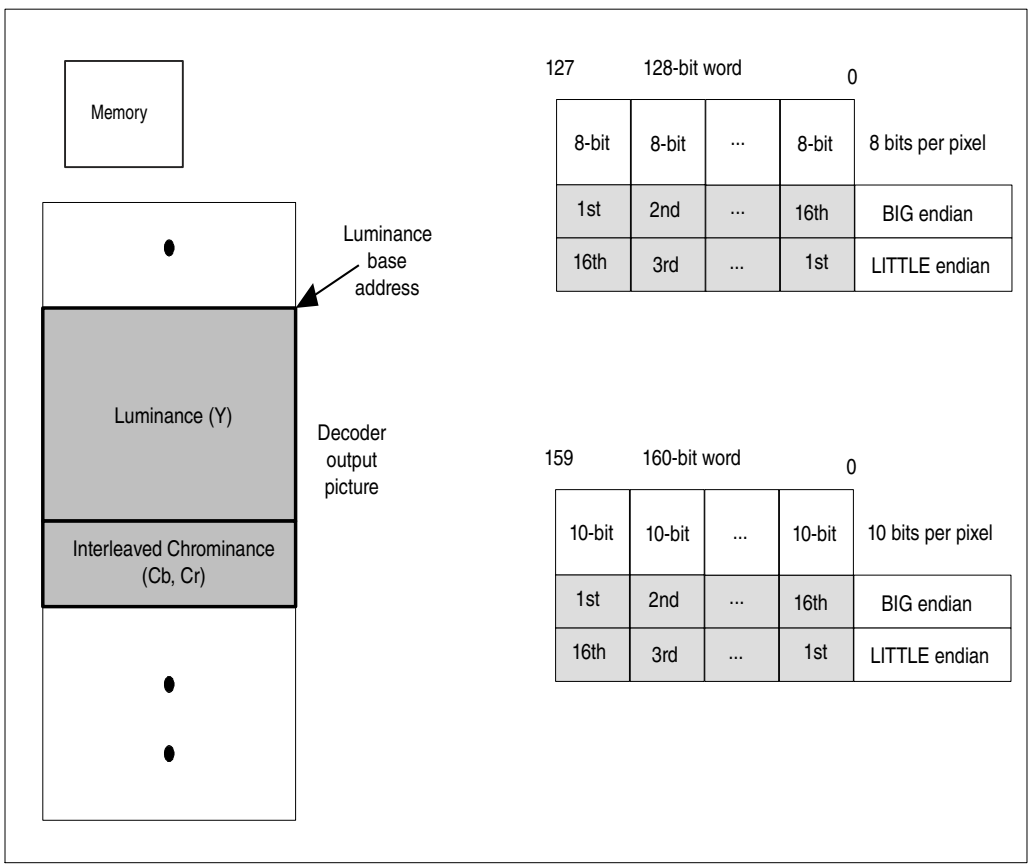

Figure 16-5. External Memory Usage

As an example, the luminance pixels of a QCIF sized (176 x 144) frame with each pixel in 8 bits are numbered as presented in Table 16-3. Table 16-4 shows the storage of the luminance pixel data of the QCIF sized video frame in raster-scan order (in little endian mode).

Table 16-3. Pixel numbers of the luminance data of the QCIF video frame

0	1	2	3	4	5	6	7	…	172	173	174	175

16.2.2.1.2 Tiled format

The output picture of the decoder is in semi-planar YCbCr 4:2:0 4x4 tiled format, i.e. luminance data forms one plane in memory, and chrominance data forms another. The distinction from raster scan format is that the output picture is grouped into tiles, which are then stored linearly and contiguously in the memory. The chrominance tiles have to be stored right after the luminance tiles in external memory as shown in Figure . The number of luminance pixels in one row must be divisible by 16.

The chrominance is stored into tiles in interleaved Cb0Cr0Cb1Cr1Cb2Cr2Cb3… format.

Figure 16-6 contains example external memory usage when using 4x4 tiles, which is used in G2 decoder.

Below is an example code of converting tiled YCbCr 4:2:0 output picture back to raster scan format. The code is in generalized form, i.e. can function on arbitrary tile sizes as long as the picture dimensions are multiple of tile sizes. In the example, chrominance data is interleaved into 4x4 tile so that one 4x4 tile contains one 2x4 block of Cb and Cr each. Output is YCbCr 4:2:0 semiplanar.

```
void ConvertTiledToRaster( DecPicture decPicture, u32 tileWidth,
            u32 tileHeight, u8 *pOutput )
            {
            u32 i, j;
            u32 k, l;
```

```
u32 s, t;
u8 *pIn;
pIn = decPicture.pOutputPicture;
/* loop all tile rows for luminance */
for( i = 0 ; i < decPicture.frameHeight ; i += tileHeight )
{
t = 0;
s = 0;
/* loop all tiles in one row */
for( j = 0 ; j < decPicture.frameWidth ; j += tileWidth )
{
/* copy one tile */
for( k = 0 ; k < tileHeight ; ++k )
{
for( l = 0 ; l < tileWidth ; ++l )
{
pOutput[ k*decPicture.frameWidth + l + s ] = pIn[t++];
}
}
/* move to next horizontal tile */
s += tileWidth;
}
/* move to next tile row */
pOutput += decPicture.frameWidth * tileHeight;
pIn += decPicture.frameWidth * tileHeight;
}
/* setup pointers to chrominance data */
pIn = decPicture.pOutputPicture +
decPicture.frameWidth * decPicture.frameHeight;
/* loop all tile rows for chrominance */
for( i = 0 ; i < decPicture.frameHeight/2 ; i += tileHeight )
{
t = 0;
s = 0;
/* loop all tiles in one row */
for( j = 0 ; j < decPicture.frameWidth ; j += tileWidth )
{
/* copy one tile */
for( k = 0 ; k < tileHeight ; ++k )
{
for( l = 0 ; l < tileWidth ; ++l )
{
pOutput[ k*decPicture.frameWidth + l + s ] = pIn[t++];
}
}
/* move to next horizontal tile */
s += tileWidth;
}
/* move to next tile row */
pOutput += decPicture.frameWidth * tileHeight;
pIn += decPicture.frameWidth * tileHeight;
}
}
```

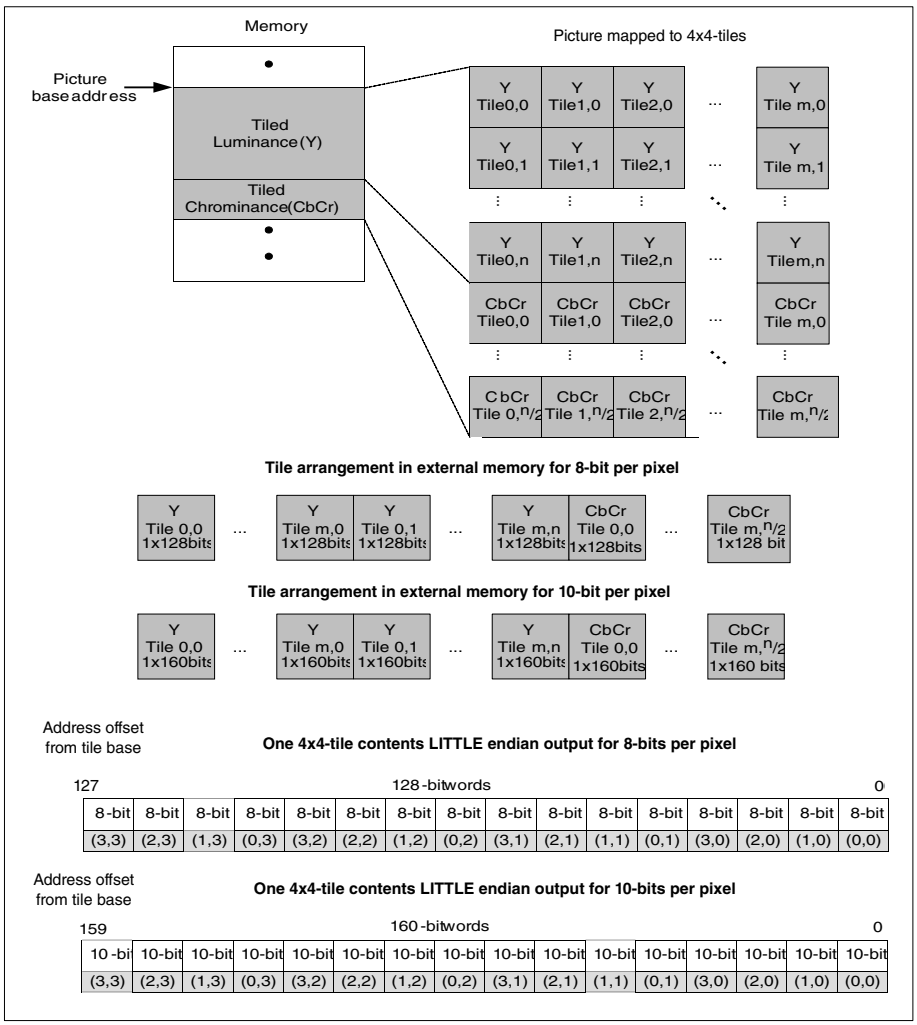

Figure 16-6. External Memory Usage in 4x4 Tiled Reference Picture Mode

16.2.2.1.3 Compressed format

G2 decoder supports compressed tiled output, when reference buffer compression (RFC) is enabled when synthesis, and user allows compressed reference frame output directly.

Reference frame compression is a feature added in G2 decoder to compress frame buffer so that the bandwidth of storing/loading reference frame can be reduced, especially when the resolution of decoded stream is of high definition.

When compression is enabled, the picture is divided into CBS rows, which is further divided into continuous CBS groups. Each CBS group is composed of 16 CBS. The luminance CBS is composed of 1 8x8 coded block (CB), which one chrominance CBS is composed of two 8x4 coded blocks, with cb CB first then cr CB following. The compression is performed to each CB in the CBS. The first CB's compressed data is

saved from the same offset of that CBS in raster scan buffer. And the compressed output of following CBs in the CBS row is saved continuously. That means there may be gaps between the compressed data of each CBS row.

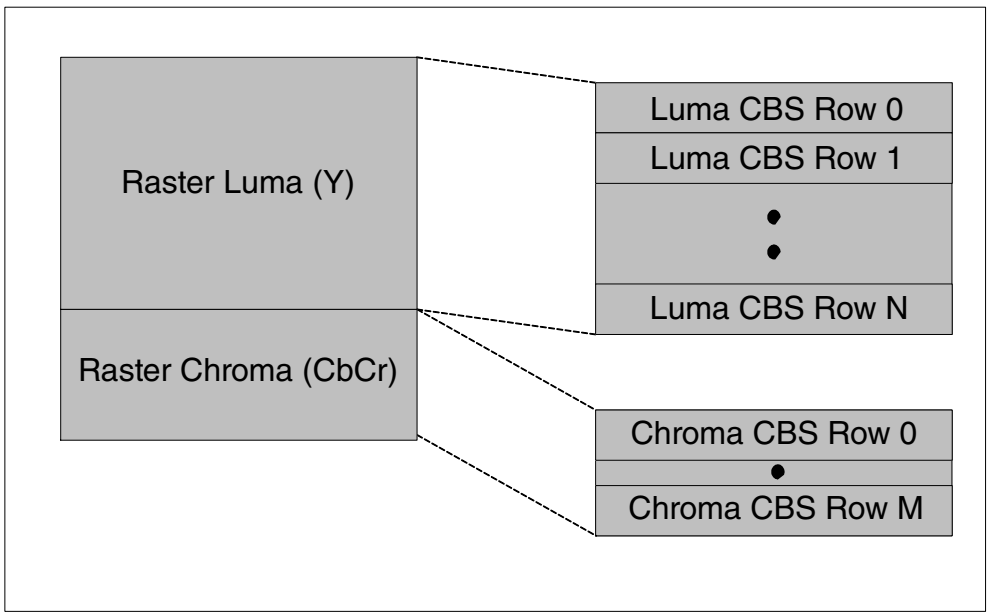

Figure 16-7. Raster scan picture mapped to CBS rows

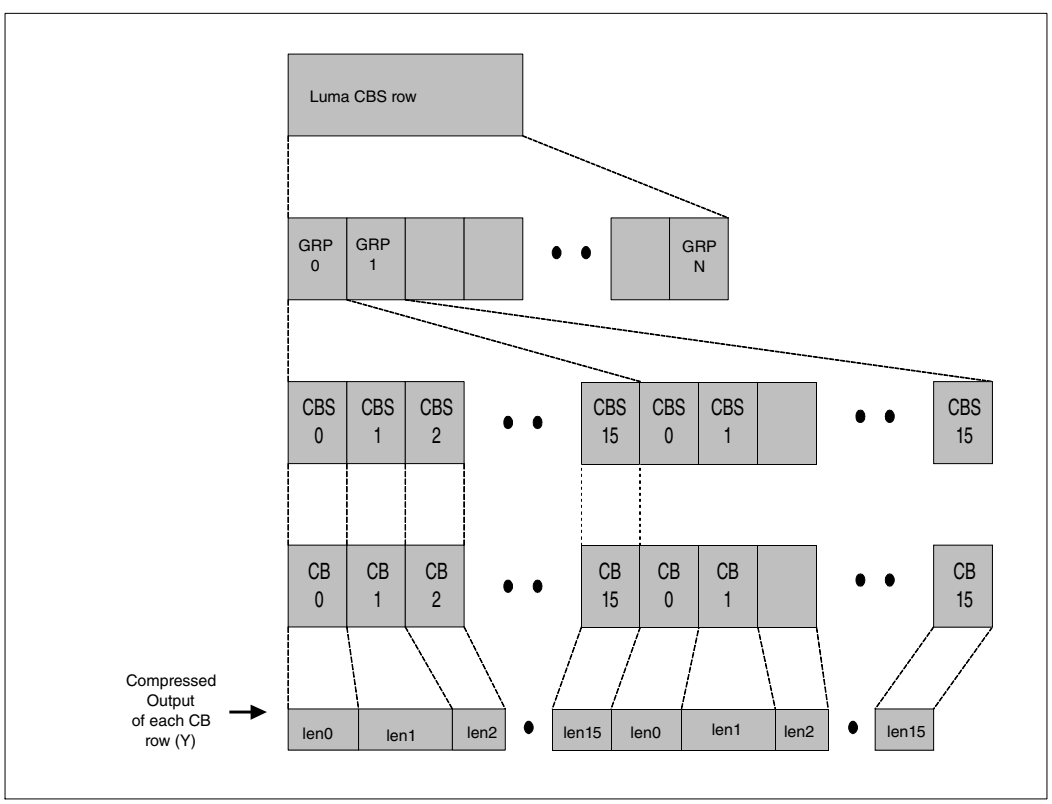

Figure 16-8. Compression performed to each Luma CBS row

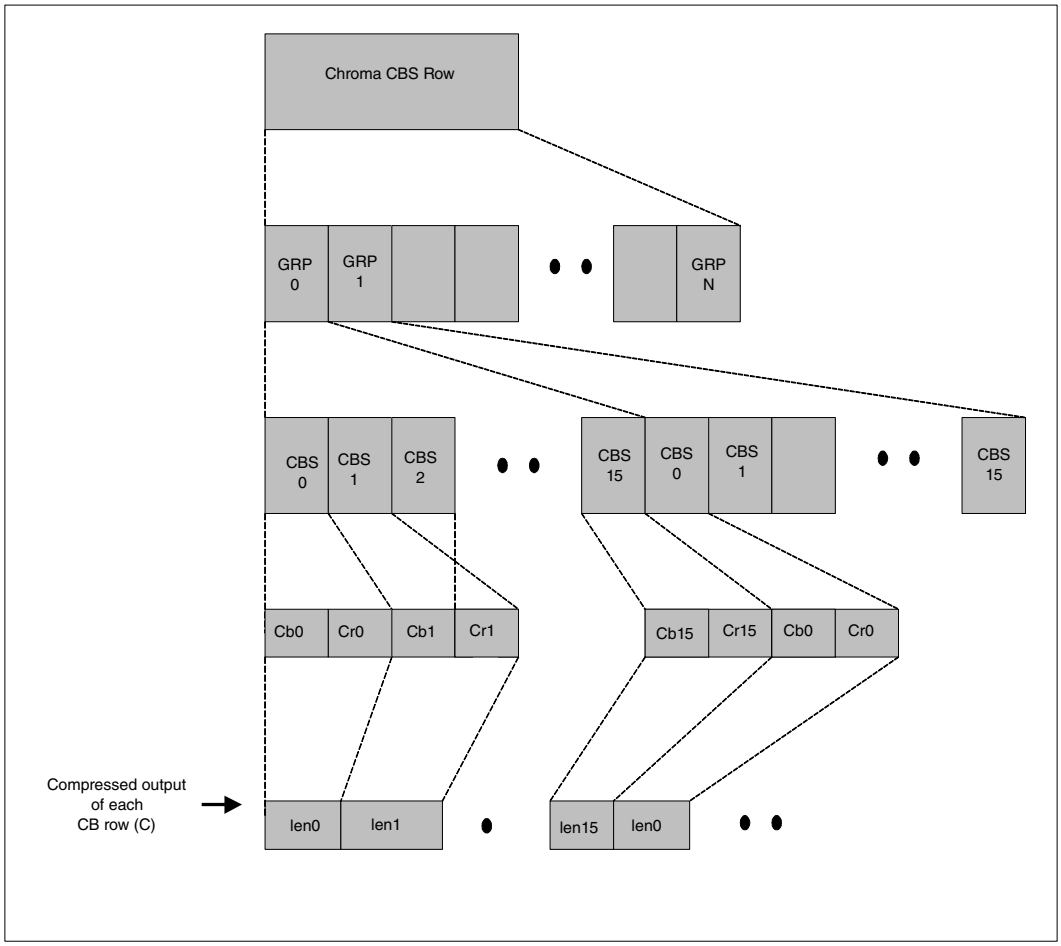

Figure 16-9. Compression performed to each Chroma CBS row

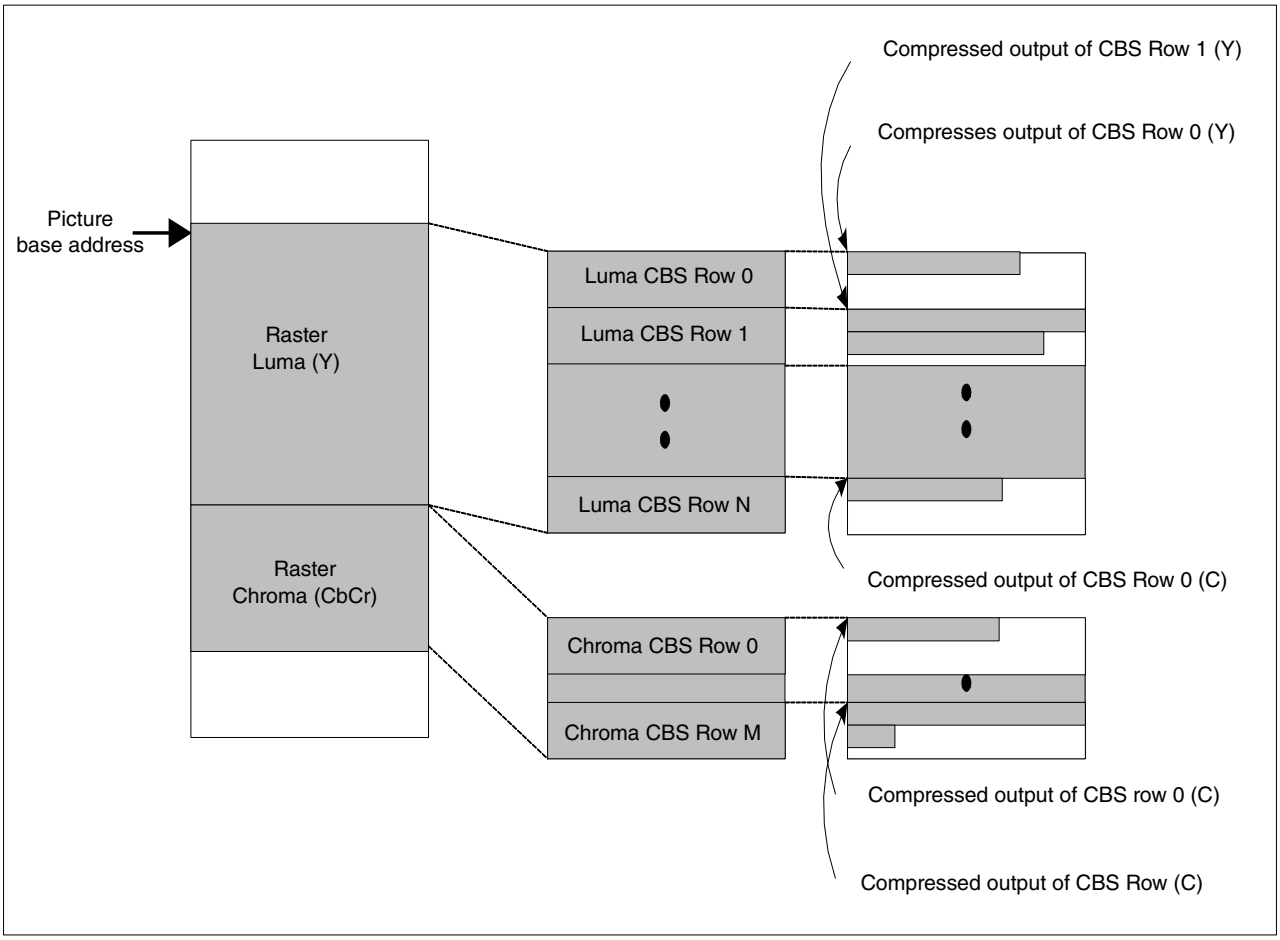

Figure 16-10. Map of external memory in RFC output buffer

Corresponding to each CBS group the starting offset of first compressed CBS output is saved in two bytes in CBS table, followed by the length of each CBS compress output, which is saved in 7 bits. So the table length of each CBS group information is 2+7*16/8=16 bytes.

This 16 bytes for each CBS group in compression table is mapped as shown in the following table. Here, X[n] means the bit-n of the length of CBS X in CBS group.

Table 16-5. Storage of the compression cache table for each CBS group

Byte	Bit7	Bit6	Bit5	Bit4	Bit 3	Bit 2	Bit 1	Bit 0
0	Offset[7:0]							
1	Offset[15:8]							
2	1[0]	0[6]	0[5]	0[4]	0[3]	0[2]	0[1]	0[0]

16.2.2.2 Clocks

The following table describes the clock sources for the VPU G2 decoder. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 16-6. VPU G2 Clocks

Clock name	Description
core_clk	VPU G2 core clock

16.2.2.3 Reset

The VPU G2 decoder has one software reset (g2_sft_rstn).

16.2.3 External Signals

There are no external signals pinned out for this module.

16.2.4 Initialization and Application Information

The VPU G2 decoder is operated via the VPU Application Programming Interface (API). Details are provided in separate API documentation.

16.2.5 VPU G2 Memory Map/Register Definition

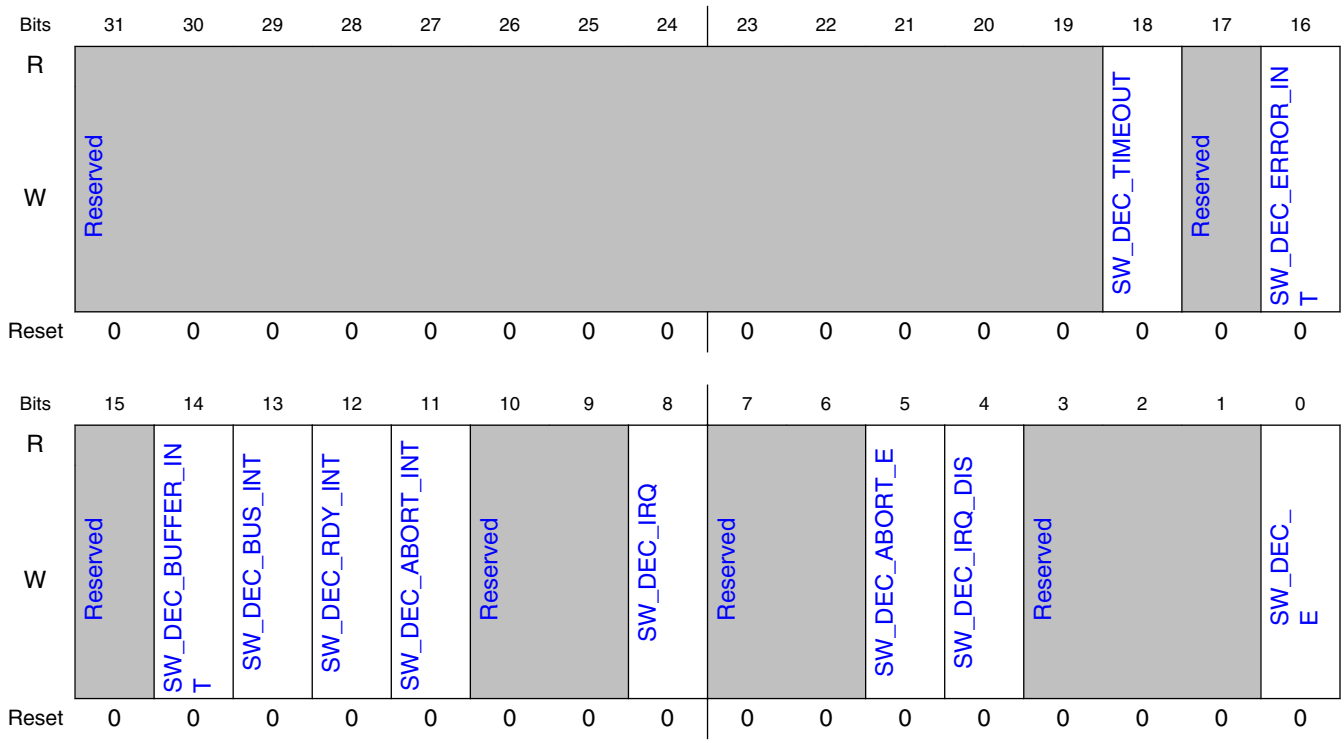
16.2.5.1.2 ID register (read only) (SWREG0)

16.2.5.1.2.1 Offset

Register	Offset
SWREG0	0h

16.2.5.1.2.2 Diagram

16.2.5.1.2.3 Fields



Field	Function
31-16 SW_PRODUCT_NUMBER	Product number (g2)
15-12 SW_MAJOR_VERSION	Major version
11-4 SW_MINOR_VERSION	Minor version
3 SW_PRODUCT_ID_EN	ASCII type product ID enable
2-0 SW_BUILD_VERSION	Build version (core number)

16.2.5.1.3 Interrupt register decoder (SWREG1)

16.2.5.1.3.1 Offset

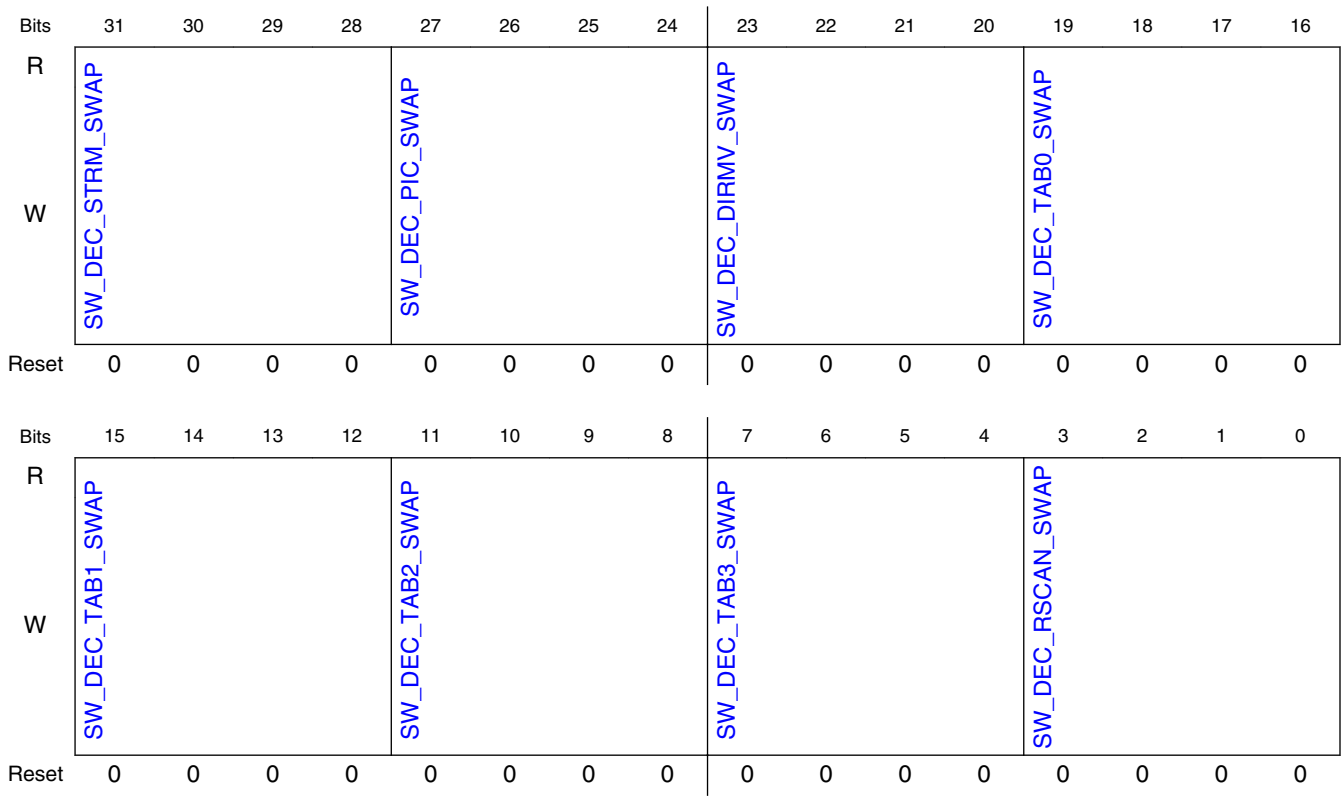
Register	Offset
SWREG1	4h

16.2.5.1.3.2 Diagram

16.2.5.1.3.3 Fields

Field	Function
31-19 —	Reserved.
18 SW_DEC_TIMEOUT	Interrupt status bit decoder timeout. When high the decoder has been idling for too long. HW will self reset. Possible only if timeout interrupt is enabled
17 —	Reserved.
16 SW_DEC_ERROR_INT	Interrupt status bit input stream error. When high an error is found in input data stream decoding. HW will self reset.
15	Reserved.

Table continues on the next page...



Field	Function
—	
14 SW_DEC_BUFFER_INT	Interrupt status bit input buffer empty. When high input stream buffer is empty but picture is not ready. HW will not self reset.
13 SW_DEC_BUS_INT	Interrupt status bit bus. Error response from bus. HW will self reset.
12 SW_DEC_RDY_INT	Interrupt status bit decoder. When this bit is high decoder has decoded a picture. HW will self reset.
11 SW_DEC_ABORT_INT	Interrupt status bit decoding aborted. When this bit is high decoder has aborted the current picture decoding as SW requested (sw_dec_abort_e). Decoder self reset and sw_dec_abort_e written low
10-9 —	Reserved.
8 SW_DEC_IRQ	Decoder IRQ. When high decoder requests an interrupt. SW will reset this after interrupt is handled.
7-6 —	Reserved.
5 SW_DEC_ABORT_E	Abort decoding enable. Setting this bit high will cause HW to abort decoding and safely to reset itself down. After abort is complete the corresponding interrupt status is set and this bit is set low as well as the decoder enable.
4 SW_DEC_IRQ_DIS	Decoder IRQ disable. When high there are no interrupts concerning decoder from HW. Polling must be used to see the interrupt statuses.
3-1 —	Reserved.
0 SW_DEC_E	Decoder enable. Setting this bit high will start the decoding operation. HW will reset this when picture is processed or ASO or stream error is detected or bus error or timeout interrupt is given.

16.2.5.1.4 Data configuration register decoder (SWREG2)

16.2.5.1.4.1 Offset

Register	Offset
SWREG2	8h

16.2.5.1.4.2 Diagram

16.2.5.1.4.3 Fields

Field	Function
31-28 SW_DEC_STRM_SWAP	Byte swap configuration for stream data 4 Bit byte order vector to control byte locations inside HW internal 128 bit data vector. For 64 and 32 bit external bus widths, the data is first gathered to 128 bit width and then bytes swapped accordingly: Bit 0: 8 bit swap Bit 1: 16 bit swap Bit 2: 32 bit swap Bit 3: 64 bit swap '0000' = 0-1-2-3-4-5-6-7-8-9-10-11-12-13-14-15 '0001' = 1-0-3-2-5-4-7-6... 16.2.5.1.8.3 Fields

Field	Function
31-0 SW_STREAM_LEN	Amount of stream data bytes in input buffer. If the given buffer size is not enough for finishing the picture the corresponding interrupt is given and new stream buffer base address and stream buffer size information should be given (assosiates with sw_rlc_vlc_base). For HEVC the buffer must include at least data for one slice/VP of the picture

16.2.5.1.9 Decoder control register 4 (SWREG7)

16.2.5.1.9.1 Offset

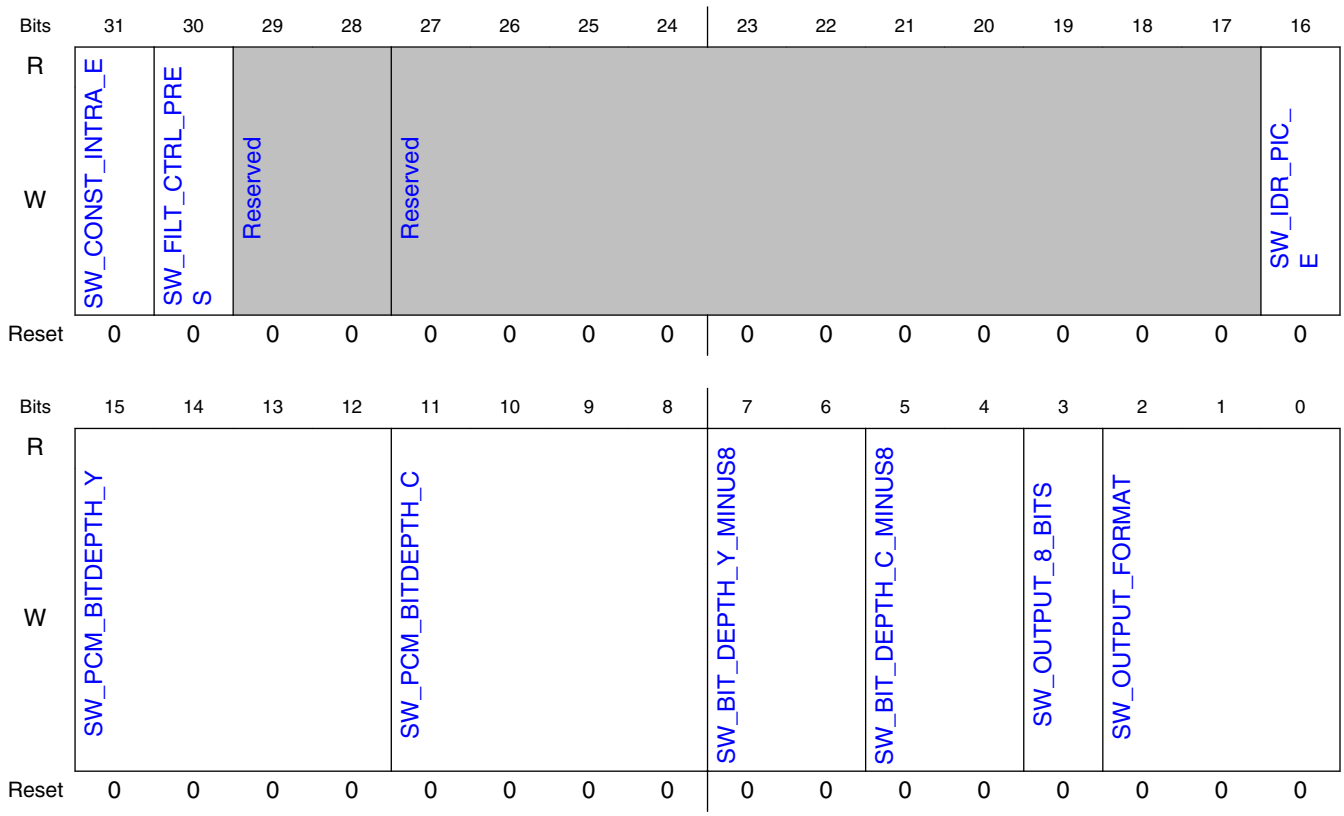
Register	Offset
SWREG7	1Ch

16.2.5.1.9.2 Diagram

16.2.5.1.9.3 Fields

Field	Function
31 SW_CABAC_INIT_PRESENT	CABAC init present enable for stream decoding
30 SW_BLACKWHITE_E	Sampling 0b - 4:2:0 sampling format 1b - 4:0:0 sampling format (H264 monochroma)
29 —	Reserved.
28 SW_WEIGHT_PRED_E	Weighted prediction enable for P slices
27-26 SW_WEIGHT_BIPR_IDC	Weighted prediction specification 00b - Default weighted prediction is applied to B slices 01b - Explicit weighted prediction shall be applied to B slices 10b - NA 11b - NA
25 SW_FILT_SLICE_BORDER	Filter enable over slice border
24 SW_FILT_TILE_BORDER	Filter enable over tile border
23 SW_ASYM_PRED_E	Asymmetric prediction flag for stream decoding
22 SW_SAO_E	Sample Adaptive Offset enable for stream decoding
21 SW_PCM_FILT_DISABLE	Disable for PCM loop filtering
20 SW_SLICE_CHQP_FLAG	Slice header flag for chroma QP present (if it is included in slice header)
19 SW_DEPEND_SLICE_E	Dependent slice enable
18 SW_FILT_OVERRIDE_E	Filter override enable
17 SW_STRONG_SMOOTH_E	Strong smoothing enable
16-12	Filter beta offset (declared as div2)

Table continues on the next page...



Field	Function
SW_FILT_OFFSET_BETA	
11-7 SW_FILT_OFFSET_TC	Filter tc offset (declared as div2)
6 SW_SLICE_HDR_EXT_E	Slice header extension enable. Reserved for future use
5-3 SW_SLICE_HDR_EBITS	Number of extra slice header bits (if enabled slice header extension)
2-0 —	Reserved.

16.2.5.1.10 Decoder control register 5 (SWREG8)

16.2.5.1.10.1 Offset

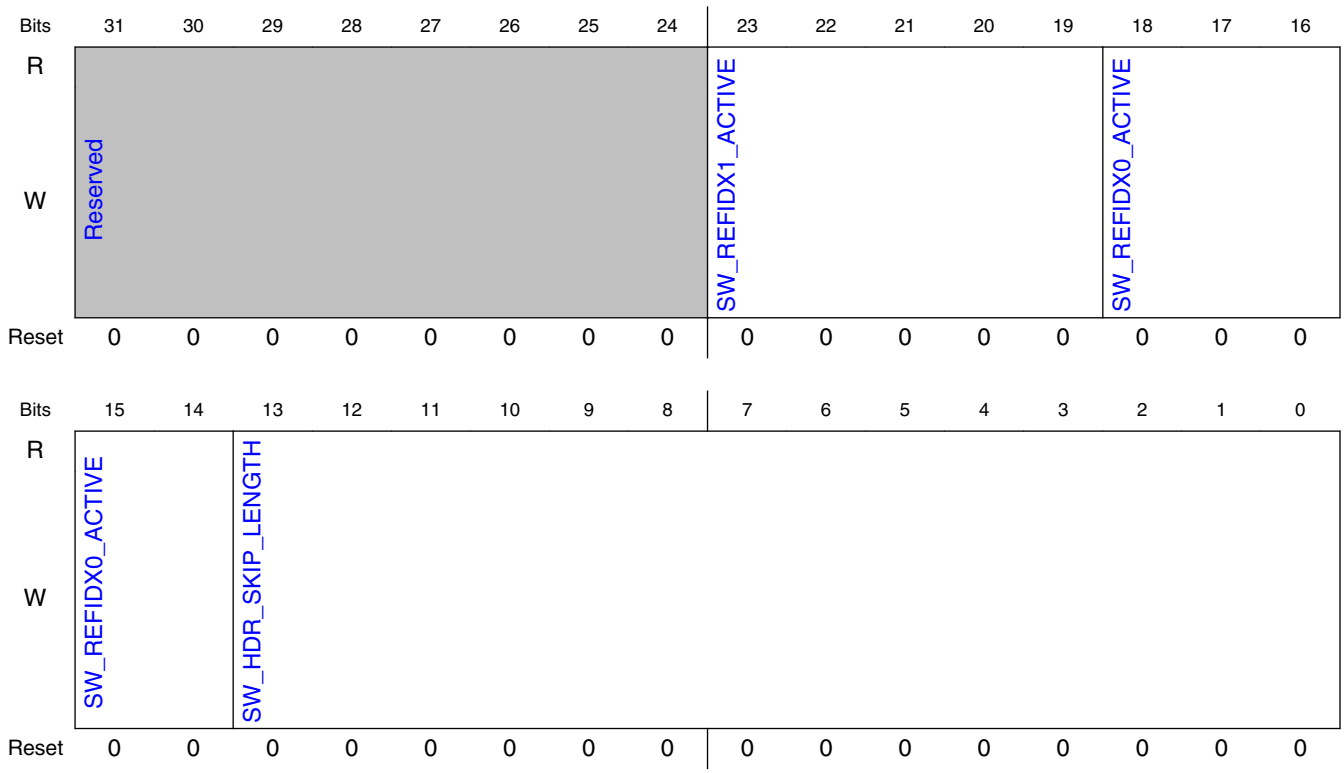
Register	Offset
SWREG8	20h

16.2.5.1.10.2 Diagram

16.2.5.1.10.3 Fields

Field	Function
31 SW_CONST_INTRA_E	constrained_intra_pred_flag equal to 1 specifies that intra prediction uses only neighbouring intra macroblocks in prediction. When equal to 0 also neighbouring inter macroblocks are used in intra prediction process.
30 SW_FILT_CTRL_PRES	deblocking_filter_control_present_flag indicates whether extra variables controlling characteristics of the deblocking filter are present in the slice header.
29-28 —	Reserved.
27-17 —	Reserved.
16 SW_IDR_PIC_E	IDR (instantaneous decoding refresh) picture flag.
15-12 SW_PCM_BITDEPTH_Y	Bit depth for PCM Y data
11-8	Bit depth for PCM C data

Table continues on the next page...



