When you enable the minor loop offset overlay (either SMLOE or DMLOE is 1), eDMA redefines TCDn_NBYTES_MLOFFNO /TCDn_NBYTES_MLOFFYES. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES specifies the sign-extended minor loop offset value (MLOFF). The same offset value (MLOFF) applies to both source and destination minor loop offsets. When the minor loop offset is enabled, you must align it to the transfer size of the source or destination it is associated with. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFNO) defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFYES is defined as follows:

- If either minor loop offset is enabled (SMLOE or DMLOE = 1), then see the TCDn_NBYTES_MLOFFYES register description.
- If SMLOE and DMLOE are both 0, then see the TCDn_NBYTES_MLOFFNO register description.

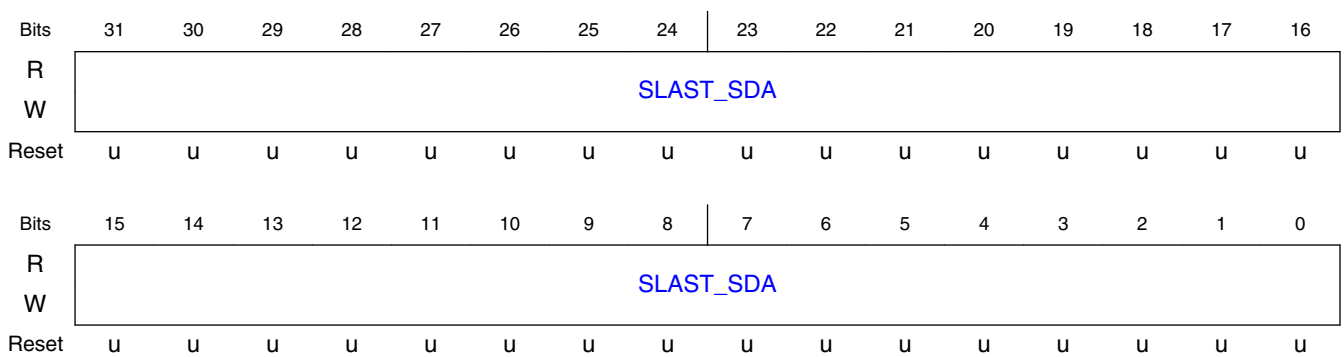
7.3.5.6.11.4 Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - Minor loop offset not applied to SADDR 1b - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion.

Table continues on the next page...

Field	Function
	0b - Minor loop offset not applied to DADDR 1b - Minor loop offset applied to DADDR
29-10 MLOFF	Minor Loop Offset If SMLOE or DMLOE is 1, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
9-0 NBYTES	Number of Bytes To Transfer Per Service Request The number of bytes to be transferred in each service request of the channel. As a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the minor byte transfer count has been reached. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major iteration count is decremented and restored to the TCD memory. If the major iteration count is complete, additional processing is performed.



7.3.5.6.12 TCD Last Source Address Adjustment / Store DADDR Address (TCD0_SLAST_SDA - TCD31_SLAST_SDA)

7.3.5.6.12.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_SLAST_SDA	2Ch + (n × 1000h)

7.3.5.6.12.2 Diagram

7.3.5.6.12.3 Fields

Field	Function
31-0 SLAST_SDA	Last Source Address Adjustment / Store DADDR Address Source last address adjustment or the system memory address for destination address (DADDR) storage. If (TCDn_CSR[ESDA] = 0), then: • Adjustment value is added to the source address at the completion of the major iteration count. This value can be used to restore the source address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final source address adjustment. Otherwise: • This address points to the 32-bit-aligned memory location where the destination address (DADDR) is to be stored in system memory. By saving the final destination address in system memory via the ESDA feature, you are able to compute the size of a variable destination data buffer by simply subtracting the beginning DADDR from the final, saved DADDR. This feature is used together with the scatter/gather operation to prevent the loss of the final DADDR, which is overwritten during the scatter/gather operation. The "Store Destination Address" (SDA) value must be a 32-bit-aligned location because the eDMA forces the lower two address bits of the SLAST_SDA field to zero when ESDA is enabled. The module performs this write operation when the major loop is done; that is, when the major iteration count (CITER) decrements to zero.

7.3.5.6.13 TCD Destination Address (TCD0_DADDR - TCD31_DADDR)

7.3.5.6.13.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_DADDR	30h + (n × 1000h)

7.3.5.6.13.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

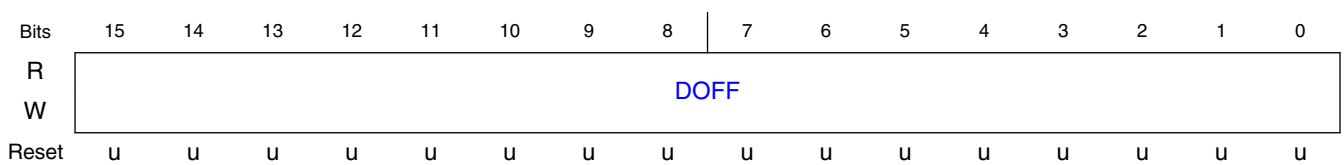
Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DADDR															
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

7.3.5.6.13.3 Fields

Field	Function
31-0 DADDR	Destination Address Memory address pointing to the destination data.



7.3.5.6.14 TCD Signed Destination Address Offset (TCD0_DOFF - TCD31_DOFF)

7.3.5.6.14.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_DOFF	34h + (n × 1000h)

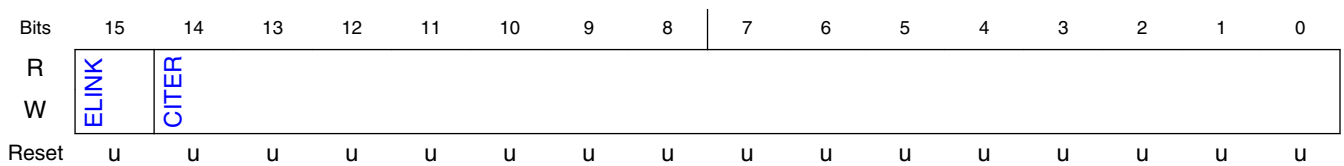
7.3.5.6.14.2 Diagram

7.3.5.6.14.3 Fields

Field	Function
15-0 DOFF	Destination Address Signed Offset Sign-extended offset that is applied to the current destination address to form the next-state value as each destination write is completed.

7.3.5.6.15 TCD Current Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD31_CITER_ELINKNO)

7.3.5.6.15.1 Offset



For n = 0 to 31:

Register	Offset
TCDn_CITER_ELINKNO	36h + (n × 1000h)

7.3.5.6.15.2 Function

If TCDn_CITER[ELINK] is 0, the TCDn_CITER register is defined as follows.

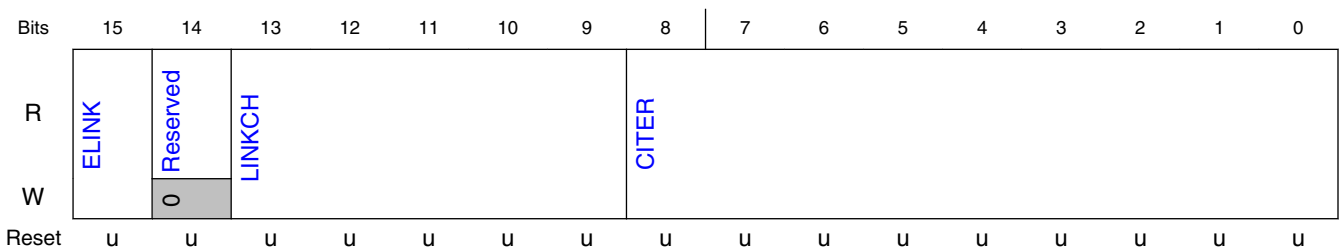
7.3.5.6.15.3 Diagram

7.3.5.6.15.4 Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel to 1. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking. **NOTE:** This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE:** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE:** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

7.3.5.6.16 TCD Current Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD31_CITER_ELINKYES)

7.3.5.6.16.1 Offset



For n = 0 to 31:

Register	Offset
TCDn_CITER_ELINKYES	36h + (n × 1000h)

7.3.5.6.16.2 Function

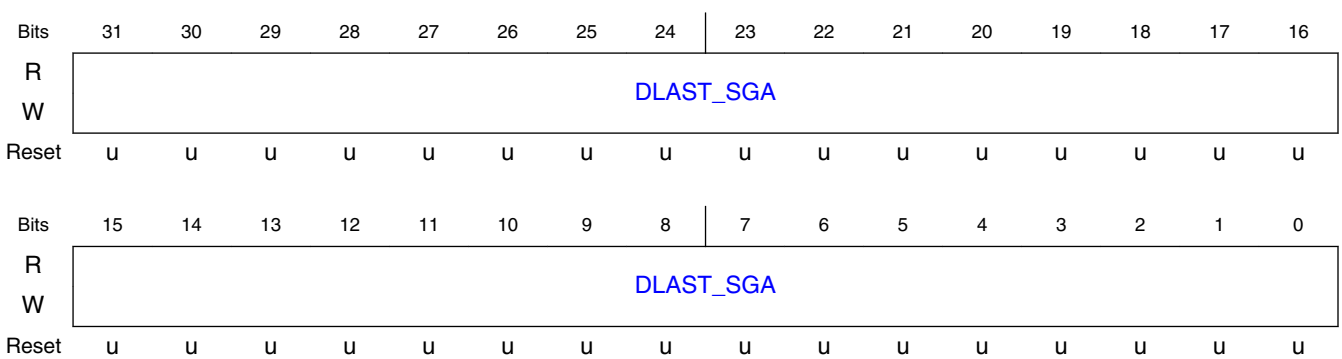
If TCDn_CITER[ELINK] is 1, the TCDn_CITER register is defined as follows.