Field	Function
SW_PCM_BITDEPTH_C	
7-6 SW_BIT_DEPTH_Y_MINUS8	Bit depth of luma samples minus 8
5-4 SW_BIT_DEPTH_C_MINUS8	Bit depth of chroma samples minus 8
3 SW_OUTPUT_8_BITS	enable rasterscan output force to 8 bit(only for hevc main10 and vp9 10bit)
2-0 SW_OUTPUT_FORMAT	Raster scan and down scale output data format 000b - Each pixel in 10 bits when luma or chroma pixel bit depth is larger than 8; or 8 bits when both luma and chroma pixel bit depth are 8 bits. (default) 001b - Store in P010 format when luma or chroma pixel bit depth is larger than 8. 010b - A customized format: please refer to register SWREG23[6].

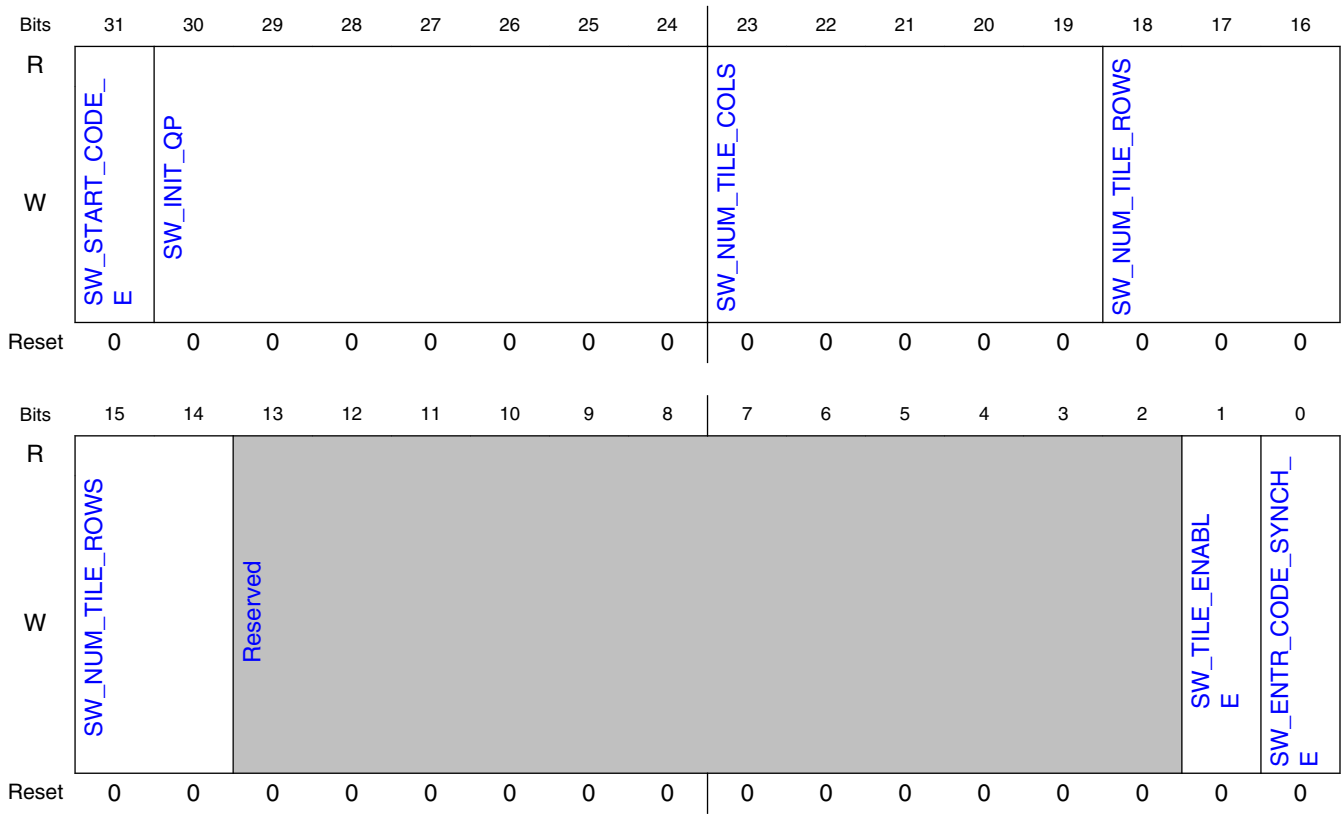
16.2.5.1.11 Decoder control register 6 (SWREG9)

16.2.5.1.11.1 Offset

Register	Offset
SWREG9	24h

16.2.5.1.11.2 Diagram

16.2.5.1.11.3 Fields



Field	Function
31-24 —	Reserved.
23-19 SW_REFIDX1_ACTIVE	Specifies the maximum reference index that can be used while decoding inter predicted macro blocks.
18-14 SW_REFIDX0_ACTIVE	Specifies the maximum reference index that can be used while decoding inter predicted macro blocks. This is same as in previous decoders (width increased with q bit)
13-0 SW_HDR_SKIP_LENGTH	Length of slice header skip length (bytes used by sw)

16.2.5.1.12 Decoder control register 7 (SWREG10)

16.2.5.1.12.1 Offset

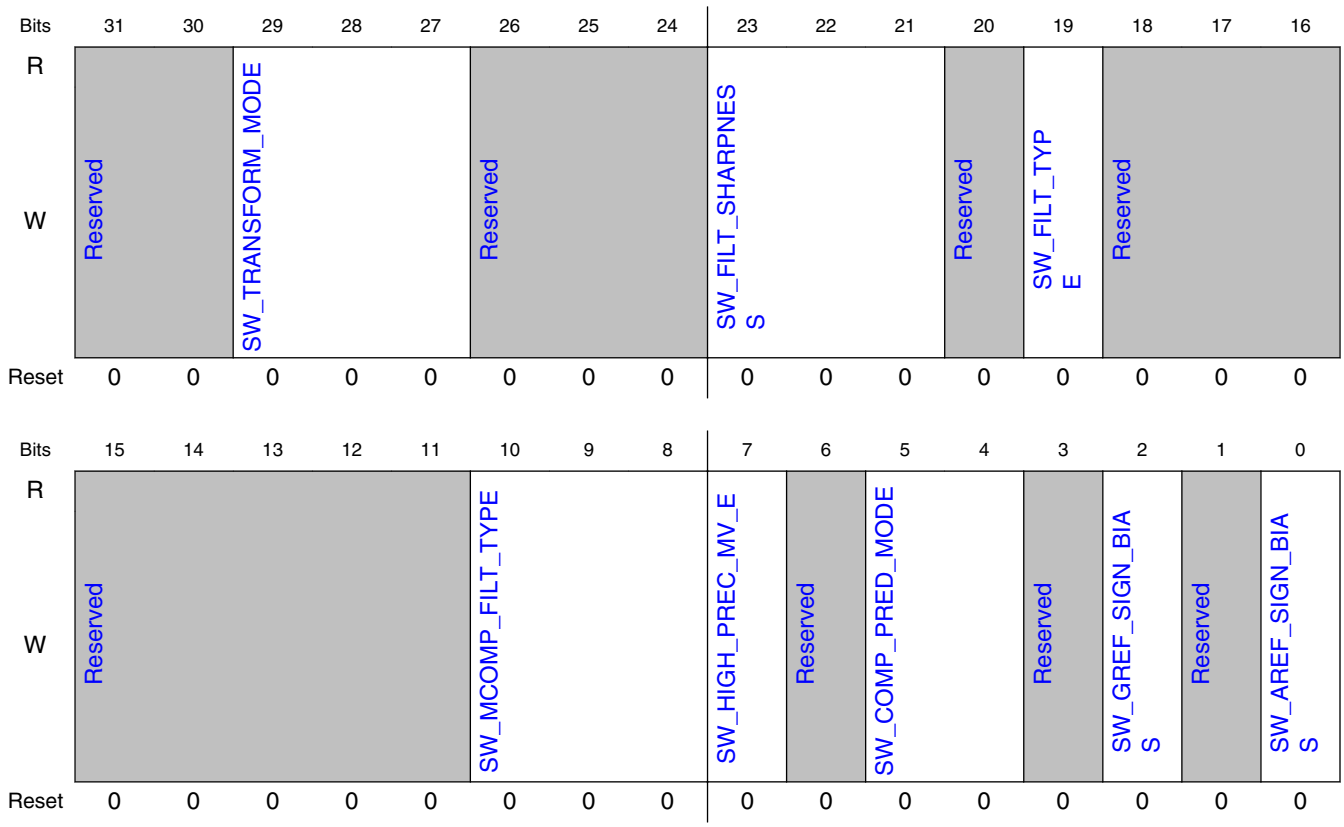
Register	Offset
SWREG10	28h

16.2.5.1.12.2 Diagram

16.2.5.1.12.3 Fields

Field	Function
31 SW_START_CODE_E	Bit for indicating stream start code existence 0b - Stream does not contain start codes 1b - Stream contains start codes
30-24 SW_INIT_QP	Initial value for quantization parameter (picture quantizer).
23-19 SW_NUM_TILE_COLS	Number of tile columns in picture
18-14	Number of tile rows in picture

Table continues on the next page...



Field	Function
SW_NUM_TILE_ROWS	
13-2 —	Reserved.
1 SW_TILE_ENABLE	Tile enable
0 SW_ENTR_CODE_SYNCH_E	Entropy coding synchronization enable (Possible parallel cabac decoding)

16.2.5.1.13 Decoder control register 8 (SWREG11)

16.2.5.1.13.1 Offset

16.3 VPU VC8000E Encoder

16.3.1 Overview

The Video Processing Unit (VPU) VC8000E encoder provides encoding support for AVC/H.264 and HEVC/H.265.

16.3.1.1 Block Diagram

The block diagram of the VPU encoder is shown below.

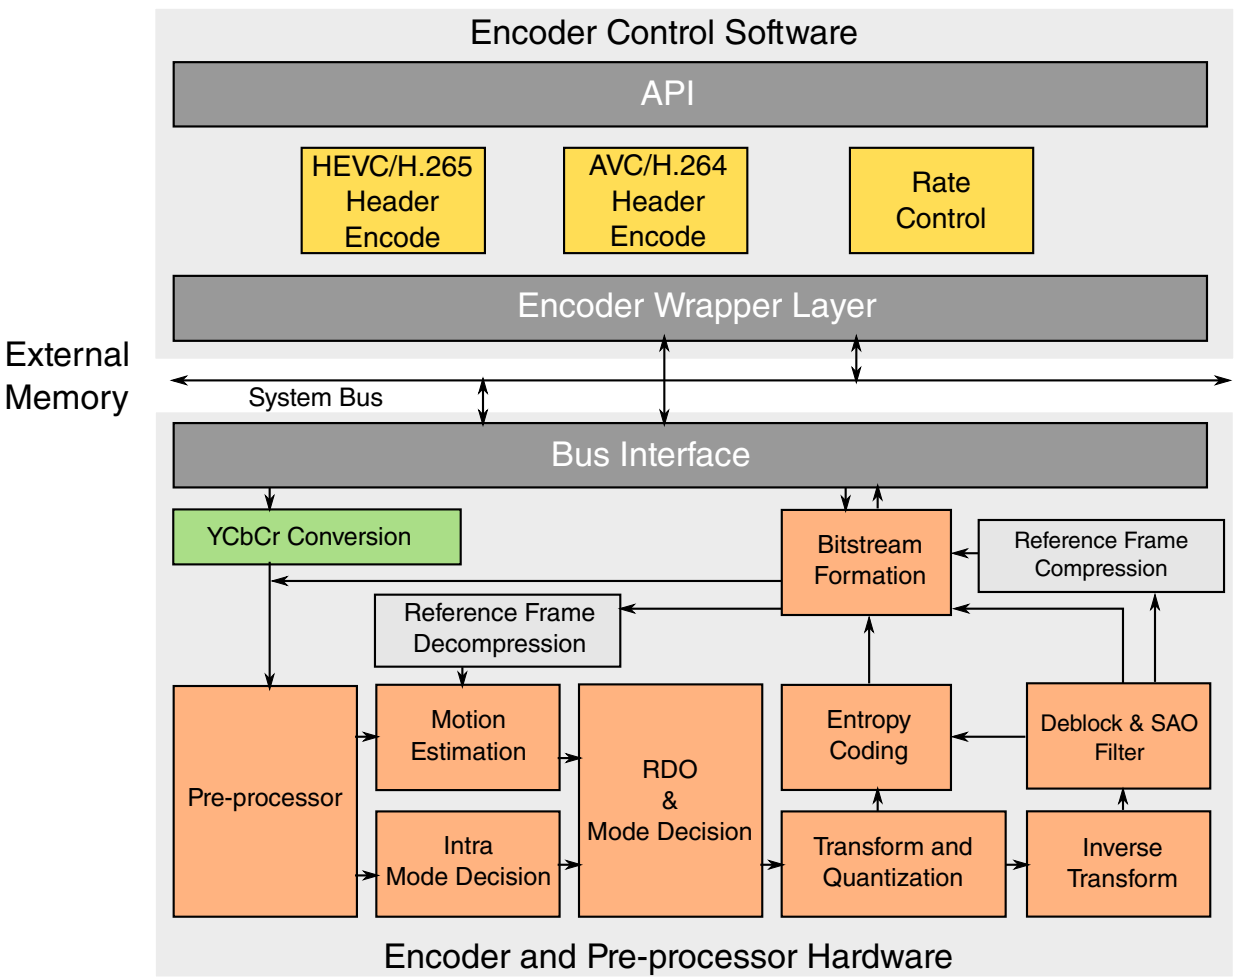

Figure 16-11. VPU Encoder Block Diagram

16.3.1.1.1 Block Descriptions

The main functional blocks of the VPU encoder are described in the table below.

Table 16-7. VPU Encoder Functional Blocks

Functional block	Description
Video Pipeline Controller	Inserts high level commands into the video pipeline.
Motion estimation	Motion vector prediction to determine which motion vectors will be transformed from one frame to another.
Mode selection	Determines the prediction mode (inter or intra) to use when encoding.
Intra Prediction	Creates prediction blocks based on samples from the current frame that were previously encoded and reconstructed.
Inter Prediction	Creates prediction blocks based on prior encoded frames, where samples are shifted in the reference frames.
Transform & Quantization	Manipulations performed on the prediction macroblock prior to encoding.
Entropy Encoder	Provides lossless coding which uses fewer bits to represent frequently occurring patterns.
Bitstream Generation	Creates the encoded bitstream of encoded data output.
Inverse Transform	Manipulations performed on the encoded macroblock.
Deblocking	Filter that reduces the visible blocking artifacts at block boundaries of decoded compressed video.
Sample Adaptive Offset	Encoding and filtering applied after deblocking to reduce banding effects and improve video quality.
Reference Frame Compression	Compresses the reference frame for use in future frame prediction.

16.3.1.2 Features

The VPU VC8000E encoder includes the following features:

- HEVC (H.265)
  - Main Profile,
  - Main10 profile, High Tier
  - Main Still Profile
- AVC (H.264)
  - Baseline Profile
  - Main Profile
  - High Profile
  - High 10 Profile
- Pre-processing
  - Color space conversion

16.3.2 Functional description

16.3.2.1 HEVC (H.265)

Additional details for the supported HEVC (H.265) features are provided in the tables below.

Table 16-8. HEVC (H.265) Feature Support

HEVC feature	Encoder support
Profiles	Main Profile, High Tier Main10 profile, High Tier Main Still Profile
Slices	I and P slices
Entropy encoding	CABAC
Error resilience	Slices
Maximum MV range	Horizontal (P slice) in pixels: +/-139 Vertical (P) in pixels: • Config1: +/-37 • Config2: +/-45 (planned) • Config3: +/-61 (planned) (=Search Window Size -3 pixels)
MV accuracy	1/4 pixel
Supported block sizes	CTU size: 64x64 CU size: 32x32/16x16/8x8 Inter PU: 2Nx2N, 2NxN, Nx2N, AMP Intra PU:2Nx2N, NxN TU size: 32x32/16x16/8x8/4x4
Intra-prediction modes	33 directional modes DC and planar modes
SAO	Supported
Maximum number of reference frames	2
Temporal scalable video coding	Up to 5 layers including the base layer
IPCM encoding	IPCM rectangle mode
ROI/ROI_map	Absolute QP and qpoffset mode (-32 ~ 31) User controllable CU coded as IPCM CU or skip CU

16.3.2.2 AVC (H.264)

Additional details for the supported AVC (H.264) features are provided in the table below.

Table 16-9. AVC (H.264) Feature Support

AVC feature	Encoder support
AVC Standard	Baseline Profile Main Profile High Profile High 10 Profile
Profiles	Main Profile High Profile High10 Profile Baseline Profile
Maximum luma pixel sample rate	1920x1080@60fps (BP, MP, HP)
Slices	I and P slices
Frame Types	Progressive
Entropy encoding	CABAC CAVLC
Error resilience	Slices
Maximum MV range	Horizontal (P slice) in pixels: +/-139 Vertical (P) in pixels: • Config1: +/-13 (planned) • Config2: +/-21 • Config3: +/-29 (planned) • Config4: +/-45 (planned) • Config5: +/-61 (planned) (= Search Window Size -3 pixels)
MV accuracy	1/4 pixel
Supported block sizes	Macroblock and sub-macroblock partitions: • Intra PU:16x16/8x8/4x4 • Inter PU: 16x16/8x16/16x8 • TU: 4x4 and 8x8 transforms
Intra-prediction modes	16x16: 4 modes 8x8: 9 modes 4x4: 9 modes
Maximum number of reference frames	2
Encoding picture type	Only progressive frame
IPCM encoding	Supported
Temporal scalable video coding	Up to 5 layers including the base layer
IPCM	IPCM rectangle mode
ROI/ROI_map	Absolute QP and qpoffset mode (-32 ~ 31) User controllable CU coded as IPCM CU or skip CU

16.3.2.3 Pre-processor

Additional details for the supported preprocessing features are provided in the table below.

Table 16-10. Pre-Processing Features

Pre-processor feature	Encoder support
8-bit YCbCr 4:2:0 color space	YCbCr 4:2:0 planar(YV12) YCbCr 4:2:0 semi-planar(NV12) YCrCb 4:2:0 semi-planar(NV21)
8-bit YCbCr 4:2:2 to YCbCr 4:2:0 color space conversion	YCbYCr 4:2:2 interleaved (YUY2) CbYCrY 4:2:2 interleaved (UYVY)
10-bit YCbCr color	I010 P010 PAK10 (VeriSilicon format) Y0L2 (TIE10) YCbCr 4:2:0 semi-planar 10
RGB to YCbCr 4:2:0 color space conversion	BT.601, BT.709, BT.2020(HDR10) or user defined coefficient conversion for RGB: • XRGB4444 and XBGR4444 • XRGB1555 and XBGR1555 • RGB565 and BGR565 • XRGB8888 and XBGR8888 • X2R10G10B10 and X2B10G10R10

16.3.2.4 Clocks

The following table describes the clock sources for the VPU VC8000E encoder. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 16-11. VPU Encoder Clocks

Clock name	Description
core_clk	VPU encoder core clock

16.3.2.5 Reset

The VPU encoder has one software reset (vc8000e_sft_rstn).

16.3.3 External Signals

There are no external signals pinned out for this module.

16.3.4 Initialization and Application Information

The VPU encoder is operated via the VPU Application Programming Interface (API). Details are provided in separate API documentation.

16.3.5 Memory map and register definition

This section includes the VC8000E encoder memory map and descriptions of the registers.

16.3.5.1 VC8000E_H264 register descriptions

16.3.5.1.1 VC8000E_H264 memory map

Interrupt register encoder

16.3.5.1.2.3 Diagram

16.3.5.1.2.4 Fields

Field	Function
31-13 —	Reserved
12 SW_ENC_STRM_SEGMENT_RDY_INT	Output stream segment IRQ. When high stream segment requests an interrupt. SW will reset this after interrupt is handled.
11	enable timeout interrupt when 1

Table continues on the next page...

Field	Function
SW_ENC_TIMEOUT_INT	
10 —	Reserved
9 SW_ENC_IRQ_FUSE_ERROR	Interrupt Interrupt status bit encoder. When this bit is high encoder has a FUSE error. SW try to setup feature but HW miss the feature set
8 SW_ENC_SLICE_RDY_STATUS	Interrupt status bit encoder. When this bit is high encoder has encoded a slice.
7 SW_ENC_IRQ_LINE_BUFFER	Interrupt status bit encoder linebuffer empty. When setting. Encoder has finished encoding input buffers.
6 SW_ENC_TIMEOUT	Interrupt status bit encoder timeout. When high the encoder has been idling for too long. Possible only if timeout interrupt is enabled
5 SW_ENC_BUFFER_FULL	IRQ buffer full status bit. bufferFullInterrupt
4 SW_ENC_SW_RESET	IRQ SW reset status bit.
3 SW_ENC_BUS_ERROR_STATUS	Interrupt status bit bus. Error response from bus.
2 SW_ENC_FRAME_RDY_STATUS	Interrupt status bit encoder. When this bit is high encoder has encoded a picture.
1 SW_ENC_IRQ_DIS	Encoder IRQ disable. When high there are no interrupts concerning encoder from HW. Polling must be used to see the interrupt statuses.
0 SW_ENC_IRQ	Encoder IRQ. When high encoder requests an interrupt. SW will reset this after interrupt is handled.

control register 1

16.3.5.1.6.3 Diagram

16.3.5.1.6.4 Fields

Field	Function
31-22 SW_ENC_PIC_WIDTH	Encoded width. lumWidthLsb(unit 8 pixels). bit[9:0]
21-11 SW_ENC_PIC_HEIGHT	Encoded height. lumHeight(unit 8 pixels):Max width x height is 4096 x 4096
10 —	Reserved
9	deblocking filter override enable flag. 0b - disable

Table continues on the next page...

Field	Function
SW_ENC_PPS_DEBLOCKING_FILTER_OVERRIDE_ENABLED_FLAG	1b - enable
8 SW_ENC_SLICE_DEBLOCKING_FILTER_OVERRIDE_FLAG	slice deblocking filter override flag. 0b - no 1b - yes
7-3 —	Reserved
2-1 SW_ENC_FRAME_CODING_TYPE	Encoded picture type. frameType.:1-I:0-P:2:B
0 SW_ENC_E	encoder enable. Setting this bit high will start the encoding operation. HW will reset this when picture is processed or bus error or timeout interrupt is given.

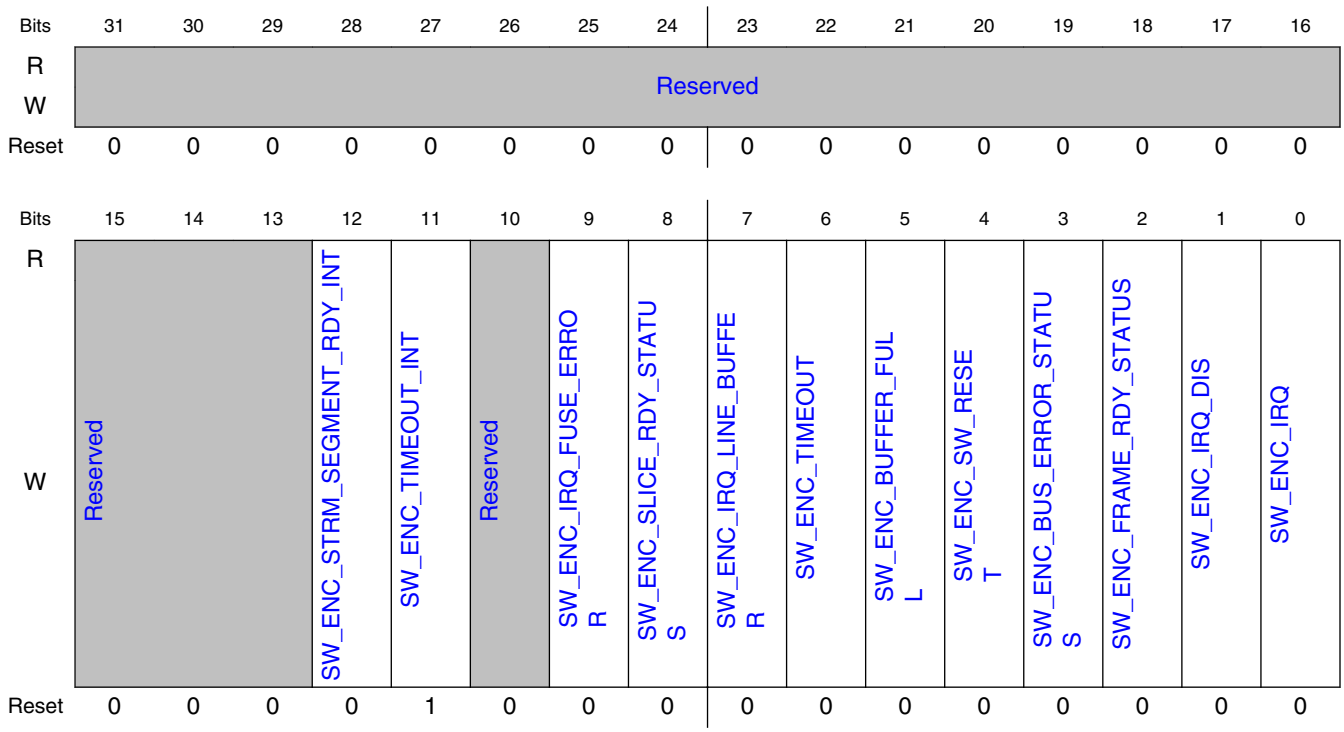
16.3.5.2.2 Interrupt register encoder (swreg1)



16.3.5.2.2.1 Offset

Register	Offset
swreg1	4h

16.3.5.2.2.2 Function

Interrupt register encoder

16.3.5.2.2.3 Diagram

16.3.5.2.2.4 Fields

Field	Function
31-13 —	Reserved
12 SW_ENC_STRM_SEGMENT_RDY_INT	Output stream segment IRQ. When high stream segment requests an interrupt. SW will reset this after interrupt is handled.
11 SW_ENC_TIMEOUT_INT	enable timeout interrupt when 1
10 —	Reserved
9 SW_ENC_IRQ_FUSE_ERROR	Interrupt Interrupt status bit encoder. When this bit is high encoder has a FUSE error. SW try to setup feature but HW miss the feature set
8 SW_ENC_SLICE_RDY_STATUS	Interrupt status bit encoder. When this bit is high encoder has encoded a slice.
7	Interrupt status bit encoder linebuffer empty. When setting. Encoder has finished encoding input buffers.

Table continues on the next page...

Field	Function
SW_ENC_IRQ_LINE_BUFFER	
6 SW_ENC_TIMEOUT	Interrupt status bit encoder timeout. When high the encoder has been idling for too long. Possible only if timeout interrupt is enabled
5 SW_ENC_BUFFER_FULL	IRQ buffer full status bit. bufferFullInterrupt
4 SW_ENC_SW_RESET	IRQ SW reset status bit.
3 SW_ENC_BUS_ERROR_STATUS	Interrupt status bit bus. Error response from bus.
2 SW_ENC_FRAME_RDY_STATUS	Interrupt status bit encoder. When this bit is high encoder has encoded a picture.
1 SW_ENC_IRQ_DIS	Encoder IRQ disable. When high there are no interrupts concerning encoder from HW. Polling must be used to see the interrupt statuses.
0 SW_ENC_IRQ	Encoder IRQ. When high encoder requests an interrupt. SW will reset this after interrupt is handled.

16.4 VPU BLK_CTRL

16.4.1 Overview

The Block Control (BLK_CTRL) module contains general purpose registers (GPRs), which control varied features of the associated peripherals.

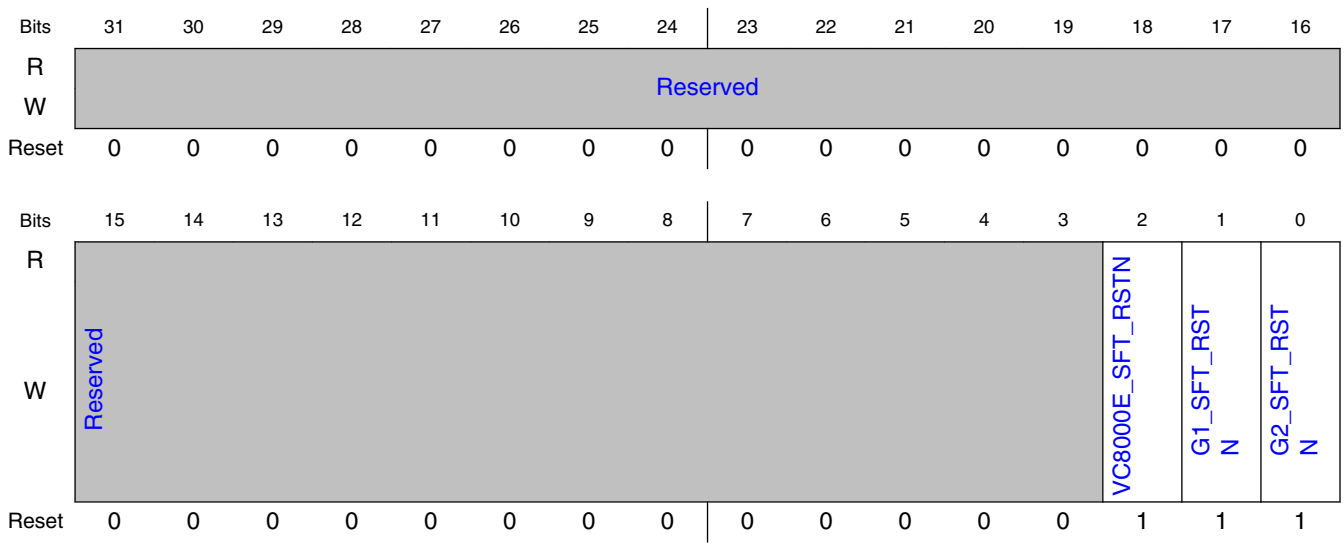
16.4.2 Memory Map and register definition

This section includes the VPU_BLK_CTRL module memory map and descriptions of all registers.

16.4.2.1 VPU_BLK_CTL register descriptions

16.4.2.1.1 VPU_BLK_CTL memory map

VPU_BLK_CTRL base address: 3833_0000h



Offset	Register	Width (In bits)	Access	Reset value
0h	VPUMIX block soft reset control (BLK_SFT_RSTN_CSR)	32	RW	0000_0007h
4h	VPUMIX block clock enable control (BLK_CLK_EN_CSR)	32	RW	0000_000Fh
8h	VPUMIX G1 fuse_dec control (G1_FUSE_DEC_CSR)	32	RW	0000_0000h
10h	VPUMIX G2 fuse_dec control (G2_FUSE_DEC_CSR)	32	RW	0000_0000h
14h	VPUMIX VC8000E fuse_enc control (VC8000E_FUSE_ENC_CSR)	32	RW	0000_0000h
18h	VPUMIX block cache enable control (VPU_CACHE_EN_CSR)	32	RW	0000_0000h
1Ch	VPUMIX block pending transaction status (VPU_NO_PENDING_CSR)	32	RO	0000_0000h
20h	VPUMIX G1 outstanding read beat limit control (G1_OTR_BEAT_LIMIT_CSR)	32	RW	0000_0000h
24h	VPUMIX G2 outstanding read beat limit control (G2_OTR_BEAT_LIMIT_CSR)	32	RW	0000_0000h
28h	VPUMIX VC8000E outstanding read beat limit control (VC8000E_OTR_BEAT_LIMIT_CSR)	32	RW	0000_0000h

Chapter 17
Low Speed Communication and Interconnects

17.1 I2C Controller (I2C)

17.1.1 Overview

This chapter describes block-level operation and programming of I2C. The chapter is intended for a block-driver software developer. To understand how the block is integrated at the SoC level, a system software developer should see discussions of the block in the appropriate SoC-level chapter(s).

References: This document assumes an understanding of the following document:

- *The I2C Bus Specification*, Version 2.1, by Philips Semiconductor

The Inter IC (I2C) provides functionality of a standard I2C slave and master. The I2C is designed to be compatible with the standard NXP I2C bus protocol.

NOTE

Four independent I2C channels are available.

I2C is a two-wire, bidirectional serial bus that provides a simple, efficient method of data exchange, minimizing the interconnection between devices. This bus is suitable for applications requiring occasional communications over a short distance between many devices. The flexible I2C standard allows additional devices to be connected to the bus for expansion and system development. See the connection diagram in the figure below.

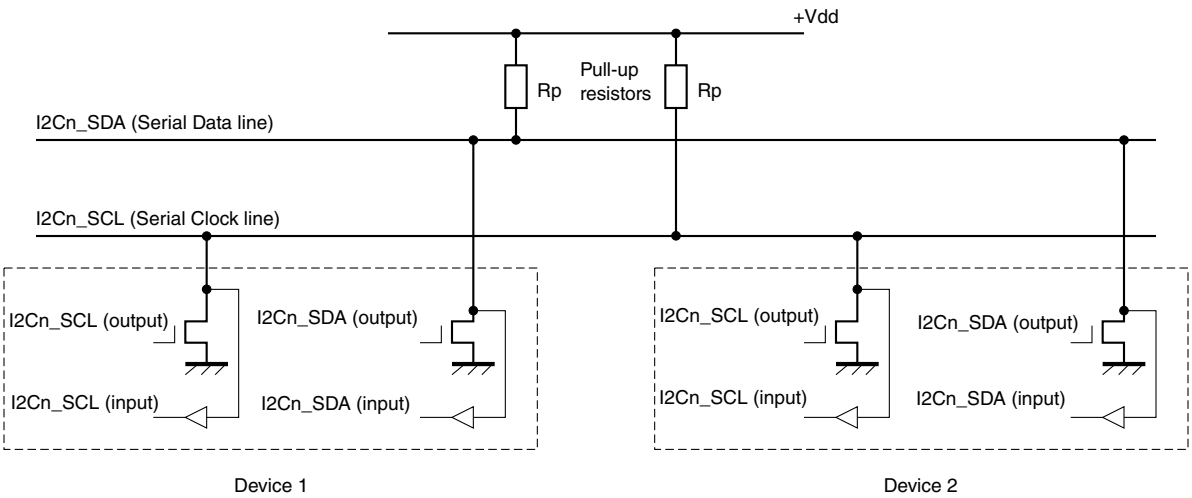

Figure 17-1. Connection of devices to I2C bus

The I2C interface speed is dependent on the I2C bus loading and timing characteristics. For pin requirement details, see *The I2C Bus Specification*.

17.1.1.1 Block Diagram

The I2C system is a true multimaster bus including arbitration and collision detection that prevents data corruption if multiple devices attempt to control the bus simultaneously. This feature supports complex applications with multiprocessor control and can be used for rapid testing and alignment of end products through external connections to an assembly-line computer. The figure below shows the block diagram of I2C.

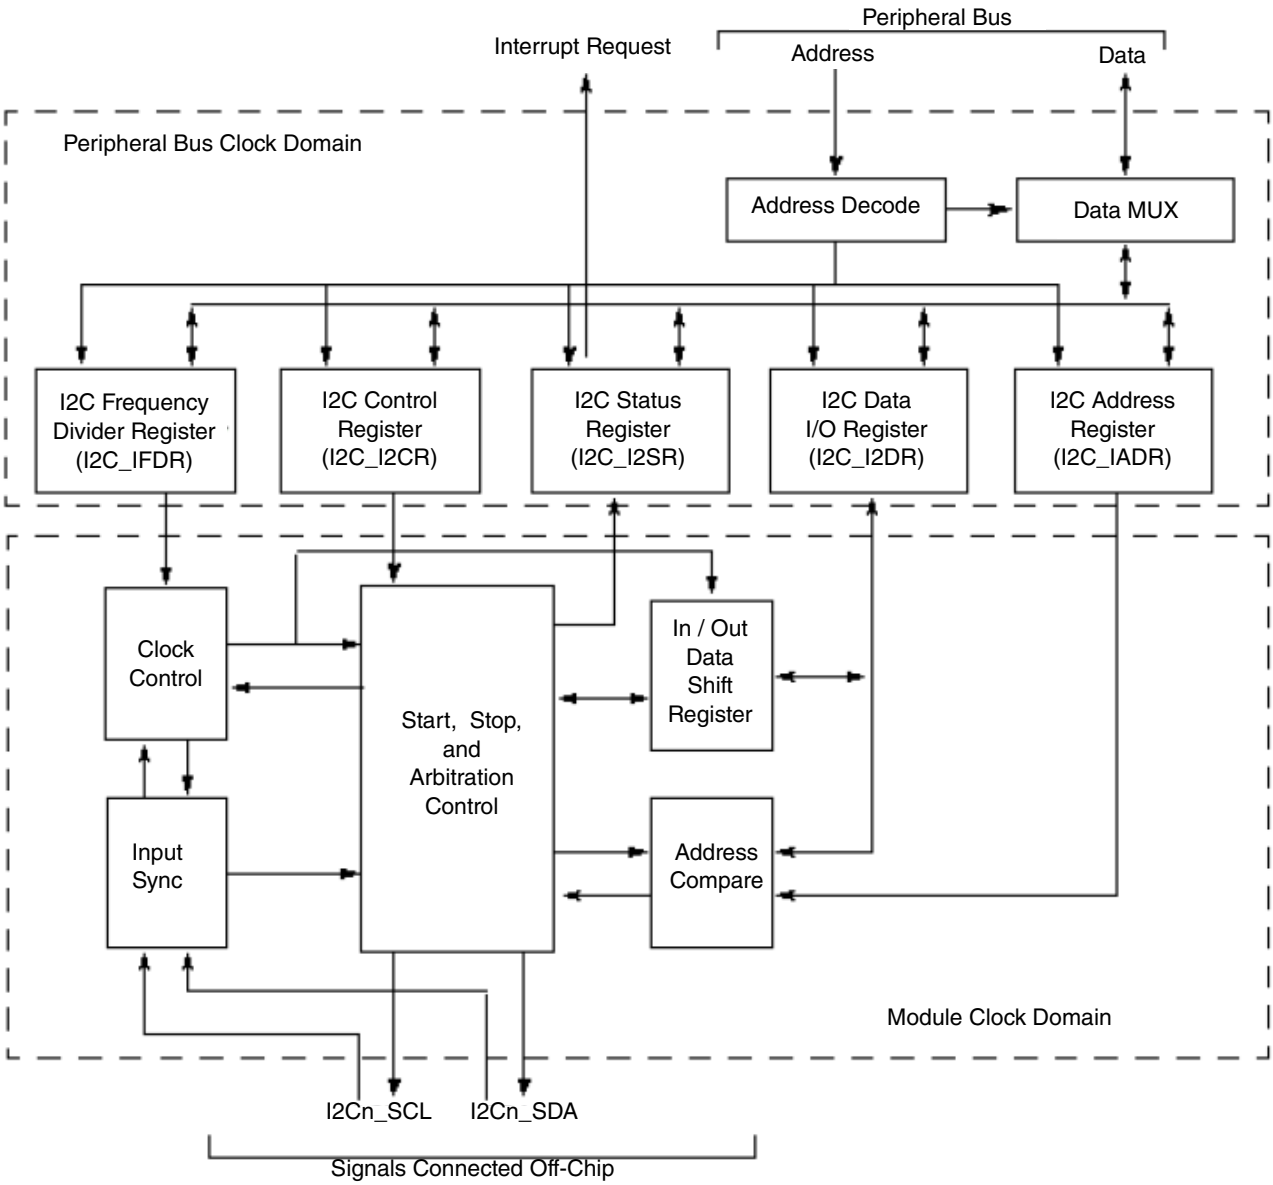

Figure 17-2. I2C block diagram

17.1.1.2 Features

The I2C has the following key features:

- Compatibility with I2C bus standard
- Multimaster operation
- Software programmability for one of 64 different serial clock frequencies
- Software-selectable acknowledge bit
- Interrupt-driven, byte-by-byte data transfer
- Arbitration-lost interrupt with automatic mode switching from master to slave

- Calling address identification interrupt
- Start and stop signal generation/detection
- Repeated Start signal generation
- Acknowledge bit generation/detection
- Bus-busy detection

17.1.2 Functional description

This section provides a complete functional description of the block.

17.1.2.1 Modes and operations

The I2C operates primarily in two functional modes: Standard mode and Fast mode.

- In Standard mode, I2C supports the data transfer rates up to 100 kbits/s.
- In Fast mode, data transfer rates up to 400 kbits/s can be achieved. Per block operation, there is no special configuration required for Fast or Standard mode. It is the data transfer rate that distinguishes Standard and Fast mode.

17.1.2.2 I2C system configuration

After a reset, the I2C defaults to Slave Receive operations. Thus, when not operating as a master or responding to a slave transmit address, the I2C defaults to the Slave Receive state.

For exceptions, see Initialization sequence.

NOTE

The I2C is designed to be compatible with the Philips™ I2C bus protocol. For information on system configuration, protocol, and restrictions, see the *I2C Bus Specification*, version 2.1, by Philips Semiconductors. The I2C supports Standard and Fast modes only.

17.1.2.3 Arbitration procedure

If multiple devices simultaneously request the bus, the bus clock is determined by a synchronization procedure in which the low period equals the longest clock-low period among the devices, and the high period equals the shortest. A data arbitration procedure determines the relative priority of competing devices.

A device loses arbitration if it sends logic high while another sends logic low; it immediately switches to Slave Receive mode and stops driving I2Cn_SDA. In this case, the transition from master to Slave mode does not generate a Stop condition. Meanwhile, hardware sets the arbitration lost bit in the I2C Status register (I2C_I2SR[IAL] to indicate loss of arbitration).

17.1.2.4 Clock synchronization

Because wire-AND logic is used, a high-to-low transition on SCL affects devices connected to the bus. Devices start counting their low period when the master drives SCL low. When a device clock goes low, it holds SCL low until the Clock High state is reached. However, the low-to-high change in this device clock may not change the state of SCL if another device clock is still in its low period. Therefore, the device with the longest low period holds the synchronized clock SCL low.

Devices with shorter low periods enter a High Wait state during this time (see Figure 17-3). When all devices involved have counted off their low periods, the synchronized clock SCL is released and pulled high. There is then no difference between device clocks and the state of SCL, so all of the devices start counting their high periods. The first device to complete its high period pulls SCL low again.