7.3.5.6.16.3 Diagram

7.3.5.6.16.4 Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. When enabled, an internal mechanism sets the TCDn_CSR[START] field of the specified channel (LINKCH) upon minor loop completion. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking. **NOTE:** This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14 —	Reserved
13-9 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted the eDMA engine initiates a channel service request to the channel defined by this field by writing that channel's TCDn_CSR[START] field to 1.
8-0 CITER	Current Major Iteration Count

Field	Function
	This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to the TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE:** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE:** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.



7.3.5.6.17 TCD Last Destination Address Adjustment / Scatter Gather Address (TCD0_DLAST_SGA - TCD31_DLAST_SGA)

7.3.5.6.17.1 Offset

For n = 0 to 31:

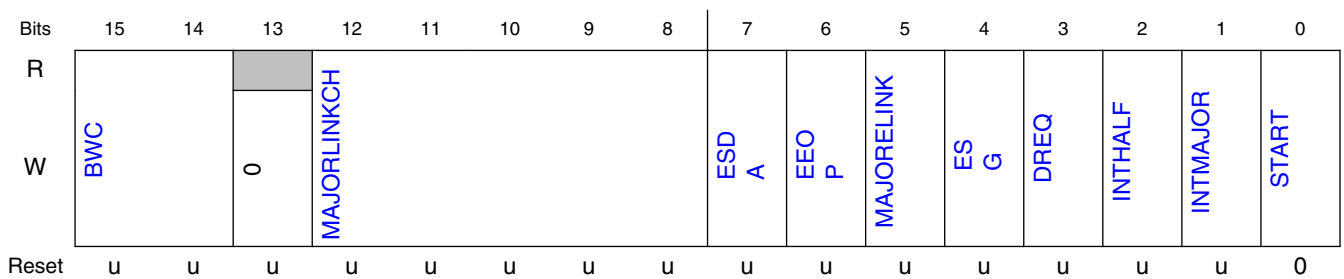
Register	Offset
TCDn_DLAST_SGA	38h + (n × 1000h)

7.3.5.6.17.2 Diagram

7.3.5.6.17.3 Fields

Field	Function
31-0 DLAST_SGA	Last Destination Address Adjustment / Scatter Gather Address Adjustment of the last destination address or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCDn_CSR[ESG] = 0) then:

Field	Function
	• Adjustment value is added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo 32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo 32-byte, or else a configuration error is reported.



7.3.5.6.18 TCD Control and Status (TCD0_CSR - TCD31_CSR)

7.3.5.6.18.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_CSR	3Ch + (n × 1000h)

7.3.5.6.18.2 Diagram

7.3.5.6.18.3 Fields

Field	Function
15-14	Bandwidth Control
BWC	Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces eDMA to stall after the completion of each read/write access, to control the bus request bandwidth seen by the system bus interconnect. **NOTE:** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency.

Table continues on the next page...

Field	Function
	00b - No eDMA engine stalls 01b - Reserved 10b - eDMA engine stalls for 4 cycles after each R/W 11b - eDMA engine stalls for 8 cycles after each R/W
13 —	Reserved
12-8 MAJORLINKCH	Major Loop Link Channel Number If (MAJORELINK = 0) then: • No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted. Otherwise: • After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field to 1.
7 ESDA	Enable Store Destination Address As the channel completes the major loop by either the current iteration counter (CITER) decrementing to 0, or by receiving an enabled end-of-packet signal, this field enables writing the destination address (DADDR) to the address stored in the SLAST_SDA field. The value written to system memory is the last DADDR value prior to the DLAST_SGA offset being applied, or overwritten by an enabled scatter/gather operation. When the SDA bit is 1, SLAST_SDA contains the write pointer instead of the final source address offset. Because this is a pointer and not a final offset, a last source address offset of zero is applied to SADDR instead of the SLAST_SGA value. 0b - Ability to store destination address to system memory disabled 1b - Ability to store destination address to system memory enabled
6 EEOP	Enable End-Of-Packet Processing When enabled by the EEOP field, an end-of-packet hardware input signal directs eDMA to discontinue executing the active channel, and to treat the shutdown as the major-loop-completed event. If the EEOP field is 1, the end-of-packet signal from supported peripherals is accepted. If the EEOP field is 0, the end-of-packet input is ignored. With an end-of-packet retirement, the current TCD destination address (or ESDA-saved destination address), minus the software-saved initial address (DADDR), reflects the total amount of data transferred. 0b - End-of-packet operation disabled 1b - End-of-packet hardware input signal enabled
5 MAJORELINK	Enable Link When Major Loop Complete As the channel completes the major loop, this flag enables linking to another channel defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. **NOTE:** To support the dynamic linking coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
4 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses TCDn_DLAST_SGA as a memory pointer to a 0-modulo 32-bit address containing a 32-byte data structure, which is loaded as the transfer control descriptor into local memory. **NOTE:** To support the dynamic scatter/gather coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0b - Current channel's TCD is normal format 1b - Current channel's TCD specifies scatter/gather format.

Table continues on the next page...

Field	Function
3 DREQ	Disable Request If this flag is 1, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches 0. 0b - No operation. Channel's ERQ field not affected 1b - Clear the ERQ field to 0 upon major loop completion, thus disabling hardware service requests. Channel's ERQ field cleared to 0 when major loop complete
2 INTHALF	Enable Interrupt If Major Counter Half-complete If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER = (BITER/2)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes, or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE:** If BITER = 1, do not use INTHALF; use INTMAJOR instead. 0b - Halfway point interrupt disabled 1b - Halfway point interrupt enabled
1 INTMAJOR	Enable Interrupt If Major count complete If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count (CITER) reaches 0. 0b - End-of-major loop interrupt disabled 1b - End-of-major loop interrupt enabled
0 START	Channel Start If this flag is 1, the channel is requesting service. The eDMA hardware automatically clears this flag to 0 after the channel begins execution. 0b - Channel not explicitly started 1b - Channel explicitly started via a software-initiated service request

7.3.5.6.19 TCD Beginning Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_BITER_ELINKNO - TCD31_BITER_ELINKNO)

7.3.5.6.19.1 Offset

For n = 0 to 31:

Register	Offset
TCDn_BITER_ELINKNO	3Eh + (n × 1000h)

7.3.5.6.19.2 Function

If the TCDn_BITER[ELINK] field is 0, the TCDn_BITER register is defined as follows.

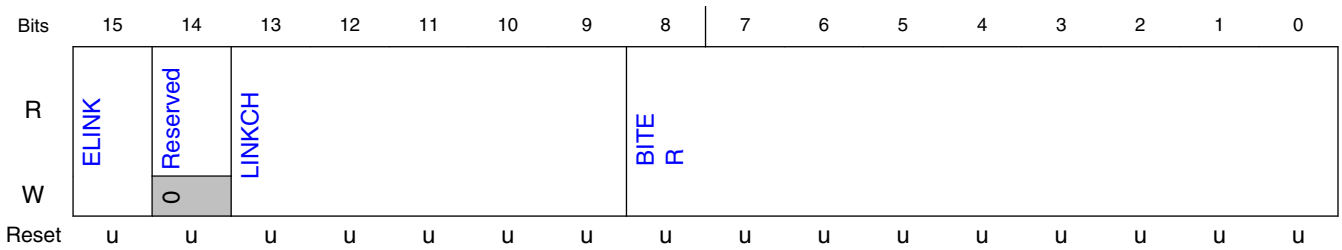
7.3.5.6.19.3 Diagram

7.3.5.6.19.4 Fields

Field	Function
15 ELINK	Enables Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be set equal to the value in the CITER field. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.

7.3.5.6.20 TCD Beginning Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_BITER_ELINKYES - TCD31_BITER_ELINKYES)

7.3.5.6.20.1 Offset



For n = 0 to 31:

Register	Offset
TCDn_BITER_ELINKYES	3Eh + (n × 1000h)

7.3.5.6.20.2 Function

If the TCDn_BITER[ELINK] field is set, the TCDn_BITER register is defined as follows.

7.3.5.6.20.3 Diagram

7.3.5.6.20.4 Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14 —	Reserved
13-9 LINKCH	Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field.
8-0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be set equal to the value in the CITER field. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.

7.4 Interrupt Request Steering (IRQ_STEER)

7.4.1 Overview

The Interrupt Request Steering (IRQ_STEER) module redirects/steers the incoming interrupts to output interrupts of a selected/designated channel as specified by a set of configuration registers.

7.4.1.1 Block diagram

A high-level block diagram of the IRQ_STEER module is provided below.

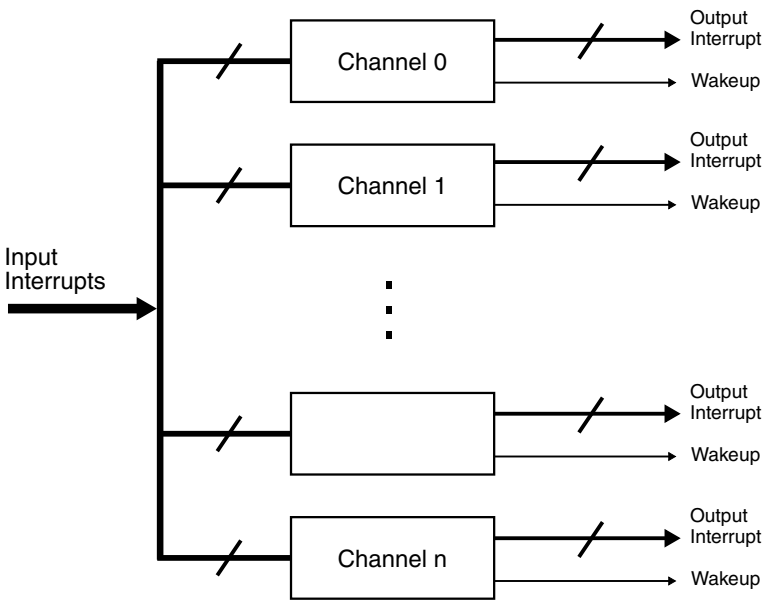


Figure 7-30. IRQ_STEER block diagram

The following figure shows the high-level operation of one channel of the IRQ_STEER module.

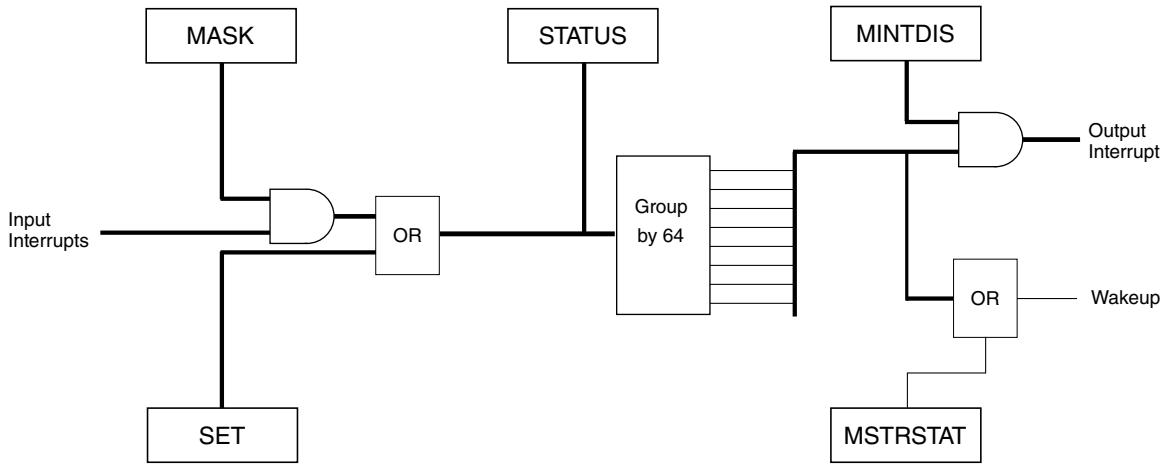

Figure 7-31. IRQ_STEER channel block diagram

7.4.1.2 Features

The IRQ_STEER module supports:

- 3 IRQ channels
- 160 interrupts per channel

7.4.2 Functional description

The IRQ_STEER module allows the user to steer 160 interrupts into one of 3 channels.

Each channel in the IRQ_STEER module supports up to 160 interrupts, and has its own set of registers consisting of:

- 5 CHn_MASK registers
- 5 CHn_SET registers
- 5 CHn_STATUS registers
- One CHn_MINTDIS register
- One CHn_MSTRSTAT register

Since this module supports 3 channels, there are 3 sets of these registers. Each set of registers will have its own base offset, which must be added to the relative offset shown in the IRQ_STEER memory map.

7.4.2.1 Interrupt Mapping

The following table shows the correlation between an interrupt and its register and bit offset for the CHn_MASK, CHn_SET, and CHn_STATUS registers of each channel.

For example:

- For a = 0, the row represents the mapping of an interrupt to the bit offset for the CHn_MASK**0**, CHn_SET**0**, and CHn_STATUS**0** registers.
- For a = 1, the row represents the mapping of an interrupt to the bit offset for the CHn_MASK**1**, CHn_SET**1**, and CHn_STATUS**1** registers.

Table 7-66. Interrupt Mapping (incomplete)

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
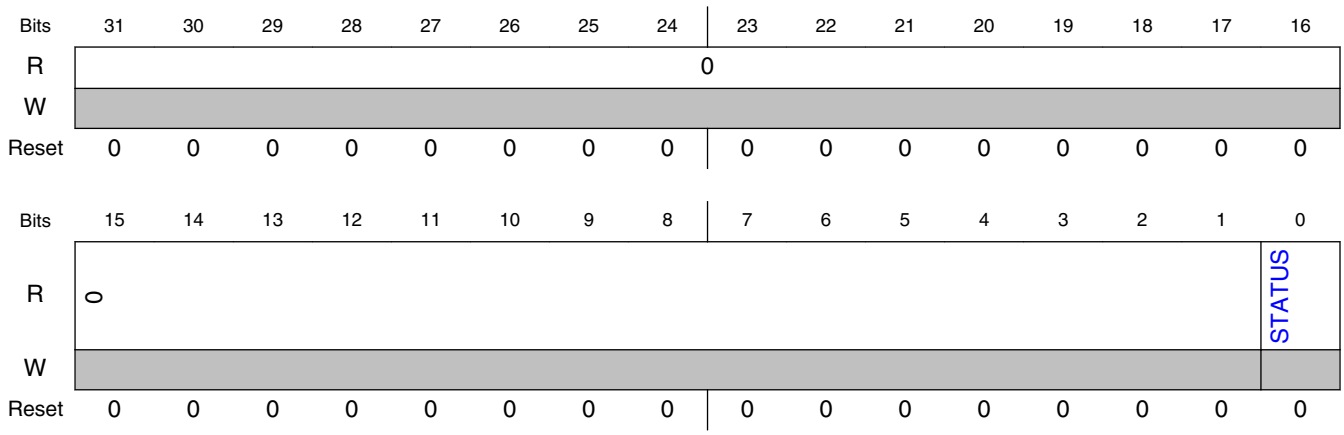
R	0													DISABLE		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

7.4.4.1.5.4 Fields



Field	Function
31-3 —	Reserved
2-0 DISABLE	Each bit of this field disables the corresponding interrupts in table above. 000b - Enable interrupts 001b - Disable interrupts

7.4.4.1.6 Channel n Master Status Register (CHn_MSTRSTAT)

7.4.4.1.6.1 Offset

Register	Offset
CHn_MSTRSTAT	44h

7.4.4.1.6.2 Diagram

7.4.4.1.6.3 Fields

Field	Function
31-1 —	Reserved
0 STATUS	Status of all interrupts 0b - No interrupts are asserted. 1b - At least one interrupt is asserted.

Chapter 8
Chip IO and Pinmux

8.1 External Signals and Pin Multiplexing

8.1.1 Overview

The chip contains a limited number of pins, most of which have multiple signal options. These signal-to-pin and pin-to-signal options are selected by the input-output multiplexer called IOMUX. The IOMUX is also used to configure other pin characteristics, such as voltage level, drive strength, and hysteresis.

The muxing options table lists the external signals grouped by the module instance, the muxing options for each signal, and the registers used to route the signal to the chosen pad.

8.1.1.1 Muxing Options

Instance	Port	Pad	Mode

8.2 IOMUX Controller (IOMUXC)

8.2.1 Overview

The IOMUX Controller (IOMUXC), together with the IOMUX, enables the IC to share one pad to several functional blocks. This sharing is done by multiplexing the pad's input and output signals.

Every module requires a specific pad setting (such as pull up or keeper), and for each pad, there are up to 8 muxing options (called ALT modes). The pad settings parameters are controlled by the IOMUXC.

The IOMUX consists only of combinatorial logic combined from several basic IOMUX cells. Each basic IOMUX cell handles only one pad signal's muxing.

Figure 8-1 illustrates the IOMUX/IOMUXC connectivity in the system.