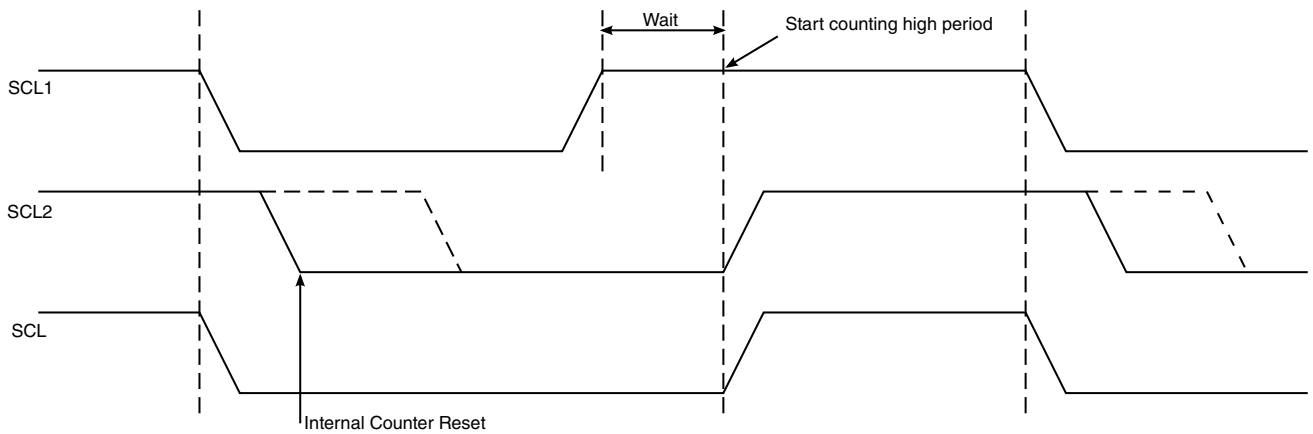

Figure 17-3. Synchronized clock SCL

17.1.2.5 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfers. Slave devices can hold SCL low after completing one byte transfer (9 bits). In such a case, the clock mechanism halts the bus clock and forces the master clock into a Wait state until the slave releases SCL.

17.1.2.6 Clock stretching

Slaves can use the clock synchronization mechanism to slow down the transfer bit rate. After the master has driven SCL low, the slave can drive SCL low for the required period and then release it. If the slave SCL low period is longer than the master SCL low period, the resulting SCL bus signal low period is stretched.

17.1.2.7 Peripheral bus accesses

I2C is a 16-bit block. Only half-word accesses should be performed to the block.

17.1.2.8 Generation of transfer error on IP bus

If an address is received on the peripheral slave bus interface but it is not implemented, an access error is generated.

17.1.2.9 Reset

The I2C can be reset in the following ways:

- Global reset: A hard asynchronous reset of the whole I2C
- Software reset: An internal reset for the whole I2C (except for I2C_IADR and I2C_IFDR registers) initiated by deasserting the I2C_I2CR[IEN] bit

17.1.2.10 Interrupts

There is only one interrupt from the block, which is enabled by setting the I2C_I2CR[IIEN] bit.

The interrupt is generated in any one of the following conditions:

- One byte transfer is completed (the interrupt is set at the falling edge of the ninth clock).
- An address is received that matches its own specific address in Slave Receive mode.
- Arbitration is lost.

17.1.2.11 Byte order

The block only supports the Little-Endian mode.

17.1.3 External Signals

This section discusses I2C signals that connect off-chip.

For I2C compliance, all devices connected to the I2Cn_SCL and I2Cn_SDA signals must have open-drain or open-collector outputs. The logic AND function is implemented on both lines with external pull-up resistors.

Inputs of I2Cn_SCL and I2Cn_SDA also need to be manually enabled by setting the SION bit in the IOMUX after the corresponding PADs are selected as I2C function.

The table below describes all I2C signals that connect off-chip.

17.1.4 Initialization

NOTE

Ensure the input select pins for IOMUXC are configured correctly for I2C.

17.1.4.1 Initialization sequence

Before the interface can transfer serial data, registers must be initialized, as listed here.

1. Set the data sampling rate (I2C_IFDR[IC] to obtain SCL frequency from the system bus clock.
2. Update the address in the (I2C_IADR) to define its slave address (address can range from 0 to 0x7f).
3. Set the I2C enable bit (I2C_I2CR[IEN]) to enable the I2C bus interface system.
4. Modify the bits in the I2C_I2CR to select Master/Slave mode, Transmit/Receive mode, and Interrupt-Enable or not.

17.1.4.2 Generation of Start

After completion of the initialization procedure, serial data can be transmitted by selecting the Master Transmit mode. On a multimaster bus system, the busy bus (I2C_I2SR[IBB]) must be tested to determine whether the serial bus is free. If the bus is

free (IBB = 0), the Start signal and the first byte (the slave address) can be sent. The data written to the data register comprises the address of the desired slave and the LSB indicates the transfer direction.

The free time between a Stop and the next Start condition is built into the hardware that generates the Start cycle. Depending on the relative frequencies of the system clock and the SCL period, it may be necessary to wait until the I2C is not busy after writing the calling address to the data register (I2C_I2DR), before proceeding to load data into the data register (I2C_I2DR).

17.1.4.3 Post-transfer software response

Sending or receiving a byte sets the data transferring bit (I2C_I2SR[ICF]), which indicates one byte of communication is finished. Upon completion, the interrupt status (I2C_I2SR[IIF]) is also set. An external interrupt is generated if the interrupt enable (I2C_I2CR[IIEN]) is set. The software must first clear the interrupt status (I2C_I2SR[IIF]) in the interrupt routine.

See the flow chart in Figure 17-5.

The data transferring bit (I2C_I2SR[ICF]) is cleared either by reading from I2C_I2DR in Receive mode or by writing to this register in Transmit mode.

The software can service the I2C I/O in the main program by monitoring the interrupt status (I2C_I2SR[IIF]) if the interrupt enable is deasserted. In this case, the interrupt status should be polled in the data transferring bit (I2C_I2SR[ICF]) because the operation is different when arbitration is lost.

When an interrupt occurs at the end of the address cycle, the master is always in Transmit mode; that is, the address is sent. If Master Receive mode is required, then I2C_I2CR[MTX] should be toggled and a dummy read of the I2C_I2DR register must be executed to trigger receive data.

During Slave-mode address cycles (I2C_I2SR[IAAS] = 1), the slave read/write bit I2C_I2SR[SRW] is read to determine the direction of the next transfer. The transmit/receive bit (I2C_I2CR[MTX]) should also be programmed accordingly. For Slave-mode data cycles (IAAS = 0), SRW is invalid. MTX should be read to determine the current transfer direction.

17.1.4.4 Generation of Stop

A data transfer ends when the master signals a Stop, which can occur after all data is sent.

For a master receiver to terminate a data transfer, it must inform the slave transmitter by not acknowledging the last data byte. This is done by setting the transmit acknowledge bit (I2C_I2CR[TXAK]) before reading the next-to-last byte. Before the last byte is read, a Stop signal must be generated.

17.1.4.5 Generation of Repeated Start

After the data transfer, if the master still requires the bus, it can signal another Start followed by another slave address without signaling a Stop.

17.1.4.6 Slave mode

In the slave interrupt service routine (see Figure 17-5), the block addressed as slave bit (IAAS) should be tested to check if a calling of its own address has just been received. If IAAS is set, software should set the Transmit/Receive mode select bit (I2C_I2CR[MTX]) according to the I2C_I2SR[SRW]. Writing to the I2C_I2CR clears the IAAS automatically. The only time IAAS is read as set is from the interrupt at the end of the address cycle where an address match occurred; interrupts resulting from subsequent data transfers will have IAAS cleared. A data transfer can now be initiated by writing information to I2C_I2DR for slave transmits, or read from I2C_I2DR in Slave Receive mode. A dummy read of I2C_I2DR in Slave Receive mode releases SCL, allowing the master to send data.

In the slave transmitter routine, the receive acknowledge bit (I2C_I2SR[RXAK]) must be tested before sending the next byte of data. Setting RXAK means an end-of-data signal from the master receiver, after which the software must switch it from Transmit to Receiver mode. Reading the data register (I2C_I2DR) then releases SCL so the master can generate a Stop signal.

17.1.4.7 Arbitration lost

If several devices try to engage the bus at the same time, one becomes master. Hardware immediately switches devices that lose arbitration to Slave Receive mode. Data output to 12Cn_SDA stops, but 12Cn_SCL is still generated until the end of the byte during which arbitration is lost. An interrupt occurs at the falling edge of the ninth clock of this transfer if the arbitration is lost (I2C_I2SR[IAL] = 1), and the Slave mode is selected (I2C_I2CR[MSTA] = 0).

See the flow chart in Figure 17-5.

If a device that is not a master tries to transmit or do a Start, hardware inhibits the transmission, clears MSTA without signaling a Stop, generates an interrupt to the Arm platform, and sets I2C_I2SR[IAL] to indicate a failed attempt to engage the bus. When considering these cases, the slave service routine should first test I2C_I2SR[IAL], and the software should clear it if it is set.

For Multimaster mode, when an I2C is enabled when the bus is busy and asserts Start, the I2C_I2SR[IAL] bit gets set only for 12Cn_SDA=0, 12Cn_SCL=0/1, 12Cn_SDA=1, and 12Cn_SCL=0; but not for 12Cn_SDA=1 and I2Cn_SCL=1, which is the equivalent of Bus Idle state.

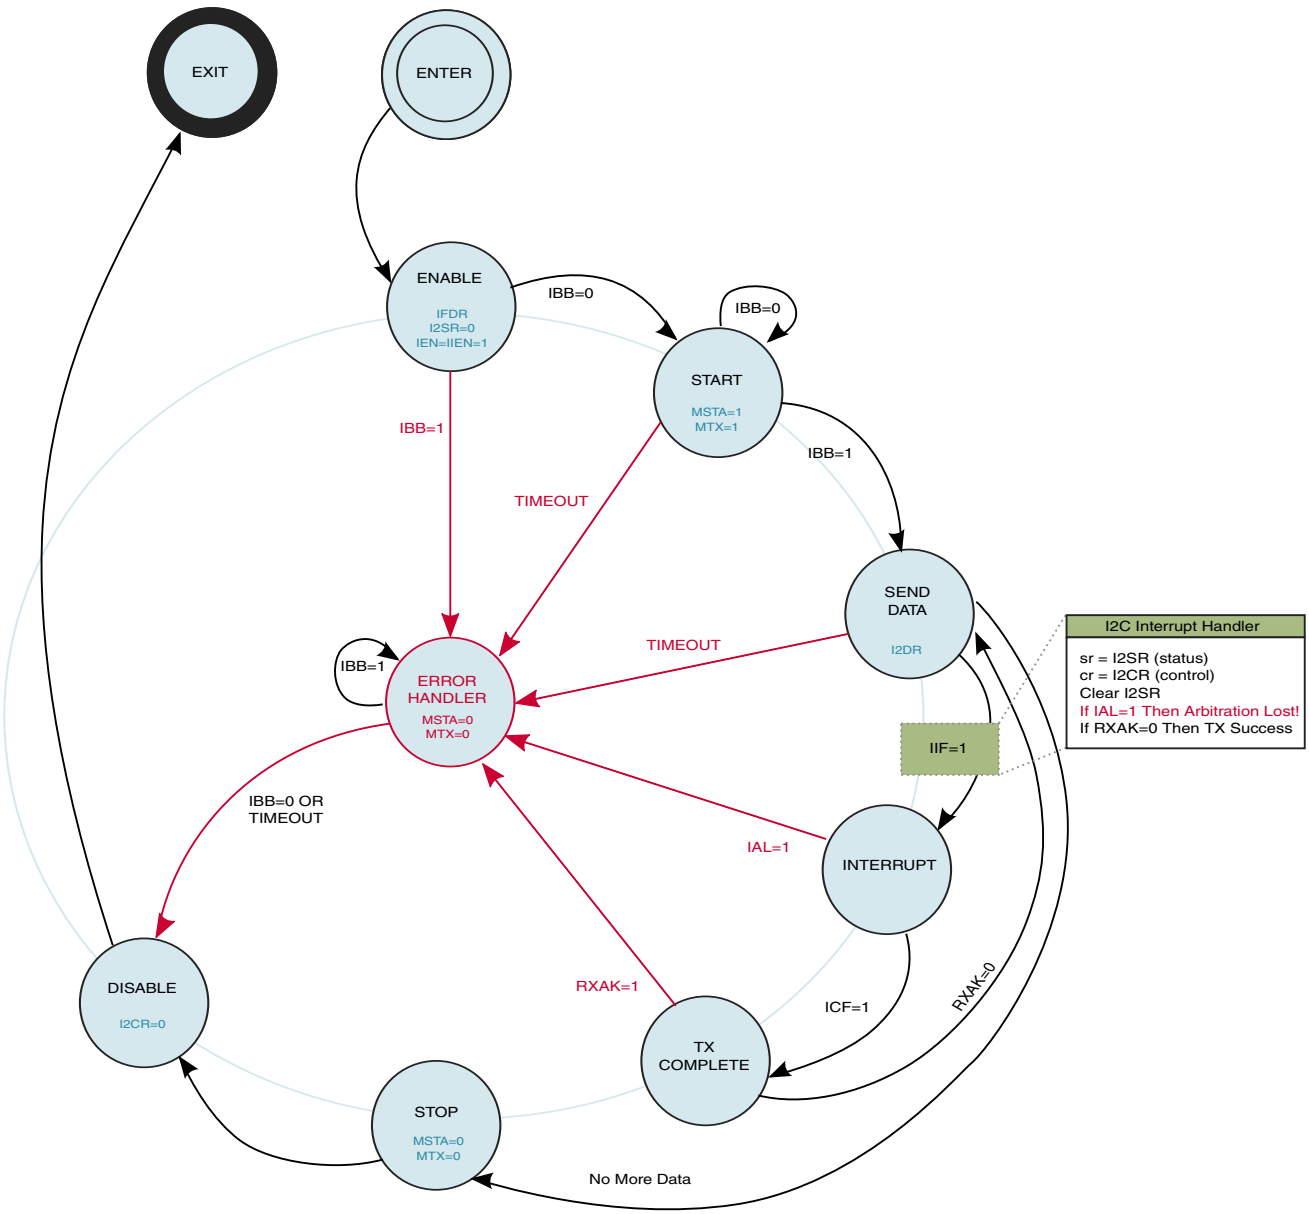

Figure 17-4. I2C Programming state diagram

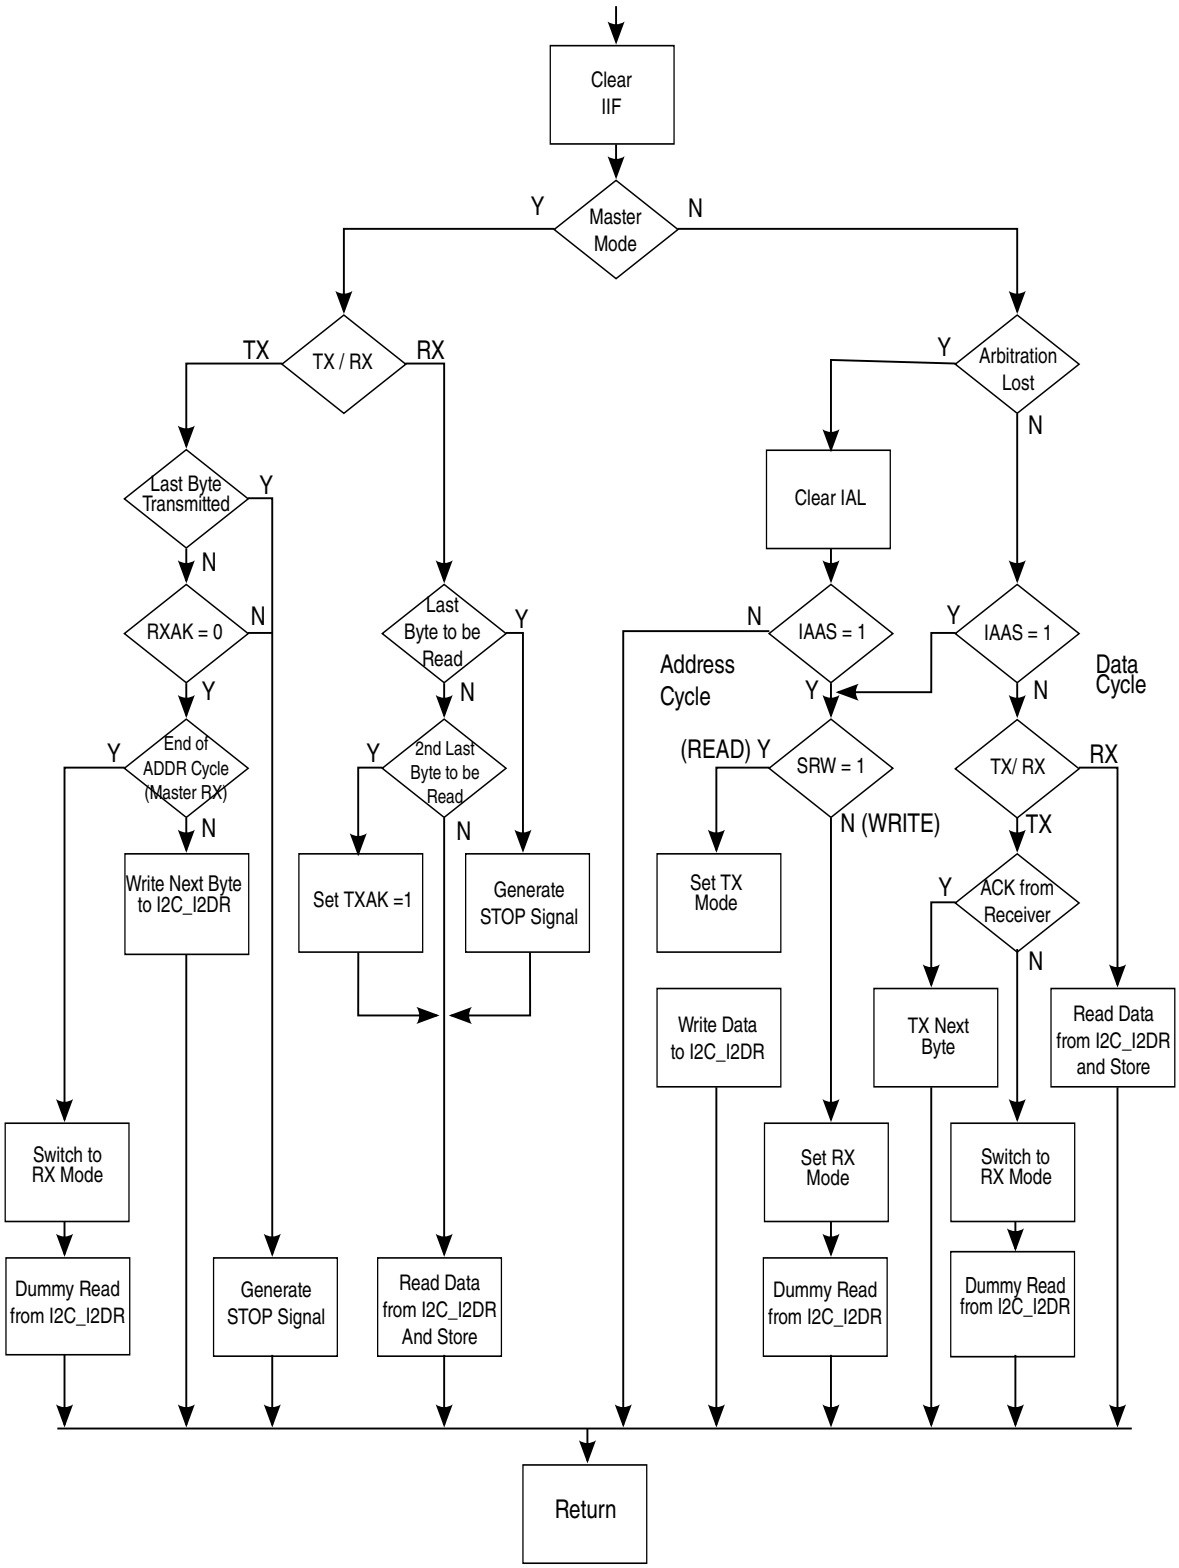

Figure 17-5. Flowchart of typical I2C interrupt routine

NOTE

For a Repeated Start only, the Stop-generation stage does not occur in Master mode. A loop repeats itself without stopping for the next start.

For Master Receive mode, I2C is programmed as Master Transmit during Address mode and after slave address transfer; the MTX bit should be cleared and a dummy read on the I2C_I2DR register should be performed so I2C can read the next receive data.

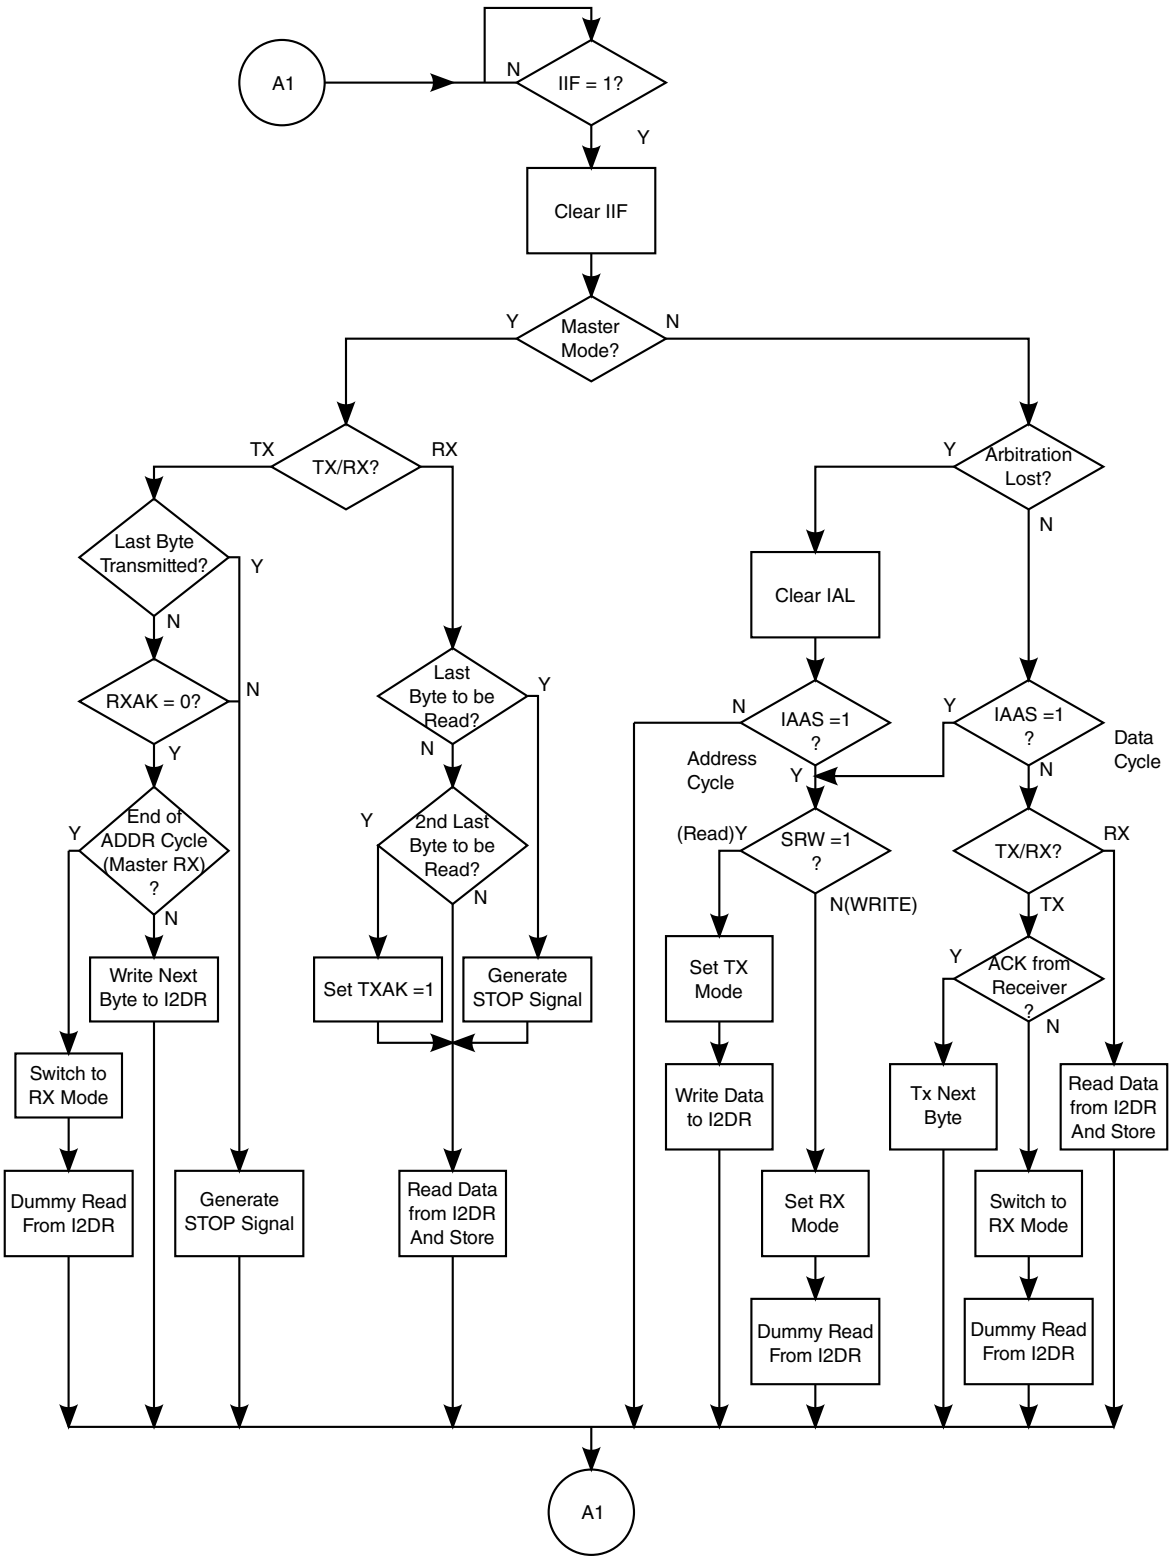

Figure 17-6. Flowchart for typical I2C polling routine

NOTE

The timeout value depends on the bus frequency at which I2C is operating. The minimum timeout for polling the IIF bit at a maximum I2C bus frequency of 400 kHz is T_{min} = 25 µs (=2.5 x 10 µs). This value can be calculated for any bus frequency. The formula is $T_{min} = 10/F_{SCL}$, where F_{SCL} is the frequency of the I2C clock (SCL).

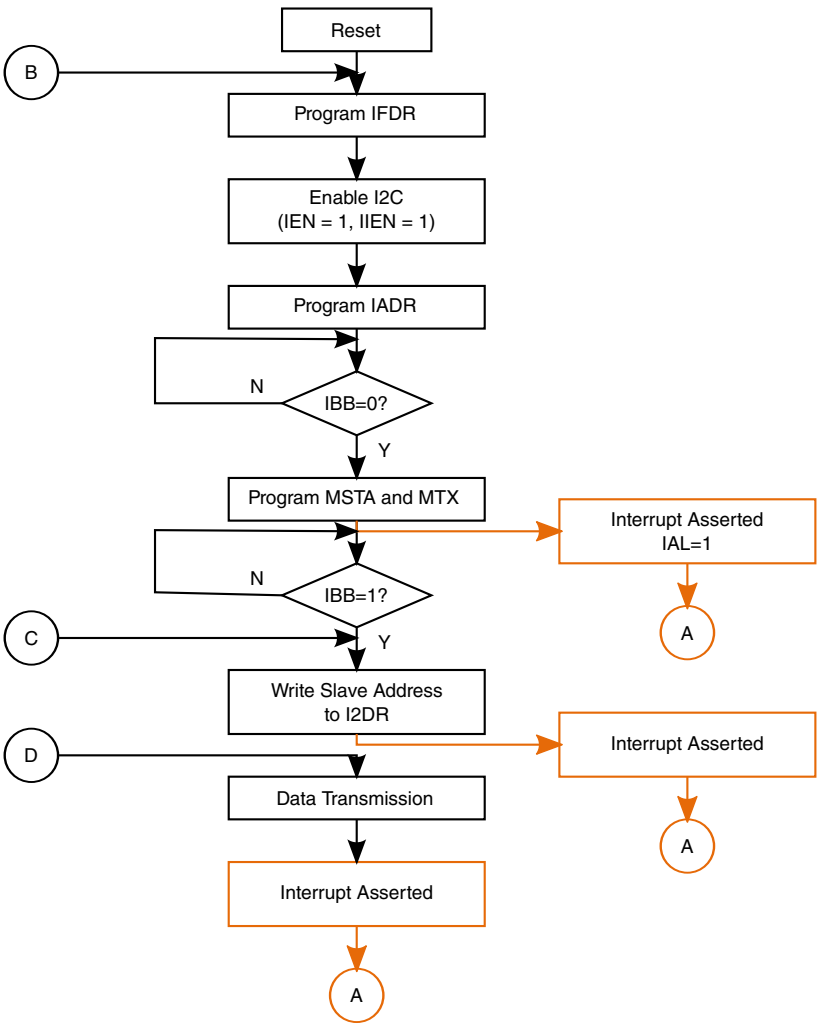

Figure 17-7. Detailed flowchart of a typical I2C Master Transmit mode, part 1

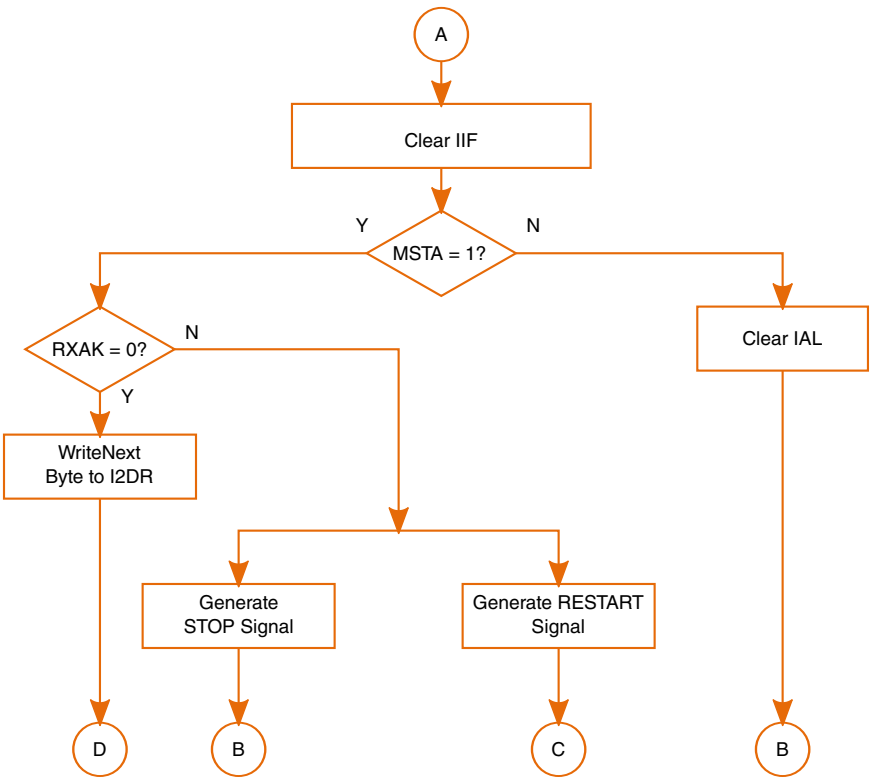

Figure 17-8. Detailed flowchart of a typical I2C Master Transmit mode, part 2

Figure 17-7 and Figure 17-8 show the Master Transmit mode operation with interrupt subroutine. If an interrupt is generated and the MSTA bit is 0, then bus arbitration is lost and IAL is set. Software can clear the IAL bit and reprogram I2C. If the MSTA bit is 1, then it is a transfer-generated interrupt. In this case, software can check the RXAK bit for a data receive acknowledgement by the slave and, accordingly, decide to do one of the following:

- Generate a STOP
- Generate a REPEATED START by writing to the I2C_I2CR register
- Perform the next data transfer by writing to the I2C_I2DR register

NOTE

The IBB bit is asserted by a Start condition on the bus, and it is deasserted by a Stop condition on the bus. Therefore, if arbitration is lost due to an unexpected Stop condition during transfer, then IBB is cleared. If arbitration is lost due to a data mismatch, then it is not cleared. Software should always clear the IEN bit and then set it if arbitration is lost.

17.1.5 Software restriction

Software should ensure that there is a delay of at least two module clock cycles after it sets the I2C_I2CR[RSTA] bit and before writing to the I2C_I2DR register. The maximum possible clock period of the module clock is 78 ns.

17.1.6 I2C Memory Map/Register Definition

The I2C contains five 16-bit registers.

NOTE

Registers at offsets 0x0002, 0x0006, 0x000A, and 0x000E are reserved for future additions.

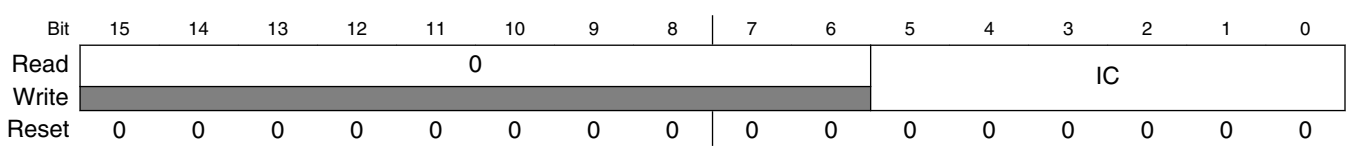
I2Cx_IADR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value 0.
7–1 ADR	Slave address. Contains the specific slave address to be used by the I2C. Slave mode is the default I2C mode for an address match on the bus. **NOTE:** The I2C_IADR holds the address to which the I2C responds when addressed as a slave. The slave address is not the address sent on the bus during the address transfer. The register is not reset by a software reset.
0 Reserved	This read-only field is reserved and always has the value 0.

17.1.6.2 I2C Frequency Divider Register (I2Cx_IFDR)



The I2C_IFDR provides a programmable prescaler to configure the clock for bit-rate selection. The register does not get reset by a software reset.

The following table describes the divider and register values for the register field "IC."

Table 17-1. I2C_IFDR Register Field Values

IC	Divider		IC	Divider		IC	Divider		IC	Divider
0x00	30		0x10	288		0x20	22		0x30	160
0x01	32		0x11	320		0x21	24		0x31	192
0x02	36		0x12	384		0x22	26		0x32	224
0x03	42		0x13	480		0x23	28		0x33	256
0x04	48		0x14	576		0x24	32		0x34	320
0x05	52		0x15	640		0x25	36		0x35	384
0x06	60		0x16	768		0x26	40		0x36	448
0x07	72		0x17	960		0x27	44		0x37	512
0x08	80		0x18	1152		0x28	48		0x38	640

I2Cx_IFDR field descriptions

Field	Description
15–6 Reserved	This read-only field is reserved and always has the value 0.
IC	I2C clock rate. Prescales the clock for bit-rate selection. Due to potentially slow I2Cn_SCL and I2Cn_SDA rise and fall times, bus signals are sampled at the prescaler frequency. The serial bit clock frequency may be lower than IPG_CLK_ROOT divided by the divider shown in the I2C Data I/O Register. **NOTE:** The IC value should not be changed during the data transfer, however, it can be changed before a Repeat Start or Start programming sequence in I2C. The I2C protocol supports bit rates of up to 400 kbps. The IC bits need to be programmed in accordance with this constraint.

17.1.6.3 I2C Control Register (I2Cx_I2CR)

The I2C_I2CR is used to enable the I2C and the I2C interrupt. It also contains bits that govern operation as a slave or a master.

Address: Base address + 8h offset

Bit	15	14	13	12	11	10	9	8
Read	0							
Write								
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read	IEN	IIEN	MSTA	MTX	TXAK	0	0	
Write						RSTA		
Reset	0	0	0	0	0	0	0	0

I2Cx_I2CR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value 0.
7 IEN	I2C enable. Also controls the software reset of the entire I2C. Resetting the bit generates an internal reset to the block. If the block is enabled in the middle of a byte transfer, Slave mode ignores the current bus transfer and starts operating when the next Start condition is detected. Master mode is not aware that the bus is busy, so initiating a start cycle may corrupt the current bus cycle, ultimately causing either the current master or the I2C to lose arbitration. Subsequently, bus operation returns to normal. 0 The block is disabled, but registers can still be accessed. 1 The I2C is enabled. This bit must be set before any other I2C_I2CR bits have an effect.
6 IIEN	I2C interrupt enable. **NOTE:** If data is written during the Start condition, that is, just after setting the I2C_I2CR[MSTA] and I2C_I2CR[MTX] bits, then the ICF bit is cleared at the falling edge of SCLK after Start. If data is

Table continues on the next page...

I2Cx_I2CR field descriptions (continued)

Field	Description
	written after the Start condition and falling edge of SCLK, then the ICF bit is cleared as soon as data is written. 0 I2C interrupts are disabled, but the status flag I2C_I2SR[IIF] continues to be set when an Interrupt condition occurs. 1 I2C interrupts are enabled. An I2C interrupt occurs if I2C_I2SR[IIF] is also set.
5 MSTA	Master/Slave mode select bit. If the master loses arbitration, MSTA is cleared without generating a Stop signal. **NOTE:** The module clock should be on for writing to the MSTA bit. **NOTE:** The MSTA bit is cleared by software to generate a Stop condition; it can also be cleared by hardware when the I2C loses the bus arbitration. 0 Slave mode. Changing MSTA from 1 to 0 generates a Stop and selects Slave mode. 1 Master mode. Changing MSTA from 0 to 1 signals a Start on the bus and selects Master mode.
4 MTX	Transmit/Receive mode select bit. Selects the direction of master and slave transfers. 0 Receive. When a slave is addressed, the software should set MTX according to the slave read/write bit in the I2C status register (I2C_I2SR[SRW]). 1 Transmit. In Master mode, MTX should be set according to the type of transfer required. Therefore, for address cycles, MTX is always 1.
3 TXAK	Transmit acknowledge enable. Specifies the value driven onto I2Cn_SDA during acknowledge cycles for both master and slave receivers. **NOTE:** Writing TXAK applies only when the I2C bus is a receiver. 0 An acknowledge signal is sent to the bus at the ninth clock bit after receiving one byte of data. 1 No acknowledge signal response is sent (that is, the acknowledge bit = 1).
2 RSTA	Repeat start. Always reads as 0. Attempting a repeat start without bus mastership causes loss of arbitration. 0 No repeat start 1 Generates a Repeated Start condition
Reserved	This read-only field is reserved and always has the value 0.

17.1.6.4 I2C Status Register (I2Cx_I2SR)

The I2C_I2SR contains bits that indicate transaction direction and status.

Address: Base address + Ch offset

Bit	15	14	13	12	11	10	9	8
Read	0							
Write								
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read	ICF	IAAS	IBB	IAL	0	SRW	IIF	RXAK
Write								
Reset	1	0	0	0	0	0	0	1

I2Cx_I2SR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value 0.
7 ICF	Data transferring bit. While one byte of data is transferred, ICF is cleared. 0 Transfer is in progress. 1 Transfer is complete. This bit is set by the falling edge of the ninth clock of the last byte transfer.
6 IAAS	I2C addressed as a slave bit. The Arm platform is interrupted if the interrupt enable (I2C_I2CR[IIEN]) is set. The Arm platform must check the slave read/write bit (SRW) and set its Transfer/Receive mode accordingly. Writing to I2C_I2CR clears this bit. 0 Not addressed 1 Addressed as a slave. Set when its own address (I2C_IADR) matches the calling address.
5 IBB	I2C bus busy bit. Indicates the status of the bus. **NOTE:** When I2C is enabled (I2C_I2CR[IEN] = 1), it continuously polls the bus data (SDA) and clock (SCL) signals to determine a Start or Stop condition. 0 Bus is idle. If a Stop signal is detected, IBB is cleared. 1 Bus is busy. When Start is detected, IBB is set.
4 IAL	Arbitration lost. Set by hardware in the following circumstances (IAL must be cleared by software by writing a "0" to it at the start of the interrupt service routine): • I2Cn_SDA input samples low when the master drives high during an address or data-transmit cycle. • I2Cn_SDA input samples low when the master drives high during the acknowledge bit of a data-receive cycle. For the above two cases, the bit is set at the falling edge of the ninth I2Cn_SCL clock during the ACK cycle. • A Start cycle is attempted when the bus is busy.

Table continues on the next page...

I2Cx_I2SR field descriptions (continued)

Field	Description
	• A Repeated Start cycle is requested in Slave mode. • A Stop condition is detected when the master did not request it. **NOTE:** Software cannot set the bit. 0 No arbitration lost. 1 Arbitration is lost.
3 Reserved	This read-only field is reserved and always has the value 0.
2 SRW	Slave read/write. When the I2C is addressed as a slave, IAAS is set, and the slave read/write bit (SRW) indicates the value of the R/W command bit of the calling address sent from the master. SRW is valid only when a complete transfer has occurred, no other transfers have been initiated, and the I2C is a slave and has an address match. 0 Slave receive, master writing to slave 1 Slave transmit, master reading from slave
1 IIF	I2C interrupt. Must be cleared by the software by writing a "0" to it in the interrupt routine. **NOTE:** The software cannot set the bit. 0 No I2C interrupt pending. 1 An interrupt is pending. This causes a processor interrupt request (if the interrupt enable is asserted [IIEN = 1]). The interrupt is set when one of the following occurs: • One byte transfer is completed (the interrupt is set at the falling edge of the ninth clock). • An address is received that matches its own specific address in Slave Receive mode. • Arbitration is lost.
0 RXAK	Received acknowledge. This is the value received from the I2Cn_SDA input for the acknowledge bit during a bus cycle. 0 An "acknowledge" signal was received after the completion of an 8-bit data transmission on the bus. 1 A "No acknowledge" signal was detected at the ninth clock.

17.1.6.5 I2C Data I/O Register (I2Cx_I2DR)

In Master Receive mode, reading the data register allows a read to occur and initiates the next byte to be received. In Slave mode, the same function is available after it is addressed.

Address: Base address + 10h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								DATA							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

I2Cx_I2DR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value 0.
DATA	Data Byte. Holds the last data byte received or the next data byte to be transferred. Software writes the next data byte to be transmitted or reads the data byte received. **NOTE:** The core-written value in I2C_I2DR cannot be read back by the core. Only data written by the I2C bus side can be read.

17.2 Universal Asynchronous Receiver/Transmitter (UART)

17.2.1 Overview

The Universal Asynchronous Receiver/Transmitter (UART) provides serial communication capability with external devices through a level converter and an RS-232 cable or through use of external circuitry that converts infrared signals to electrical signals (for reception) or transforms electrical signals to signals that drive an infrared LED (for transmission) to provide low speed IrDA compatibility.

UART supports NRZ encoding format , RS485 compatible 9 bit data format and IrDA-compatible infrared slow data rate (SIR) format.

17.2.1.1 Block Diagram

The following figure shows the UART block diagram.

The "Module Clock" is the UART_CLK and the "Peripheral Clock" is the IPG_CLK. Both come from CCM.