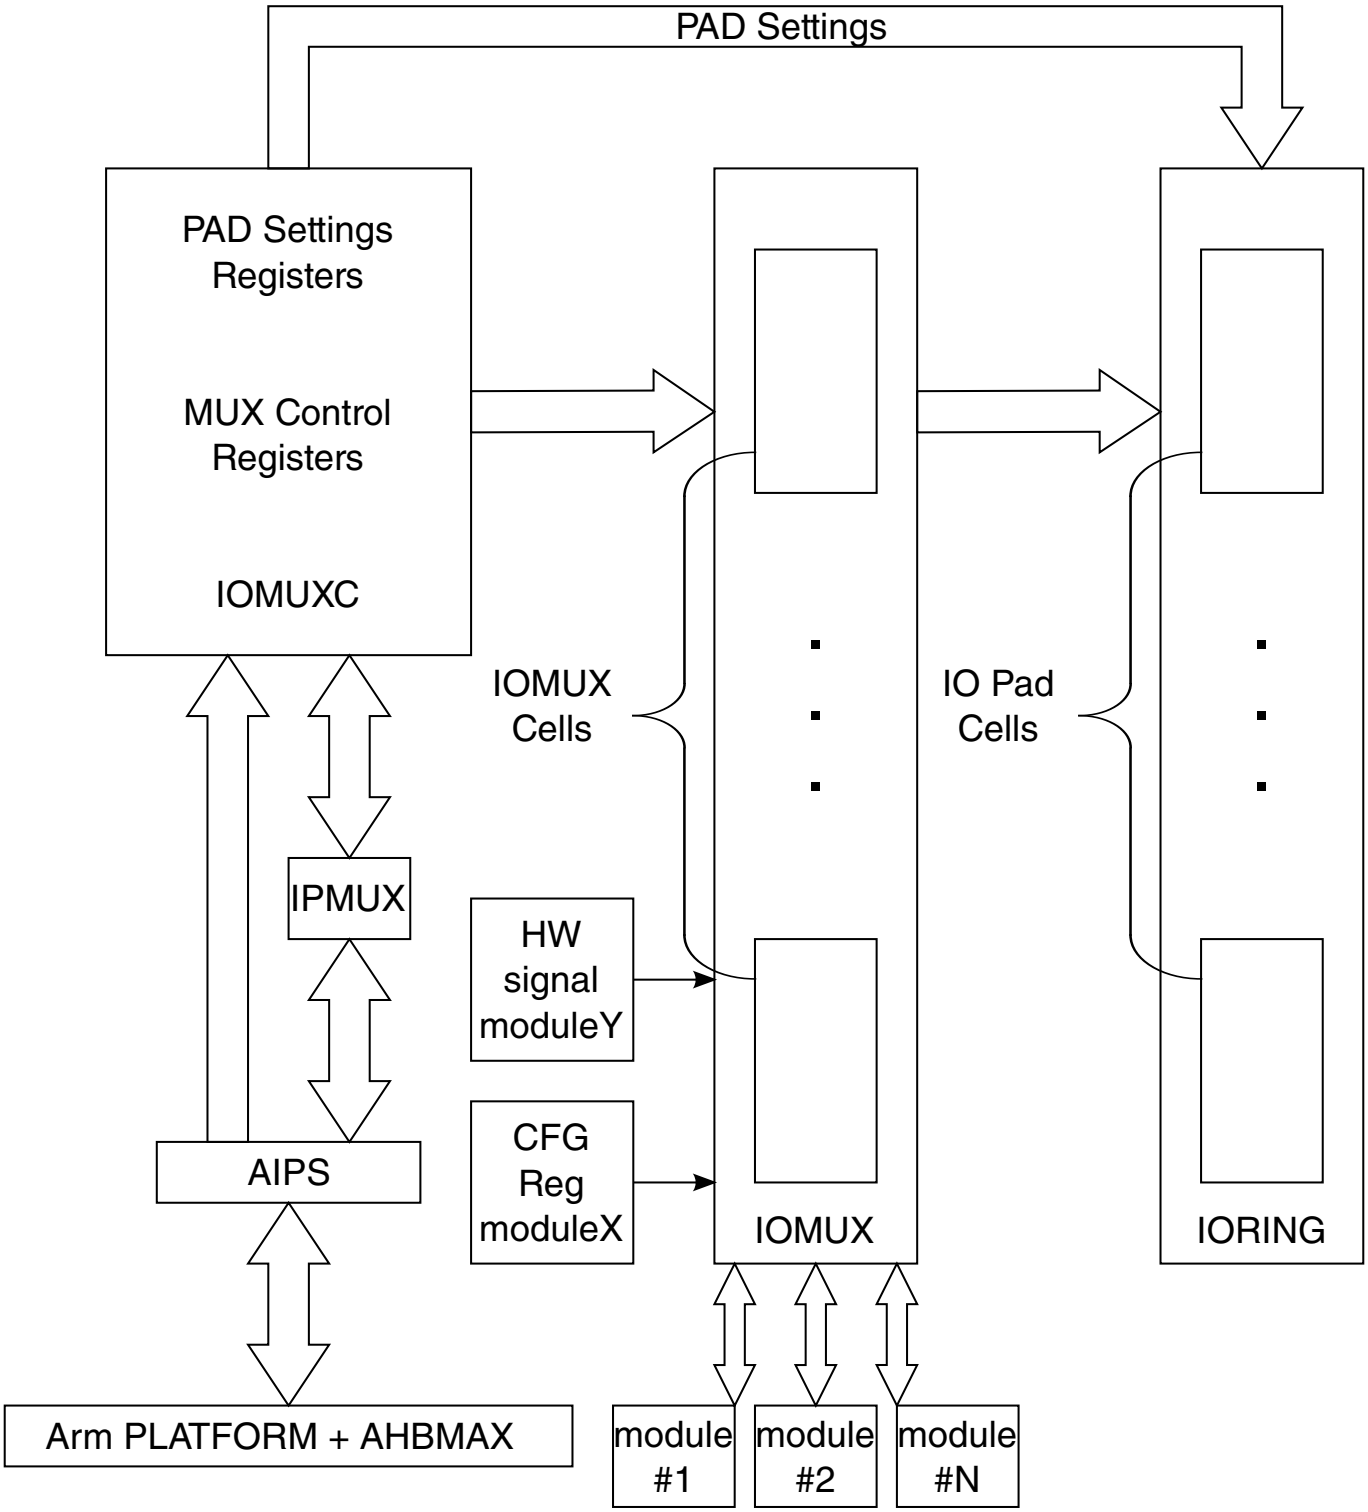

Figure 8-1. IOMUX SoC Level Block Diagram

8.2.1.1 Block Diagram

The high level illustration of the IO cells is shown in Figure 8-3

8.2.1.2 Features

The IOMUXC features include:

- 32-bit software mux control registers (IOMUXC_SW_MUX_CTL_PAD_<PAD NAME> or IOMUXC_SW_MUX_CTL_GRP_<GROUP NAME>) to configure 1 of 8 alternate (ALT) MUX_MODE fields of each pad or a predefined group of pads and to enable the forcing of an input path of the pad(s) (SION bit).
- 32-bit software pad control registers (IOMUXC_SW_PAD_CTL_PAD_<PAD_NAME> or IOMUXC_SW_PAD_CTL_GRP_<GROUP NAME>) to configure specific pad settings of each pad, or a predefined group of pads.
- 32-bit general purpose registers - several (GPR0 to GPR*n*) 32-bit registers according to SoC requirements for any usage.
- 32-bit input select control registers to control the input path to a module when more than one pad drives this module input.

Each SW MUX/PAD CTL IOMUXC register handles only one pad or one pad's group.

Only the minimum number of registers required by software are implemented by hardware. For example, if only ALT0 and ALT1 modes are used on Pad x then only one bit register will be generated as the MUX_MODE control field in the software mux control register of Pad x.

The software mux control registers may allow the forcing of pads to become input (input path enabled) regardless of the functional direction driven. This may be useful for loopback and GPIO data capture.

8.2.2 Functional description

This section provides a complete functional description of the block.

The IOMUXC consists of two sub-blocks:

- IOMUXC_REGISTERS includes all of the IOMUXC registers (see Features).
- IOMUXC_LOGIC includes all of the IOMUXC combinatorial logic (IP interface controls, address decoder, observability muxes).

The IOMUX consists of a number (about the number of pads in the SoC) of basic iomux_cell units. If only one functional mode is required for a specific pad, there is no need for IOMUX and the signals can be connected directly from the module to the I/O. The IOMUX cell is required whenever two or more functional modes are required for a specific pad or when one functional mode and the one test mode are required.

The basic iomux_cell design, which allows two levels of HW signal control (in ALT6 and ALT7 modes - ALT7 gets highest priority) is shown in Figure 8-2.