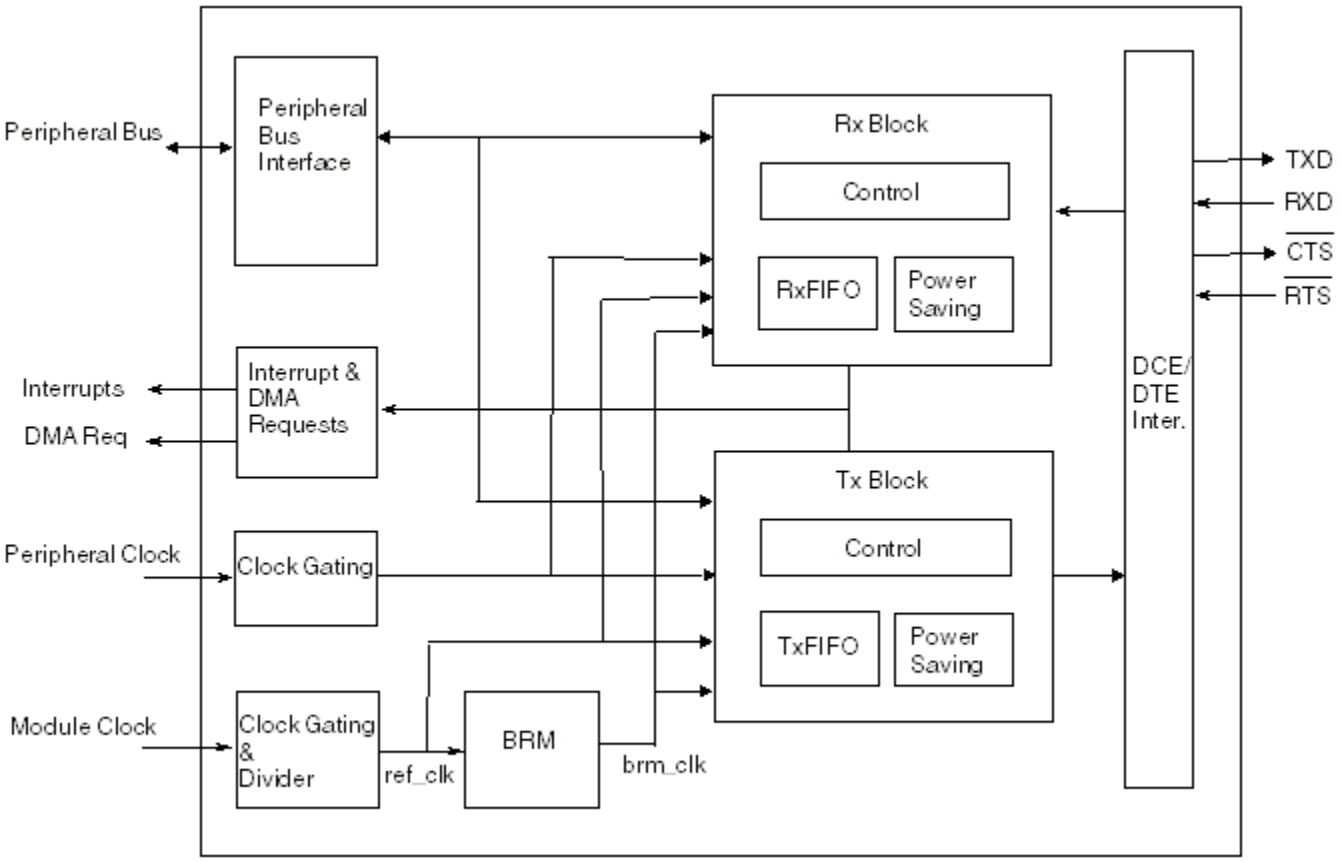

Figure 17-9. UART Block Diagram

17.2.1.2 Features

The UART includes the following features:

- High-speed TIA/EIA-232-F compatible, up to Mbit/s
- Serial IR interface low-speed, IrDA-compatible (up to 115.2 Kbit/s)
- 9-bit or Multidrop mode (RS-485) support (automatic slave address detection)
- 7 or 8 data bits for RS-232 characters, or 9 bit RS-485 format
- 1 or 2 stop bits
- Programmable parity (even, odd, and no parity)
- Hardware flow control support for request to send (RTS_B) and clear to send (CTS_B) signals
- RS-485 driver direction control via CTS_B signal
- Edge-selectable RTS_B and edge-detect interrupts
- Status flags for various flow control and FIFO states
- Voting logic for improved noise immunity (16x oversampling)
- Transmitter FIFO empty interrupt suppression

- UART internal clocks enable/disable
- Auto baud rate detection (up to 115.2 Kbit/s)
- Receiver and transmitter enable/disable for power saving
- RX_DATA input and TX_DATA output can be inverted respectively in RS-232/ RS-485 mode
- DCE/DTE capability
- RTS_B, IrDA asynchronous wake (AIRINT), receive asynchronous wake (AWAKE) interrupts wake the processor from STOP mode
- Maskable interrupts
- Two DMA Requests (TxFIFO DMA Request and RxFIFO DMA Request)
- Escape character sequence detection
- Software reset (SRST_B)
- Two independent, 32-entry FIFOs for transmit and receive
- The peripheral clock can be totally asynchronous with the module clock. The module clock determines baud rate. This allows frequency scaling on peripheral clock (such as during DVFS mode) while remaining the module clock frequency and baud rate.

17.2.1.3 Modes of operation

- Serial RS-232NRZ mode
- 9-bit RS-485 mode
- IrDA mode

To set UART in different modes, see the table below.

Table 17-2. UART mode definition

MDEN (UMCR[0])	IREN (UCR1[7])	UART Mode	Descriptioin
0	0	RS-232	RXD/TXD data is serial RS-232 NRZ format
0	1	IrDA (Interface)	RXD/TXD data is IrDA-compatible infrared slow data rate (SIR) format
1	0	RS-485	RXD/TXD data is RS485 compatible 9 bit data format
1	1	Undefined	Undefined

17.2.2 Functional Description

This section provides a complete functional description of the block.

17.2.2.1 Interrupts and DMA Requests

See the following table for the lists of all interrupt and DMA signals and associated interrupt and DMA sources of the UART. See register description section for explanation of interrupt/DMA enable and status.

Table 17-3. Interrupts and DMA

Interrupt/DMA Output	Interrupt/DMA Enable	Enable Register Location	Interrupt/DMA Flag	Flag Register Location
interrupt_uart	RRDYEN	UCR1 (bit 9)	RRDY	USR1 (bit 9)
	IDEN	UCR1 (bit 12)	IDLE	USR2 (bit 12)
	DREN	UCR4 (bit 0)	RDR	USR2 (bit 0)
	RXDSEN	UCR3 (bit 6)	RXDS	USR1 (bit 6)

	ATDMAEN	UCR1 (bit 2)	AGTIM	USR1 (bit 8)
	IDDMAEN	UCR4 (bit 6)	IDLE	USR2 (bit 12)
dma_req_tx	TXDMAEN	UCR1 (bit 3)	TRDY	USR1 (bit 13)

17.2.2.2 Clocks

This section describes clocks and special clocking requirements of the UART.

17.2.2.2.1 Clock requirements

UART module receives 2 clocks, *peripheral_clock* and *module_clock*. The *peripheral_clock* is used as write clock of the TxFIFO, read clock of the RxFIFO and synchronization of the modem control input pins. It must always be running when UART is enabled. There is an exception in stop mode (see Clocking in Low-Power Modes).

The *module_clock* is for all the state machines, writing RxFIFO, reading TxFIFO, etc. It must always be running when UART is sending or receiving characters.This clock is used in order to allow frequency scaling on *peripheral_clock* without changing configuration of baud rate (*module_clock* staying at a fixed frequency).

The constraints on *peripheral_clock* and *module_clock* are as follows:

- *peripheral_clock* and *module_clock* can totally be asynchronous. They can also be synchronous.
- Due to the 16x oversampling of the incoming characters, *module_clock* frequency must always be greater or equal to 16x the maximum baud rate. For example, if max baud rate is 4 Mbit/s, *module_clock* must be greater or equal to 4 M x 16 = 64 MHz.

NOTE

The restriction that *peripheral_clock* frequency must be higher or equal to 16x baud rate has been removed. There is no limitation on *peripheral_clock* frequency to baud rate.

17.2.2.2.2 Maximum Baud Rate

The max baud rate the UART can support is determined by the max frequency of the module_clock.

For example, if the SoC can provide the fastest module_clock 66.5 MHz, the UART can transmit and receive serial data with the maximum baud rate 66.5M/16 = 4.15 Mbit/s.

The UART supports serial IR interface low speed. In the low speed IrDA mode, the max baud rate is 115.2 Kbit/s. To support the 115.2 Kbit/s, module_clock frequency must be higher or equal to 1.8432 MHz.

17.2.2.2.3 Clocking in Low-Power Modes

The UART supports 2 low-power modes: DOZE and STOP.

In STOP mode (input pin *stop_req* is at '1'), the UART doesn't need any clock. In this mode the UART can wake-up the Arm platform with the asynchronous interrupts (see Low Power Modes).

- If before entering in STOP mode the software has enabled RTSDEN interrupt, when RTS will change state (put at '0' by external device started to send), the asynchronous interrupt will wake-up the system, *peripheral_clock* and *module_clock* will be provided to the UART before first start bit, so that no data will be lost.
- If RTS doesn't change state (already at '0' before entering in STOP mode), then wake-up interrupt (AWAKE) will be sent at the arrival of first Start bit (on falling edge). In this case, the UART must receive the *peripheral_clock* and *module_clock* during the first half of start bit to correctly receive this character (for example, at 115.2 Kbit/s, UART must receive *peripheral_clock* and *module_clock* at maximum 4.3 microseconds after falling edge of Start bit). If the UART receives *peripheral_clock* and *module_clock* too late, first character will be lost, and so should be dropped. Also, if autobaud detection is enabled, the first character won't be correctly received and another autobaud detection will need to be initiated.

In Doze mode, UART behavior is programmable through DOZE bit (UCR1[1]). If DOZE bit is set to '1', then UART is disabled in Doze mode, and in consequence, UART clocks can be switched-off (after being sure UART is not transmitting nor receiving). On the contrary, if DOZE bit is set to '0', UART is enabled and it must receive *peripheral_clock* and *module_clock* .

17.2.2.3 General UART Definitions

Definitions of terms that occurs the following discussions are given in this section.

- Bit Time-The period of time required to serially transmit or receive 1 bit of data (1 cycle of the baud rate frequency).
- Start bit-The bit time of a logic 0 that indicates the beginning of a data frame. A start bit begins with a 1-to-0 transition, and is preceded by at least 1 bit time of logic 1.
- Stop bit-1 bit time of logic 1 that indicates the end of a data frame.
- BREAK-A frame in which all of the data bits, including the stop bit, are logic 0. This type of frame is usually sent to signal the end of a message or the beginning of a new message.
- Mark - When no data is being sent, the serial port's transmit pin's voltage is 1 and is said to be in a MARK state.

- Space - The serial port can also be forced to keep the transmit pin at a 0 and is said to be the SPACE or BREAK state.
- Frame-A start bit followed by a specified number of data or information bits and terminated by a stop bit. The number of data or information bits depends on the format specified and must be the same for the transmitting device and the receiving device. The most common frame format is 1 start bit followed by 8 data bits (least significant bit first) and terminated by 1 stop bit. An additional stop bit and a parity bit also can be included.
- Framing Error-An error condition that occurs when the stop bit of a received frame is missing, usually when the frame boundaries in the received bit stream are not synchronized with the receiver bit counter. Framing errors can go undetected if a data bit in the expected stop bit time happens to be a logic 1. A framing error is always present on the receiver side when the transmitter is sending BREAKs. However, when the UART is programmed to expect 2 stop bits and only the first stop bit is received, this is not a framing error by definition.
- Parity Error-An error condition that occurs when the calculated parity of the received data bits in a frame does not match the parity bit received on the RX_DATA input. Parity error is calculated only after an entire frame is received.
- Idle-One in NRZ encoding format and selectable polarity in IrDA mode.
- Overrun Error-An error condition that occurs when the latest character received is ignored to prevent overwriting a character already present in the UART receive buffer (RxFIFO). An overrun error indicates that the software reading the buffer (RxFIFO) is not keeping up with the actual reception of characters on the RX_DATA input.

17.2.2.3.1 RTS_B - UART Request To Send

The UART Request To Send input controls the transmitter. The modem or other terminal equipment signals the UART when it is ready to receive by setting '0' on the RTS_B pin.

Normally, the transmitter waits until this signal is active (low) before transmitting a character, however when the Ignore RTS (IRTS) bit is set, the transmitter sends a character as soon as it is ready to transmit. An interrupt (RTSD) can be posted on any transition of this pin and can wake the Arm platform from STOP mode on its assertion. When RTS_B is set to '1' during a transmission, the UART transmitter finishes transmitting the current character and shuts off. The contents of the TxFIFO (characters to be transmitted) remain undisturbed. The operation of this input is the same regardless of whether the UART is in DTE or DCE mode.

17.2.2.3.2 RTS Edge Triggered Interrupt

The input to the RTS_B pin can be programmed to generate an interrupt on a selectable edge.

See the table below for summary of the operation of the RTS edge triggered interrupt (RTSF).

To enable the RTS_B pin to generate an interrupt, set the request to send interrupt enable (RTSEN) bit (UCR2[4]) to 1. Writing 1 to the RTS_B edge triggered interrupt flag (RTSF) bit (USR2[4]) clears the interrupt flag. The interrupt can occur on the rising edge, falling edge, or either edge of the RTS_B input. The request to send edge control (RTEC) field (UCR2[10:9]) programs the edge that generates the interrupt. When RTEC is set to 0x00 and RTSEN = 1, the interrupt occurs on the rising edge (default). When RTEC is set to 0x01 and RTSEN = 1, the interrupt occurs on the falling edge. When RTEC is set to 0x1X and RTSEN = 1, the interrupt occurs on either edge. This is a synchronous interrupt. The RTSF bit is cleared by writing 1 to it. Writing 0 to RTSF has no effect.

Table 17-4. RTS_B Edge Triggered Interrupt Truth Table

RTS_B	RTSEN	RTEC [1]	RTEC [0]	RTSF	Interrupt Occurs On…	interrupt_uart
X	0	X	X	0	Interrupt disabled	1
1->0	1	0	0	0	Rising edge	1
0->1	1	0	0	1	Rising edge	0
1->0	1	0	1	1	Falling edge	0
0->1	1	0	1	0	Falling edge	1
1->0	1	1	X	1	Either edge	0
0->1	1	1	X	1	Either edge	0

There is another RTS_B interrupt that is not programmable. The status bit RTSD asserts the *interrupt_uart* interrupt when the RTS_B delta interrupt enable = 1. This is an asynchronous interrupt. The RTSD bit is cleared by writing 1 to it. Writing 0 to the RTSD bit has no effect.

17.2.2.3.3 CTS_B - Clear To Send

This output pin serves two purposes. Normally, the receiver indicates that it is ready to receive data by asserting this pin (low). When the CTS_B trigger level is programmed to trigger at 32 characters received and the receiver detects the valid start bit of the 33 character, it de-asserts this pin. The operation of this output is the same regardless of whether the UART is in DTE or DCE mode.

17.2.2.3.4 Programmable CTS_B Deassertion

The CTS_B output can also be programmed to deassert when the RxFIFO reaches a certain level. Setting the CTS trigger level (UCR4[15:10]) at any value less than 32 deasserts the CTS_B pin on detection of the valid start bit of the N + 1 character (where N is the trigger level setting). However, the receiver continues to receive characters until the RxFIFO is full.

17.2.2.3.5 TX_DATA - UART Transmit

This is the transmitter serial output. When operating in RS-232/RS-485 mode, NRZ encoded data is transmitted, and the data can be inverted (controlled by INVT (UCR3[1])) before transmitted. When operating in infrared mode, a 3/16 bit-period pulse is output for each 0 bit transmitted, and no pulse is output for each 1 bit transmitted.

For RS-232/RS-485 applications, this pin must be connected to an RS-232/RS-485 transmitter. The operation of this output is the same regardless of whether the UART is in DTE or DCE mode. See Figure 17-10.

17.2.2.3.6 RX_DATA - UART Receive

This is the receiver serial input. When operating in RS-232/RS-485 mode, NRZ encoded data is expected, and the data can be inverted (controlled by INVR (UCR4[9])) before sampled. When operating in infrared mode, a narrow pulse is expected for each 0 bit received and no pulse is expected for each 1 bit received.

External circuitry must convert the IR signal to an electrical signal. RS-232/RS-485 applications require an external RS-232/RS-485 receiver to convert voltage levels. The operation of this input is the same regardless of whether the UART is in DTE or DCE mode. See the figure below.

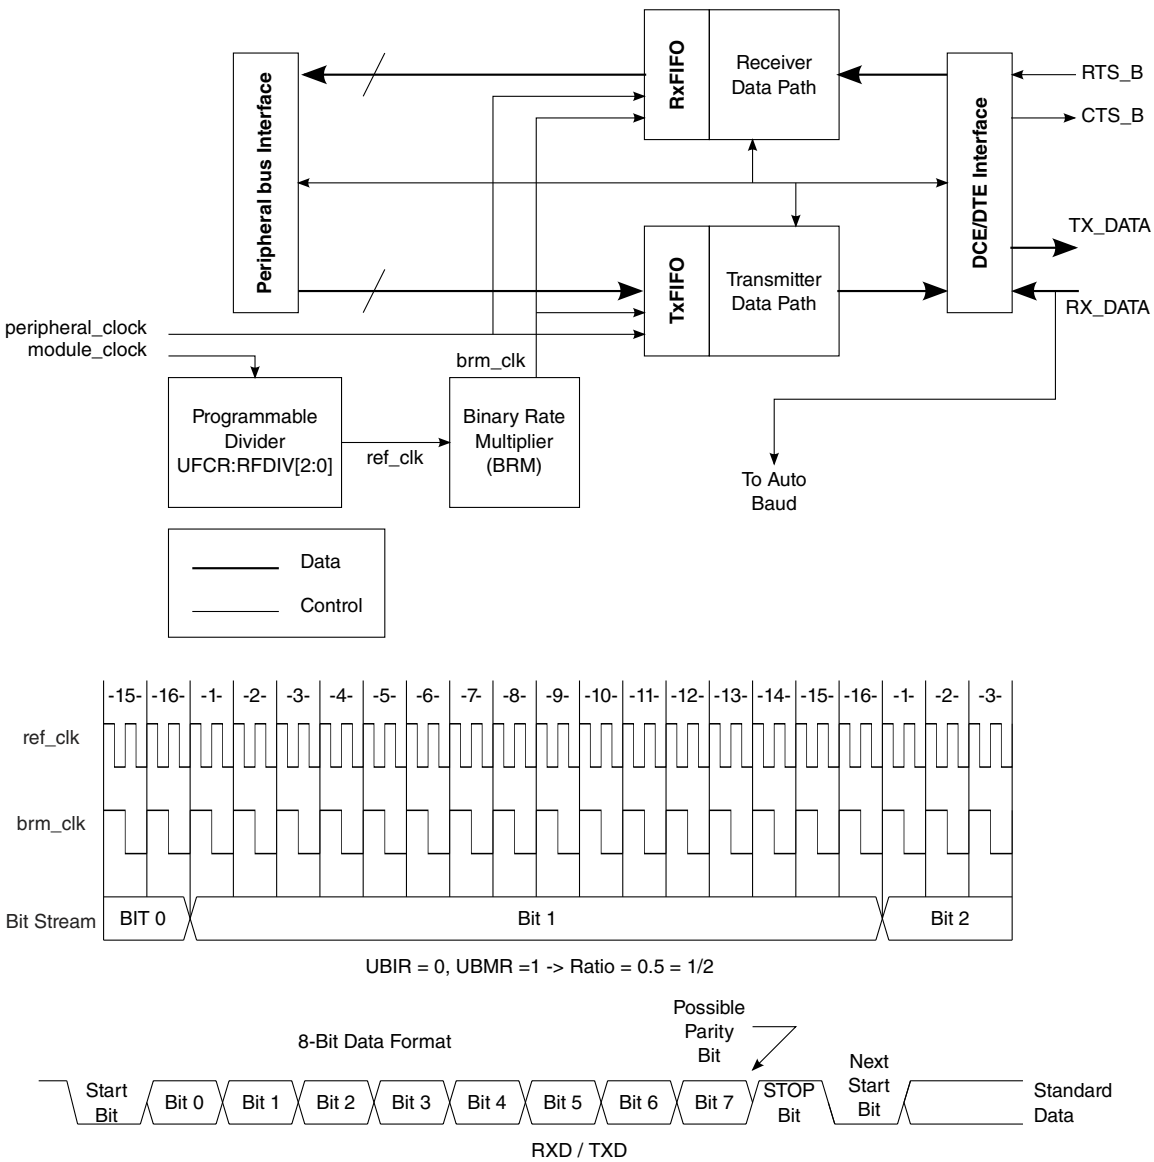

Figure 17-10. UART Simplified Block and Clock Generation Diagrams

17.2.2.4 Transmitter

The transmitter accepts a parallel character from the Arm platform and transmits it serially. The start, stop, and parity (when enabled) bits are added to the character.

When the ignore RTS bit (IRTS) is set, the transmitter sends a character as soon as it is ready to transmit. RTS_B can be used to provide flow-control of the serial data. When RTS_B is set to '1', the transmitter finishes sending the character in progress (if any), stops, and waits for RTS_B to be set to '0' again. Generation of BREAK characters and parity errors (for debugging purposes) is supported. The transmitter operates from the clock provided by the Binary Rate Multiplier(BRM). Normal NRZ encoded data is transmitted when the IR interface is disabled.

The transmitter FIFO (TxFIFO) contains 32 bytes. The data is written to TxFIFO by writing to the UTXD register with the byte data to the [7:0] bits. The data is written consecutively if the TxFIFO is not full. It is read (internally) consecutively if the TxFIFO is not empty. TXFULL bit (UTS[4]) can be used to control whether TXFIFO is full or not. The TxFIFO can be written regardless of the transmitter is disabled or enabled. If the UART is disabled, user can still write data into the TxFIFO correctly. But in this case the write access will yield to a transfer error.

17.2.2.4.1 Transmitter FIFO Empty Interrupt Suppression

The transmitter FIFO empty interrupt suppression logic suppresses the TXFE interrupt between writes to the TxFIFO.

When TxFIFO is empty, the software can either send one or several characters. If the software sends one character, it would write the character into the UTXD register, then that character is immediately transferred to the transmitter shift register, assuming the transmitter is already enabled. Without interrupt suppression logic, the TXFE interrupt flag would be set immediately. But, with this logic, the interrupt flag is set when the last bit of the character has been transmitted, for example, before the transmission of the parity bit (if exists) and the stop bit(s).

So, the suppression logic doesn't immediately send the TXFE interrupt flag. It allows the software to write another character to the TxFIFO before the interrupt flag is asserted.

When the transmitter shift register empties before another character is written to the TxFIFO, the interrupt flag is asserted. Writing data to the TxFIFO would release the interrupt flag. The interrupt flag is asserted on the following conditions:

- System Reset
- UART software reset

- When a single character has been written to Transmitter FIFO and then the Transmitter FIFO and the Transmitter Shift Register become empty until another character is written to the Transmitter FIFO
- The last character in the TxFIFO is transferred to the shift register, when TxFIFO contains two or more characters. See the figure below.

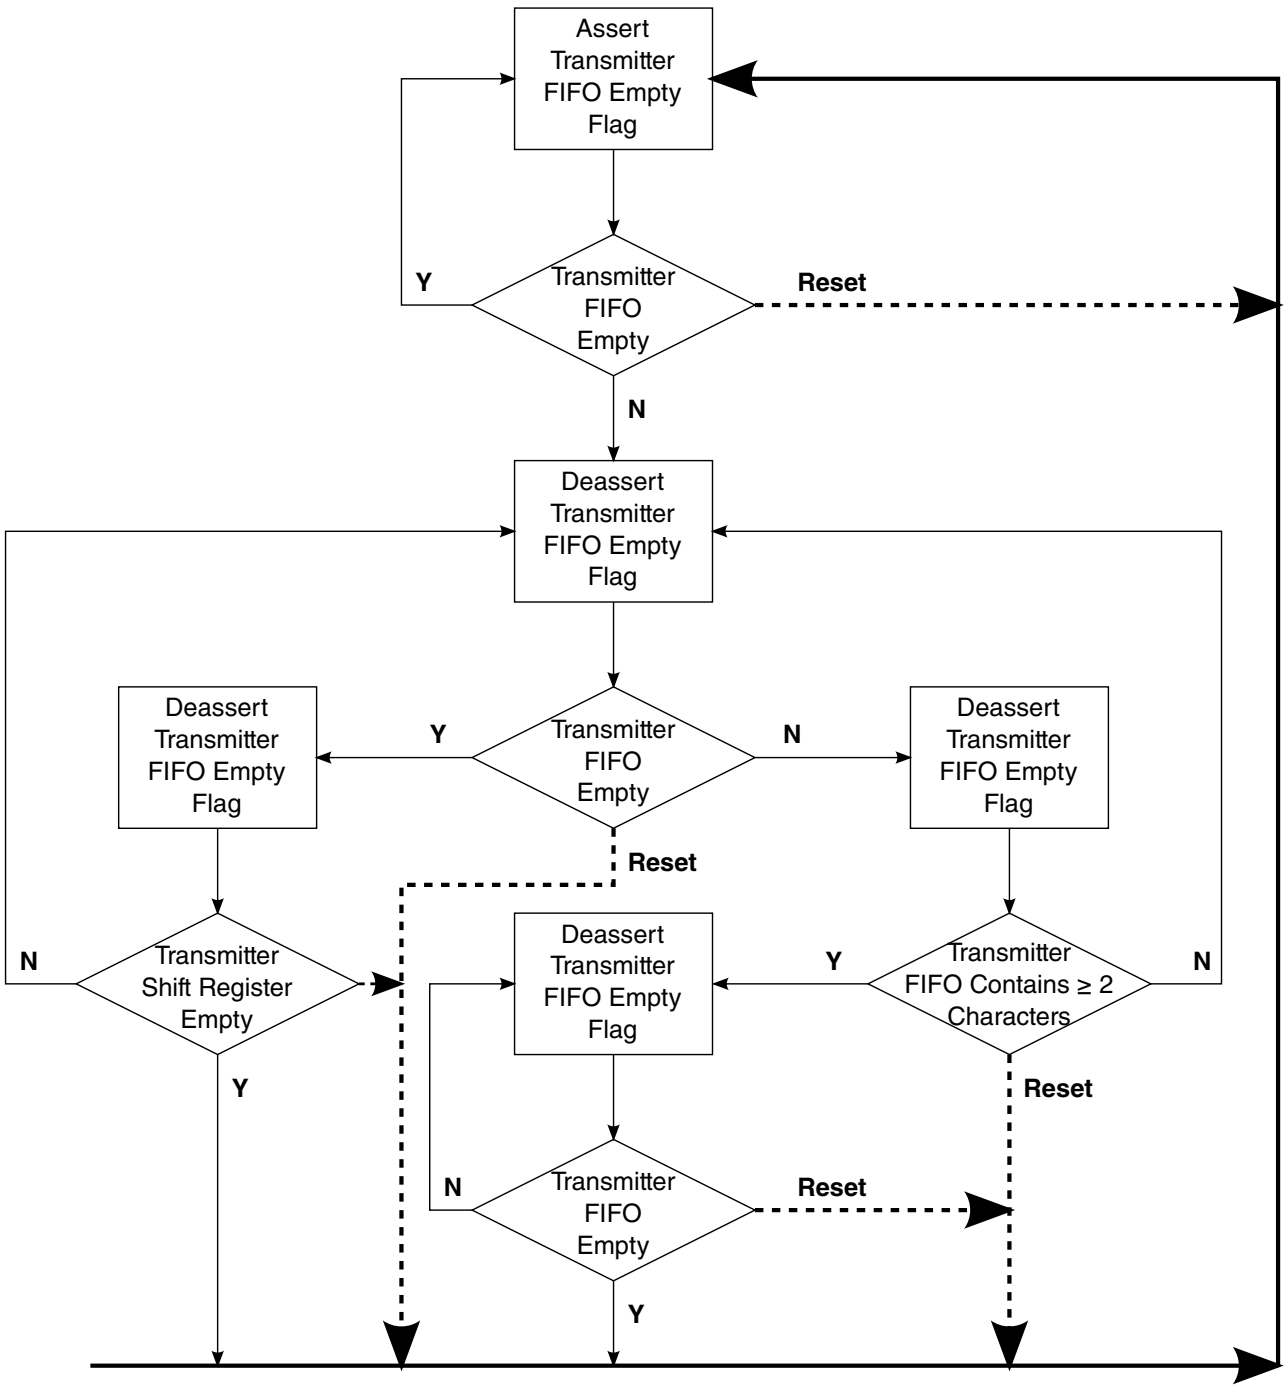

Figure 17-11. Transmitter FIFO Empty Interrupt Suppression Flow Chart

17.2.2.4.2 Transmitting a Break Condition

Asserting SNDBRK bit of the UCR1 Register forces the transmitter to send a break character (continuous zeros). The transmitter will finish sending the character in progress (if any) before sending break until this bit is reset.

The user is responsible to ensure that this bit is high for long enough to generate a valid BREAK. The transmitter samples SNDBRK after every bit is transmitted. Following completion of the BREAK transmission, the UART will transmit two mark bits. The user can continue to fill the FIFO and any character remaining will be transmitted when the break is terminated.

17.2.2.5 Receiver

See the figure below for the receiver flow chart.

The receiver accepts a serial data stream and converts it into parallel characters. When enabled, it searches for a start bit, qualifies it, and samples the following data bits at the bit-center.

Jitter tolerance and noise immunity are provided by sampling at a 16x rate and using voting techniques to clean up the samples. Once the start bit is found, the data bits, parity bit (if enabled), and stop bits (either 1 or 2 depending on user selection) are shifted in. Parity is checked and its status reported in the URXD register when parity is enabled. Frame errors and BREAKs are also checked and reported. When a new character is ready to be read by the Arm platform from the RxFIFO, the receive data ready (RDR = USR2[0]) bit is asserted and an interrupt is posted (if DREN = UCR4[0] = 1). If the receiver trigger level is set to 2 (RXTL[5:0] = UFCR[5:0] = 2), and 2 chars have been received into RxFIFO, the receiver ready interrupt flag (RRDY = USR1[9]) is asserted and an interrupt is posted if the receiver ready interrupt enable bit is set (RRDYEN = UCR1[9] = 1). If the UART Receiver Register (URXD) is read once, and in consequence there is only 1 character in the RxFIFO, the interrupt generated by the RDR bit is automatically cleared. The RRDY bit is cleared when the data in the RxFIFO falls below the programmed trigger level.

Normal NRZ encoded data is expected when the IR interface is disabled. The RxFIFO contains 32 half-word entries. Characters received are written consecutively into this FIFO. If the FIFO is full and a 33rd characters is received, this character will be ignored and the USR2[ORE] bit will be set.

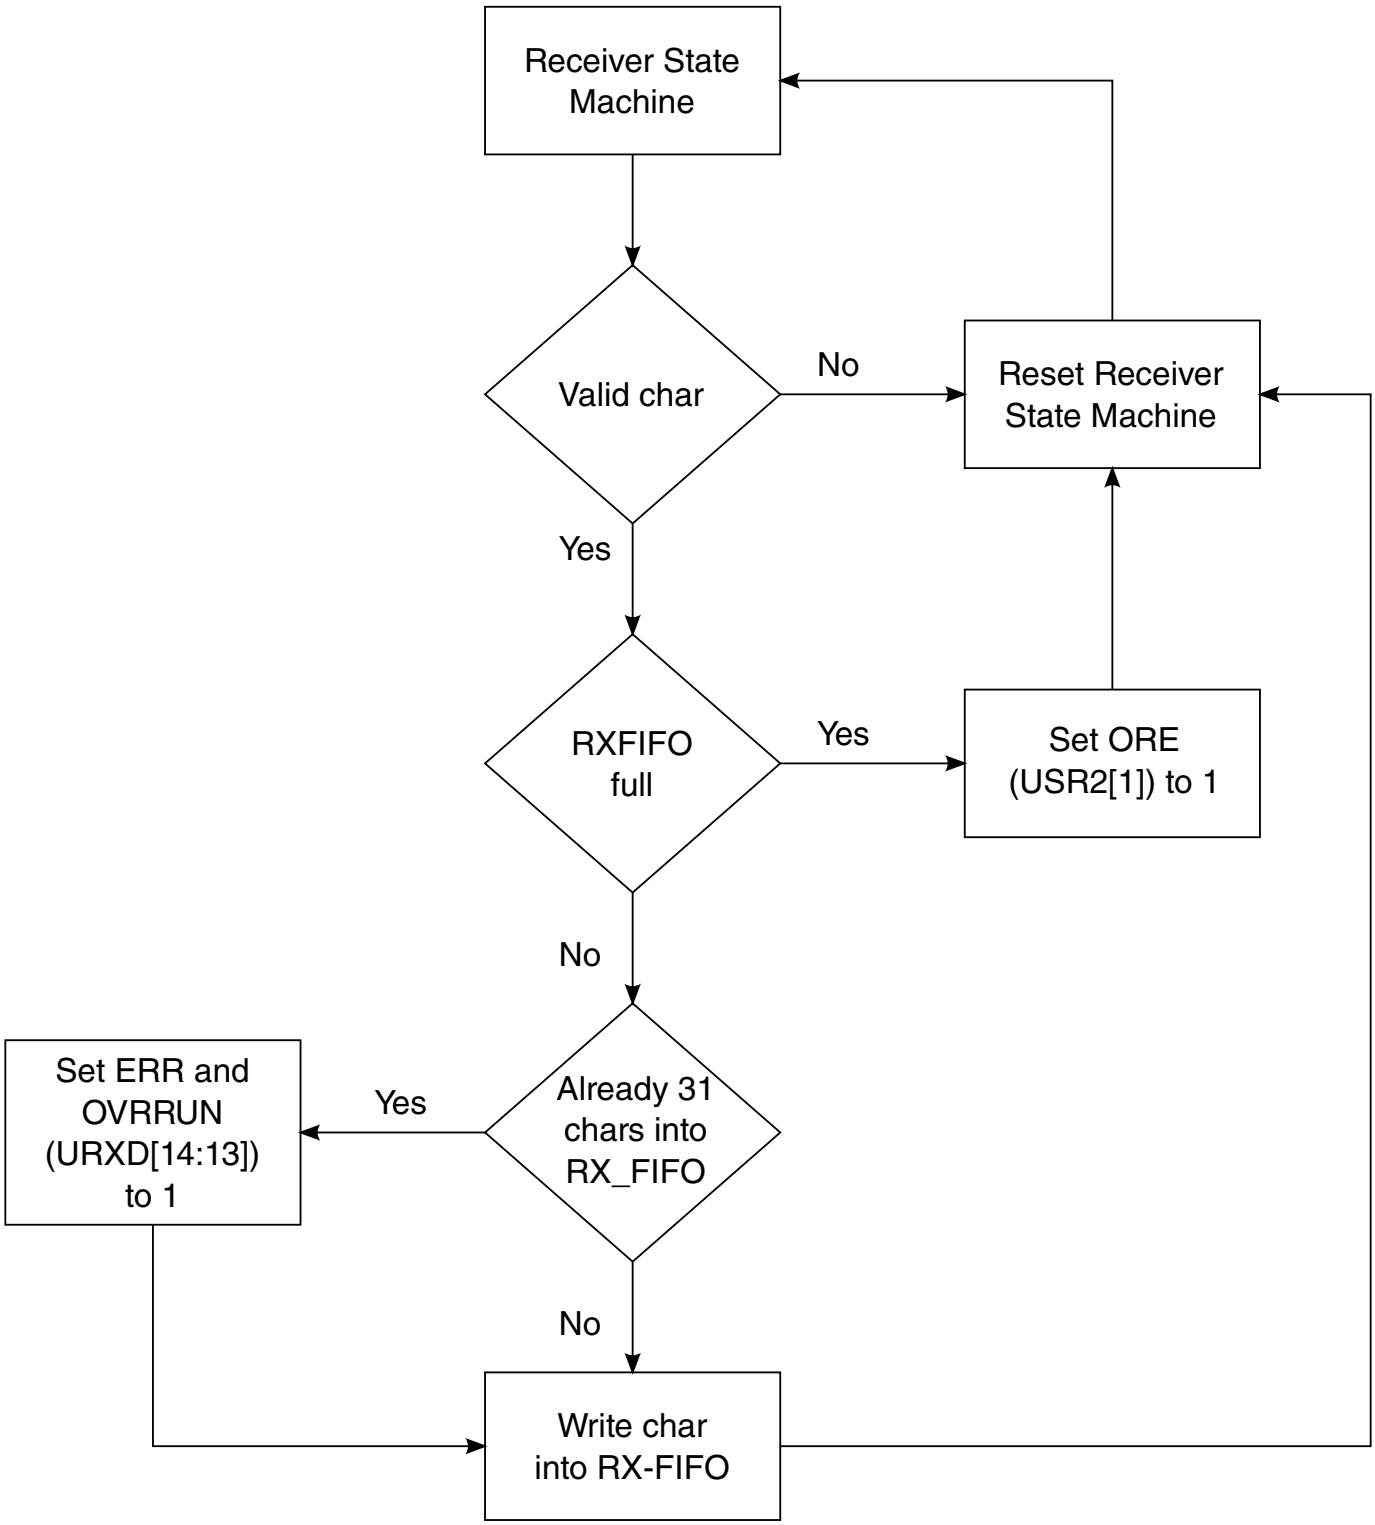

Figure 17-12. Receiver Flow Chart

17.2.2.5.1 Idle Line Detect

The receiver logic block includes the ability to detect an idle line. Idle lines indicate the end or the beginning of a message.

For an idle condition to occur:

- RxFIFO must be empty and
- RX_DATA pin must be idle for more than a configured number of frames (ICD[1:0] = UCR1[11:10]).

When the idle condition detected interrupt enable (IDEN = UCR1[12]) is set and the line is idle for 4 (default), 8, 16, or 32 (maximum) frames, the detection of an idle condition flags an interrupt (see the table below). When an idle condition is detected, the IDLE (USR2[12]) bit is set. Clear the IDLE bit by writing 1 to it. Writing 0 to the IDLE bit has no effect.

Table 17-5. Detection Truth Table

IDEN	ICD [1]	ICD [0]	IDLE	*interrupt_uart*
0	X	X	0	1
1	0	0	asserted after 4 idle frames	asserted after 4 idle frames
1	0	1	asserted after 8 idle frames	asserted after 8 idle frames
1	1	0	asserted after 16 idle frames	asserted after 16 idle frames
1	1	1	asserted after 32 idle frames	asserted after 32 idle frames
NOTE: This table assumes that no other interrupt is set at the same time this interrupt is set for the *interrupt_uart* signal. This table shows how this interrupt affects the *interrupt_uart* signal.				

During a normal message there is no idle time between frames. When all of the information bits in a frame are logic 1s, the start bit ensures that at least one logic 0 bit time occurs for each frame so that the IDLE bit is not asserted.

17.2.2.5.2 Aging Character Detect

The receiver block also includes the possibility to detect when at least one character has been sitting into the RxFIFO for a time corresponding to 8 characters. This aging character capability allows the UART to inform the Arm platform that there is less character into the RxFIFO than the Rx trigger and, no new character has been detected on the RXD line.

The aging capability is a timer which starts to count as soon as the RxFIFO is not empty and its trigger level is not reached (RRDY=0). This counter is reset when either a RxFIFO read is performed or another character starts to present on the RXD line. If none of those two events occurs, the bit AGTIM (USR1[8]) is set when the counter has

measured a time corresponding to 8 characters. AGTIM is cleared by writing a 1 to it. AGTIM can flag an interrupt to Arm platform on *interrupt_uart* if ATEN (UCR2[3]) has been set.

To summarize, AGTIM is set when:

- There is at least one character into RxFIFO.
- No read has occurred on RxFIFO and RXD line has stayed high, for a time corresponding to 8 characters.
- The RxFIFO trigger is not reached (RRDY=0)

17.2.2.5.3 Receiver Wake

The WAKE bit (USR2[7]) is set when the receiver detects a qualified Start bit. For this, two conditions must be fulfilled, firstly a falling edge on RX_DATA line must be detected and secondly the RX_DATA line must stays at low level for more than a half-bit duration.

When the wake interrupt enable WKEN (UCR4[7]) bit is enabled, the receiver flags an interrupt (*interrupt_uart*) if the WAKE status bit is set. The WAKE bit is cleared by writing 1 to it. Writing 0 to the WAKE bit has no effect. The WAKE status bit can be asserted in either serial RS-232 mode or IR mode. The generation of the WAKE interrupt needs the clock *module_clock* .

When the asynchronous wake interrupt (AWAKE) is enabled (AWAKEN = UCR3[4] = 1), and the Arm platform is in STOP mode, and UART clocks have been shut-off, then a falling edge detected on the receive pin (RX_DATA) asserts the AWAKE bit (USR1[4]) and the *interrupt_uart* interrupt to wake the Arm platform from STOP mode. Re-enable UART clocks and clear the AWAKE bit by writing 1 to it. Writing 0 to the AWAKE bit has no effect. When IR interface is enabled (UCR1[7]=1), the AWAKE bit is always not asserted. The generation of the asynchronous AWAKE interrupt does not need any clocks.

In IR mode, if the asynchronous IR WAKE interrupt is enabled (AIRINTEN = UCR3[5] = 1), and if the Arm platform is in STOP mode (UART clocks are off when Arm platform in STOP mode), then the detection of a falling edge on the receive pin (RXD_IR), asserts the AIRINT bit (USR1[5]), and the *interrupt_uart* interrupt. This interrupt wakes the Arm platform from STOP mode. Software re-enables UART clocks and clear the AIRINT bit by writing 1 to it. Writing 0 to the AIRINT bit has no effect. When IR interface is disabled (UCR1[7]=0), the AIRINT bit is always not asserted. The generation of the asynchronous AIRINT interrupt does not need any clocks.

Recommended procedure for programming the asynchronous interrupts is to first clear them by writing 1 to the appropriate bit in the UART Status Register 1 (USR1). Poll or enable the interrupt for the Receiver IDLE Interrupt Flag (RXDS) in the USR1. When asserted, the RXDS bit indicates to the software that the receiver state machine is in the idle state, the next state is idle, and the RX_DATA pin is idle (high). After following this procedure, enable the asynchronous interrupt and enter STOP mode.

17.2.2.5.4 Receiving a BREAK Condition

A BREAK condition is received when the receiver detects all 0s (including a 0 during the bit time of the stop bit) in a frame. The BREAK condition asserts the BRCD bit (USR2[2]) and writes only the first BREAK character to the RxFIFO. Clear the BRCD bit by writing 1 to it. Writing 0 to the BRCD bit has no effect.