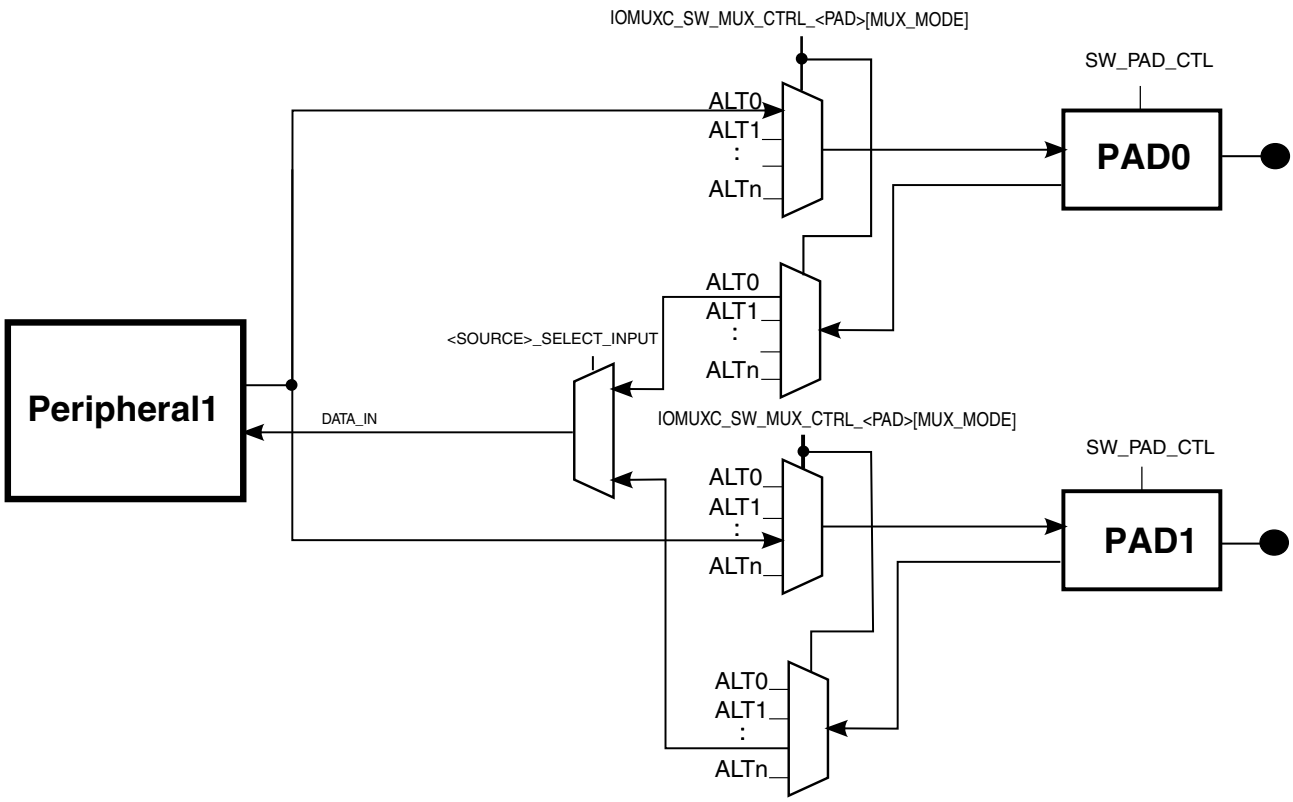

Figure 8-2. IOMUX Cell Block Diagram

8.2.2.1 GPIO pad features

The GPIO pad includes the following features:

- Wide-range voltage interface
  - 1.8V ~ 3.3V I/O interface
- CMOS input / Schmitt trigger Input
- 3-state and open-drain output
- Two slew rate control levels
- Programmable feature support
  - Controllable input enable

- Controllable CMOS/Schmitt trigger input
- Controllable pull-up/pull-down resistor
- Controllable output drive strength (x1 / x2 / x4 / x6)
- Controllable slew rate control (slow slew / fast slew)

8.2.2.1.1 Pull up/Pull down control

Pull up/Pull down function is controlled by the PE and PS pin.

Table 8-1. Pull up / Pull down control truth table

Mode	State	
	PE	PS
Disable	0	X
Pull-down enable	1	0
Pull-up enable	1	1

8.2.2.1.2 Input control

The IS pin selects CMOS and Schmitt trigger.

Table 8-2. Input control truth table

Mode	State	
	IE	IS
Disable	0	X
CMOS input	1	0
Schmitt trigger input	1	1

8.2.2.1.3 Output driver control

Output drive strength is controlled by the DS0, DS1 pin.

Table 8-3. Drive strength control truth table

State		Driver Strength
DS1	DS0	
0	0	X1
1	0	X2
0	1	X4
1	1	X6

The SR pin controls slew-rate of output driver.

Table 8-4. Slew-rate of output driver

State	Driver Slew
SR	
0	Fast Slew
1	Slow Slew

8.2.2.2 ALT6 and ALT7 extended muxing modes

The ALT7 and ALT6 extended muxing modes allow any signal in the system (such as fuse, pad input, JTAG, or software register) to override any software configuration and to force the ALT6/ALT7 muxing mode.

It also allows an IOMUX software register to control a group of pads.

8.2.2.3 SW Loopback through SION bit

A limited option exists to override the default pad functionality and force the input path to be active (ipp_ibe==1'b1) regardless of the value driven by the corresponding module. This can be done by setting the SION (Software Input On) bit in the IOMUXC_SW_MUX_CTL register (when available) to "1".

Uses include:

- LoopBack - Module x drives the pad and also receives pad value as an input.
- GPIO Capture - Module x drives the pad and the value is captured by GPIO.

8.2.2.4 Daisy chain - multi pads driving same module input pin

In some cases, more than one pad may drive a single module input pin. Such cases require the addition of one more level of IOMUXing; all of these input signals are muxed, and a dedicated software controlled register controls the mux in order to select the required input path.

A module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programable via the IOMUXC_SW_MUX_CTL_<PAD> registers) and one for defining it as the input path (via the daisy chain registers).

This means that a module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programable via the IOMUXC_SW_MUX_CTL_<PAD> registers) and one for defining it as the input path (via the daisy chain registers). The daisy chain is illustrated in the figure below.

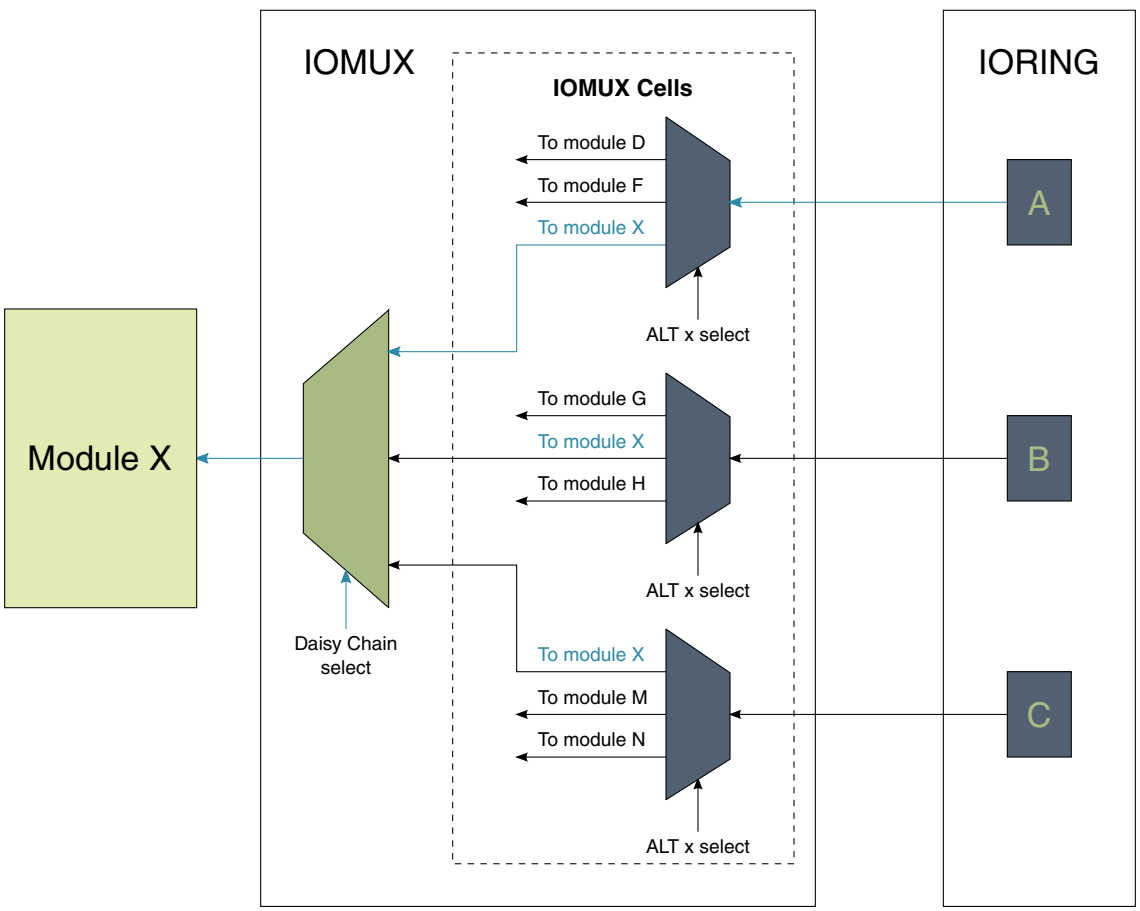

Figure 8-3. Daisy chain illustration

8.2.2.5 Clocks

The table found here describes the clock sources for IOMUXC.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 8-5. IOMUXC Clocks

Clock name	Clock Root	Description

8.2.3.6 General Purpose Register 5 (IOMUXC_GPR_GPR5)

Address: 3034_0000h base + 14h offset = 3034_0014h

IOMUXC_GPR_GPR5 field descriptions

Field	Description
31–21 -	This field is reserved.
20 GPR_WDOG3_MASK	This bit is only used to mask the internal WDOG3 int signal for output of GPIO1_IO02.ALT5_OUT, which is combined with WDOG1/2/3. 0 WDOG3 low will make the GPIO1_IO02.ALT5_OUT low 1 WDOG3 low will NOT impact the GPIO1_IO02.ALT5_OUT
19–8 -	This field is reserved.
7 GPR_WDOG2_MASK	This bit is only used to mask the internal WDOG2 int signal for output of GPIO1_IO02.ALT5_OUT, which is combined with WDOG1/2/3. 0 WDOG2 low will make the GPIO1_IO02.ALT5_OUT low 1 WDOG2 low will NOT impact the GPIO1_IO02.ALT5_OUT
6 GPR_WDOG1_MASK	Normally, WDOG1 output is in GPIO1_IO02.ALT1_OUT. This bit is only used to mask the internal WDOG1 int signal for output of GPIO1_IO02.ALT5_OUT, which is combined with WDOG1/2/3. 0 WDOG1 low will make the GPIO1_IO02.ALT5_OUT low 1 WDOG1 low will NOT impact the GPIO1_IO02.ALT5_OUT
5–3 -	This field is reserved.

Table continues on the next page...

IOMUXC_GPR_GPR5 field descriptions (continued)

Field	Description
2 GPR_ENABLE_UPSIZER	Enable to upsize 32=bit SDMA1 burst transaction to 64-bit
1 GPR_RMW_S_WAIT_BVALID_CPL	If this bit set to 1, RMW will write back the next data after bvalid_s is 1
0 GPR_RMW_WAIT_BVALID_CPL	If this bit set to 1, RMW will write back the next data after bvalid_s is 1

8.2.3.7 General Purpose Register 6 (IOMUXC_GPR_GPR6)

IOMUXC_GPR_GPR24 field descriptions

Field	Description
-	This field is reserved.

8.2.4 IOMUXC Memory Map/Register Definition

IOMUXC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3033_0014	SW_MUX_CTL_PAD_GPIO1_IO00 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO00)	32	R/W	0000_0000h	8.2.4.1/ 1408
3033_0018	SW_MUX_CTL_PAD_GPIO1_IO01 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO01)	32	R/W	0000_0000h	8.2.4.2/ 1409

Table continues on the next page...

IOMUXC memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3033_001C	SW_MUX_CTL_PAD_GPIO1_IO02 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO02)	32	R/W	0000_0000h	8.2.4.3/ 1410
3033_0020	SW_MUX_CTL_PAD_GPIO1_IO03 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO03)	32	R/W	0000_0000h	8.2.4.4/ 1412
3033_0024	SW_MUX_CTL_PAD_GPIO1_IO04 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO04)	32	R/W	0000_0000h	8.2.4.5/ 1413
3033_0028	SW_MUX_CTL_PAD_GPIO1_IO05 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO05)	32	R/W	0000_0000h	8.2.4.6/ 1414
3033_002C	SW_MUX_CTL_PAD_GPIO1_IO06 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO06)	32	R/W	0000_0000h	8.2.4.7/ 1416
3033_0030	SW_MUX_CTL_PAD_GPIO1_IO07 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO07)	32	R/W	0000_0000h	8.2.4.8/ 1417
3033_0034	SW_MUX_CTL_PAD_GPIO1_IO08 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO08)	32	R/W	0000_0000h	8.2.4.9/ 1418
3033_0038	SW_MUX_CTL_PAD_GPIO1_IO09 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO09)	32	R/W	0000_0000h	8.2.4.10/ 1420
3033_003C	SW_MUX_CTL_PAD_GPIO1_IO10 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO10)	32	R/W	0000_0000h	8.2.4.11/ 1421
3033_0040	SW_MUX_CTL_PAD_GPIO1_IO11 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO11)	32	R/W	0000_0000h	8.2.4.12/ 1422
3033_0044	SW_MUX_CTL_PAD_GPIO1_IO12 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO12)	32	R/W	0000_0000h	8.2.4.13/ 1424
3033_0048	SW_MUX_CTL_PAD_GPIO1_IO13 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO13)	32	R/W	0000_0000h	8.2.4.14/ 1425
3033_004C	SW_MUX_CTL_PAD_GPIO1_IO14 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO14)	32	R/W	0000_0000h	8.2.4.15/ 1426
3033_0050	SW_MUX_CTL_PAD_GPIO1_IO15 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_GPIO1_IO15)	32	R/W	0000_0000h	8.2.4.16/ 1427
3033_0054	SW_MUX_CTL_PAD_ENET_MDC SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_ENET_MDC)	32	R/W	0000_0005h	8.2.4.17/ 1428
3033_0058	SW_MUX_CTL_PAD_ENET_MDIO SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_ENET_MDIO)	32	R/W	0000_0005h	8.2.4.18/ 1430
3033_005C	SW_MUX_CTL_PAD_ENET_TD3 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_ENET_TD3)	32	R/W	0000_0005h	8.2.4.19/ 1431
3033_0060	SW_MUX_CTL_PAD_ENET_TD2 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_ENET_TD2)	32	R/W	0000_0005h	8.2.4.20/ 1432
3033_0064	SW_MUX_CTL_PAD_ENET_TD1 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_ENET_TD1)	32	R/W	0000_0005h	8.2.4.21/ 1434
3033_0068	SW_MUX_CTL_PAD_ENET_TD0 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_ENET_TD0)	32	R/W	0000_0005h	8.2.4.22/ 1435
3033_006C	SW_MUX_CTL_PAD_ENET_TX_CTL SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_ENET_TX_CTL)	32	R/W	0000_0005h	8.2.4.23/ 1436
3033_0070	SW_MUX_CTL_PAD_ENET_TXC SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_ENET_TXC)	32	R/W	0000_0005h	8.2.4.24/ 1438

Table continues on the next page...

IOMUXC memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3033_0074	SW_MUX_CTL_PAD_ENET_RX_CTL SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_ENET_RX_CTL)	32	R/W	0000_0005h	8.2.4.25/ 1439
3033_0078	SW_MUX_CTL_PAD_ENET_RXC SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_ENET_RXC)	32	R/W	0000_0005h	8.2.4.26/ 1440
3033_007C	SW_MUX_CTL_PAD_ENET_RD0 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_ENET_RD0)	32	R/W	0000_0005h	8.2.4.27/ 1442
3033_0080	SW_MUX_CTL_PAD_ENET_RD1 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_ENET_RD1)	32	R/W	0000_0005h	8.2.4.28/ 1443
3033_0084	SW_MUX_CTL_PAD_ENET_RD2 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_ENET_RD2)	32	R/W	0000_0005h	8.2.4.29/ 1444
3033_0088	SW_MUX_CTL_PAD_ENET_RD3 SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_ENET_RD3)	32	R/W	0000_0005h	8.2.4.30/ 1446
3033_008C	SW_MUX_CTL_PAD_SD1_CLK SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_SD1_CLK)	32	R/W	0000_0005h	8.2.4.31/ 1447
3033_0090	SW_MUX_CTL_PAD_SD1_CMD SW MUX Control Register (IOMUXC_SW_MUX_CTL_PAD_SD1_CMD)	32	R/W	0000_0005h	8.2.4.32/ 1448

8.3 General Purpose Input/Output (GPIO)

8.3.1 Overview

The General-Purpose Input/Output (GPIO) peripheral provides dedicated general-purpose pins that can be configured as either inputs or outputs.

When configured as an output, it is possible to write to an internal register to control the state driven on the output pin. When configured as an input, it is possible to detect the state of the input by reading the state of an internal register. In addition, the GPIO peripheral can produce CORE interrupts.

8.3.1.1 Block Diagram

The GPIO subsystem contains multiple GPIO blocks, which can generate and control up to 32 signals for general purpose.

The block diagram for the GPIO block is provided below.