Asserting BRCD would generate an interrupt on *interrupt_uart*. The interrupt generation can be masked using the control bit BKEN (UCR4[2]). Receiving a break condition will also effect the following bits in the receiver register URXD:

URXD(11) = BRK. While high this bit indicates that the current char was detected as a break.

URXD(12) = FRMERR. The frame error bit will always be set when BRK is set.

URXD(10) = PRERR. If odd parity was selected the parity error bit will also be set when BRK is set.

URXD(14) = ERR. The error detect bit indicates that the character present in the rx data field has an error status. This can be asserted by a break.

17.2.2.5.5 Vote Logic

The vote logic block provides jitter tolerance and noise immunity by sampling with respect to a 16x clock (*brm_clk*) and using voting techniques to clean up the samples. The voting is implemented by sampling the incoming signal constantly on the rising edge of the *brm_clk*.

See Figure 17-13. The receiver is provided with the majority vote value, which is 2 out of the 3 samples. For examples of the majority vote results of the vote logic, see the following table.

Table 17-6. Majority Vote Results

Samples	Vote
000	0

Table continues on the next page...

Table 17-6. Majority Vote Results (continued)

Samples	Vote
101	1
001	0
111	1

The vote logic captures a sample on every rising edge of *brm_clk*, however the receiver uses 16x oversampling to take its value in the middle of the sample character.

The receiver starts to count when the Start bit is set however it does not capture the contents of the RxFIFO at the time the Start bit is set. The start bit is validated when 0s are received for 7 consecutive 1/16 of bit times following the 1-to-0 transition. Once the counter reaches 0xF, it starts counting on the next bit and captures it in the middle of the sampling frame (see Table 17-6). All data bits are captured in the same manner. Once the stop bit is detected, the receiver shift register (SIPO_OUT) data is parallel shifted to the RxFIFO.

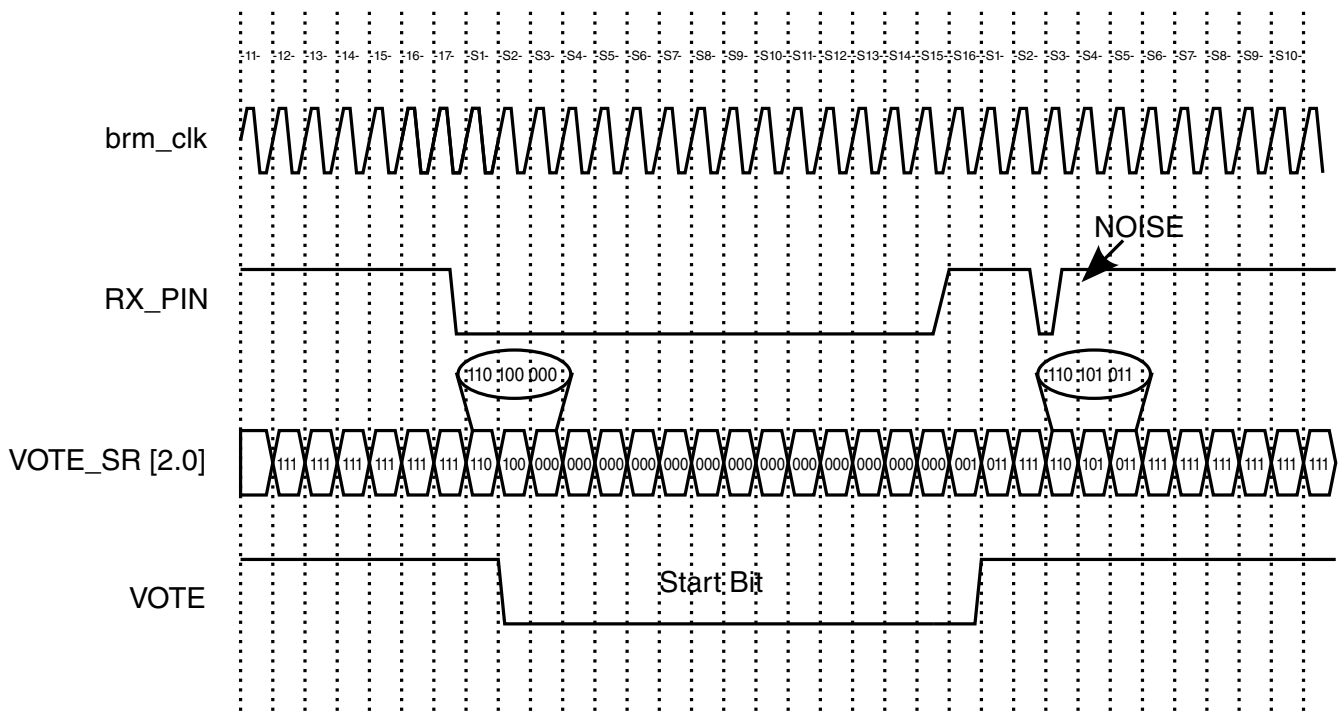

Figure 17-13. Majority Vote Results

A new feature has been recently implemented, it allows to re-synchronize the counter on each edge of RX_DATA line. This is automatic and allows to improve the immunity of UART against signal distortion.

There is a special case when the *brm_clk* frequency is too low and is unable to capture a 0 pulse in IrDA. In this case, the software must set the IRSC (UCR4[5]) bit so that the reference clock (after internal divider) is used for the voting logic. The pulse is validated by counting the length of the pulse.

Refer to Infrared Interface for more details.

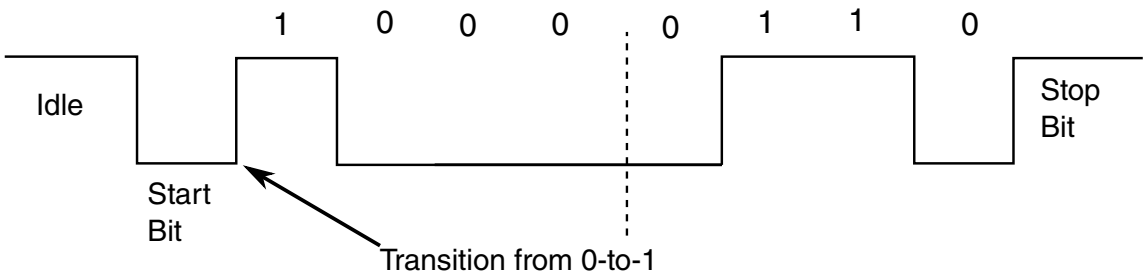
17.2.2.5.6 Baud Rate Automatic Detection Logic

When the baud rate automatic detection logic is enabled, the UART locks onto the incoming baud rate. To enable this feature, set the automatic detection of baud rate bit (ADBR = UCR1[14] = 1) and write 1 to the ADET bit (USR2[15]) to clear it.

When ADET=0 and ADBR =1, the detection starts. Then, once the beginning of start bit (transition from 1-to-0 of RX_DATA) has been detected, UART starts a counter (UBRC) working at reference frequency. Once the end of start bit is detected (transition from 0-to-1 of RX_DATA), the value of UBRC - 1 is directly copied into UBMR register. UBIR register is filled with 0x000F.

So, at the end of start bit, registers gets following values:

```
UBRC = number of reference clock periods (after divider) during Start bit.
UBIR = 0x000F
UBMR = UBRC - 1
```



The updated values of the 3 registers can be read.

See Table 17-7 for list of parameters for baud rate detection and Figure 17-14 for baud rate detection protocol diagram.

If any of the UART BRM registers are simultaneously written by the baud rate automatic detection logic and by the peripheral data bus, the peripheral data bus would have lower priority.

Table 17-7. Baud Rate Automatic Detection

ADBR	ADET	Baud Rate Detection	*interrupt_uart*
0	X	Manual Configuration	1
1	0	Auto Detection Started	1
1	1	Auto Detection Complete	0
NOTE: This table assumes that no other interrupt is set at the same time this interrupt is set for the *interrupt_uart* signal.			

Note: LSB Transmitted first.

Figure 17-14. Baud Rate Detection Protocol Diagram

17.2.2.5.6.1 Baud Rate Automatic Detection Protocol

The receiver must receive an ASCII character "A" or "a" to verify proper detection of the incoming baud rate. When an ASCII character "A" (0x41) or "a" (0x61) is received and no error occurs, the Automatic Detect baud rate bit is set (ADET=1) and if the interrupt is enabled (ADEN=UCR1[15]=1), an interrupt *interrupt_uart* is generated.

When an ASCII character "A" or "a" is not received (because of a bit error or the reception of another character), the auto detection sequence restarts and waits for another 1-to-0 transition.

As long as ADET = 0 and ADBR = 1, the UART continues to try to lock onto the incoming baud rate. Once the ASCII character "A" or "a" is detected and the ADET bit is set, the receiver ignores the ADBR bit and continues normal operation with the calculated baud rate.

The UART interrupt is active (*interrupt_uart* = 0) as long as ADET = 1 and ADBR = 1. This can be disabled by clearing the automatic baud rate detection interrupt enable bit (ADEN = 0). Before starting an automatic baud rate detection sequence, set ADET = 0 and ADBR = 1.

The RxFIFO must contain the ASCII character "A" or "a" following the automatic baud rate detection interrupt.

The 16-bit UART Baud Rate Count Register (UBRC) is reset to 4 and stays at 0xFFFF when an overflow occurs. The UBRC register counts (measures) the duration of start bit. When the start bit is detected and counted, the UART Baud Rate Count Register retains its value until the next automatic baud rate detection sequence is initiated.

The Baud Rate Count Register counts only when auto detection is enabled.

17.2.2.5.6.2 New Baud Rate Determination

In order to fight against the problems caused by the distortion and the noise on the RX_DATA line, the duration of the baud rate measurement has been extended.

Previously, as described above, this determination was based on the measurement of the START bit duration. Now, this measurement is based on the duration of START bit + bit0. Bit0 is the first bit following the START bit. In fact, the counter which is started at the falling edge of START bit is no longer stopped at next rising edge (end of START bit), but it is stopped at the next falling edge (end of bit0). As the character sent is always a "A" (41h) or a "a" (61h), this second falling edge will always be present and it will indicate the end of bit0. Once this counter is stopped, the result is divided by 2 and used by the BRM to determine the incoming baud rate.

NOTE

UBRC register contains the result of this division by two, in consequence it reflects the measurement of the duration of one bit.

17.2.2.5.6.2.1 New Autobaud Counter Stopped bit and Interrupt

A new bit has been added in USR2 register: ACST (USR2[11]). This bit is set immediately after the determination of the baud rate.

So,

- if ADNIMP is not set (default), ACST is set to 1 after the end of bit0,
- If ADNIMP is set to 1, ACST is set to 1 at the end of START bit.

If ACIEN (UCR3[0]) is set to 1, ACST will flag an interrupt on *interrupt_uart* signal. This interrupt informs the Arm platform that the BRM has just been set with the result of the bit length measurement. If needed, the Arm platform can perform a read of UBMR (or UBRC) register and determine by itself the baud rate measured. Then the Arm platform has the possibility to correct the BRM registers with the nearest standardized baud rate.

NOTE

ACST is set only if ADBR is set to 1, for example, the UART is autobauding.

Clear the ACST bit by writing 1 to it. Writing 0 to the ACST bit has no effect.

17.2.2.6 Escape Sequence Detection

An escape sequence typically consists of 3 characters entered in rapid succession (such as +++). Because these are valid characters by themselves, the time between characters determines if it is a valid escape sequence.

Too much time between two of the "+" characters is interpreted as two "+" characters, and not part of an escape sequence.

The software chooses the escape character and writes its value to the UART Escape Character Register (UESC). The software must also enable escape detection feature by setting ESCEN (UCR2[11]) to 1. The hardware compares this value to incoming characters in the RxFIFO. When an escape character is detected, the internal escape timer starts to count. The software specifies a time-out value for the maximum allowable time between 2 successive escape characters (see the table below). The escape timer is programmable in intervals of 2 ms to a maximum interval of 8.192 seconds.

Table 17-8. Escape Timer Scaling

UTIM Register	Maximum Time Between Specified Escape Characters
0x000	2 ms
0x001	4 ms
0x002	6 ms
0x003	8 ms
0x004	10 ms
...	...
0F8	498 ms
0F9	500 ms
...	...
9C3	5 s
...	...
FFD	8.188 s
FFE	8.190 s
FFF	8.192 s
NOTE: To calculate the time interval: (UTIM_Value + 1) x 0.002 = Time_Interval Example: (09C3 + 1) x 0.002 = 5 s.	

The escape sequence detection feature is available for all the reference frequencies. Before using Escape Sequence Detection, the user must fill the ONEMS register. This 24-bit register must contain the value of the UART internal frequency divided by 1000. The internal frequency is obtained after the UART internal divider which is applied on *module_clock* clock.

Example I:

- If the input clock *module_clock* frequency is 66.5 MHz.
- And if the input clock *module_clock* is divided by 2 with the internal divider: UFCR[9:7] = 3'b100

$$ONEMS = \frac{66.5 \times 10^6}{2 \times 1000} = 33250 = 81E2h$$

Figure 17-15. Calculation of Frequency for ONEMS Register

Example II:

- If the input clock *module_clock* frequency is 66.5 MHz.
- And if the input clock *module_clock* is divided by 1with the internal divider: UFCR[9:7] = 3'b101

$$ONEMS = \frac{66.5 \times 10^6}{1000} = 66500 = 103C4h$$

Figure 17-16. Calculation of Frequency for ONEMS Register

The escape sequence detection interrupt is asserted when the escape sequence interrupt enable (ESCI) bit is set and an escape sequence is detected (ESCF set). Clear the ESCF bit by writing 1 to it. Writing 0 to the ESCF bit has no effect.

17.2.3 Binary Rate Multiplier (BRM)

The BRM sub-block receives *ref_clk* (*module_clock* clock after divider). From this clock, and with integer and non-integer division, BRM generates a 16x baud rate clock .

The UART transmitte will shift data out based on this 16x baud rate clock. The UART receiver will sample the serial data line based on this 16x baud rate clock. The input and output frequency ratio is programmed in the UART BRM Incremental Register (UBIR) and UART BRM MOD Register (UBMR). The output frequency is divided by the input frequency to produce this ratio. For integer division, set the UBIR = 0x000F and write the divisor to the UBMR register. All values written to these registers must be one less than the actual value to eliminate division by 0 (undefined), and to increase the maximum range of the registers.

Updating the BRM registers requires writing to both registers. The UBIR register must be written before writing to the UBMR register. If only one register is written to by the software, the BRM continues to use the previous values.

The following examples show how to determine what values are to be programmed into UBIR and UBMR for a given reference frequency and desired baud rate. The following equation can be used to help determine these values:

$$\text{BaudRate} = \frac{\text{Ref Freq}}{\left(16 \times \frac{\text{UBMR} + 1}{\text{UBIR} + 1} \right)}$$

Figure 17-17. Frequency and Baud Rate for UBIR and UBMR

With:

Reference Frequency (Hz): UART Reference Frequency (*module_clock* after RFDIV divider)

Baud Rate (bit/s): Desired baud rate.

Integer Division ÷ 21

Reference Frequency = 19.44 MHz

UBIR = 0x000F

UBMR = 0x0014

Baud Rate = 925.7 kbit/s

NOTE

Observe that each value written to the registers is one less than the actual value.

Non-Integer Division

```
Reference Frequency = 16 MHz
Desired Baud Rate = 920 Kbits/s
```

$$\frac{UBMR + 1}{UBIR + 1} = \frac{RefFreq}{16 \times BaudRate} = \frac{16 \times 10^6}{16 \times 920 \times 10^3} = 1.087$$

```
Ratio = 1.087 = 1087 / 1000
UBIR = 999 (decimal)= 0x3E7
UBMR = 1086 (decimal)= 0x43E
Non-Integer Division
Reference Frequency = 25 MHz
Desired Baud Rate = 920 kbit/s
Ratio = 1.69837 = 625 / 368
UBIR = 367 (decimal)= 0x16F
UBMR = 624 (decimal)= 0x270
```

Non-Integer Division

```
Reference Frequency: 30 MHz
Desired Baud Rate = 115.2 kbit/s
Ratio = 16.276043 = 65153 / 4003
UBIR = 4002 (decimal) = 0x0FA2
UBMR = 65152 (decimal) = 0xFE80
```

17.2.4 Infrared Interface

17.2.4.1 Generalities-Infrared

The Infrared interface is selected when IREN (UCR1[7]) is set to 1.

The Infrared Interface is compatible with IrDA Serial Infrared Physical Layer Specification. In this specification, a "zero" is represented by a positive pulse, and a "one" is represented by no pulse (line remains low).

In the UART:

In TX: For each "zero" to be transmitted, a narrow positive pulse which is 3/16 of a bit time is generated. For each "one" to be transmitted no pulse is generated (output is low). External circuitry has to be provided to drive an Infrared LED.

In RX: When receiving, a narrow negative pulse is expected for each "zero" transmitted while no pulse is expected for each "one" transmitted (input is high).

NOTE

Rx part of IR block expects to receive an inverted signal compared to IrDA specification. Circuitry external to the IC transforms the Infrared signal to an electrical signal.

The IR interface has an edge triggered interrupt (IRINT). This interrupt validates a zero bit being received. This interrupt is enabled by writing a "one" to ENIRI bit.

The behavior of Infrared Interface is determined by 3 bits INVT (UCR3[1]), INVR (UCR4[9]) and IRSC (UCR4[5]).

17.2.4.2 Inverted Transmission and Reception bits (INVT & INVR)

The values of INVT and INVR depend of the IrDA transceiver connected on the TXD_IR and RXD_IR pins of the UART. If this transceiver is not inverting on both paths Tx and Rx, a Zero is represented by a positive pulse and a One is represented by no pulse (line remains low). In this case, the bit INVT must be set to 0 and the bit INVR must be set to 1 (because Rx IR block expects an inverted signal).

On the contrary user must set INVT=1 and INVR=0 if both paths of the transceiver are inverting, that is, a Zero is represented as a negative pulse and a One is represented by no pulse (line remains high). The transceiver can also be inverting on only one path (Tx or Rx), in this case INVT and INVR must be together equal to 1 or to 0, depending on which path is inverted.

17.2.4.3 InfraRed Special Case (IRSC) Bit

The value to apply to IRSC bit is based on 2 parameters: the baud rate and the Minimum Pulse Duration (MPD) of the transceiver.

According to IrDA Standard Specification, for SIR (Serial IR) baud rates from 2.4 Kbit/s to 115.2 Kbit/s this nominal pulse duration is equal to 3/16 of a bit duration (at the selected baud rate). But, for all the baud rates a Minimum Pulse Duration is also specified. According to IrDA Standard, a Zero is represented by a light pulse, so the IrDA transceiver can't emit a light pulse shorter than the MPD. For SIR, the MPD is constant and equal to 1.41 µs.

But user must take into account the electrical MPD associated with the transceiver on the receiver path. Typically this value is 2.0 µs, but for some manufacturers MPD can go down to 1.0 µs.

In order to understand the meaning of IRSC bit, one must understand how the RX path works in IrDA mode.

When the UART is in IrDA mode, a Zero is not only detected by the state of the RXD_IR line, but also with the duration of the pulse. This pulse duration can be measured with 2 different clocks. In this case, clock is selected with the IRSC bit.

- If IRSC = 0, the clock used is the BRM clock.
- If IRSC = 1, the clock used is the UART internal clock (UART clock after the divider (RFDIV)).

In normal operation, IRSC=0. This means that at any time, the user must ensure that the frequency of BRM_clock is high enough to measure the pulse. The pulse must last at least 2 BRM clock cycles. If this condition is not fulfilled, IRSC must be set to 1.

Let's examine two examples, for a Minimum Pulse Duration equal to the MPD from the IrDA SIR specification (i.e., 1.41 µs).

1: Calculation of BRM Clock Period (Clock Period < 1.41 µs)

The user wants to receive IrDA data at 115.2 Kbit/s. The UBIR and UBMR registers are set in order to create the BRM_clock with a frequency of 16*baud rate = 16 * 115.2K = 1.843 MHz. But at the same time, in order to correctly detect the pulse, the user must be sure that 2* BRM_clock period is lower than 1.41 µs. Lets check:

BRM_clock period = 1/1843000 = 542 ns

So 2*BRM_clock period = 1.09 µs < 1.41 µs. It is fine.

2: Calculation of BRM Clock Period (Clock Period > 1.41 µs)

This time the user wants to receive at 19.2 Kbit/s. So, the BRM_clock is set to 16*19200 = 307.2 kHz. Let's check if 2* BRM_clock period < 1.41 µs:

1. BRM_clock period =1/307200 = 3.25 µs

   So 2*BRM_clock period = 6.50 µs >> 1.41 µs. It doesn't work.

   So, in this case, the BRM clock can't be used to measure the pulse duration and the user must select the UART internal clock by setting IRSC =1.

NOTE

Like for Escape character detection, when IR Special Case is enabled (IRSC=1), the UART must measure a duration. In order to do that, the user must fill the ONEMS register. Refer to Escape Sequence Detection.

17.2.4.4 IrDA interrupt

Serial infrared mode (SIR) uses an edge triggered interrupt flag IRINT (USR2[8]). When INVR =0, detection of a falling edge on the RXD pin asserts the IRINT bit. When INVR=1, detection of a rising edge on the RXD pin asserts the IRINT bit. When IRINT and ENIRI bits are both asserted, the *interrupt_uart* interrupt is asserted. Clear the IRINT bit by writing 1 to it. Writing 0 to the IRINT bit has no effect.

17.2.4.5 Conclusion about IrDA

Before using the UART in IrDA, the baud rate limit must be calculated. This baud rate limit will inform the user if IRSC bit has to be set or not.

Let's determine this limit:

As already described, if IRSC = 0, the following condition must always be fulfilled

$$2 \times BRMClockPeriod < MinPulseDuration$$

Figure 17-18. Calculation of Baud Rate

So,

$$BRMClockFrequency > \frac{2}{MPD}$$

So, knowing BRM_clock frequency = 16 * Baud Rate, we get:

$$BaudRate > \frac{1}{8 \times MinPulseDuration}$$

So, the user needs to set IRSC = 0 when:

- If Minimum Pulse Duration = 2.5 us and Baud Rate > 50 Kbit/s.
- If Minimum Pulse Duration = 2.0 us and Baud Rate > 62.5 Kbit/s.
- If Minimum Pulse Duration = 1.41 us and Baud Rate > 88.6 Kbit/s.

NOTE

For baud rates lower than the limit, IRSC must be set to1.

17.2.4.6 Programming IrDA Interface

17.2.4.6.1 High Speed

As an example, the following sequence can be used to program the IrDA interface in order to send and receive characters at 115.2 Kbit/s.

Assumptions:

- Input UART clock = 90 MHz
- Internal clock divider = 3 (divide Input UART clock by 3)
- Baud rate = 115.2 Kbit/s
- IrDA transceiver is not inverting on both channels: for Tx and Rx, a Zero is represented by a positive pulse, and a One is represented by no pulse (line stays low).
- Interrupt: Sent to Arm platform when 1 char is received into the Rx FIFO (RDR)

Registers values and Programming orders:

```
UCR1 = 0x0085
UCR1[7] = IREN = 1: Enable IR interface
UCR1[0] = UARTEN = 1: Enable UART
UTS = 0x0000
UFCR = 0x0981
TXTL[5:0] = 0x02: Default value
RFDIV[2:0] = 0x3: Divide Input UART clock by 3 (resulting internal clock  is 30 MHz)
RXTL[5:0] = 0x01: Default value
UBIR = 0x0202
UBMR = 0x20BE Baud rate = 115.2 kbit/s with internal clock = 30 MHz
UCR2 = 0x4027
UCR2[14] = IRTS = 1: Ignore level of RTS input signal
UCR2[5] = WS = 1: Characters are 8-bit length
UCR2[2] = TXEN = 1: Enable Rx path
UCR2 [1] = RXEN = 1: Enable Tx path
UCR2[0] = SRST_B = 1: No software reset
UCR3 = 0x0000

         UCR4 = 0x8201
CTSTL[5:0] = 0x20: Default value
UCR4[9] = INVR = 1: Inverted Infrared Reception (because IrDA transceiver is not inverting)
UCR4[1] = DREN = 1: To enable RDR interrupt (sent when one char is received)
```

The UART is ready to send a character as soon as there is a write into UTXD register. And an interrupt will be sent to Arm platform when a character is received.

17.2.4.6.2 Low Speed

This time, we keep the same assumptions but the speed is now 9.6 Kbit/s. So, this baud rate is below the limit (even with a Min. Pulse Duration of 2.5 us) and thus IRSC must be set to 1.

Assumptions:

- Input UART clock = 90 MHz
- Internal clock divider = 3 (divide Input UART clock by 3)
- Baud rate = 9.6 Kbit/s
- IrDA transceiver is not inverting on both channels: for Tx and Rx, a Zero is represented by a positive pulse, and a One is represented by no pulse (line stays low).
- Interrupt: Sent to Arm platform when 1 char is received into the Rx FIFO (RDR).

Registers values and Programming orders:

```
UCR1 = 0x0085
UCR1[7] = IREN = 1: Enable IR interface
UCR1[0] = UARTEN = 1: Enable UART
UFCR = 0x0981
UFCR[15:10] = TXTL[5:0] = 0x02: Default value
RFDIV[2:0] = 0x3: Divide Input UART clock by 3 (resulting internal clock  is 30 MHz)
UFCR[5:0] = RXTL[5:0] = 0x01: Default value
UBIR = 0x00FF
UBMR = 0xC354 Baud rate = 9.6 kbit/s with internal clock = 30 MHz
UCR2 = 0x4027
UCR2[14] = IRTS = 1: Ignore level of RTS input signal
UCR2[5] = WS = 1: Characters are 8-bit length
UCR2[2] = TXEN = 1: Enable Rx path
UCR2 [1] = RXEN = 1: Enable Tx path
UCR2[0] = SRST_B = 1: No software reset
UCR3 = 0x0000
UCR3[1] = INVT = 0: Positive pulse represents 0.
UCR4 = 0x8221
UCR4[15:10] = CTSTL[5:0] = 0x20: Default value
UCR4[9] = INVR = 1: Inverted Infrared Reception (because IrDA transceiver is not inverting)
UCR4[5] = IRSC = 1: Because data rate is below the limit and thus the UART internal clock is
used to measure the pulse duration.
UCR4[1] = DREN = 1: To enable RDR interrupt (sent when one char is received)
```

The UART is now ready to send a character as soon as there is a write into UTXD register. An interrupt will be sent to Arm platform when a character is received.

17.2.5 9-bit RS-485 Mode

17.2.5.1 Generalities

The UART provides a 9-bit mode to facilitate multidrop (RS-485) network communication. To enable this mode, set MDEN bit in the UMCR register to 1. When 9-bit RS-485 mode is enabled, UART transmitter can transmit the ninth bit (9^{th} bit) set by TXB8, and UART receiver can differentiate between data frames (9^{th} bit = 0) and address frames (9^{th} bit = 1).

The CTS_B pin can be used to control RS-485 output driver outside the chip.

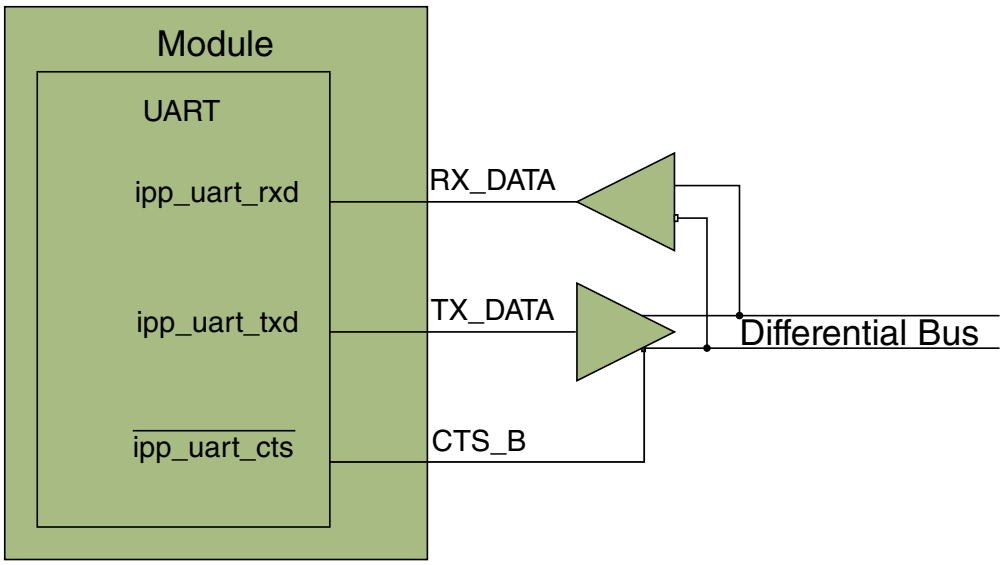


Figure 17-19. RS-485 driver connection (UART in DCE mode)

17.2.5.2 Transmit 9-bit RS-485 frames

To transmit 9-bit RS-485 frames, user need to enable parity (PREN=1) to enable trasmitting the ninth data bit, set 8-bit data word size (WS=1), and write TXB8 (UMCR[2]) as the 9th bit (bit [8]) to be transmitted (write '0' to TXB8 to transmit a data frame, write '1' to transmit a address frame). The other data bit [7:0] is written to TxFIFO by writing to the UTXD same as normal RS-232 operation.

17.2.5.3 Receive 9-bit RS-485 frames

To receive 9-bit RS-485 frames, user need to enable parity (PREN=1) to enable receiving the ninth data bit, set 8-bit data word size (WS=1). The receiver will save the 9-bit data to RxFIFO, and user should read the 9th databit (bit [8]) by reading the PRERR (URXD[10]) bit, and read data bit [7:0] by reading the RX_DATA (URXD[7:0]).

There are two slave address detect modes, normal detect mode and automatic detect mode, and can be selected by SLAM (UMCR[1]).

17.2.5.3.1 RS-485 Slave Address Normal Detect Mode

To enable Normal Detect mode, clear SLAM (UMCR[1] to 0). The receiver ignores all data frames (9th bit = 0) until an address frame is received (9th bit = 1). At that time, the slave address detected (SAD = USR1[3]) bit is asserted and the *interrupt_uart* interrupt is

generated (if SADEN = UMCR[3] = 1). The address byte and sebsequent bytes are all put into RxFIFO along with their 9th bit. The UART will also generate DMA request *dma_req_rx* when the RxFIFO reaches the selected threshold (controlled by RXTL) if receive ready DMA (RXDMAEN = UCR1[8]) request is enabled.

User should read the 9th databit (bit [8]) by reading the PRERR (URXD[10]) bit, and read data bit [7:0] by reading the RX_DATA (URXD[7:0]).

In this mode, once the UART has detected a 9th bit is equal to '1', it will always save the subsequent frames to RxFIFO. So the software must decide whether the address and data in RxFIFO are needed or not.

17.2.5.3.2 RS-485 Slave Address Automatic Detect Mode

To enable Automatic Detect Mode, set SLAM (UMCR[1]) to 1. The receiver tries to detect an address byte (frame 9th bit = 1) that matches the programmed SLADDR (UMCR[15:8]) character. If the received byte is a data or an address byte that does not match the programmed SLADDR character, the receiver will discard these data.

Once the UART receives a matching address byte, it will assert the slave address detected (SAD = USR1[3]) bit and the *interrupt_uart* interrupt will be generated (if SADEN = UMCR[3] = 1). The address byte and sebsequent bytes are all put into RxFIFO along with their 9th bit. If receive ready DMA(RXDMAEN = UCR1[8]) request is enabled, the UART will also generate DMA request *dma_req_rx* when the RxFIFO reaches the selected threshold (controlled by RXTL).

If another address byte is received and this address byte does not match SLADDR character, the receiver will discard the address byte and subsequent data byte. If the address byte again matches SLADDR character, the receiver will put this address byte and subsequent data byte in the RxFIFO along with their 9th bit.

User should read the 9th databit (bit [8]) by reading the PRERR (URXD[10]) bit, and read data bit [7:0] by reading the RX_DATA (URXD[7:0]).

See Initialization for 9-bit RS-485 programming guide.

17.2.6 Low Power Modes

These modes are controlled by the signals *doze_req* and *stop_req*. The control/status/data registers won't change when getting in/out of low power modes.

Table 17-9. UART Low Power State Operation

	Normal State (*doze_req* = 1'b0 & *stop_req* = 1'b0)	Doze State (*doze_req* = 1'b1)		Stop State (*stop_req* = 1'b1)
		DOZE bit = 0	DOZE bit = 1	
UART-Clock	ON	ON	ON	OFF
UART Serial / IrDA	ON	ON	OFF	OFF

17.2.6.1 UART Operation in System Doze Mode

While in Doze State (when *doze_req* input pin is set to 1'b1), the UART behavior depends on the DOZE (UCR1[1]) control bit.

While the DOZE bit is negated, the UART serial interface is enabled. While the system is in the Doze State, and the DOZE bit is asserted, the UART is disabled. If the Doze State is entered with the DOZE bit asserted while the UART serial interface was receiving or transmitting data, it will complete the receive/transmit of the current character and signal to the far-end transmitter/receiver to stop sending/receiving.

17.2.6.2 UART Operation in System Stop Mode

The internal baud rate clocks of the transmitter and receiver are gated off if the *stop_req* signal to UART is asserted. Even though the clocks at the input of the UART continue to run during system Stop mode, the UART will not do any transmission or reception.

The following UART interrupts wake the Arm platform processor from STOP mode:

- RTS (RTSD)
- IrDA Asynchronous WAKE (AIRINT)
- Asynchronous WAKE (AWAKE)
- RI (RIDELT in DTE mode only)
- DCD (DCDDELT in DTE mode only)
- DTR (DTRD in DCE mode only)
- DSR (DTRD in DTE mode only)

When an asynchronous WAKE (awake) interrupt exits the Arm platform from STOP mode, make sure that a dummy character is sent first because the first character may not be received correctly.

17.2.6.3 Power Saving Method in UART

The RXEN (UCR2[1]), TXEN (UCR2[2]) and UARTEN (UCR1[0]) bits are set by the user and provide software control of low-power modes.

Setting the UARTEN (UCR1[0]) bit to 0 shuts off the receiver and transmitter logic and the associated clocks.

If the UART is used only in transmit mode, UARTEN and TXEN must be set to 1. If the UART is used only in receive mode, UARTEN and RXEN must be set to 1. Setting TXEN or RXEN to 0 allows to save a lot of power.

17.2.7 UART Operation in System Debug State

The bit UTS [11] controls whether the UART will respond to the input signal *debug_req*, or whether it will continue to run as normal.

If the UART is programmed to respond to *debug_req*:

1. The UART will halt all operations upon detecting the *debug_req* input.
2. A transfer in progress, either to/from a core (using the IP Bus interface) or to/from an external device, will be completed before halting. This means a single byte/word transfer, not an entire FIFO. Reception of any further data from an external device will be disabled.
3. Internal registers will continue to be writable and readable using the IP Bus interface. A read will leave the contents unaffected.
4. The RX FIFO is affected in debug mode in the following way:
   - All writes into the RX FIFO are prevented.
   - The bit RXDBG (UTS[9]) is used to select the readability of the RX FIFO during debug mode:

     RXDBG = 0: hold the read pointer at the location it had upon entering debug mode, and URXD register returns only the data value at that location, no matter how many reads attempted.

RXDBG = 1, selectable at any time: Allow to read the characters received in Rx FIFO. It will not be possible to re-read previously read locations, nor will it be possible to readjust the read pointer to the value it had prior to entering debug mode.

17.2.8 Reset

This section describes how to reset the block and explains special requirements related to reset.

17.2.8.1 Hardware reset

All of registers, FIFOs, state machines and sequential elements can be reset to their initial values by hardware reset or power on reset.

17.2.8.2 Software reset

The status registers USR1 and USR2, BRM registers UBIR and UBMR, TxFIFO and RxFIFO, and transmitter and receiver state machines can be reset by software reset. Internal logic will keep the software reset asserted for about 4 *module_clock* cycles.

Programmer can follow the following software reset sequence:

1. Clear the SRST_B bit (UCR2[0])
2. Wait for software reset complete: poll SOFTRST bit (UTS[0]) until it is 0.
3. Re-program baud rate registers: Re-write UBIR and UBMR.

17.2.9 Transfer Error

The UART can generate a transfer error on the peripheral bus in the following cases:

- Core is writing into a read-only register.
- Core is accessing (read or write) an unused location within the assigned address space reserved to UART.
- Core is writing into UTXD register with transmit interface disabled (TXEN=0 or UARTEN=0)
- Core is reading URXD register with receive interface disabled (RXEN=0 or UARTEN=0)

17.2.10 Functional Timing

This section includes timing diagrams for functional signaling.

17.2.10.1 IrDA Mode

According to IrDA specification, the low speed (115.2Kbit/s and below) IR frame format is compatible with UART frame.

In this figure, an example data 0x65 is used.

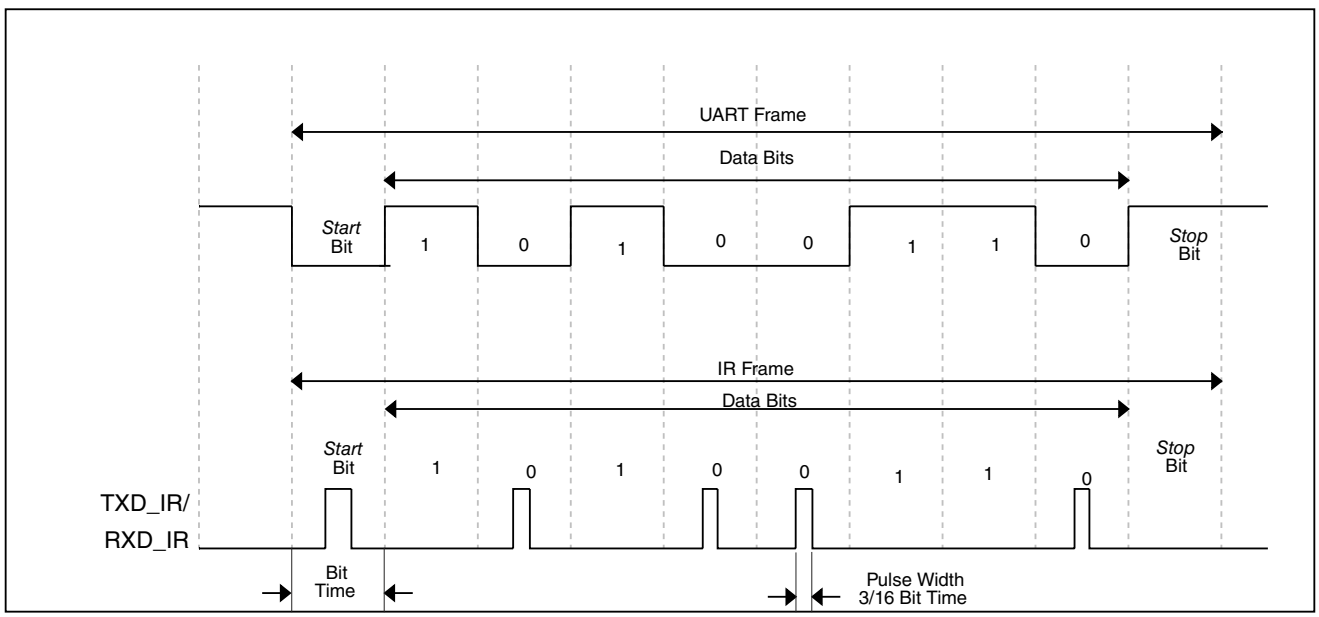

Figure 17-20. Timing diagram of Low Speed IR (<=115.2 Kbit/s) Data Line

17.2.11 External Signals

Tables that lists the conventions for representing signals and describing all UART signals that connect off-chip can be found here.

The chip-level IOMUX modifies the direction and routing of the UART signals based on whether the UART is operating in DCE mode (UARTn_UFCR[DCEDTE]=0) or DTE mode (UARTn_UFCR[DCEDTE]=1). The routing of the external signals to the UART module is shown in the figure below.

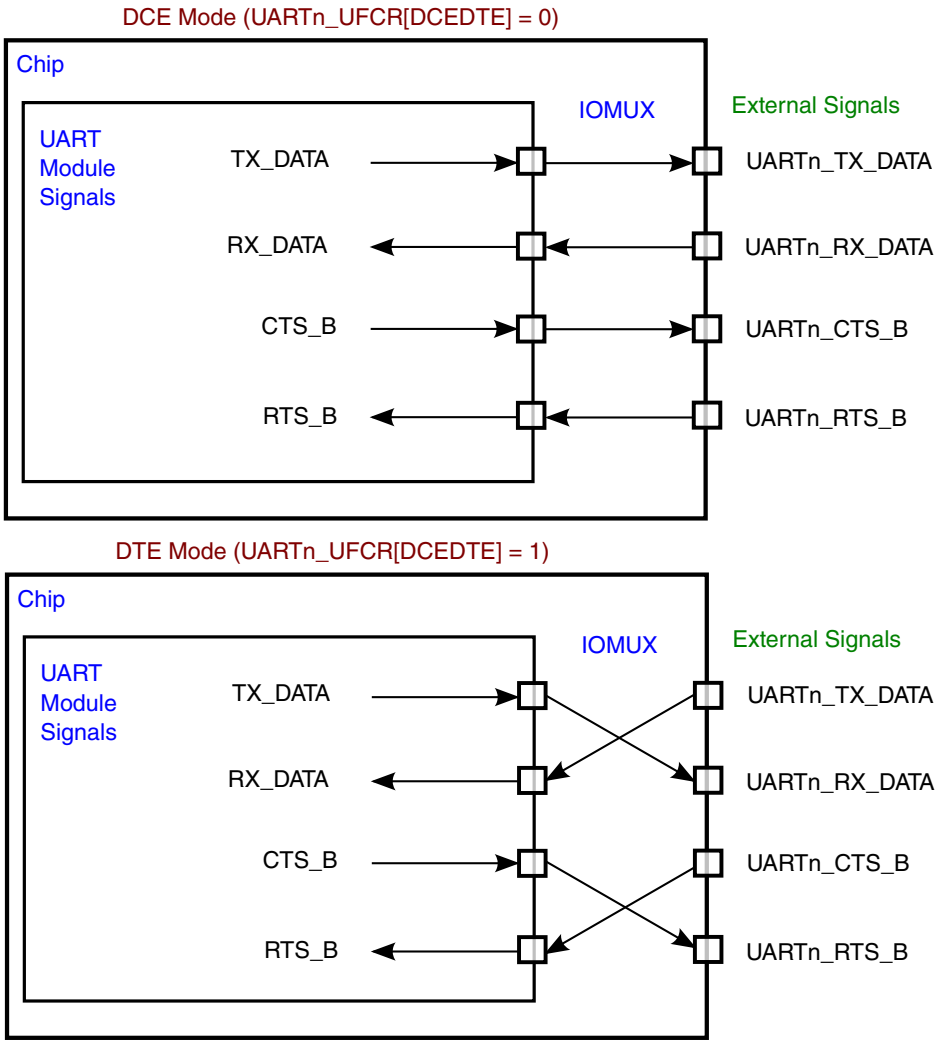

Figure 17-21. UART external signals to module signals routing with respect to DCE/DTE mode

The following tables describes the external signals of UART:

The user must configure the input path to the UART by properly configuring the DAISY bits in the IOMUXC_UARTn_RX_DATA_INPUT and the IOMUXC_UARTn_UART_RTS_B_SELECT_INPUT registers.