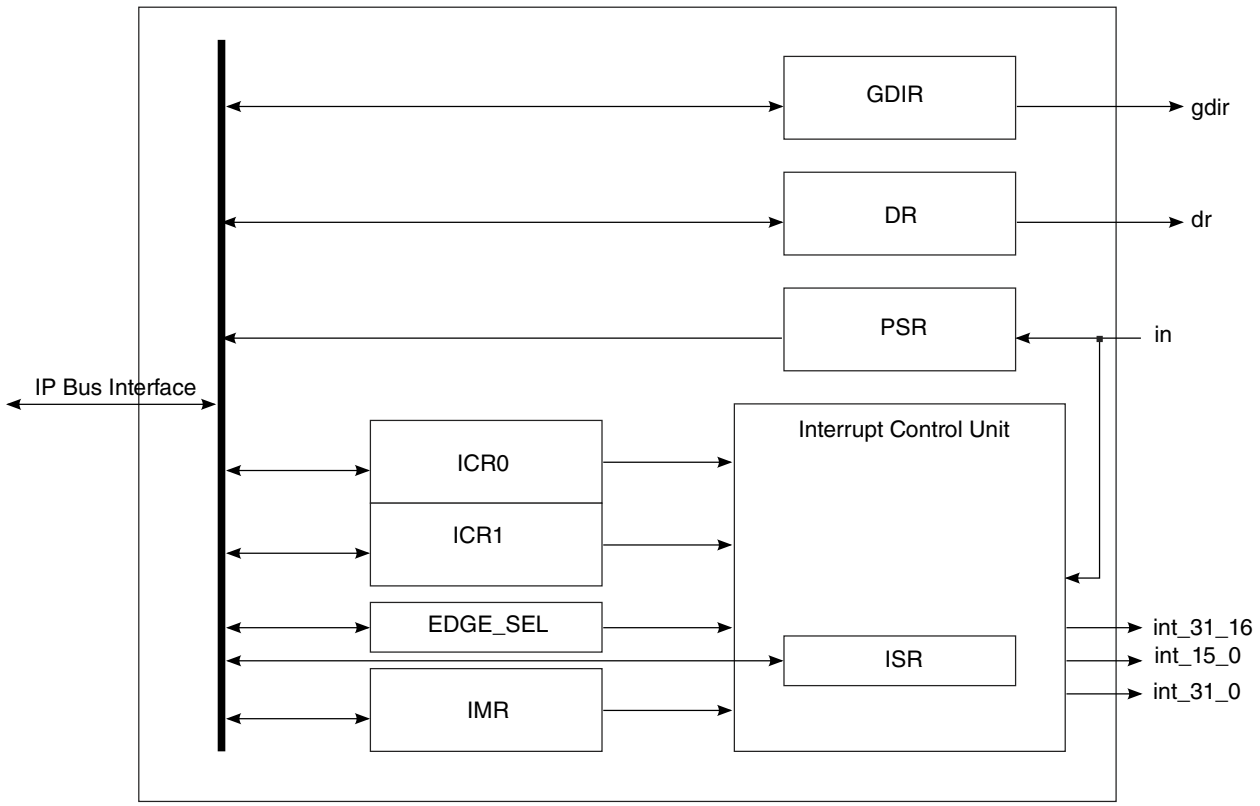

Figure 8-4. GPIO Block Diagram

8.3.1.2 Features

The GPIO includes the following features:

- General purpose input/output logic capabilities:
  - Drives specific data to output using the data register (DR)
  - Controls the direction of the signal using the GPIO direction register (GDIR)
  - Enables the core to sample the status of the corresponding inputs by reading the pad sample register (PSR).
- GPIO interrupt capabilities:
  - Supports 32 interrupts
  - Identifies interrupt edges
  - Generates three active-high interrupts to the SoC interrupt controller

8.3.2 Functional Description

The GPIO is one of the blocks controlling the IOMUX of the chip.

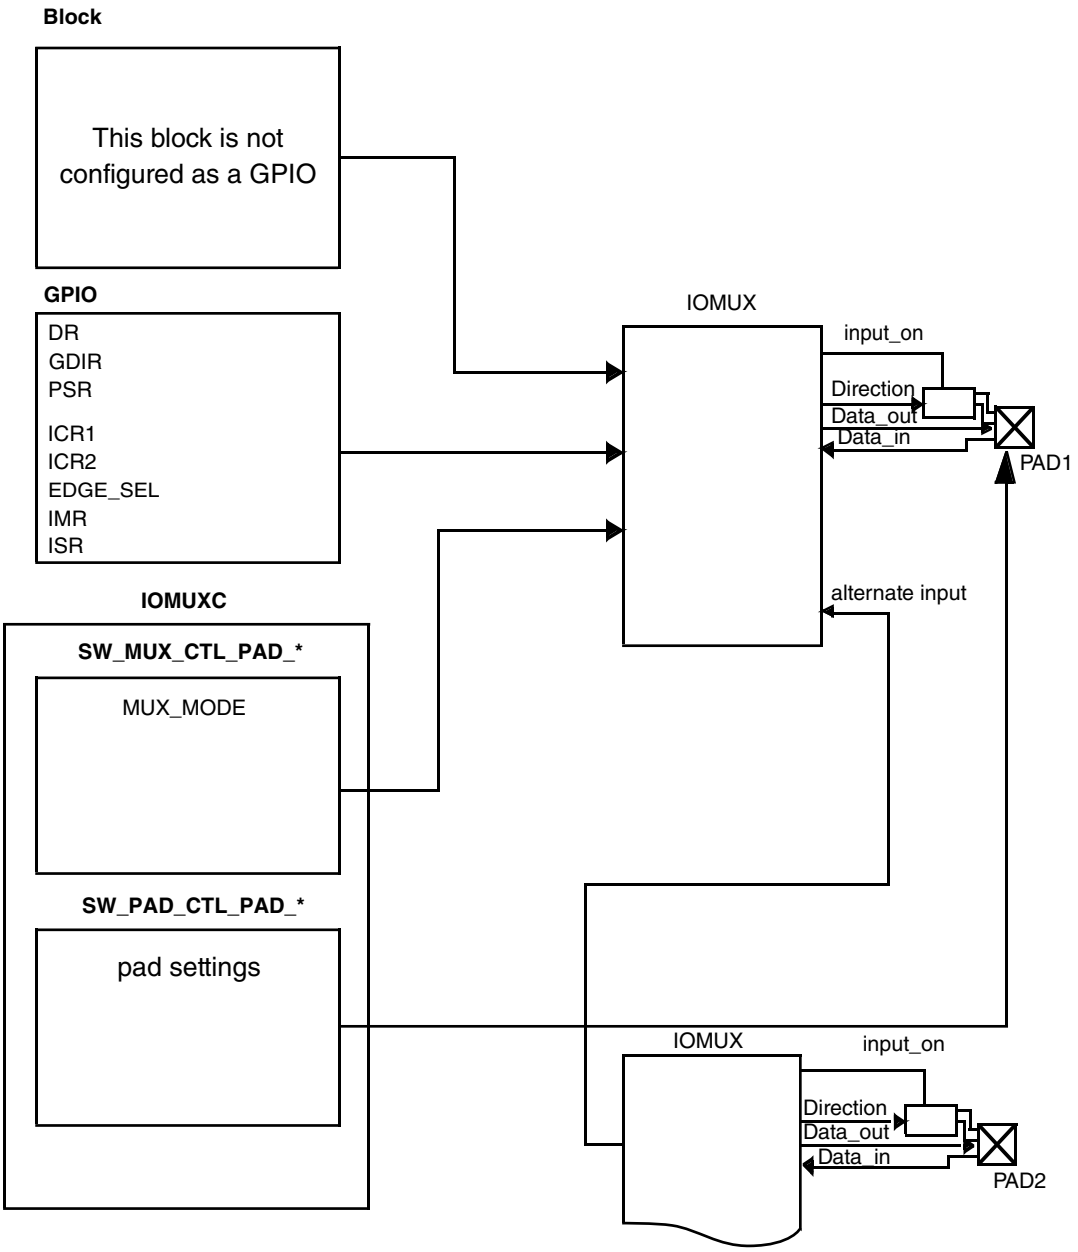

Figure 8-5. Chip IOMUX Scheme

A GPIO signal can operate as a general-purpose input/output when the IOMUX is set to GPIO mode. Each GPIO signal may be independently configured as either an input or an output using the GPIO direction register (GDIR).

When configured as an output (GDIR[GDIR] = 1), the value in the data bit in the GPIO data register (DR) is driven on the corresponding GPIO line. When a signal is configured as an input (GDIR[GDIR] = 0), the state of the input can be read from the corresponding PSR[PSR] bit.

The GPIO functionality is provided through eight registers, an edge-detect circuit, and interrupt generation logic.

The eight registers are:

- Data register (DR)
- GPIO direction register (GDIR)
- Pad sample register (PSR)
- Interrupt control registers (ICR1, ICR2)
- Edge select register (EDGE_SEL)
- Interrupt mask register (IMR)
- Interrupt status register (ISR)

The above registers are described in detail in the Register section.

Each GPIO input has a dedicated edge-detect circuit which can be configured through software to detect rising edges, falling edges, logic low-levels or logic high-levels on the input signals. The outputs of the edge detect circuits are optionally masked by setting the corresponding bit in the interrupt mask register (IMR). These qualified outputs are OR'ed together to generate two one-bit interrupt lines:

- Combined interrupt indication for GPIOx signals 0 - 15
- Combined interrupt indication for GPIOx signals 16 - 31

In addition, GPIO1 provides visibility to each of its 8 low order interrupt sources (i.e. GPIO1 interrupt n, for n = 0 – 7). However, individual interrupt indications from other GPIOx are not available.