For IOMUXC_UARTn_UART_RTS_B_SELECT_INPUT[DAISY]:

- Configurations that select UARTn_RTS_B for the pad are only valid when UARTn_UFCR[DCEDTE]=0 (DCE mode)
- Configurations that select UARTn_CTS_B for the pad are only valid when UARTn_UFCR[DCEDTE]=1 (DTE mode)

For IOMUXC_UARTn_UART_RX_DATA_B_SELECT_INPUT[DAISY]:

- Configurations that select UARTn_RX_DATA for the pad are only valid when UARTn_UFCR[DCEDTE]=0 (DCE mode)
- Configurations that select UARTn_TX_DATA for the pad are only valid when UARTn_UFCR[DCEDTE]=1 (DTE mode)

17.2.11.1 Detailed Signal Descriptions

17.2.11.1.1 Interrupt Signals

17.2.11.1.1.1 *interrupt_uart* - UART Interrupt

Output interrupt request.

17.2.11.1.2 DMA Request Signals

17.2.11.1.2.1 *dma_req_rx* - Receiver DMA Request

Output DMA Request signal for receiver interface.

17.2.11.1.2.2 *dma_req_tx* - Transmitter DMA Request

Output DMA Request signal for transmitter interface. Set at 0 when TXDMAEN (UCR1[3]) is at 1 and TRDY (USR1[13]) is also at 1.

17.2.11.1.3 Special Signals

17.2.11.1.3.1 *stop_req* - Stop Mode

Input stop mode. Indicates to UART that Arm platform is going to enter in Stop Mode and clocks are going to stop running.

See Low Power Modes for more information about Stop Mode.

17.2.11.1.3.2 *doze_req* - Doze Mode

Input doze mode. Arm platform requests UART to switch in doze mode (power saving mode).

See Low Power Modes for more information about Doze Mode.

17.2.11.1.3.3 *debug_req* - Debug Mode

Input debug mode. Indicates UART it has to enter in debug mode.

See UART Operation in System Debug State, for more information about Debug Mode.

17.2.12 Initialization

17.2.12.1 Programming the UART in RS-232 mode

As an example, the following sequence can be used to program the UART in order to send and receive characters in RS-232 mode.

Assumptions:

- Input uart clock = 100 MHz
- Baud rate = 921.6 Kbps
- Data bits = 8 bits
- Parity = Even
- Stop bits = 1 bit
- Flow control = Hardware

Main program:

1. UCR1 = 0x0001

   Enable the UART.

2. UCR2 = 0x2127

   Set hardware flow control, data format and enable transmitter and receiver.

3. UCR3 = 0x0704

   Set UCR3[RXDMUXSEL] = 1.

4. UCR4 = 0x7C00

   Set CTS trigger level to 31,

5. UFCR = 0x089E

   Set internal clock divider = 5 (divide input uart clock by 5). So the reference clock is 100 MHz/5 = 20 MHz.

Set TXTL = 2 and RXTL = 30.

6. UBIR = 0x08FF
7. UBMR = 0x0C34

   In the above two steps, set baud rate to 921.6Kbps based on the 20MHz reference clock.

8. UCR1 = 0x2201

   Enable the TRDY and RRDY interrupts.

9. UMCR = 0x0000

   UMCR stay at default value 0x0000

Interrupt service routine for the transmitter:

- Write characters into UTXD

The TRDY interrupt will be automatically de-asserted when the data level of the TxFIFO exceeds the TXTL=2. Note: For the first time the interrupt may be de-asserted after 4 characters are written into the TxFIFO because of the shift register.

Interrupt service routine for the receiver:

- Read characters from URXD

The RRDY interrupt will be automatically de-asserted when the data level of the RxFIFO is below the RXTL=30.

17.2.12.2 Programming the UART in 9-bit RS-485 mode

As an example, the following sequence can be used to program the UART in order to send and receive frames in RS-485 mode.

Assumptions:

- Input uart clock = 100 MHz
- Baud rate = 5 Mbps

Main program:

1. UCR1 = 0x0001

   Enable the UART.

2. UCR2 = 0x4127

Set software flow control ($\overline{CTS}$ pin is controlled by UCR2[12]), enable parity(enable 9th bit rxd/txd), 8-bit word size , and enable transmitter and receiver.

3. UCR4 = 0x7C00

   Set CTS trigger level to 31,

4. UFCR = 0x0A9E

   Set RFDIV = 5 (divide input uart clock by 1), so the reference clock is 100 MHz. Set UART in DCE mode (RS-485 driver connection outside the chip is the same as Figure 17-19)

   Set TXTL = 2 and RXTL = 30.

5. UBIR = 0x0003
6. UBMR = 0x0004

   In the above two steps, set baud rate to 5 Mbps based on the 100 MHz reference clock.

7. UCR1 = 0x2001 when UART as a master ,

   or UCR1 = 0x0201 (or 0x0101) when UART as a slave.

   Enable TRDY interrupt when UART as a master, enable RRDY interrupt or DMA request when UART as a slave.

8. UMCR = 0xA50B

   Enable 9-bit RS-485 mode, enable SAD interrupt, set automatic slave address detect mode, set slave address is 0xA5.

Interrupt service routine for the transmitter:

- Transmit data: write its ninth bit (bit[8]) to UMCR[2], write its bit [7:0] into UTXD[7:0]

The TRDY interrupt will be automatically de-asserted when the data level of the TxFIFO exceeds the TXTL=2.

Note: For the first time the interrupt may be de-asserted after 4 characters are written into the TxFIFO because of the shift register.

Interrupt service routine for the receiver:

- Receive data: read its ninth bit (bit[8]) from URXD[10] , read its bit [7:0] from URXD[7:0].

Note: in RS-485 mode, URXD[10] bit is not the parity error, instead it holds the ninth bit (bit[8]) of the received data.

The SAD interrupt can not de-assert automatically, it needs MCU write 1 to USR1[3] to clear it . The RRDY interrupt or DMA request will be automatically de-asserted when the data level of the RxFIFO is below the RXTL=30.

17.2.14 UART Memory Map/Register Definition

UART supports 8-bit, 16-bit and 32-bit accesses to 32-bit memory-mapped addresses. Any access to unmapped memory location will yield a transfer error.

All registers except the ONEMS described in this section are 16-bit registers. The ONEMS register is a 24-bit register.

- For 32-bit write accesses, the upper two bytes will not be taken into account.
- For 32-bit read accesses the upper two bytes will return 0.

The ONEMS register is expanded from 16 bits to 24 bits in order to support the high frequency of the BRM internal clock *ref_clk* (*module_clock* after divider). The ONEMS register can be accessed as 8 bits, 16 bits or 32 bits.

- For 32-bit write accesses, the most significant byte of the ONEMS will be discarded.
- For 32-bit read accesses, the most significant byte of the ONEMS will be read as 0.

17.2.14.1 UART Receiver Register (UARTx_URXD)

NOTE

The UART will yield a transfer error on the peripheral bus when core is reading URXD register with receive interface disabled (RXEN=0 or UARTEN=0).

Address: Base address + 0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

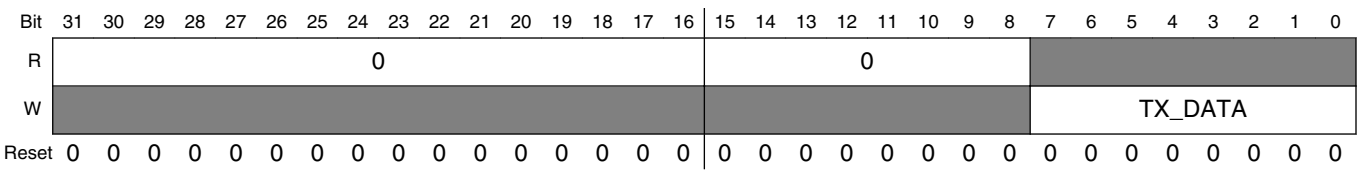
R	CHARRDY	ERR	OVRRUN	FRMERR	BRK	PRERR	Reserved		RX_DATA							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

UARTx_URXD field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 CHARRDY	Character Ready. This read-only bit indicates an invalid read when the FIFO becomes empty and software tries to read the same old data. This bit should not be used for polling for data written to the RX FIFO. 0 Character in RX_DATA field and associated flags are invalid. 1 Character in RX_DATA field and associated flags valid and ready for reading.
14 ERR	**Error Detect.** Indicates whether the character present in the RX_DATA field has an error (OVRRUN, FRMERR, BRK or PRERR) status. The ERR bit is updated and valid for each received character. 0 No error status was detected 1 An error status was detected
13 OVRRUN	**Receiver Overrun.** This read-only bit, when HIGH, indicates that the corresponding character was stored in the last position (32nd) of the Rx FIFO. Even if a 33rd character has not been detected, this bit will be set to '1' for the 32nd character. 0 No RxFIFO overrun was detected 1 A RxFIFO overrun was detected
12 FRMERR	**Frame Error.** Indicates whether the current character had a framing error (a missing stop bit) and is possibly corrupted. FRMERR is updated for each character read from the RxFIFO. 0 The current character has no framing error 1 The current character has a framing error
11 BRK	**BREAK Detect.** Indicates whether the current character was detected as a BREAK character. The data bits and the stop bit are all 0. The FRMERR bit is set when BRK is set. When odd parity is selected, PRERR is also set when BRK is set. BRK is valid for each character read from the RxFIFO. 0 The current character is not a BREAK character 1 The current character is a BREAK character
10 PRERR	**In RS-485 mode, it holds the ninth data bit (bit [8]) of received 9-bit RS-485 data** **In RS232/IrDA mode, it is the Parity Error flag**. Indicates whether the current character was detected with a parity error and is possibly corrupted. PRERR is updated for each character read from the RxFIFO. When parity is disabled, PRERR always reads as 0. 0 = No parity error was detected for data in the RX_DATA field 1 = A parity error was detected for data in the RX_DATA field
9–8 -	This field is reserved. **Reserved**
RX_DATA	**Received Data**. Holds the received character. In 7-bit mode, the most significant bit (MSB) is forced to 0. In 8-bit mode, all bits are active.



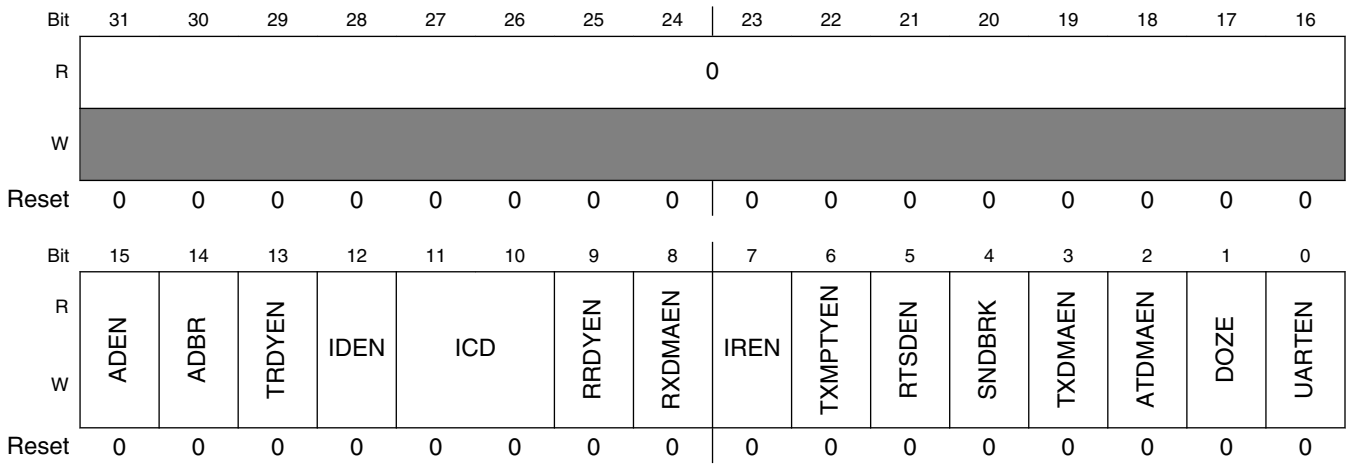
17.2.14.2 UART Transmitter Register (UARTx_UTXD)

NOTE

The UART will yield a transfer error on the peripheral bus when core is writing into UART_URXD register with transmit interface disabled (TXEN=0 or UARTEN=0).

Memory space between UART_URXD and UART_UTXD registers is reserved. Any read or write access to this space will be considered as an invalid access and yield a transfer error.

Address: Base address + 40h offset



UARTx_UTXD field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–8 Reserved	This read-only field is reserved and always has the value 0.
TX_DATA	**Transmit Data**. Holds the parallel transmit data inputs. In 7-bit mode, D7 is ignored. In 8-bit mode, all bits are used. Data is transmitted least significant bit (LSB) first. A new character is transmitted when the TX_DATA field is written. The TX_DATA field must be written only when the TRDY bit is high to ensure that corrupted data is not sent.

17.2.14.3 UART Control Register 1 (UARTx_UCR1)

Address: Base address + 80h offset

UARTx_UCR1 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 ADEN	**Automatic Baud Rate Detection Interrupt Enable**. Enables/Disables the automatic baud rate detect complete (ADET) bit to generate an interrupt (*interrupt_uart* = 0). 0 Disable the automatic baud rate detection interrupt 1 Enable the automatic baud rate detection interrupt
14 ADBR	**Automatic Detection of Baud Rate**. Enables/Disables automatic baud rate detection. When the ADBR bit is set and the ADET bit is cleared, the receiver detects the incoming baud rate automatically. The ADET flag is set when the receiver verifies that the incoming baud rate is detected properly by detecting an ASCII character "A" or "a" (0x41 or 0x61). 0 Disable automatic detection of baud rate 1 Enable automatic detection of baud rate
13 TRDYEN	**Transmitter Ready Interrupt Enable**. Enables/Disables the transmitter Ready Interrupt (TRDY) when the transmitter has one or more slots available in the TxFIFO. The fill level in the TXFIFO at which an interrupt is generated is controlled by TxTL bits. When TRDYEN is negated, the transmitter ready interrupt is disabled. **NOTE:** An interrupt will be issued as long as TRDYEN and TRDY are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TRDY interrupt. 0 Disable the transmitter ready interrupt 1 Enable the transmitter ready interrupt
12 IDEN	**Idle Condition Detected Interrupt Enable**. Enables/Disables the IDLE bit to generate an interrupt (*interrupt_uart* = 0). 0 Disable the IDLE interrupt 1 Enable the IDLE interrupt

Table continues on the next page...

UARTx_UCR1 field descriptions (continued)

Field	Description
11–10 ICD	**Idle Condition Detect**. Controls the number of frames RXD is allowed to be idle before an idle condition is reported. 00 Idle for more than 4 frames 01 Idle for more than 8 frames 10 Idle for more than 16 frames 11 Idle for more than 32 frames
9 RRDYEN	**Receiver Ready Interrupt Enable**. Enables/Disables the RRDY interrupt when the RxFIFO contains data. The fill level in the RxFIFO at which an interrupt is generated is controlled by the RXTL bits. When RRDYEN is negated, the receiver ready interrupt is disabled. 0 Disables the RRDY interrupt 1 Enables the RRDY interrupt
8 RXDMAEN	**Receive Ready DMA Enable**. Enables/Disables the receive DMA request *dma_req_rx* when the receiver has data in the RxFIFO. The fill level in the RxFIFO at which a DMA request is generated is controlled by the RXTL bits. When negated, the receive DMA request is disabled. 0 Disable DMA request 1 Enable DMA request
7 IREN	**Infrared Interface Enable**. Enables/Disables the IR interface. See the IR interface description in Infrared Interface, for more information. Note: MDEN(UMCR[0]) must be cleared to 0 when using IrDA interface. See Table 17-2 0 Disable the IR interface 1 Enable the IR interface
6 TXMPTYEN	**Transmitter Empty Interrupt Enable**. Enables/Disables the transmitter FIFO empty (TXFE) interrupt. *interrupt_uart*. When negated, the TXFE interrupt is disabled. **NOTE:** An interrupt will be issued as long as TXMPTYEN and TXFE are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TXFE interrupt. 0 Disable the transmitter FIFO empty interrupt 1 Enable the transmitter FIFO empty interrupt
5 RTSDEN	**RTS Delta Interrupt Enable**. Enables/Disables the RTSD interrupt. The current status of the RTS_B pin is read in the RTSS bit. 0 Disable RTSD interrupt 1 Enable RTSD interrupt
4 SNDBRK	**Send BREAK**. Forces the transmitter to send a BREAK character. The transmitter finishes sending the character in progress (if any) and sends BREAK characters until SNDBRK is reset. Because the transmitter samples SNDBRK after every bit is transmitted, it is important that SNDBRK is asserted high for a sufficient period of time to generate a valid BREAK. After the BREAK transmission completes, the UART transmits 2 mark bits. The user can continue to fill the TxFIFO and any characters remaining are transmitted when the BREAK is terminated. 0 Do not send a BREAK character 1 Send a BREAK character (continuous 0s)
3 TXDMAEN	**Transmitter Ready DMA Enable**. Enables/Disables the transmit DMA request *dma_req_tx* when the transmitter has one or more slots available in the TxFIFO. The fill level in the TxFIFO that generates the *dma_req_tx* is controlled by the TXTL bits.

Table continues on the next page...

UARTx_UCR1 field descriptions (continued)

Field	Description
	NOTE: A DMA request will be issued as long as TXDMAEN and TRDY are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the transmit DMA request. 0 Disable transmit DMA request 1 Enable transmit DMA request
2 ATDMAEN	**Aging DMA Timer Enable**. Enables/Disables the receive DMA request *dma_req_rx* for the aging timer interrupt (triggered with AGTIM flag in USR1[8]). 0 Disable AGTIM DMA request 1 Enable AGTIM DMA request
1 DOZE	**DOZE**. Determines the UART enable condition in the DOZE state. When *doze_req* input pin is at '1', (the Arm Platform executes a doze instruction and the system is placed in the Doze State), the DOZE bit affects operation of the UART. While in the Doze State, if this bit is asserted, the UART is disabled. See the description in Low Power Modes. 0 The UART is enabled when in DOZE state 1 The UART is disabled when in DOZE state
0 UARTEN	**UART Enable**. Enables/Disables the UART. If UARTEN is negated in the middle of a transmission, the transmitter stops and pulls the TXD line to a logic 1. UARTEN must be set to 1 before any access to UTXD and URXD registers, otherwise a transfer error is returned. This bit can be set to 1 along with other bits in this register. There is no restriction to the sequence of programing this bit and other control registers. 0 Disable the UART 1 Enable the UART

17.2.14.4 UART Control Register 2 (UARTx_UCR2)

Address: Base address + 84h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ESCI	IRTS	CTSC	CTS	ESCEN	RTEC		PREN	PROE	STPB	WS	RTSEN	ATEN	TXEN	RXEN	SRST
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

UARTx_UCR2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 ESCI	**Escape Sequence Interrupt Enable**. Enables/Disables the ESCF bit to generate an interrupt. 0 Disable the escape sequence interrupt 1 Enable the escape sequence interrupt
14 IRTS	**Ignore RTS Pin**. Forces the RTS input signal presented to the transmitter to always be asserted (set to low), effectively ignoring the external pin. When in this mode, the RTS pin serves as a general purpose input. 0 Transmit only when the RTS pin is asserted 1 Ignore the RTS pin
13 CTSC	CTS **Pin Control**. Controls the operation of the CTS_B module output. When CTSC is asserted, the CTS_B module output is controlled by the receiver. When the RxFIFO is filled to the level of the programmed trigger level and the start bit of the overflowing character (TRIGGER LEVEL + 1) is validated, the CTS_B module output is negated to indicate to the far-end transmitter to stop transmitting. When the trigger level is programmed for less than 32, the receiver continues to receive data until the RxFIFO is full. When the CTSC bit is negated, the CTS_B module output is controlled by the CTS bit. On reset, because CTSC is cleared to 0, the CTS_B pin is controlled by the CTS bit, which again is cleared to 0 on reset. This means that on reset the CTS_B signal is negated. 0 The CTS_B pin is controlled by the CTS bit 1 The CTS_B pin is controlled by the receiver
12 CTS	**Clear to Send**. Controls the CTS_B pin when the CTSC bit is negated. CTS has no function when CTSC is asserted. 0 The CTS_B pin is high (inactive) 1 The CTS_B pin is low (active)
11 ESCEN	**Escape Enable**. Enables/Disables the escape sequence detection logic. 0 Disable escape sequence detection 1 Enable escape sequence detection
10–9 RTEC	**Request to Send Edge Control**. Selects the edge that triggers the RTS interrupt. This has no effect on the RTS delta interrupt. RTEC has an effect only when RTSEN = 1 (see Table 17-4). 00 Trigger interrupt on a rising edge 01 Trigger interrupt on a falling edge 1X Trigger interrupt on any edge
8 PREN	**Parity Enable**. Enables/Disables the parity generator in the transmitter and parity checker in the receiver. When PREN is asserted, the parity generator and checker are enabled, and disabled when PREN is negated. 0 Disable parity generator and checker 1 Enable parity generator and checker
7 PROE	**Parity Odd/Even**. Controls the sense of the parity generator and checker. When PROE is high, odd parity is generated and expected. When PROE is low, even parity is generated and expected. PROE has no function if PREN is low. 0 Even parity 1 Odd parity

Table continues on the next page...

UARTx_UCR2 field descriptions (continued)

Field	Description
6 STPB	**Stop**. Controls the number of stop bits after a character. When STPB is low, 1 stop bit is sent. When STPB is high, 2 stop bits are sent. STPB also affects the receiver. 0 The transmitter sends 1 stop bit. The receiver expects 1 or more stop bits. 1 The transmitter sends 2 stop bits. The receiver expects 2 or more stop bits.
5 WS	**Word Size**. Controls the character length. When WS is high, the transmitter and receiver are in 8-bit mode. When WS is low, they are in 7-bit mode. The transmitter ignores bit 7 and the receiver sets bit 7 to 0. WS can be changed in-between transmission (reception) of characters, however not when a transmission (reception) is in progress, in which case the length of the current character being transmitted (received) is unpredictable. 0 7-bit transmit and receive character length (not including START, STOP or PARITY bits) 1 8-bit transmit and receive character length (not including START, STOP or PARITY bits)
4 RTSEN	**Request to Send Interrupt Enable.** Controls the RTS edge sensitive interrupt. When RTSEN is asserted and the programmed edge is detected on the RTS_B pin (the RTSF bit is asserted), an interrupt will be generated on the *interrupt_uart* pin. (See Table 17-4.) 0 Disable request to send interrupt 1 Enable request to send interrupt
3 ATEN	**Aging Timer Enable**. This bit is used to enable the aging timer interrupt (triggered with AGTIM) 0 AGTIM interrupt disabled 1 AGTIM interrupt enabled
2 TXEN	**Transmitter Enable**. Enables/Disables the transmitter. When TXEN is negated the transmitter is disabled and idle. When the UARTEN and TXEN bits are set the transmitter is enabled. If TXEN is negated in the middle of a transmission, the UART disables the transmitter immediately, and starts marking 1s. The transmitter FIFO cannot be written when this bit is cleared. 0 Disable the transmitter 1 Enable the transmitter
1 RXEN	**Receiver Enable**. Enables/Disables the receiver. When the receiver is enabled, if the RXD input is already low, the receiver does not recognize BREAK characters, because it requires a valid 1-to-0 transition before it can accept any character. 0 Disable the receiver 1 Enable the receiver
0 SRST	**Software Reset**. Once the software writes 0 to SRST_B, the software reset remains active for 4 *module_clock* cycles before the hardware deasserts SRST_B. The software can only write 0 to SRST_B. Writing 1 to SRST_B is ignored. 0 Reset the transmit and receive state machines, all FIFOs and register USR1, USR2, UBIR, UBMR, UBRC , URXD, UTXD and UTS[6-3]. 1 No reset

17.2.14.5 UART Control Register 3 (UARTx_UCR3)

Address: Base address + 88h offset

UARTx_UCR3 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–14 DPEC	This bit is not used in this chip.
13 DTREN	This bit is not used in this chip.
12 PARERREN	**Parity Error Interrupt Enable. Enables/Disables the interrupt. When asserted, PARERREN causes the PARITYERR bit to generate an interrupt.** 0 Disable the parity error interrupt 1 Enable the parity error interrupt
11 FRAERREN	**Frame Error Interrupt Enable. Enables/Disables the interrupt. When asserted, FRAERREN causes the FRAMERR bit to generate an interrupt.** 0 Disable the frame error interrupt 1 Enable the frame error interrupt
10 DSR	This bit is not used in this chip.
9 DCD	This bit is not used in this chip.
8 RI	This bit is not used in this chip.
7 ADNIMP	**Autobaud Detection Not Improved-. Disables new features of autobaud detection (See Baud Rate Automatic Detection Protocol, for more details).** 0 Autobaud detection new features selected 1 Keep old autobaud detection mechanism

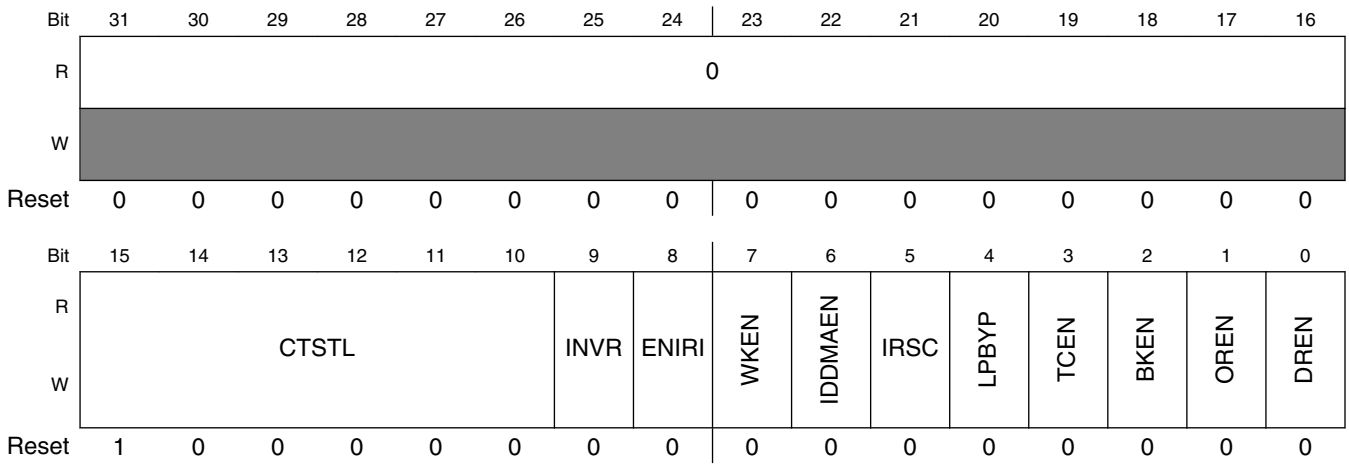

Table continues on the next page...

UARTx_UCR3 field descriptions (continued)

Field	Description
6 RXDSEN	Receive Status Interrupt Enable. Controls the receive status interrupt (*interrupt_uart*). When this bit is enabled and RXDS status bit is set, the interrupt *interrupt_uart* will be generated. 0 Disable the RXDS interrupt 1 Enable the RXDS interrupt
5 AIRINTEN	Asynchronous IR WAKE Interrupt Enable. Controls the asynchronous IR WAKE interrupt. An interrupt is generated when AIRINTEN is asserted and a pulse is detected on the RXD pin. 0 Disable the AIRINT interrupt 1 Enable the AIRINT interrupt
4 AWAKEN	Asynchronous WAKE Interrupt Enable. Controls the asynchronous WAKE interrupt. An interrupt is generated when AWAKEN is asserted and a falling edge is detected on the RXD pin. 0 Disable the AWAKE interrupt 1 Enable the AWAKE interrupt
3 DTRDEN	This bit is not used in this chip.
2 RXDMUXSEL	RXD Muxed Input Selected. Selects proper input pins for serial and Infrared input signal. **NOTE:** In this chip, UARTs are used in MUXED mode, so that this bit should always be set.
1 INVT	Invert TXD output in RS-232/RS-485 mode, set TXD active level in IrDA mode. In RS232/RS-485 mode(UMCR[0] = 1), if this bit is set to 1, the TXD output is inverted before transmitted. In **IrDA mode**, when INVT is cleared, the infrared logic block transmits a positive IR 3/16 pulse for all 0s and 0s are transmitted for 1s. When INVT is set (INVT = 1), the infrared logic block transmits an active low or negative infrared 3/16 pulse for all 0s and 1s are transmitted for 1s. 0 **TXD is not inverted** 1 **TXD is inverted** 0 **TXD** Active low transmission 1 **TXD** Active high transmission
0 ACIEN	**Autobaud Counter Interrupt Enable.** This bit is used to enable the autobaud counter stopped interrupt (triggered with ACST (USR2[11]). 0 ACST interrupt disabled 1 ACST interrupt enabled

17.2.14.6 UART Control Register 4 (UARTx_UCR4)

Address: Base address + 8Ch offset

UARTx_UCR4 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–10 CTSTL	**CTS Trigger Level**. Controls the threshold at which the CTS_B pin is deasserted by the RxFIFO. After the trigger level is reached and the CTS_B pin is deasserted, the RxFIFO continues to receive data until it is full. The CTSTL bits are encoded as shown in the Settings column. Settings 0 to 32 are in use. All other settings are Reserved. 000000 0 characters received 000001 1 characters in the RxFIFO ... — ... — 100000 32 characters in the RxFIFO (maximum)
9 INVR	**Invert RXD input in RS-232/RS-485 Mode, d**etermine **RXD input** logic level being sampled in **In IrDA mode.** **In RS232/RS-485 Mode(UMCR[0] = 1), if this bit is set to 1, the RXD input is inverted before sampled.** **In IrDA mode**,when cleared, the infrared logic block expects an active low or negative IR 3/16 pulse for 0s and 1s are expected for 1s. When INVR is set (INVR 1), the infrared logic block expects an active high or positive IR 3/16 pulse for 0s and 0s are expected for 1s. 0 **RXD input is not inverted** 1 **RXD input is inverted** 0 **RXD** active low detection 1 **RXD** active high detection
8 ENIRI	**Serial Infrared Interrupt Enable**. Enables/Disables the serial infrared interrupt. 0 Serial infrared Interrupt disabled 1 Serial infrared Interrupt enabled

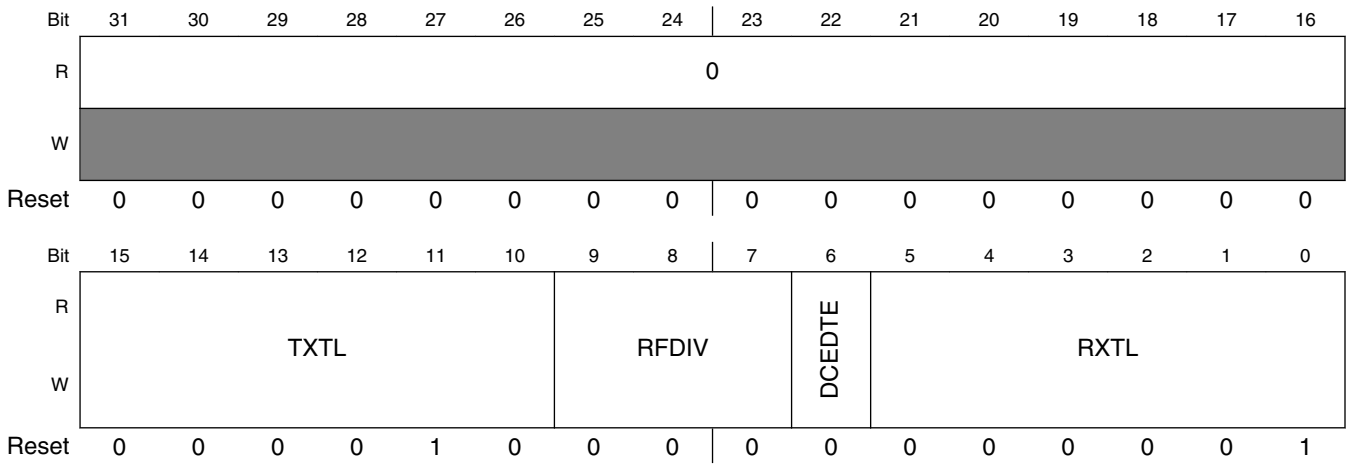

Table continues on the next page...

UARTx_UCR4 field descriptions (continued)

Field	Description
7 WKEN	**WAKE Interrupt Enable**. Enables/Disables the WAKE bit to generate an interrupt. The WAKE bit is set at the detection of a start bit by the receiver. 0 Disable the WAKE interrupt 1 Enable the WAKE interrupt
6 IDDMAEN	**DMA IDLE Condition Detected Interrupt Enable** Enables/Disables the receive DMA request *dma_req_rx* for the IDLE interrupt (triggered with IDLE flag in USR2[12]). 0 DMA IDLE interrupt disabled 1 DMA IDLE interrupt enabled
5 IRSC	**IR Special Case**. Selects the clock for the vote logic. When set, IRSC switches the vote logic clock from the sampling clock to the UART reference clock. The IR pulses are counted a predetermined amount of time depending on the reference frequency. See InfraRed Special Case (IRSC) Bit. 0 The vote logic uses the sampling clock (16x baud rate) for normal operation 1 The vote logic uses the UART reference clock
4 LPBYP	**Low Power Bypass**. Allows to bypass the low power new features in UART. To use during debug phase. 0 Low power features enabled 1 Low power features disabled
3 TCEN	**TransmitComplete Interrupt Enable**. Enables/Disables the TXDC bit to generate an interrupt (*interrupt_uart* = 0) **NOTE:** An interrupt will be issued as long as TCEN and TXDC are high even if the transmitter is not enabled. In general, user should enable the transmitter before enabling the TXDC interrupt. 0 Disable TXDC interrupt 1 Enable TXDC interrupt
2 BKEN	**BREAK Condition Detected Interrupt Enable**. Enables/Disables the BRCD bit to generate an interrupt. 0 Disable the BRCD interrupt 1 Enable the BRCD interrupt
1 OREN	**Receiver Overrun Interrupt Enable**. Enables/Disables the ORE bit to generate an interrupt. 0 Disable ORE interrupt 1 Enable ORE interrupt
0 DREN	**Receive Data Ready Interrupt Enable**. Enables/Disables the RDR bit to generate an interrupt. 0 Disable RDR interrupt 1 Enable RDR interrupt

17.2.14.7 UART FIFO Control Register (UARTx_UFCR)

Address: Base address + 90h offset

UARTx_UFCR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–10 TXTL	**Transmitter Trigger Level**. Controls the threshold at which a maskable interrupt is generated by the TxFIFO. A maskable interrupt is generated whenever the data level in the TxFIFO falls below the selected threshold. The bits are encoded as shown in the Settings column. Settings 0 to 32 are in use. All other settings are Reserved. 000000 Reserved 000001 Reserved 000010 TxFIFO has 2 or fewer characters ... — ... — 011111 TxFIFO has 31 or fewer characters 100000 TxFIFO has 32 characters (maximum)
9–7 RFDIV	Reference Frequency Divider. Controls the divide ratio for the reference clock. The input clock is *module_clock*. The output from the divider is *ref_clk* which is used by BRM to create the 16x baud rate oversampling clock (*brm_clk*). 000 Divide input clock by 6 001 Divide input clock by 5 010 Divide input clock by 4 011 Divide input clock by 3 100 Divide input clock by 2 101 Divide input clock by 1 110 Divide input clock by 7 111 Reserved
6 DCEDTE	**DCE/DTE mode select**. Select UART as data communication equipment (DCE mode) or as data terminal equipment (DTE mode).

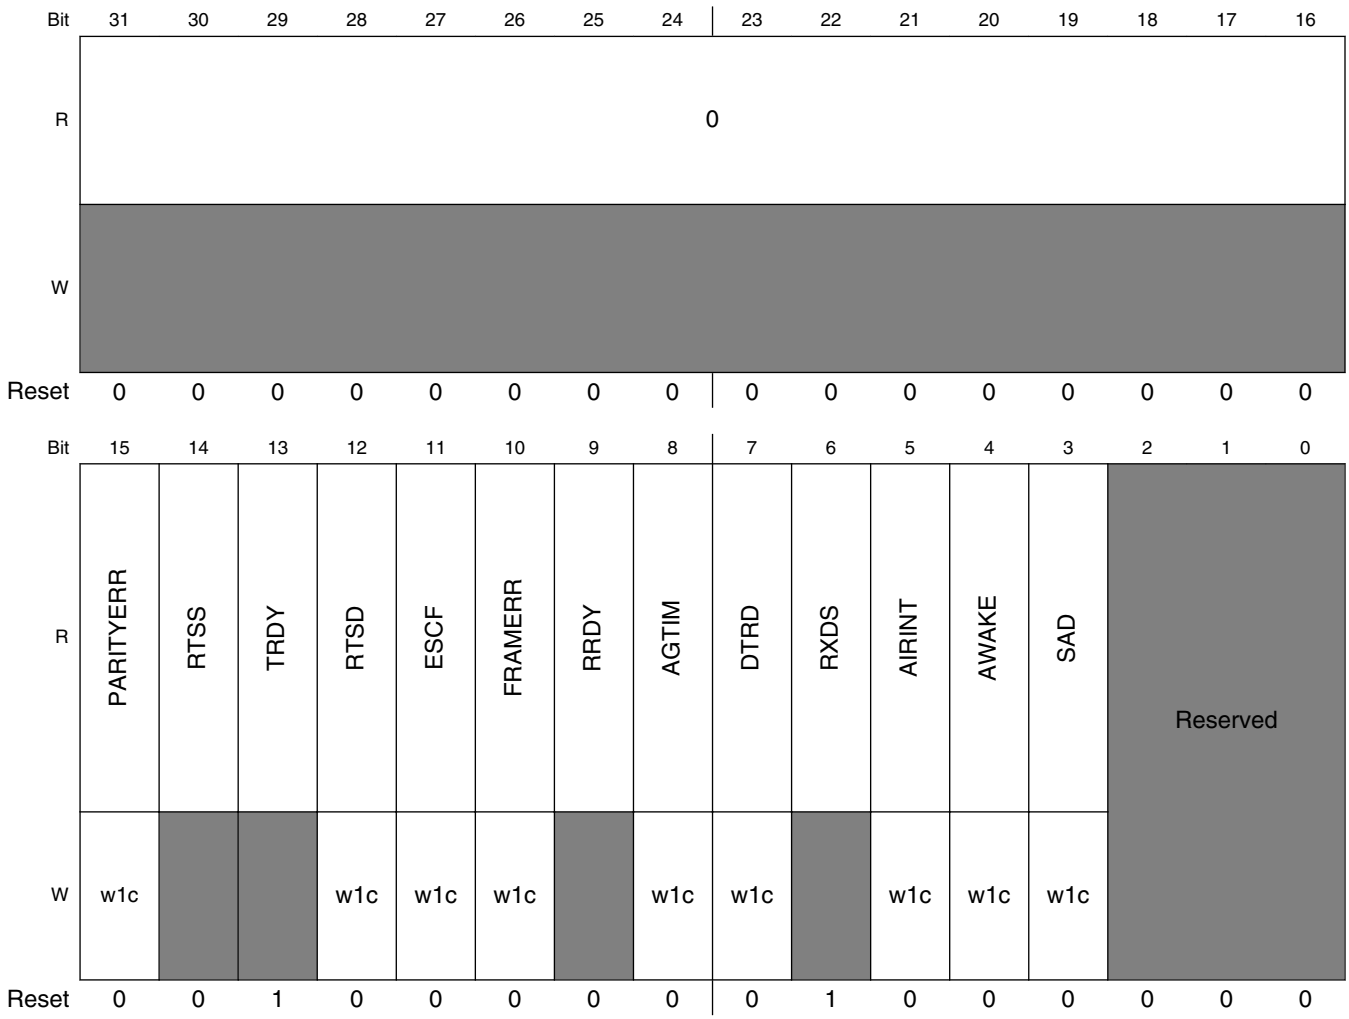

Table continues on the next page...

UARTx_UFCR field descriptions (continued)

Field	Description
	0 DCE mode selected 1 DTE mode selected
RXTL	**Receiver Trigger Level**. Controls the threshold at which a maskable interrupt is generated by the RxFIFO. A maskable interrupt is generated whenever the data level in the RxFIFO reaches the selected threshold. The RXTL bits are encoded as shown in the Settings column. Setting 0 to 32 are in use. All other settings are Reserved. 000000 0 characters received 000001 RxFIFO has 1 character ... — ... — 011111 RxFIFO has 31 characters 100000 RxFIFO has 32 characters (maximum)

17.2.14.8 UART Status Register 1 (UARTx_USR1)

Address: Base address + 94h offset

UARTx_USR1 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 PARITYERR	**Parity Error Interrupt Flag**. Indicates a parity error is detected. PARITYERR is cleared by writing 1 to it. Writing 0 to PARITYERR has no effect. When parity is disabled, PARITYERR always reads 0. At reset, PARITYERR is set to 0. 0 No parity error detected 1 Parity error detected (write 1 to clear)
14 RTSS	RTS_B **Pin Status**. Indicates the current status of the RTS_B pin. A "snapshot" of RTS_B is taken immediately before RTSS is presented to the data bus. RTSS cannot be cleared because all writes to RTSS are ignored. At reset, RTSS is set to 0.

Table continues on the next page...

UARTx_USR1 field descriptions (continued)

Field	Description
	0 The RTS_B module input is high (inactive) 1 The RTS_B module input is low (active)
13 TRDY	**Transmitter Ready Interrupt / DMA Flag**. Indicates that the TxFIFO emptied below its target threshold and requires data. TRDY is automatically cleared when the data level in the TxFIFO exceeds the threshold set by TXTL bits. At reset, TRDY is set to 1. 0 The transmitter does not require data 1 The transmitter requires data (interrupt posted)
12 RTSD	**RTS Delta.** Indicates whether the RTS_B pin changed state. It (RTSD) generates a maskable interrupt. When in STOP mode, RTS assertion sets RTSD and can be used to wake the processor. The current state of the RTS_B pin is available on the RTSS bit. Clear RTSD by writing 1 to it. Writing 0 to RTSD has no effect. At reset, RTSD is set to 0. 0 RTS_B pin did not change state since last cleared 1 RTS_B pin changed state (write 1 to clear)
11 ESCF	**Escape Sequence Interrupt Flag**. Indicates if an escape sequence was detected. ESCF is asserted when the ESCEN bit is set and an escape sequence is detected in the RxFIFO. Clear ESCF by writing 1 to it. Writing 0 to ESCF has no effect. 0 No escape sequence detected 1 Escape sequence detected (write 1 to clear).
10 FRAMERR	**Frame Error Interrupt Flag**. Indicates that a frame error is detected. The *interrupt_uart* interrupt will be generated if a frame error is detected and the interrupt is enabled. Clear FRAMERR by writing 1 to it. Writing 0 to FRAMERR has no effect. 0 No frame error detected 1 Frame error detected (write 1 to clear)
9 RRDY	**Receiver Ready Interrupt / DMA Flag**. Indicates that the RxFIFO data level is above the threshold set by the RXTL bits. (See the RXTL bits description in UART FIFO Control Register (UART_UFCR) for setting the interrupt threshold.) When asserted, RRDY generates a maskable interrupt or DMA request. RRDY is automatically cleared when data level in the RxFIFO goes below the set threshold level. At reset, RRDY is set to 0. 0 No character ready 1 Character(s) ready (interrupt posted)
8 AGTIM	Ageing Timer Interrupt Flag. Indicates that data in the RxFIFO has been idle for a time of 8 character lengths (where a character length consists of 7 or 8 bits, depending on the setting of the WS bit in UCR2, with the bit time corresponding to the baud rate setting) and FIFO data level is less than RxFIFO threshold level (RXTL in the UFCR). Clear by writing a 1 to it. 0 AGTIM is not active 1 AGTIM is active (write 1 to clear)
7 DTRD	This bit is not used in this chip.
6 RXDS	Receiver IDLE Interrupt Flag. Indicates that the receiver state machine is in an IDLE state, the next state is IDLE, and the receive pin is high. RXDS is automatically cleared when a character is received. RXDS is active only when the receiver is enabled. 0 Receive in progress 1 Receiver is IDLE

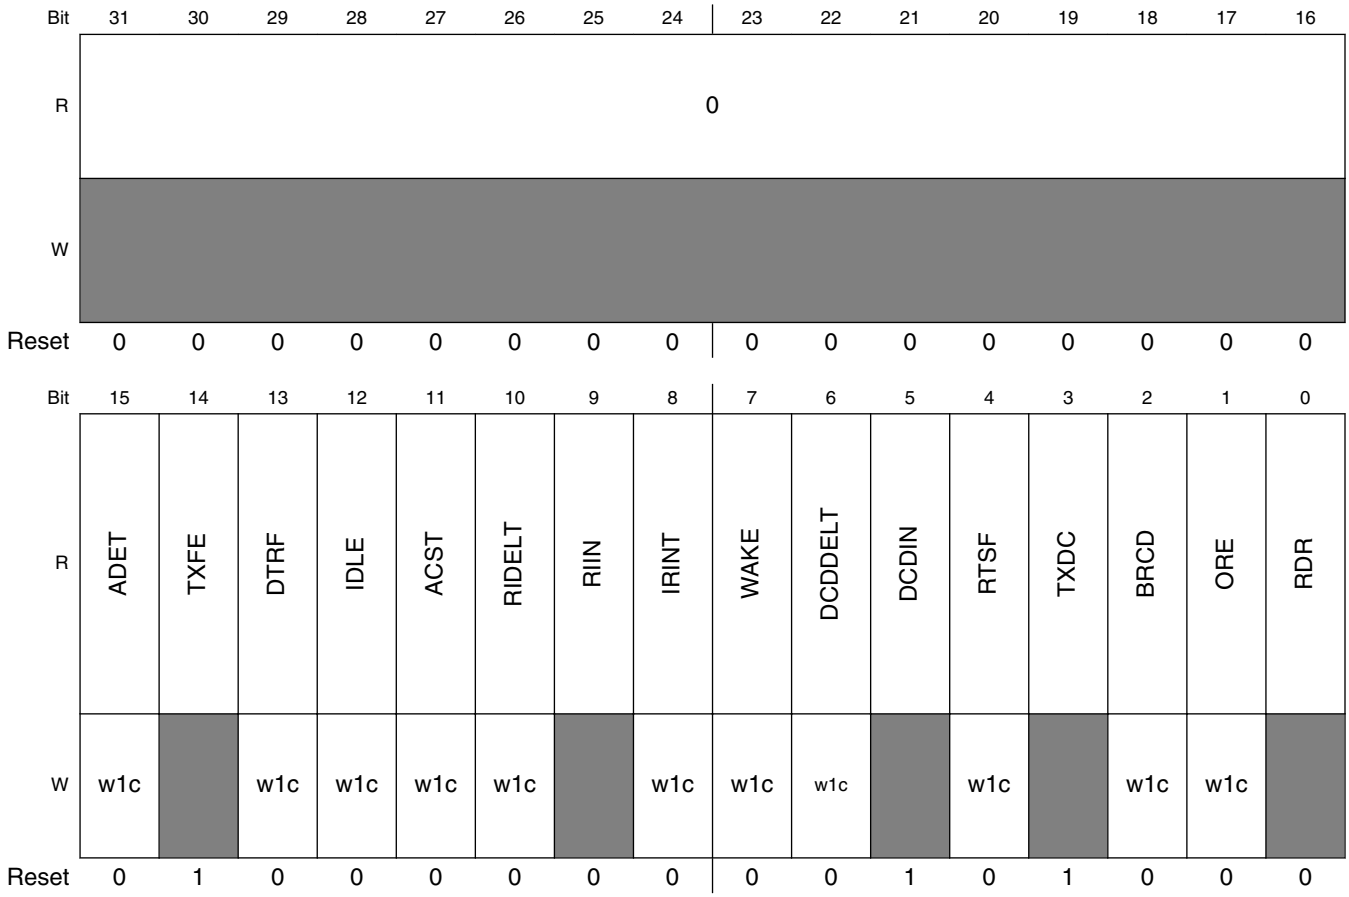

Table continues on the next page...

UARTx_USR1 field descriptions (continued)

Field	Description
5 AIRINT	Asynchronous IR WAKE Interrupt Flag. Indicates that the IR WAKE pulse was detected on the RXD pin. Clear AIRINT by writing 1 to it. Writing 0 to AIRINT has no effect. 0 No pulse was detected on the RXD IrDA pin 1 A pulse was detected on the RXD IrDA pin
4 AWAKE	Asynchronous WAKE Interrupt Flag. Indicates that a falling edge was detected on the RXD pin. Clear AWAKE by writing 1 to it. Writing 0 to AWAKE has no effect. 0 No falling edge was detected on the RXD Serial pin 1 A falling edge was detected on the RXD Serial pin
3 SAD	RS-485 Slave Address Detected Interrupt Flag. Indicates if RS-485 Slave Address was detected . SAD was asserted in RS-485 mode when the SADEN bit is set and Slave Address is detected in RxFIFO (in Nomal Address Detect Mode, the 9th data bit = 1; in Automatic Address Detect Mode, the received charater matches the programmed SLADDR). 0 No slave address detected 1 Slave address detected
-	This field is reserved. Reserved

17.2.14.9 UART Status Register 2 (UARTx_USR2)

Address: Base address + 98h offset

UARTx_USR2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15 ADET	**Automatic Baud Rate Detect Complete**. Indicates that an "A" or "a" was received and that the receiver detected and verified the incoming baud rate. Clear ADET by writing 1 to it. Writing 0 to ADET has no effect. 0 ASCII "A" or "a" was not received 1 ASCII "A" or "a" was received (write 1 to clear)
14 TXFE	**Transmit Buffer FIFO Empty**. Indicates that the transmit buffer (TxFIFO) is empty. TXFE is cleared automatically when data is written to the TxFIFO. Even though TXFE is high, the transmission might still be in progress. 0 The transmit buffer (TxFIFO) is not empty 1 The transmit buffer (TxFIFO) is empty
13 DTRF	This bit is not used in this chip.

Table continues on the next page...

UARTx_USR2 field descriptions (continued)

Field	Description
12 IDLE	**Idle Condition**. Indicates that an idle condition has existed for more than a programmed amount frame (see Idle Line Detect. An interrupt can be generated by this IDLE bit if IDEN (UCR1[12]) is enabled. IDLE is cleared by writing 1 to it. Writing 0 to IDLE has no effect. 0 No idle condition detected 1 Idle condition detected (write 1 to clear)
11 ACST	**Autobaud Counter Stopped**. In autobaud detection (ADBR=1), indicates the counter which determines the baud rate was running and is now stopped. This means either START bit is finished (if ADNIMP=1), or Bit 0 is finished (if ADNIMP=0). See New Autobaud Counter Stopped bit and Interrupt, for more details. An interrupt can be flagged on *interrupt_uart* if ACIEN=1. 0 Measurement of bit length not finished (in autobaud) 1 Measurement of bit length finished (in autobaud). (write 1 to clear)
10 RIDELT	This bit is not used in this chip.
9 RIIN	This bit is not used in this chip.
8 IRINT	**Serial Infrared Interrupt Flag.** When an edge is detected on the RXD pin during SIR Mode, this flag will be asserted. This flag can cause an interrupt which can be masked using the control bit ENIRI: UCR4 [8]. 0 no edge detected 1 valid edge detected (write 1 to clear)
7 WAKE	**Wake**. Indicates the start bit is detected. WAKE can generate an interrupt that can be masked using the WKEN bit. Clear WAKE by writing 1 to it. Writing 0 to WAKE has no effect. 0 start bit not detected 1 start bit detected (write 1 to clear)
6 DCDDELT	This bit is not used in this chip.
5 DCDIN	This bit is not used in this chip.
4 RTSF	**RTS Edge Triggered Interrupt Flag. Indicates if** a programmed edge is detected on the RTS_B pin. The RTEC bits select the edge that generates an interrupt (see Table 17-4). RTSF can generate an interrupt that can be masked using the RTSEN bit. Clear RTSF by writing 1 to it. Writing 0 to RTSF has no effect. 0 Programmed edge not detected on RTS_B 1 Programmed edge detected on RTS_B (write 1 to clear)
3 TXDC	**Transmitter Complete**. Indicates that the transmit buffer (TxFIFO) and Shift Register is empty; therefore the transmission is complete. TXDC is cleared automatically when data is written to the TxFIFO. 0 Transmit is incomplete 1 Transmit is complete
2 BRCD	**BREAK Condition Detected**. Indicates that a BREAK condition was detected by the receiver. Clear BRCD by writing 1 to it. Writing 0 to BRCD has no effect. 0 No BREAK condition was detected 1 A BREAK condition was detected (write 1 to clear)
1 ORE	**Overrun Error**. When set to 1, ORE indicates that the receive buffer (RxFIFO) was full (32 chars inside), and a 33rd character has been fully received. This 33rd character has been discarded. Clear ORE by writing 1 to it. Writing 0 to ORE has no effect.

Table continues on the next page...

UARTx_USR2 field descriptions (continued)

Field	Description
	0 No overrun error 1 Overrun error (write 1 to clear)
0 RDR	**Receive Data Ready**-Indicates that at least 1 character is received and written to the RxFIFO. If the URXD register is read and there is only 1 character in the RxFIFO, RDR is automatically cleared. 0 No receive data ready 1 Receive data ready

17.2.14.10 UART Escape Character Register (UARTx_UESC)

Address: Base address + 9Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																								ESC_CHAR							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0	1	1

UARTx_UESC field descriptions

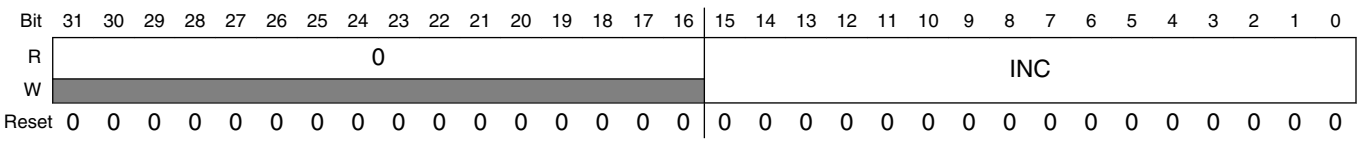
Field	Description
31–8 Reserved	This read-only field is reserved and always has the value 0.
ESC_CHAR	**UART Escape Character**. Holds the selected escape character that all received characters are compared against to detect an escape sequence.

17.2.14.11 UART Escape Timer Register (UARTx_UTIM)

Address: Base address + A0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																				TIM											
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

UARTx_UTIM field descriptions



Field	Description
31–12 Reserved	This read-only field is reserved and always has the value 0.
TIM	UART Escape Timer. Holds the maximum time interval (in ms) allowed between escape characters. The escape timer register is programmable in intervals of 2 ms. See Escape Sequence Detection and Table 17-8 for more information on the UART escape sequence detection. Reset value 0x000 = 2 ms up to 0xFFF = 8.192 s.

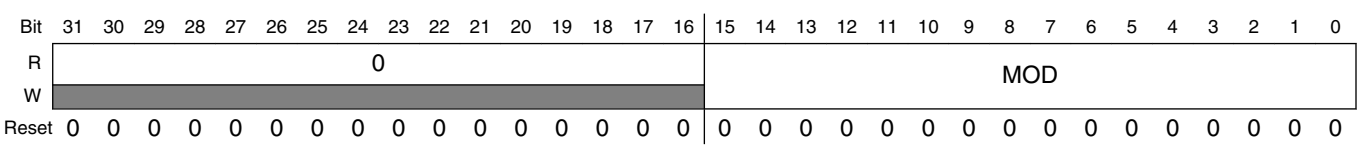
17.2.14.12 UART BRM Incremental Register (UARTx_UBIR)

This register can be written by both software and hardware. When enabling the automatic baud rate detection feature hardware can write 0x000F value into the UBIR after finishing detecting baud rate. Hardware has higher priority when both software and hardware try to write it at the same cycle[3].

Please note software reset will reset the register to its reset value.

Address: Base address + A4h offset

UARTx_UBIR field descriptions



Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
INC	Incremental Numerator. Holds the numerator value minus one of the BRM ratio (see Binary Rate Multiplier (BRM)). The UBIR register MUST be updated before the UBMR register for the baud rate to be updated correctly. If only one register is written to by software, the BRM will ignore this data until the other register is written to by software. Updating this field using byte accesses is not recommended and is undefined.

17.2.14.13 UART BRM Modulator Register (UARTx_UBMR)

This register can be written by both software and hardware. When enabling the automatic baud rate detection feature hardware can write a proper value into the UBMR based on detected baud rate. Hardware has higher priority when both software and hardware try to write it at the same cycle[4].

Please note software reset will reset the register to its reset value.

Address: Base address + A8h offset

3. Note: The write priority in the new design is not same as the original UART. In the orginal design, software has higher priority than hardware when writing this register at the same time.
4. Note: The write priority in the new design is not same as the original UART. In the orginal design, software has higher priority than hardware when writing this register at the same time.

UARTx_UBMR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
MOD	**Modulator Denominator.** Holds the value of the denominator minus one of the BRM ratio (see Binary Rate Multiplier (BRM)). The UBIR register MUST be updated before the UBMR register for the baud rate to be updated correctly. If only one register is written to by software, the BRM will ignore this data until the other register is written to by software. Updating this register using byte accesses is not recommended and undefined.

17.2.14.14 UART Baud Rate Count Register (UARTx_UBRC)

Address: Base address + ACh offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																BCNT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

UARTx_UBRC field descriptions

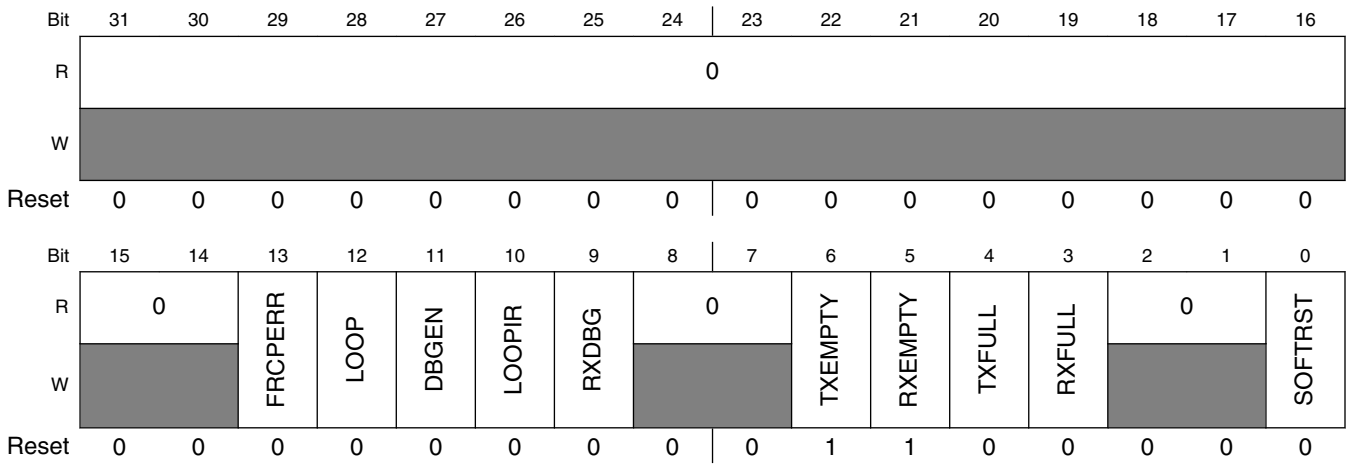
Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
BCNT	**Baud Rate Count Register.** This read only register is used to count the start bit of the incoming baud rate (if ADNIMP=1), or start bit + bit0 (if ADNIMP=0). When the measurement is done, the Baud Rate Count Register contains the number of UART internal clock cycles (clock after divider) present in an incoming bit. BCNT retains its value until the next Automatic Baud Rate Detection sequence has been initiated. The 16 bit Baud Rate Count register is reset to 4 and stays at hex FFFF in the case of an overflow.

17.2.14.15 UART One Millisecond Register (UARTx_ONEMS)

NOTE

This register has been expanded from 16 bits to 24 bits. In previous versions, the 16-bit ONEMS can only support the maximum 65.535MHz (0xFFFFx1000) *ref_clk*. To support 4Mbps Bluetooth application with 66.5MHz *module_clock*, the value 0x103C4 (66.5M/1000) should be written into this register. In this case, the 16 bits are not enough to contain the 0x103C4. So this register was expanded to 24 bits to support high frequency of the *ref_clk*.

Address: Base address + B0h offset



Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								ONEMS																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

UARTx_ONEMS field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value 0.
ONEMS	**One Millisecond Register.** This 24-bit register must contain the value of the UART internal frequency (*ref_clk* in Block Diagram) divided by 1000. The internal frequency is obtained after the UART BRM internal divider (F (*ref_clk*) = F(*module_clock*) / RFDIV). In fact this register contains the value corresponding to the number of UART BRM internal clock cycles present in one millisecond. The ONEMS (and UTIM) registers value are used in the escape character detection feature (Escape Sequence Detection) to count the number of clock cycles left between two escape characters. The ONEMS register is also used in infrared special case mode (IRSC = UCR4[5] = 1'b1), see InfraRed Special Case (IRSC) Bit.

17.2.14.16 UART Test Register (UARTx_UTS)

Address: Base address + B4h offset

UARTx_UTS field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value 0.
13 FRCPERR	Force Parity Error. Forces the transmitter to generate a parity error if parity is enabled. FRCPERR is provided for system debugging. 0 Generate normal parity 1 Generate inverted parity (error)
12 LOOP	Loop TX and RX for Test. Controls loopback for test purposes. When LOOP is high, the receiver input is internally connected to the transmitter and ignores the RXD pin. The transmitter is unaffected by LOOP. If RXDMUXSEL (UCR3[2]) is set to 1, the loopback is applied on serial and IrDA signals. If RXDMUXSEL is set to 0, the loopback is only applied on serial signals. 0 Normal receiver operation 1 Internally connect the transmitter output to the receiver input
11 DBGEN	This bit is not used in this chip. debug_enable_B**.** This bit controls whether to respond to the *debug_req* input signal. 0 UART will go into debug mode when *debug_req* is HIGH 1 UART will not go into debug mode even if *debug_req* is HIGH
10 LOOPIR	**Loop TX and RX for IR Test (LOOPIR)**. This bit controls loopback from transmitter to receiver in the InfraRed interface. 0 No IR loop 1 Connect IR transmitter to IR receiver
9 RXDBG	This bit is not used in this chip. **RX_fifo_debug_mode.** This bit controls the operation of the RX fifo read counter when in debug mode. 0 rx fifo read pointer does not increment 1 rx_fifo read pointer increments as normal

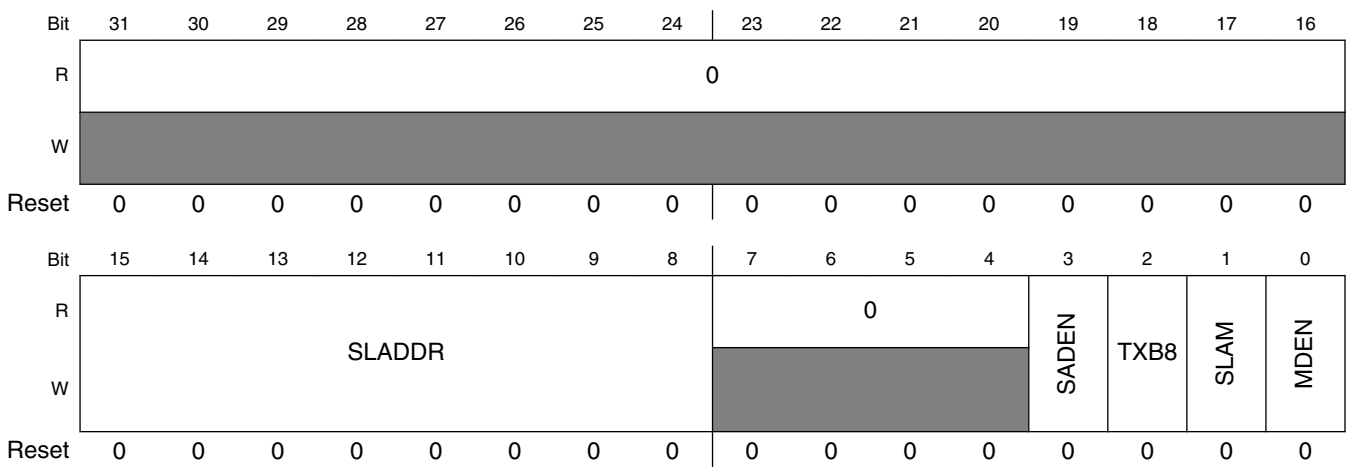


Table continues on the next page...

UARTx_UTS field descriptions (continued)

Field	Description
8–7 Reserved	This read-only field is reserved and always has the value 0.
6 TXEMPTY	TxFIFO Empty. Indicates that the TxFIFO is empty. 0 The TxFIFO is not empty 1 The TxFIFO is empty
5 RXEMPTY	RxFIFO Empty. Indicates the RxFIFO is empty. 0 The RxFIFO is not empty 1 The RxFIFO is empty
4 TXFULL	TxFIFO FULL. Indicates the TxFIFO is full. 0 The TxFIFO is not full 1 The TxFIFO is full
3 RXFULL	RxFIFO FULL. Indicates the RxFIFO is full. 0 The RxFIFO is not full 1 The RxFIFO is full
2–1 Reserved	This read-only field is reserved and always has the value 0.
0 SOFTRST	Software Reset. Indicates the status of the software reset (SRST_B bit of UCR2). 0 Software reset inactive 1 Software reset active

17.2.14.17 UART RS-485 Mode Control Register (UARTx_UMCR)

Address: Base address + B8h offset

UARTx_UMCR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value 0.
15–8 SLADDR	RS-485 Slave Address Character. Holds the selected slave adress character that the receiver wil try to detect.
7–4 Reserved	This read-only field is reserved and always has the value 0.
3 SADEN	RS-485 Slave Address Detected Interrupt Enable. 0 Disable RS-485 Slave Address Detected Interrupt 1 Enable RS-485 Slave Address Detected Interrupt
2 TXB8	Transmit RS-485 bit 8 (the ninth bit or 9th bit). In RS-485 mode, software writes TXB8 bit as the 9th data bit to be transmitted. 0 0 will be transmitted as the RS485 9th data bit 1 1 will be transmitted as the RS485 9th data bit
1 SLAM	RS-485 Slave Address Detect Mode Selection. 0 Select Normal Address Detect mode 1 Select Automatic Address Detect mode
0 MDEN	9-bit data or Multidrop Mode (RS-485) Enable. 0 Normal RS-232 or IrDA mode, see Table 17-2 for detail. 1 Enable RS-485 mode, see Table 17-2 for detail

Appendix A
SDMA Scripts

A.1 Introduction

This appendix provides descriptions of scripts that may be used to perform data transfers using the Smart DMA (SDMA) block of the SoC.

The SDMA block supports data transfer from core memory space to core memory, from core memory space to peripherals, and vice versa.

A.1.1 SDMA Scripts Overview

Table A-1 gives an overview of the SDMA scripts.

Table A-1. SDMA Scripts Overview

Data Transfer	Script to Use	Use Case	Parameters Through Context	Parameters Through Buffer Descriptor
Memory	ap_2_ap	Memory Copy	None	Word length (2'b01 or 2'b10 or 2'b11 or 2'b00), Counter, first address is memory source address, second address is memory destination address
Shared UART	uartsh_2_mcu	Uart Rx	UART Rx FIFO address (r6) Event_mask (r1) Event2_mask (r0) Watermark level (r7)	Periph size (2'b01), Counter, Memory destination address, Second address not used
UART	uart_2_mcu	Uart Rx	Uart Rx FIFO address (r6) Event_mask (r1) Event2_mask (r0) Watermark level (r7)	Periph size (2'b01), Counter, Memory source address, Second address not used
SPDIF	mcu_2_spdif	Spdif Playback	SPDIF Tx FIFO address (r6) Event_mask (r1) Event2_mask (r0) Watermark level (r7)	Periph size (2'b10 or 2'b00), Counter, Memory source address, Second address not used

Table continues on the next page...

Table A-1. SDMA Scripts Overview (continued)

Data Transfer	Script to Use	Use Case	Parameters Through Context	Parameters Through Buffer Descriptor
	spdif_2_mcu	Spdif Record	SPDIF Rx FIFO address (r6) Event_mask (r1) Event2_mask (r0) Watermark level (r7)	Periph size (2'b10 or 2'b00), Counter, Memory source address, Second address not used
Shared Peripheral	mcu_2_shp	Peripheral Transmit	Tx fifo address (r6) Event_mask (r1) Event2_mask(r0) Watermark level (r7)	Periph size (2'b01 or 2'b10 or 2'b11 or 2'b00), Counter, Memory source address, Second address not used
	shp_2_mcu	Peripheral Receive	RX fifo address (r6) Event_mask (r1) Event2_mask(r0) Watermark level (r7)	Periph size (2'b01 or 2'b10 or 2'b11 or 2'b00), Counter, Memory destination address, Second address not used

In Table A-1, the data transfer column lists the possible types of DMA channels that involve the SDMA and a specific script is attached to each channel. It must be noted that some scripts cover several DMA channels. The scripts deal with the channels that have generic peripherals where only the watermark level is needed (no aging timer, no end_of_packet feature, and so on). The location refers to whether a script resides in ROM or in RAM and the size of the script is given in the instructions. The parameters columns are explained in the next section.

The following terms are used in Table A-1 which lists all the supported data transfers.

EMI or External Memory:

The external memories are connected to the External Memory Interface. Thus, a data transfer to EMI means a data transfer to any of the external memories (NAND Flash, NOR Flash, PSRAM, SDRAM, and so on).

Host mem or ARM internal memory:

The memory space accessible through the MAX of the ARM platform. It does not correspond to the peripherals, although they are accessible through the MAX as well. A data transfer from Host mem means data is read from the internal memory of the ARM or from the external memory. It is possible to point to an external memory through the MAX because it is also connected to EMI module. The next diagram replaces the SDMA and its DMA port in the hardware architecture. The Host mem is accessible through the Per DMA port of the SDMA, the EMI is accessible through the Burst DMA and the DSP mem through the DSP port.

Shared Peripheral:

A same peripheral can be connected to the shared peripheral bus (output of SPBA module) and to the ARM platform. This is the case for some UART, CSPI, and SSI. Therefore, "shared UART" indicates that the UART is connected to the shared peripheral, whereas "UART" means the UART is connected to the ARM platform.

Figure A-1 gives an overview of the SDMA in its hardware environment.

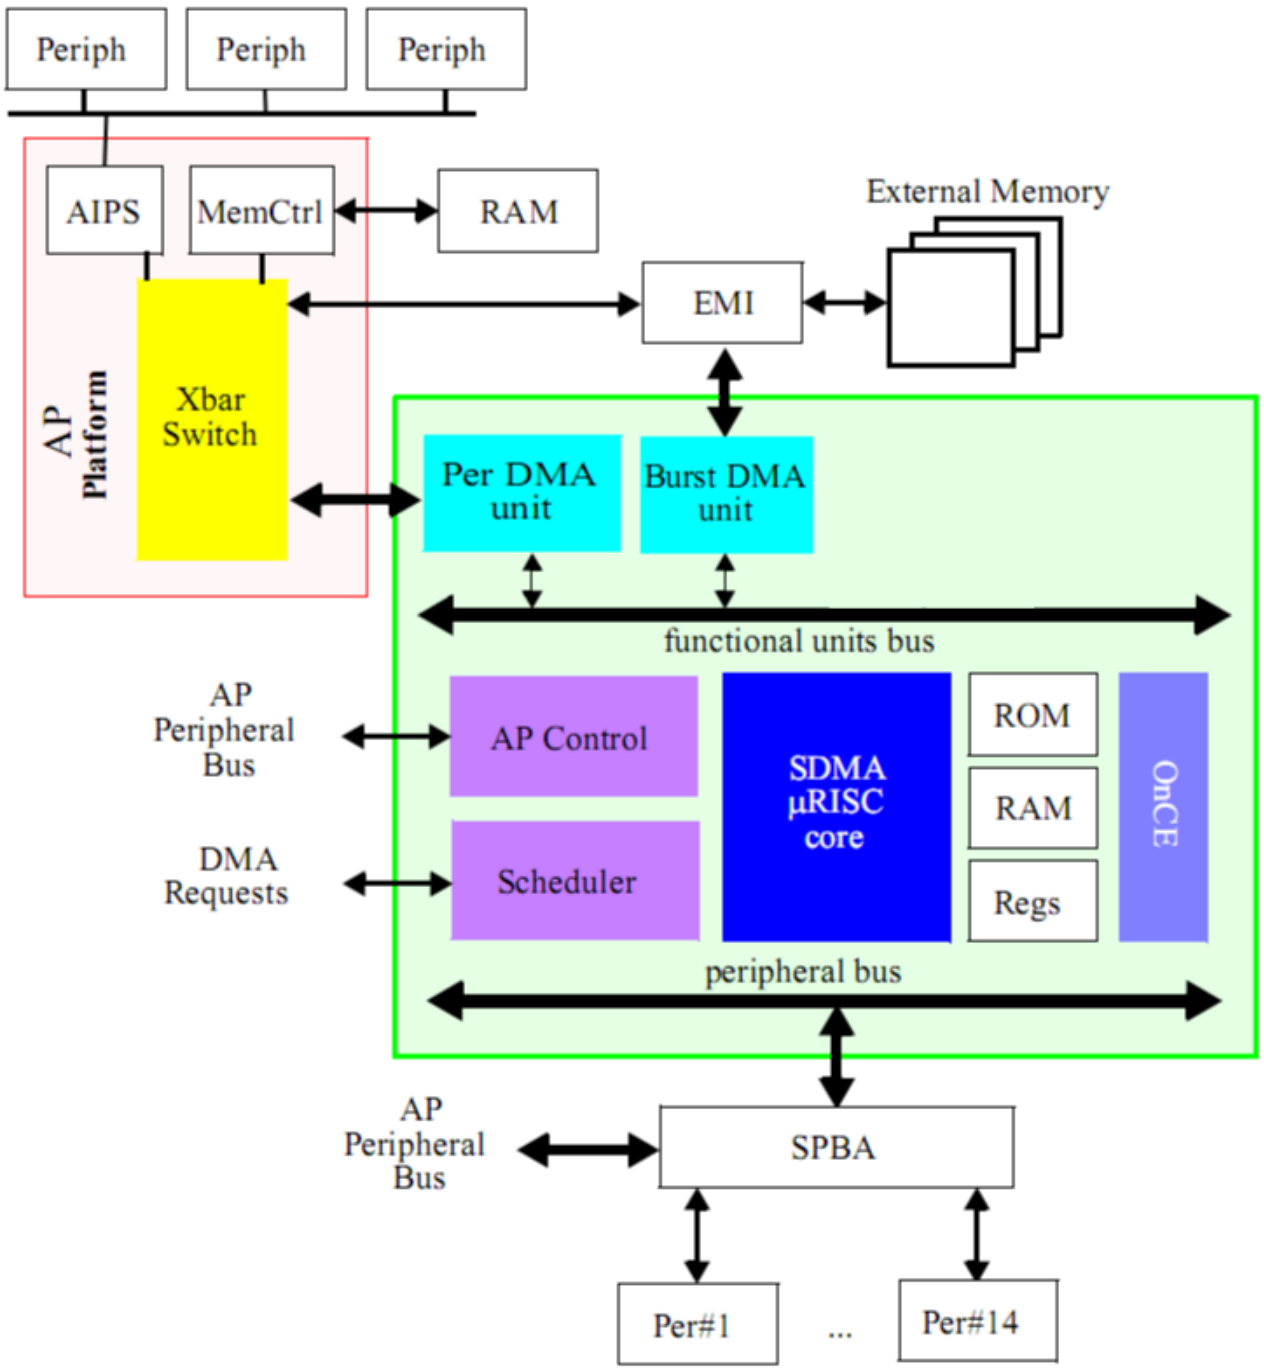

Figure A-1. SDMA Connections

A.2 Scripts Parameters: Definition

A.2.1 Parameters Definition

A.2.1.1 Parameters Required by Data Transfer Script Involving a Peripheral

The scripts that have a peripheral as a player in the transfer of data need to have the following input parameters:

A.2.1.1.1 Watermark Level (WML)

It is the upper or the lower threshold of the receive or transmit FIFO of the peripheral that triggers a DMA request to the SDMA.

The WML determines the data transfer loop size, meaning the number of bytes that will be read/write from/to the receive/transmit FIFO. This parameter must be a multiple of the peripheral FIFO data size. As an example, if UART1 is the data transfer destination, data must be written to the Tx FIFO of the peripheral. For instance, the watermark level can be set to 8 bytes (the UART is a 1 byte FIFO data size), meaning the UART_TX DMA request will be sent to the SDMA each time there are more than 8 free locations in the FIFO; therefore SDMA loop size will be set to 8 and 8 bytes will be written to the UART_TX FIFO. In fact, the loop size is the minimum between the WML and the count field of the buffer descriptor attached to the channel. This concept is explained later on in the chapter. Similarly, if the UART is the source of a data transfer and if the WML is set to 16, each time the DMA request is received by the SDMA, which triggers the associated channel, the data transfer loop size is set to 16. This means 16 bytes will be read from the UART_RX FIFO. The watermark level is a "long" (32-bit data) programmed by the ARM and is not supposed to evaluate a lot during application. The WML is always given in bytes.

NOTE

For the transmit FIFO, the WML = FIFO_SIZE - FIFOTX_THRESHOLD For the receive FIFO, the WML = FIFORX_THRESHOLD The FIFOTX_THRESHOLD/ FIFORX_THRESHOLD are the values of the peripheral transmit and receive FIFO level at which a DMA request is triggered. For instance, if TX FIFO is 32 bytes depth and if the DMA request is sent when the number of bytes present in the FIFO is below a threshold of 10, the WML will be 22. It means that when the SDMA will receive the DMA request from the

peripheral, it will be possible to store 22 bytes in the TX FIFO.
For the receive FIFO, the WML equals the threshold.

A.2.1.1.2 Event_mask and Event2_mask

As previously said, when the WML threshold is over or under passed, a DMA request is sent to the scheduler part of the SDMA.

The SDMA scheduler has 48 input pins, called "events", which are connected to the different DMA request.

The mapping between the DMA request name and the event number is SoC dependent and defined in the "Interrupts and SDMA Events" chapter. For instance, in SoC A, the UART_RX DMA request is connected to events pin 5; whereas for SoC B, it may be connected to events pin 15. The script reads the EVENTS(32 events requests) and EVENTS2(remaining 16 events requests) register to check if the received DMA request is compliant with the expected one and it guaranteed that a second DMA request sent during the data transfer is not lost.

For instance, while SDMA is reading the UART_RX FIFO (again, the number of data to be read is given by WML value), the peripheral may receive new data from its input ports. Therefore after the first data transfer, the number of data available in the UART received FIFO can be still higher than the WML threshold, so a second DMA request may be sent.

The event_mask value is generally a 1-bit high value, which means that if the script attached to the channel must be triggered by DMA request number I, event_mask[I] must be set to 1, if the script attached to the channel must be triggered by DMA request number 32+I, event2_mask[I] must be set to 1. Some scripts (like ata_2_mcu) may be triggered by several DMA requests; in that case several bits of the event_mask must be asserted. The event_mask and event2_mask are long (32-bit) data.

A.2.1.1.3 Peripheral Address

The scripts of the SDMA scripts library are SoC independent but as their goal is to address peripheral, they required the base address or the FIFO address of the peripheral.

Passing FIFO or peripheral base address depends on the scripts.

A.2.1.1.4 Data Length

The scripts whose name contains the key word "app" or "shp" are generic: they are used to transfer data from/to a 8, 16, 24 or 32-bit peripheral data size.

Some jumps to some routines of these scripts depend on this peripheral size. This parameter is required as input of these scripts. This parameter is passed through the command field of the buffer descriptor and is coded on bits 25 and 24 of the mode:

00: 32-bit data transfer.

01: 8-bit data transfer.

10: 16-bit datatransfer.

11: 24-bit data transfer.

A.3 Scripts

The following scripts are all based on buffer descriptor mechanism.

A.3.1 SDMA ROM Scripts

The ROM holds the generic memory to memory scripts (ap_2_ap, ap_2_bp, bp_2_ap, bp_2_bp) and the peripheral most useful scripts (app_2_mcu, mcu_2_app, uart_2_mcu, uartsh_2_mcu, mcu_2_shp, shp_2_mcu).

In these memory to memory scripts, the number of bytes to transfer from the source memory to the destination is divided by 4 to get the number of 32-bit words that can be transferred. Most of the time, the transfer will be a transfer of words. There will be a byte or half data transfer at the end of the transfer if the total number of bytes to transfer is not an multiple of 4.

A.3.1.1 ap_2_ap

This script is used to transfer data inside the application processor memory using BurstDMA.

Using this script there is no restriction on the number of bytes to transmit, the source address and destination address alignment, or on the source memory and destination memory type. But word alignment and source/destination memory type will impact performance. In case that the source and destination are in the same memory type, being word aligned allows the SDMA to use the copy capability of the DMA units. When it is not the case the SRAM of the SDMA is used as temporary buffer.

A.3.1.1.1 Parameters Transmitted Through the Context ap_2_ap

A.3.1.1.2 Parameters Transmitted Through the Buffer Descriptor ap_2_ap

The number of bytes to transmit is stored in the first Buffer descriptor word.

The source address is stored in the second Buffer descriptor word (address field).

The destination address is stored in the Extended Buffer address

A.3.1.1.3 Use of the General Register During the Execution ap_2_ap

- r0: nb of bytes to transfer, counter during loop
- r2: channel cb address, scratch
- r3: current buffer descriptor pointer, AP destination address, scratch
- r4: mode
- r5: source address loaded by getbd,
- r6: destination address loaded by getcb, scratch
- r7: pointer in the scratch buffer

A.3.1.1.4 Overview of Script Functionality ap_2_ap

The parameters of the transfer (number of bytes to transfer, source address and destination address) are retrieved from the buffer descriptor.

Depending on the address alignment and the DMA units involved, if possible, the transfer is performed using the copy capability of the DMA unit, or using the SDMA SRAM as a temporary buffer.

When the transfer is finished, this algorithm restarts (a new buffer descriptor is read).

The count in the BD mode word after the script is over is meaningful only if error was reported, else it has the same value as was fed as input to the script.

A.3.1.2 uartsh_2_mcu

This script is used to transfer data from the shared UART to the External memory. The UART is connected to the ARM platform.

The UART is an 8-bit peripheral, but when reading the FIFO, 16 bits are retrieved. In fact, the 8 MSB are the status bytes for the current data. At each access the value of this byte is checked to verify that a valid data was retrieved. If an error is detected the transfer is stopped and the information is sent back to the Host through the buffer descriptor with the byte count field updated.

A.3.1.2.1 Parameters Transmitted Through the Context uartsh_2_mcu

r0: mask to check events2 - If script is triggered by event 32+I, r0[I] must be set to 1. (Project dependent)

r1: mask to check event - If script is triggered by event I, r1[I] must be set to 1. (Project dependent)

r6: address of the peripheral Rx FIFO (project dependent)

r7: Watermark level - Used to determine the maximum of data that can be sent to the peripheral each time the channel is started.

A.3.1.2.2 Parameters Transmitted Through the Buffer Descriptor uartsh_2_mcu

The number of bytes to transmit is stored in the first Buffer descriptor word.

The destination address is stored in the second Buffer descriptor word (address field).

The Extended Buffer address is not used.

A.3.1.2.3 Use of the General Register During the Execution uartsh_2_mcu

r0 = mask to check events2

r1 = mask to check events

r2 = AP M3 destination address

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.3.1.2.4 Overview of Script Functionality uartsh_2_mcu

When the UART sends a DMA request, it can be for three different reasons.

When the RX threshold is over passed. It deals with the most frequent event.

When the AGEING timer has reached its final value, meaning there is less data than the RX threshold in the RX FIFO, and they have been present for too long. It is called the aging DMA request.

When IDLE timer reached its final value; meaning the RX FIFO has been empty for too long. It is called the iddle dma request. The IDLE timer is not used, so only normal and AGEING DMA requests are supported by the script.

The first time the script is executed, a buffer descriptor is opened, the buffer destination address and its size are retrieved from the BD.

Then the script checks if the RRDY bit of USR1 is set. If yes, it means that the Watermark level has been reached, there are "WML" bytes in RX FIFO. If the count field of the opened BD is higher than WML-1, the SDMA script will perform WML-1 read accesses to the RX FIFO and WML write access to the destination buffer (a read access then a write access is call a data transfer loop). If the count field is lesser than the WML-1 value, the count field will be the data transfer loop size. So the data transfer loop size equals min(WML-1,BD count)

So there will be always one data remaining in the UART RX FIFO after every data transfer loop and the ageing timer will always trigger a DMA request. It means that the channel on which the script is run will be always closed on an AGEING DMA request.

Now assume the script is triggered by a DMA request, but RRDY is not set. It means that it deals with an AGEING DMA request; there is at least one data in the RX FIFO. The data is read and written into the destination buffer, and then the RDR is checked again. If it is set and if the destination data buffer is not full (BD count is not 0), a new data is read and so on until RDR is 0. When RDR is 0, the ageing timer interrupt flag is disabled by setting the AGTIM bit, the count field of BD is updated and the current BD is closed. Then the script tries to open the next BD if the Continuous bit of the current BD was set, if there is no more BD to open, the channel is stopped.

When reading a data from the UART RX FIFO, the MSB are check to verify that a valid data has been retrieved. If an error is detected the transfer is stopped, the error bit is set in the BD, the count is updated, the BD is closed and an interrupt is sent to the ARM.

When the buffer is full, this algorithm restarts (a new buffer descriptor is read, if it exists).

The next diagram illustrates the script algorithm, it is quite complex but things become more obvious when we notice that there is a loop for the normal DMA request (in sky-blue) and on when the AGEING DMA request was detected (in yellow).

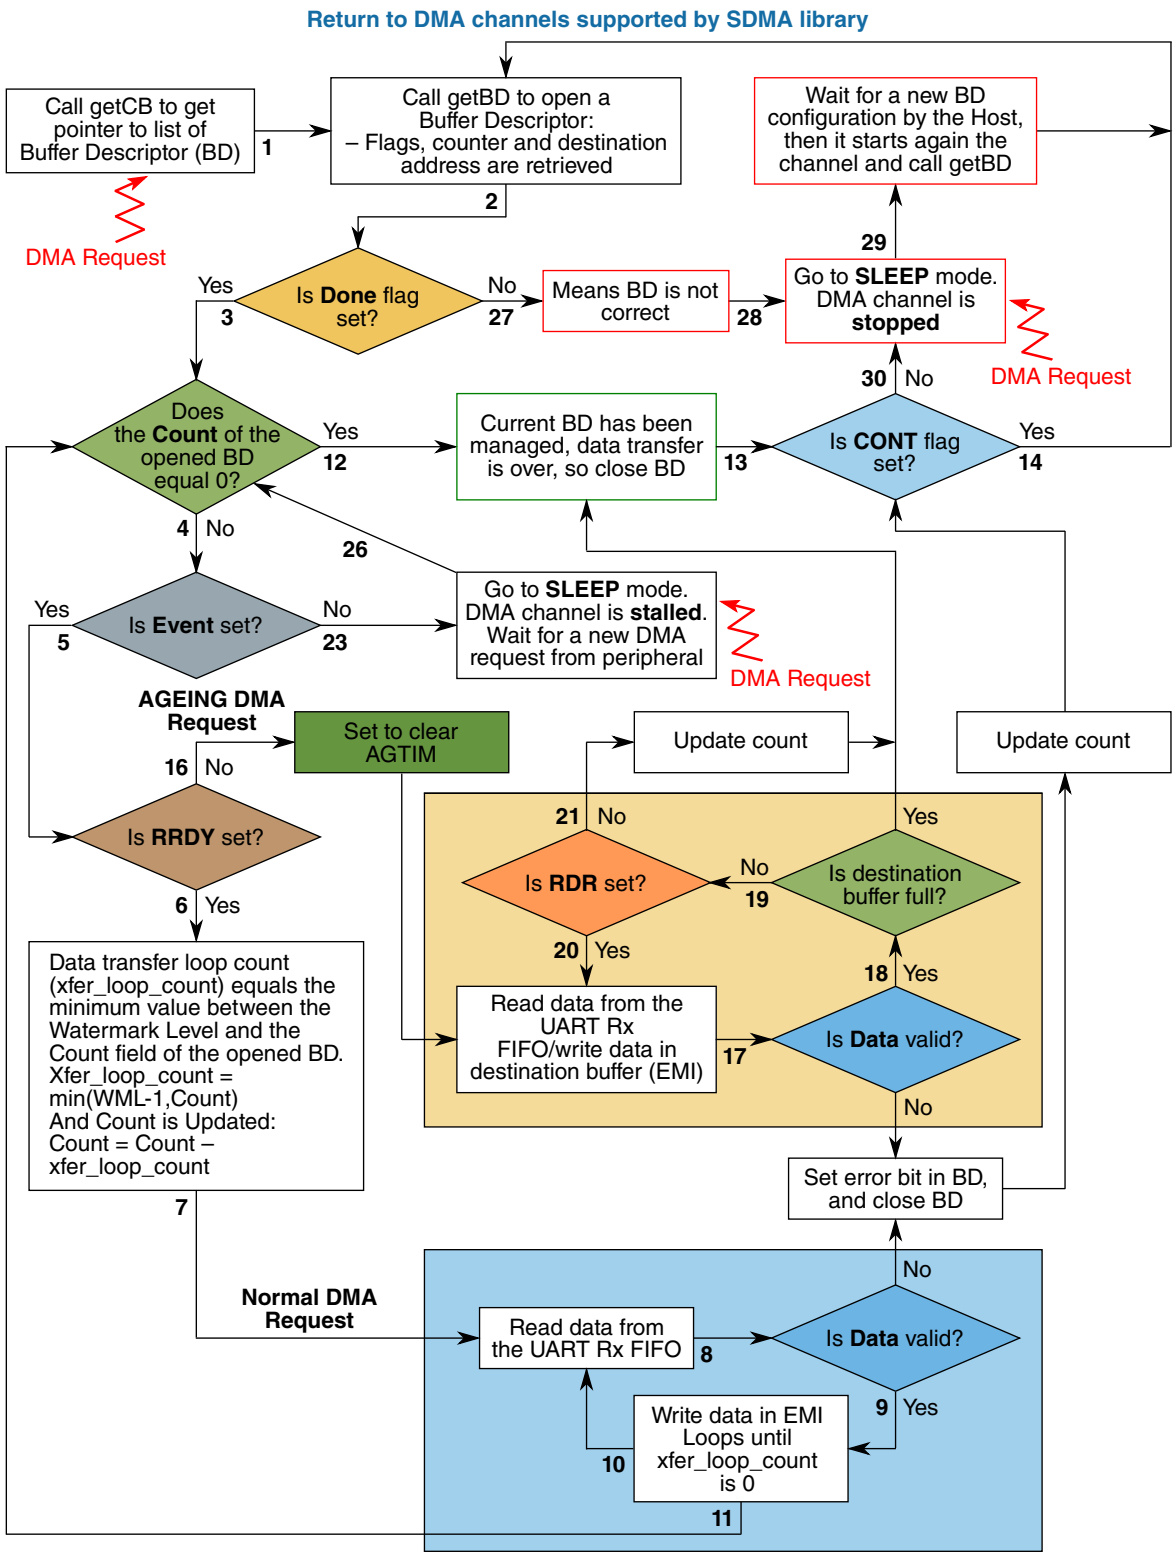

Figure A-2. Script Algorithm

A.3.1.3 shp_2_mcu

This generic script is used to transfer data from a 8, 16, 24 or 32-bit peripheral connected to the shared peripheral bus accessed through the SPBA to memories accessed by the BurstDMA (External memories).

It can be used for SSI (8, 16, 24 or 32-bit data size), for CSPI (32-bit data size) or for SDHC(MMC)/SIM (16-bit data size), these peripherals being connected to the shared peripheral bus.

A.3.1.3.1 Parameters Transmitted Through the Context shp_2_mcu

r0: mask to check events2 - If script is triggered by event 32+I, r0[I] must be set to 1. (Project dependent)

r1: mask to check event - If script is triggered by event I, r1[I] must be set to 1. (Project dependent)

r6: address of the peripheral Rx FIFO (project dependent)

r7: Watermark level - Used to determine the maximum of data that can be sent to the peripheral each time the channel is started.

A.3.1.3.2 Parameters Transmitted Through the Buffer Descriptor shp_2_mcu

The peripheral size/data length is set in the command field of the first Buffer descriptor word, especially bits 24 and 25.

The number of bytes to transmit is stored in the first Buffer descriptor word (count field)

The destination address in the external memory is stored in the second Buffer descriptor word (address field).

The Extended Buffer address is not used.

A.3.1.3.3 Use of the General Register During the Execution shp_2_mcu

r0 = mask to check events2

r1 = mask to check events

r2 = BD destination address

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.3.1.3.4 Overview of Script Functionality shp_2_mcu

The parameters of the transfer (peripheral size, number of bytes to transfer and source address) are retrieved from the buffer descriptor.

When the peripheral sends an event, a data transfer loop is executed. This event is set when there is at least "watermark level" data in the FIFO.

During this data transfer loop, the number of bytes that are transferred from the RX FIFO of the peripheral to the EMI is equal to the minimum value between the "watermark level" and the number of data that have not been transferred yet. For each data transfer (one read, one write), the size of the memory write access is fixed by the parameter peripheral size.

The necessary number of transfer loops are executed in order to fill the buffer, but they are executed only if the event is set. While the event is not set, the channel is not executable.

When the buffer is filled, this algorithm restarts (a new buffer descriptor is read).

A.3.1.4 mcu_2_shp

This generic script is used to transfer data from memories accessed by the BurstDMA (External memories) to a 8, 16, 24 or 32-bit peripheral connected to the shared peripheral bus accessed through the SPBA

. It can be used for SSI (8, 16, 24 or 32-bit data size), for CSPI (32-bit data size), for SDHC(MMC)/SIM (16-bit data size) or for UART3,4 (8-bit data size), these peripherals being connected to the shared peripheral bus.

A.3.1.4.1 Parameters Transmitted Through the Context mcu_2_shp

r0: mask to check events2 - If script is triggered by event 32+I, r0[I] must be set to 1. (Project dependent)

r1: mask to check events - If script is triggered by event I, r1[I] must be set to 1. (Project dependent)

r6: address of the peripheral Tx FIFO (project dependent)

r7: Watermark level - Used to determine the maximum of data that can be retrieved from the peripheral each time the channel is started.

A.3.1.4.2 Parameters Transmitted Through the Buffer Descriptor mcu_2_shp

The peripheral size/data length is set in the command field of the first Buffer descriptor word, especially bits 24 and 25.

The number of bytes to transmit is stored in the first Buffer descriptor word (count field)

The source address in the external memory is stored in the second Buffer descriptor word (address field).

The Extended Buffer address is not used.

A.3.1.4.3 Use of the General Register During the Execution mcu_2_shp

r0 = mask to check events2

r1 = mask to check events

r2 = EVENTS / EVENTS2

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.3.1.4.4 Overview of Script Functionality mcu_2_shp

The parameters of the transfer (peripheral size, number of bytes to transfer and source address) are retrieved from the buffer descriptor.

When the peripheral sends an event, a data transfer loop is executed. This event is set when there is at least "watermark level" empty rooms in the FIFO.

During this data transfer loop, the number of bytes that are transferred from the EMI to the TX FIFO of the peripheral is equal to the minimum value between the "watermark level" and the number of data that have not been transferred yet. For each data transfer (one read, one write), the size of the memory read access is fixed by the parameter peripheral size.

The necessary number of transfer loops are executed in order to empty the buffer, but they are executed only if the event is set. While the event is not set, the channel is not executable.

When the buffer is empty, this algorithm restarts (a new buffer descriptor is read).

A.3.1.5 uart_2_mcu

This script is similar to uartsh_2_mcu script. The only difference between these scripts is the way SDMA access UART RX FIFO.

In case of uartsh_2_mcu, the UART RX FIFO can directly be accessed by SDMA as it is on Shared Peripheral Bus. In case of uart_2_mcu, SDMA script uses one of its DMA (Peripheral DMA) to access UART RX FIFO.

A.3.1.6 app_2_mcu

This generic script is used to transfer data from a 8, 16, 24 or 32-bit peripheral connected to the AIPS accessed through the Periphera DMA of SDMA, to memories accessed by the BurstDMA (External memories).

It can be used for SSI (8, 16, 24 or 32-bit data size), for CSPI (32-bit data size) or for SDHC(MMC)/SIM (16-bit data size).

A.3.1.6.1 Parameters Transmitted Through the Context app_2_mcu

r0: mask to check events2 - If script is triggered by event 32+I, r0[I] must be set to 1. (Project dependent)

r1: mask to check event - If script is triggered by event I, r1[I] must be set to 1. (Project dependent)

r6: address of the peripheral Rx FIFO (project dependent)

r7: Watermark level - Used to determine the maximum of data that can be sent to the peripheral each time the channel is started.

A.3.1.6.2 Parameters Transmitted Through the Buffer Descriptor app_2_mcu

The Data Length peripheral size/data length is set in the command field of the first buffer descriptor word, specially bits 24 and 25.

The number of bytes to transmit is stored in the first buffer descriptor word (count field).

The destination address in the external memory is stored in the second buffer descriptor word (address field).

The Extended Buffer address is not used.

A.3.1.6.3 Use of the General Register During the Execution app_2_mcu

r0 = mask to check events2

r1 = mask to check events

r2 = AP M3 destination address

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.3.1.6.4 Overview of Script Functionality app_2_mcu

The parameters of the transfer (peripheral size, number of bytes to transfer and source address) are retrieved from the buffer descriptor.

When the peripheral sends an event, a data transfer loop is executed. This event is set when there is at least "watermark level" data in the FIFO.

During this data transfer loop, the number of bytes that are transferred from the RX FIFO of the peripheral to the EMI is equal to the minimum value between the "watermark level" and the number of data that have not been transferred yet. For each data transfer (one read, one write), the size of the memory write access is fixed by the parameter peripheral size.

The necessary number of transfer loops are executed in order to fill the buffer, but they are executed only if the event is set. While the event is not set, the channel is not executable.

When the buffer is filled, this algorithm restarts (a new buffer descriptor is read).

A.3.1.7 mcu_2_app

This generic script is used to transfer data from memories accessed by the BurstDMA (External memories), to a 8, 16, 24 or 32-bit peripheral connected to the AIPS accessed through the Periphera DMA of SDMA.

It can be used for SSI (8, 16, 24 or 32-bit data size), for CSPI (32-bit data size) or for SDHC(MMC)/SIM (16-bit data size).

A.3.1.7.1 Parameters Transmitted Through the Context mcu_2_app

r0: mask to check events2 - If script is triggered by event 32+I, r0[I] must be set to 1. (Project dependent)

r1: mask to check event - If script is triggered by event I, r1[I] must be set to 1. (Project dependent)

r6: address of the peripheral Tx FIFO (project dependent)

r7: Watermark level - Used to determine the maximum of data that can be sent to the peripheral each time the channel is started.

A.3.1.7.2 Parameters Transmitted Through the Buffer Descriptor mcu_2_app

The peripheral size/data length is set in the command field of the first buffer descriptor word, specially bits 24 and 25.

The number of bytes to transmit is stored in the first buffer descriptor word (count field).

The source address in the external memory is stored in the second buffer descriptor word (address field).

The Extended Buffer address is not used.

A.3.1.7.3 Use of the General Register During the Execution mcu_2_app

r0 = mask to check events2

r1 = mask to check events

r2 = TX FIFO address

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.3.1.7.4 Overview of Script Functionality mcu_2_app

The parameters of the transfer (peripheral size, number of bytes to transfer and source address) are retrieved from the buffer descriptor.

When the peripheral sends an event, a data transfer loop is executed. This event is set when there is at least "watermark level" empty room in the FIFO.

During this data transfer loop, the number of bytes that are transferred from the EMI to the TX FIFO of the peripheral is equal to the minimum value between the "watermark level" and the number of data that have not been transferred yet. For each data transfer (one read, one write), the size of the memory read access is fixed by the parameter peripheral size.

The necessary number of transfer loops are executed in order to fill the buffer, but they are executed only if the event is set. While the event is not set, the channel is not executable.

When the buffer is filled, this algorithm restarts (a new buffer descriptor is read).

A.3.1.8 mcu_2_spdif

This script performs a data move from AP buffer to 24 bits FIFO of the SPDIF.

This peripheral is on the peripheral bus, the SDMA accesses it through the SPBA. The MCU buffer is accessed through the burst DMA.

A.3.1.8.1 Parameters Transmitted Through the Context mcu_2_spdif

r0: mask to check events2 - If script is triggered by event 32+I, r0[I] must be set to 1. (Project dependent)

r1: mask to check events - If script is triggered by event I, r1[I] must be set to 1. (Project dependent)

r6: Address of SPDIF STL register

r7: Watermark level - Used to determine the maximum data that can be sent to the peripheral each time the channel is started.

A.3.1.8.2 Parameters Transmitted Through the Buffer Descriptor mcu_2_spdif

The data length (Either 32-bit or 16-bit) is set in the command field of the first Buffer descriptor word, especially bits 24, 25.

The number of bytes to transmit is stored in the first Buffer descriptor word (count field)

The source address in the external memory is stored in the second Buffer descriptor word (address field).

The Extended Buffer address is not used.

A.3.1.8.3 Use of the General Register During the Execution mcu_2_spdif

r0 = mask to check events2

r1 = mask to check events

r2 = EVENTS / EVENTS2

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.3.1.8.4 Overview of Script Functionality mcu_2_spdif

The parameters of the transfer (data length, number of bytes to transfer and source address) are retrieved from the buffer descriptor.

When the spdif sends an event, a data transfer loop is executed. This event is set when there is at least "watermark level" of empty room in the FIFO (Sum of left and right FIFO's).

During this data transfer loop, the number of bytes that are transferred from the EMI to the TX FIFO of the spdif is equal to the minimum value between the "watermark level" and the number of data that have not been transferred yet. For each data transfer (one read, one write), the size of the memory read access is fixed by the parameter data length.

The necessary numbers of transfer loops are executed in order to empty the buffer, but they are executed only if the event is set. While the event is not set, the channel is not executable.

When the buffer is empty, this algorithm restarts (a new buffer descriptor is read).

A.3.1.9 spdif_2_mcu

This script performs a data move from 24 bits FIFO of the SPDIF to AP buffer.

This peripheral is on the peripheral bus, the SDMA accesses it through the SPBA. The MCU buffer is accessed through the burst DMA.

A.3.1.9.1 Parameters Transmitted Through the Context spdif_2_mcu

r0: mask to check events2 - If script is triggered by event 32+I, r0[I] must be set to 1. (Project dependent)

r1: mask to check events - If script is triggered by event I, r1[I] must be set to 1. (Project dependent)

r6: Address of SPDIF SRL register

r7: Watermark level - Used to determine the maximum data that can be sent to the peripheral each time the channel is started.

A.3.1.9.2 Parameters Transmitted Through the Buffer Descriptor spdif_2_mcu

The data length (Either 32 bit or 16 bit) is set in the command field of the first Buffer descriptor word, especially bits 24, 25.

The number of bytes to transmit is stored in the first Buffer descriptor word (count field)

The destination address in the external memory is stored in the second Buffer descriptor word (address field).

The Extended Buffer address is not used.

A.3.1.9.3 Use of the General Register During the Execution spdif_2_mcu

r0 = mask to check events2

r1 = mask to check events

r2 = EVENTS / EVENTS2

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.3.1.9.4 Overview of Script Functionality spdif_2_mcu

The parameters of the transfer (data length, number of bytes to transfer and destination address) are retrieved from the buffer descriptor.

When the spdif sends an event, a data transfer loop is executed. This event is set when there is at least "watermark level" date in the FIFO (Sum of left and right FIFO's).

During this data transfer loop, the number of bytes that are transferred from the RX FIFO of the spdif to the EMI is equal to the minimum value between the "watermark level" and the number of data that have not been transferred yet. For each data transfer (one read, one write), the size of the memory write access is fixed by the parameter data length.

The necessary numbers of transfer loops are executed in order to empty the buffer, but they are executed only if the event is set. While the event is not set, the channel is not executable.

When the buffer is empty, this algorithm restarts (a new buffer descriptor is read).

A.3.2 SDMA RAM scripts

A.3.2.1 mcu_2_ssiapp

This script performs a data move from AP buffer to 8, 16, 24 or 32-bit FIFO of the SSI in the AP region with 2 FIFOs enabled.

The MCU buffer is accessed through the burst DMA, while SSI is accessed with Per DMA.

A.3.2.1.1 Parameters Transmitted Through the Context mcu_2_ssiapp

r0: mask to check events2 - If script is triggered by event 32+I, r0[I] must be set to 1. (Project dependent)

r1: mask to check events - If script is triggered by event I, r1[I] must be set to 1. (Project dependent)

r6: Address of SSI Transmit FIFO 0 register

r7: Watermark level - Used to determine the maximum data that can be sent to the peripheral each time the channel is started.

A.3.2.1.2 Parameters Transmitted Through the Buffer Descriptor mcu_2_ssiapp

The data length (8, 16, 24 or 32-bit) is set in the command field of the first buffer descriptor word, especially bits 24 and 25.

The number of bytes to transmit is stored in the first buffer descriptor word (count field).

The source address in the memory is stored in the second buffer descriptor word (address field).

The Extended Buffer address is not used.

A.3.2.1.3 Use of the General Register During the Execution mcu_2_ssiapp

r0 = mask to check events2

r1 = mask to check events

r2 = Tx FIFO address

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.3.2.1.4 Overview of Script Functionality mcu_2_ssiapp

The parameters of the transfer (data length, number of bytes to transfer and source address) are retrieved from the buffer descriptor.

When the SSI sends an event, a data transfer loop is executed. This event is set when there is at least "watermark level" of empty room in the FIFO (Sum of left and right FIFO's).

During this data transfer loop, the number of bytes that are transferred from the EMI to the TX FIFO of the SSI is equal to the minimum value between the "watermark level" and the number of data that have not been transferred yet. For each data transfer (one read, one write), the size of the memory read access is fixed by the parameter data length.

The necessary numbers of transfer loops are executed in order to empty the buffer, but they are executed only if the event is set. While the event is not set, the channel is not executable.

When the buffer is empty, this algorithm restarts (a new buffer descriptor is read).

A.3.2.2 ssiapp_2_mcu

This script performs a data move from the 8, 16, 24 or 32-bit FIFO of the SSI to the AP buffer.

The SSI is in the AP region and 2 FIFO enabled. The MCU buffer is accessed through the burst DMA while the SSI is accessed through Per DMA.

A.3.2.2.1 Parameters Transmitted Through the Context ssiapp_2_mcu

r0: mask to check events2 - If script is triggered by event 32+I, r0[I] must be set to 1. (Project dependent)

r1: mask to check event - If script is triggered by event I, r1[I] must be set to 1. (Project dependent)

r6: address of the SSI RX FIFO 0

r7: Watermark level - Used to determine the maximum of data that can be sent to the peripheral each time the channel is started.

A.3.2.2.2 Parameters Transmitted Through the Buffer Descriptor ssiapp_2_mcu

The data length (8, 16, 24, 32 bits) is set in the command field of the first buffer descriptor word, especially bits 24 and 25.

The number of bytes to transmit is stored in the first buffer descriptor word (count field)

The destination address is stored in the second buffer descriptor word (address field).

The Extended Buffer address is not used

A.3.2.2.3 Use of the General Register During the Execution ssiapp_2_mcu

r0 = mask to check events2

r1 = mask to check events

r2 = AP M3 destination address

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.3.2.2.4 Overview of Script Functionality ssiapp_2_mcu

When the SSI sends an event, a data transfer loop is executed. This event is set when there is at least "watermark level" of data in the FIFO(sum of left and right FIFOs).

During this data transfer loop, the number of bytes that are transferred from the RX FIFO of the SSI to the EMI is equal to the minimum value between the "watermark level" and the number of data that have not been transferred yet. For each data transfer (one read, one write), the size of the memory write access is fixed by the parameter data length.

The necessary numbers of transfer loops are executed in order to fill the buffer, but they are executed only if the event is set. While the event is not set, the channel is not executable.

When the buffer is full, this algorithm restarts (a new buffer descriptor is read).

A.3.2.3 mcu_2_ssish

This script is similar to mcu_2_ssiapp.

The only difference is the way SDMA core accesses the SSI TX FIFO. For script of mcu_2_ssiapp, SDMA core accesses the TX FIFO through Functional Unit Bus and regards it as the peripheral DMA, whereas for the mcu_2_ssish, the access is through the Shared Peripheral Bus and SSI can be directly accessed by SDMA.

A.3.2.4 ssish_2_mcu

This script is similar to ssiapp_2_mcu. The only difference is the way SDMA core accesses the SSI RX FIFO.

For script of ssiapp_2_mcu, SDMA core accesses the RX FIFO through Functional Unit Bus and regards it as the peripheral DMA, whereas for the ssish_2_mcu, the access is through the Shared Peripheral Bus and SSI can be directly accessed by SDMA.

A.3.2.5 p_2_p

This script performs a data move of 32 bits from the peripheral's FIFO connected either on SPBA or AIPS bus to another.

If destination FIFO belongs to ASRC then pad adding is performed after every N samples from the source device. If the source FIFO belongs to ASRC then after transmitting N samples a pad is swallowed. In case there is a transaction between ASRC(source) and SPDIF (destination) no pad adding or swallowing is required because SPDIF expects even number of samples.

This script presently does not deal with the transactions involving two devices connected to AIPS bus.

A.3.2.5.1 Parameters Transmitted Through the Context p_2_p

r0: LWML event mask

r1: HWML event mask

r2: source address

r6: destination address

r7: INFO. See details in the following table.

p_2_p (r7 INFO)

Bits	Name	Description
0-7	Lower WML	Watermark Level
8	PS	1 : Pad Swallowing 0 : No Pad swallowing
9	PA	1 : Pad Adding 0 : No Pad swallowing
10	SPDIF	If this bit is set both source and destination are on SPBA
11	Source Bit(SP)	1 : Source on SPBA 0 : Source on AIPS
12	Destination Bit (DP)	1 : Destination on SPBA 0 : Destination on AIPS
13-15	----------	MUST BE 0
16-23	Higher WML	HWML
24-27	N	Total number of samples after which Pad adding/Swallowing must be done. It must be odd.
28	Lower WML Event (LWE)	SDMA events reg to check for LWML event mask 0 : LWE in EVENTS register 1 : LWE in EVENTS2 register
29	Higher WML Event(HWE)	SDMA events reg to check for HWML event mask 0 : HWE in EVENTS register 1 : HWE in EVENTS2 register
30	----------	MUST BE 0
31	CONT	1 : Amount of samples to be transferred is unknown and script will keep on transferring samples as long as both events are detected and script must be manually stopped by the application 0 : The amount of samples to be is equal to the count field of mode word

A.3.2.5.2 Parameters Transmitted Through the Buffer Descriptor p_2_p

In the first buffer descriptor word, the mode and number of types to transfer is included.

The Buffer address and Extended Buffer address are not used.

A.3.2.5.3 Use of the General Register During the Execution p_2_p

The register usage for each case(spba_2_spba, asrc_2_spba…) are different, so don't present here.

A.3.2.5.4 Overview of Script Functionality p_2_p

The script get the number of data to transfer per event according to the bit 31(CONT) of INFO.

If CONT is 0, each transfer loop will transmit the number of data as in the mode count; Or else, it means the number of samples to be transferred is not known and the transfer must take place as long as both events are detected and the script must be manually stopped by the application in case the transfer needs to be stopped.

When PS or PA is set, then after each N words transfer, a pad swallowing or pad adding will be done. This is to handle the ASRC involved transfer.

The transfer is executed only when the event is set. After each transfer for the event, the script will try to obtain a new BD.

A.3.2.6 hdmi_dma

This script sets up the HDMI DMA start and end address from the buffer chain, and launches an HDMI DMA transfer on the HDMI DMA done event.

A.3.2.6.1 Parameters Transmitted Through the Context hdmi_dma

r4: Number of DMA buffers in loop

r6: Address of data structure setup by software. Detailed data structure below:

Table A-2. SDMA Scripts Overview

Name	Offset	Width (bytes)	Description
CONTROL	0	4	Address of HDMI DMA control register
STATUS	4	4	Address of HDMI DMA status register
START	8	4	Address of HDMI DMA start address register
START1	12	4	Start address of buffer 1 for HDMI DMA transfer
END1	16	4	End address of buffer 1 for HDMI DMA transfer
START2	20	4	Start address of buffer 1 for HDMI DMA transfer. Available only when value of r4>1
END2	24	4	End address of buffer 1 for HDMI DMA transfer. Available only when value of r4>1

Table continues on the next page...

Table A-2. SDMA Scripts Overview (continued)

Name	Offset	Width (bytes)	Description
STARTn	4+8*n	4	Start address of buffer 1 for HDMI DMA transfer. n is the value of r4.
ENDn	8+8*n	4	End address of buffer 1 for HDMI DMA transfer. n is ghe value in r4.

A.3.2.6.2 Parameters Transmitted Through the Buffer Descriptor hdmi_dma

None

A.3.2.6.3 Use of the General Register During the Execution hdmi_dma

r0 = N/A

r1 = control register address

r2 = status register address

r3 = DMA start address register address

r4 = offset of DMA buffer chain end

r5 = offset of current DMA buffer

r6 = pointer of data structure that described above

r7 = N/A

A.3.2.6.4 Overview of Script Functionality hdmi_dma

The parameters of the data structure used in the script are retrieved from the channel context. No parameter is retrieved through the buffer descriptor as no real SDMA transfer performed.

When the HDMI DMA done request is captured, the script will clear the DMA done bit in the status register and set up the DMA start and end address to the next buffer (rewind if it reaches the end of the buffer chain). Next it will restart the HDMI DMA transfer, then yield and wait for the next DMA done request.

When an error is captured, it will stop the channel.

A.3.2.7 mcu_2_ecspi

This script is similar to mcu_2_app, but it uses SPI Exchange (XCH) as PIO mode in the SDMA script instead of using Start Mode Control (SMC), for the i.MX6/7/8M Family of Applications Processors affected by the Errata (ERR009165) on ECSPI. Please note, in this case, do not program the ECSPIx_CONREG[XCH] bit since the script will set XCH every time after the FIFO is filled.

A.3.2.7.1 Parameters Transmitted Through the Context mcu_2_ecspi

r0: mask to check events2 - If script is triggered by event 32+I, r0[I] must be set to 1.

r1: mask to check event - If script is triggered by event I, r1[I] must be set to 1.

r6: address of the peripheral TX FIFO.

r7: Watermark level - Used to determine the maximum data that can be sent to the peripheral each time the channel is started. Bit 31 is used by the script to determine if ERR009165 is fixed. If ERR009165 is fixed, set bit 31 to 1, so that the script uses SMC mode for higher performance.

A.3.2.7.2 Parameters Transmitted Through the Buffer Descriptor mcu_2_ecspi

The peripheral size/data length is set in the command field of the first buffer descriptor word, especially bits 24 and 25.

The number of bytes to transmit is stored in the first buffer descriptor word (count field).

The source address in the external memory is stored in the second buffer descriptor word (address field).

The Extended Buffer address is not used.

A.3.2.7.3 Use of the General Register During the Execution mcu_2_ecspi

r0 = mask to check events2

r1 = mask to check events

r2 = TX FIFO address

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.3.2.7.4 Overview of Script Functionality mcu_2_ecspi

The functionality of this script is similar to mcu_2_app, with the exception of the following:

1. First, the script checks the value of the ECSPIx_TESTREG[RXCNT] bit field. No action is performed if there is a lot of data (3/4 of FIFO size) that cannot be fetched in time from the RX FIFO. Otherwise, filling the TX FIFO may cause the ECSPI RX FIFO to overflow since the same size of data will be shifted in during data shift out.
2. The script checks the value of bit 31 of r7 (Watermark). If bit 31 is set to 1, this step is ignored. If bit 31 is not set, the mode is set to XCH every time after the FIFO is filled, to trigger SPI transfer.

A.3.2.8 mcu_2_sai

This script is used for the audio multi-FIFO case, where the destination/source address is not fixed, but incremental and the address will rollback to the first FIFO after traversing all the FIFO's. This script is based on the mcu_2_shp script, with additional parameter defines added for r7 (Watermark).

A.3.2.8.1 Parameters Transmitted Through the Context mcu_2_sai

r0: mask to check events2

r1: mask to check events

r6: address of the peripheral TX FIFO

r7: Details are provided in the following table.

Bits	Name	Description
0-11	WML	Watermark level (wml*fifo_number)
12-15	FIFO number	Number of FIFOs to fill.
16-19	FIFO offset	Offset between two FIFOs. Note that the offset between all the FIFOs should be the same.

Table continues on the next page...

Bits	Name	Description
		0: No offset between the FIFOs, which means it is continuous. For example, FIFO1 address is 0x30010020 and FIFO2 address is 0x30010024. 1: 1 word offset between the FIFOs. For example, FIFO1 address is 0x30010020 and FIFO2 is 0x30010028 ... N: N words offset between the FIFOs.
23	SW done	SW done enabled/disabled. Some modules cannot clear events automatically once the DMA request is serviced, so SW done is used to notify the module that the DMA request is done.
24-27	SW done selector	SW done selector for the right IP/event. Please refer to the SDMAARMx_DONE0_CONFIG and SDMAARMx_DONE1_CONFIG registers for additional details.
28-31	Words per FIFO	Number of words per FIFO. 0: Only one word per FIFO filling, then jump to the next FIFO. 1: Two words per FIFO filling, then jump to the next FIFO. ... N: N words per FIFO filling, then jump to the next FIFO.

A.3.2.8.2 Parameters Transmitted Through the Buffer Descriptor mcu_2_sai

The peripheral size/data length is set in the command field of the first buffer descriptor word, especially bits 24 and 25.

The number of bytes to transmit is stored in the first buffer descriptor word (count field).

The source address in the external memory is stored in the second buffer descriptor word (address field).

The Extended Buffer address is not used.

A.3.2.8.3 Use of the General Register During the Execution mcu_2_sai

r0 = mask to check events2

r1 = mask to check events

r2 = EVENTS / EVENTS2

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.3.2.8.4 Overview of Script Functionality mcu_2_sai

This script is based on the mcu_2_shp script, with additional parameters for audio multi-FIFO cases. The additional parameters are defined in Table A-2.

For example, if there are 4 FIFOs, 1 word offset between the FIFOs, 2 words per FIFO, and SW done selector 0, the script runs as shown below:

1. Check r7 to get the value of the fields: FIFO number, FIFO offset, number of words per FIFO, SW done selector, and the other fields defined for r7.
2. Start to fill FIFO1 with 2 words continuously and then jump to FIFO2 (FIFO1 + 2 * 4).
3. After filling FIFO4 with 2 words continuously, rollback to FIFO1.
4. Repeat steps 3 and 4 until FIFO1-4 fill to the Watermark level.
5. Configure the SW done selector to trigger SW done and wait for the next DMA request event to jump to step 1 again.

A.3.2.9 sai_2_mcu

This script is similar to the mcu_2_sai script. The only difference is the direction of the data transfer. This script performs a data move from the FIFO of the SAI to AP buffer.

A.3.2.10 zcanfd_2_mcu

This script is based on the app_2_mcu script. This script adds a 'done 4' instruction that triggers every time the Watermark level is reached, since CAN FD cannot clear the DMA event automatically. The RX FIFO of zcanfd is incremental.

A.3.2.10.1 Parameters Transmitted Through the Context zcanfd_2_mcu

r0: mask to check events2

r1: mask to check event

r6: address of the peripheral RX FIFO.

r7: Watermark level - Used to determine the maximum data that can be sent to the peripheral each time the channel is started.

A.3.2.10.2 Parameters Transmitted Through the Buffer Descriptor zcanfd_2_mcu

The peripheral size/data length is set in the command field of the first buffer descriptor word, especially bits 24 and 25.

The number of bytes to transmit is stored in the first buffer descriptor word (count field).

The destination address in the external memory is stored in the second buffer descriptor word (address field).

The Extended Buffer address is not used.

A.3.2.10.3 Use of the General Register During the Execution zcanfd_2_mcu

r0 = mask to check events2

r1 = mask to check events

r2 = AP M3 destination address

r3 = Ram channel context address

r4 = Bd mode

r5 = Bd mode Count

r6 = SDMA memory mapped regs base address

r7 = Watermark

A.3.2.10.4 Overview of Script Functionality zcanfd_2_mcu

This script is based on app_2_mcu script. This script adds a 'done 4' instruction so that the SDMA can clear the DMA request event (EP), since CAN FD cannot clear the DMA request event automatically after all the data in RX FIFO is fetched.

A.3.2.11 zqspi_2_mcu

This script is similar to zcanfd_2_mcu script.

A.3.2.12 zzmcu_2_qspi

This script performs a data move from AP buffer to FIFO of the QSPI.

This script is similar to zqspi_2_mcu script, with an additional parameter (bit 31) defined for r7.

Bit31 is used to determine if the FIFO address is incremental (bit31 = 1) or fixed (bit31 = 0).

Appendix B
Revision History

B.1 Substantive changes from revision 0 to revision 1

Substantive changes from revision 0 to revision 1 are as follows:

B.1.1 Reference Manual Revision History

Topic Cross-Reference	Change Description
-	Updates to the following chapters: • Introduction • Fusemap • System Boot • Arm Cortex M7 Platform (CM7) • Interrupts and DMA Events Added the following chapters: • Arm Cortex A53 Platform (A53) • Messaging Unit (MU) • Network Interconnect Bus System (NIC) • Shared Peripheral Bus Arbiter (SPBA) • TrustZone Address Space Controller (TZASC) • System Counter (SYS_CTR) • Clock Control Module (CCM) • Crystal Oscillator (XTALOSC) • Thermal Monitoring Unit (TMU) • On-Chip OTP Controller (OCOTP_CTRL) • System Reset Controller (SRC) • Watchdog Timer (WDOG) • Interrupt Request Steering (IRQ_STEER) • IOMUX Controller (IOMUXC) • External Memory Overview • DDR Controller (DDRC) • DDR BLK_CTRL • DDR PHY (DDR_PHY) • AHB-to-APBH Bridge with DMA (APBH-Bridge-DMA) • 62BIT Correcting ECC Accelerator (BCH) • General Purpose Media Interface (GPMI) • Enhanced Configurable SPI (ECSPI) • FlexSPI Controller (FlexSPI)

Limited warranty and liability — Information in this document is believed to be accurate and reliable. However, NXP Semiconductors does not give any representations or warranties, expressed or implied, as to the accuracy or completeness of such information and shall have no liability for the consequences of use of such information. NXP Semiconductors takes no responsibility for the content in this document if provided by an information source outside of NXP Semiconductors. In no event shall NXP Semiconductors be liable for any indirect, incidental, punitive, special or consequential damages (including - without limitation - lost profits, lost savings, business interruption, costs related to the removal or replacement of any products or rework charges) whether or not such damages are based on tort (including negligence), warranty, breach of contract or any other legal theory.

Notwithstanding any damages that customer might incur for any reason whatsoever, NXP Semiconductors' aggregate and cumulative liability towards customer for the products described herein shall be limited in accordance with the Terms and conditions of commercial sale of NXP Semiconductors.

Security — Customer understands that all NXP products may be subject to unidentified or documented vulnerabilities. Customer is responsible for the design and operation of its applications and products throughout their lifecycles to reduce the effect of these vulnerabilities on customer's applications and products. Customer's responsibility also extends to other open and/or proprietary technologies supported by NXP products for use in customer's applications. NXP accepts no liability for any vulnerability. Customer should regularly check security updates from NXP and follow up appropriately.

Customer shall select products with security features that best meet rules, regulations, and standards of the intended application and make the ultimate design decisions regarding its products and is solely responsible for compliance with all legal, regulatory, and security related requirements concerning its products, regardless of any information or support that may be provided by NXP. NXP has a Product Security Incident Response Team (PSIRT) (reachable at PSIRT@nxp.com) that manages the investigation, reporting, and solution release to security vulnerabilities of NXP products.

Right to make changes — NXP Semiconductors reserves the right to make changes to information published in this document, including without limitation specifications and product descriptions, at any time and without notice. This document supersedes and replaces all information supplied prior to the publication hereof.

Suitability for use — NXP Semiconductors products are not designed, authorized or warranted to be suitable for use in life support, life-critical or safety-critical systems or equipment, nor in applications where failure or malfunction of an NXP Semiconductors product can reasonably be expected to result in personal injury, death or severe property or environmental damage. NXP Semiconductors and its suppliers accept no liability for inclusion and/or use of NXP Semiconductors products in such equipment or applications and therefore such inclusion and/or use is at the customer's own risk.

Applications — Applications that are described herein for any of these products are for illustrative purposes only. NXP Semiconductors makes no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

Customers are responsible for the design and operation of their applications and products using NXP Semiconductors products, and NXP Semiconductors accepts no liability for any assistance with applications or customer product design. It is customer's sole responsibility to determine whether the NXP Semiconductors product is suitable and fit for the customer's applications and products planned, as well as for the planned application and use of customer's third party customer(s). Customers should provide appropriate design and operating safeguards to minimize the risks associated with their applications and products.

NXP Semiconductors does not accept any liability related to any default, damage, costs or problem which is based on any weakness or default in the customer's applications or products, or the application or use by customer's third party customer(s). Customer is responsible for doing all necessary testing for the customer's applications and products using NXP Semiconductors products in order to avoid a default of the applications and the products or of the application or use by customer's third party customer(s). NXP does not accept any liability in this respect.

Export control — This document as well as the item(s) described herein may be subject to export control regulations. Export might require a prior authorization from competent authorities.

Table continues on the next page...

Evaluation products —This product is provided on an “as is” and “with all faults” basis for evaluation purposes only. NXP Semiconductors, its affiliates and their suppliers expressly disclaim all warranties, whether express, implied or statutory, including but not limited to the implied warranties of non-infringement, merchantability and fitness for a particular purpose. The entire risk as to the quality, or arising out of the use or performance, of this product remains with customer. In no event shall NXP Semiconductors, its affiliates or their suppliers be liable to customer for any special, indirect, consequential, punitive or incidental damages (including without limitation damages for loss of business, business interruption, loss of use, loss of data or information, and the like) arising out the use of or inability to use the product, whether or not based on tort (including negligence), strict liability, breach of contract, breach of warranty or any other theory, even if advised of the possibility of such damages.

Notwithstanding any damages that customer might incur for any reason whatsoever (including without limitation, all damages referenced above and all direct or general damages), the entire liability of NXP Semiconductors, its affiliates and their suppliers and customer’s exclusive remedy for all of the foregoing shall be limited to actual damages incurred by customer based on reasonable reliance up to the greater of the amount actually paid by customer for the product or five dollars (US$5.00). The foregoing limitations, exclusions and disclaimers shall apply to the maximum extent permitted by applicable law, even if any remedy fails of its essential purpose.

Translations — A non-English (translated) version of a document is for reference only. The English version shall prevail in case of any discrepancy between the translated and English versions.