The GPIO edge detection is described further in Interrupt Control Unit.

8.3.2.1 Interrupt Control Unit

In addition to the general-purpose input/output function, the edge-detect logic in the GPIO peripheral reflects whether a transition has occurred on a given GPIO signal that is configured as an input (GDIR[GDIR] = 0). The interrupt control registers (ICR1 and ICR2) may be used to independently configure the interrupt condition of each input signal (low-to-high transition, high-to-low transition, low, or high). For information about ICR1 and ICR2 settings, see the Register section.

The interrupt control unit is built of 32 interrupt control subunits, where each subunit handles a single interrupt line.

8.3.2.2 Clocks

The following table describes the clock sources for GPIO. Please see the CCM for clock setting, configuration and gating information.

Table 8-6. GPIO Clocks

Clock name	Description
ipg_clk_s	Peripheral access clock

8.3.3 External Signals

The following table describes the external signals of GPIO.

Table 8-7. GPIO External Signals

Signal	Description
IOn	GPIO Signal

8.3.4 Application Information

8.3.4.1 GPIO Read Mode

The programming sequence for reading input signals should be as follows:

1. Configure IOMUX to select GPIO mode (via IOMUX Controller (IOMUXC)).
2. Configure GPIO direction register to input (GDIR[GDIR] = 0b).
3. Read value from data register/pad status register.

A pseudocode description to read [input3:input0] values is as follows:

```
// SET INPUTS TO GPIO MODE.
write sw_mux_ctl_<input0>_<input1>_<input2>_<input3>, 32'h00000000
// SET GDIR TO INPUT.
write GDIR[31:4,input3_bit, input2_bit, input1_bit, input0_bit,] 32'hxxxxxxx0
// READ INPUT VALUE FROM DR.
read DR
// READ INPUT VALUE FROM PSR.
read PSR
```

NOTE

While the GPIO direction is set to input (GDIR[GDIR] = 0), a read access to DR does not return DR data. Instead, it returns the PSR data, which is the corresponding input signal value.

8.3.4.2 GPIO Write Mode

The programming sequence for driving output signals should be as follows:

1. Configure IOMUX to select GPIO mode (via IOMUXC). If needed, enable SION to read the loopback pad value through PSR.
2. Configure GPIO direction register to output (GDIR[GDIR] = 1b).
3. Write value to data register (DR).

A pseudocode description to drive 4'b0101 on [output3:output0] is as follows:

```
// SET PADS TO GPIO MODE VIA IOMUX.
write sw_mux_ctl_pad_<output[0-3]>.mux_mode, <GPIO_MUX_MODE>
// Enable loopback to capture pad value into PSR in output mode
write sw_mux_ctl_pad_<output[0-3]>.sion, 1
// SET GDIR=1 TO OUTPUT BITS.
write GDIR[31:4,output3_bit,output2_bit, output1_bit, output0_bit,] 32'hxxxxxxxF
// WRITE OUTPUT VALUE=4'b0101 TO DR.
write DR, 32'hxxxxxxx5
// READ OUTPUT VALUE FROM PSR ONLY.
read_cmp PSR, 32'hxxxxxxx5
```

8.3.5 Memory Map/Register Definition

This section includes the memory map and descriptions of all registers.

8.3.5.1 GPIO register descriptions

There are eight 32-bit GPIO registers. All registers are accessible from the IP interface. Only 32-bit access is supported.

The GPIO memory map is shown in the following table.

8.3.5.1.1 GPIO memory map

GPIO1 base address: 3020_0000h

GPIO2 base address: 3021_0000h

GPIO3 base address: 3022_0000h

GPIO4 base address: 3023_0000h

GPIO5 base address: 3024_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	GPIO data register (DR)	32	RW	0000_0000h
4h	GPIO direction register (GDIR)	32	RW	0000_0000h
8h	GPIO pad status register (PSR)	32	RO	0000_0000h
Ch	GPIO interrupt configuration register1 (ICR1)	32	RW	0000_0000h
10h	GPIO interrupt configuration register2 (ICR2)	32	RW	0000_0000h
14h	GPIO interrupt mask register (IMR)	32	RW	0000_0000h
18h	GPIO interrupt status register (ISR)	32	W1C	0000_0000h
1Ch	GPIO edge select register (EDGE_SEL)	32	RW	0000_0000h

8.3.5.1.2 GPIO data register (DR)

8.3.5.1.2.1 Offset

Register	Offset
DR	0h

8.3.5.1.2.2 Function

The 32-bit DR register stores data that is ready to be driven to the output lines. If the IOMUXC is in GPIO mode and a given GPIO direction bit is set, then the corresponding DR bit is driven to the output. If a given GPIO direction bit is cleared, then a read of DR register reflects the value of the corresponding signal. Two wait states are required in read access for synchronization.

The results of a read of a DR bit depends on the IOMUXC input mode settings and the corresponding GDIR bit as follows:

- If GDIR[*n*] is set and IOMUXC input mode is GPIO, then reading DR[*n*] returns the contents of DR[*n*].
- If GDIR[*n*] is cleared and IOMUXC input mode is GPIO, then reading DR[*n*] returns the corresponding input signal's value.

- If GDIR[*n*] is set and IOMUXC input mode is not GPIO, then reading DR[*n*] returns the contents of DR[*n*].
- If GDIR[*n*] is cleared and IOMUXC input mode is not GPIO, then reading DR[*n*] always returns zero.

8.3.5.1.2.3 Diagram

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

8.3.5.1.2.4 Fields

Field	Function
31-0 DR	DR data bits This register defines the value of the GPIO output when the signal is configured as an output (GDIR[n]=1). Writes to this register are stored in a register. Reading DR register returns the value stored in the register if the signal is configured as an output (GDIR[n]=1), or the input signal's value if configured as an input (GDIR[n]=0). **NOTE:** The IOMUXC must be configured to GPIO mode for the DR register value to connect with the signal. Reading the data register with the input path disabled always returns a zero value.

8.3.5.1.3 GPIO direction register (GDIR)

8.3.5.1.3.1 Offset

Register	Offset
GDIR	4h

8.3.5.1.3.2 Function

The GDIR register functions as direction control when the IOMUXC is in GPIO mode. Each bit specifies the direction of a one-bit signal. The mapping of each DIR bit to a corresponding SoC signal is determined by the SoC's pin assignment and the IOMUX table. For more details consult the IOMUXC chapter.

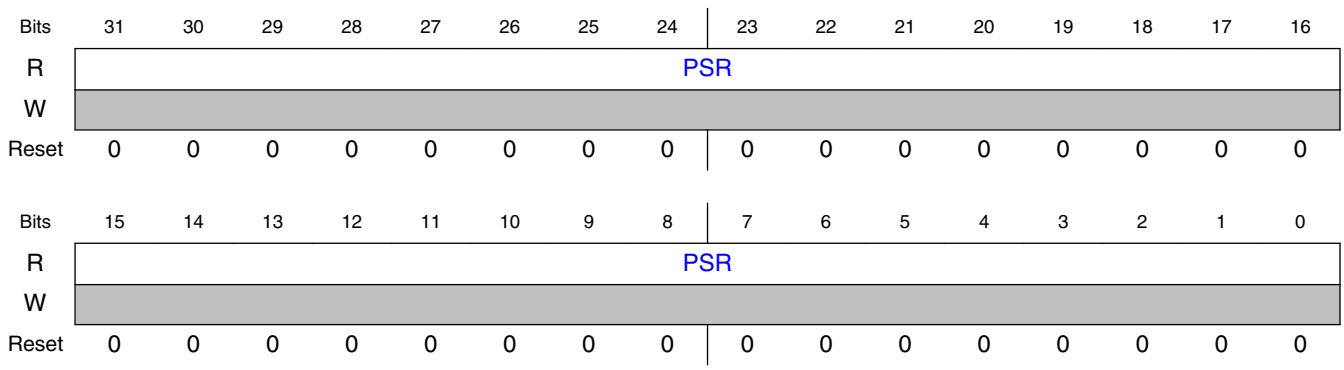
8.3.5.1.3.4 Fields

Field	Function
31-0 GDIR	GPIO direction bits Bit n of this register defines the direction of the GPIO[n] signal. **NOTE:** The GDIR register affects only the direction of the I/O signal when the corresponding bit in the IOMUXC is configured for GPIO. 0b - GPIO is configured as input. 1b - GPIO is configured as output.

8.3.5.1.4 GPIO pad status register (PSR)



8.3.5.1.4.1 Offset

Register	Offset
PSR	8h

8.3.5.1.4.2 Function

The PSR register is a read-only register. Each bit stores the value of the corresponding input signal (as configured in the IOMUX). This register is clocked with the ipg_clk_s clock, meaning that the input signal is sampled only when accessing this location. Two wait states are required any time this register is accessed for synchronization.

8.3.5.1.4.3 Diagram

8.3.5.1.4.4 Fields

Field	Function
31-0 PSR	GPIO pad status bits Reading the PSR register returns the state of the corresponding input signal. **NOTE:** The IOMUXC must be configured to GPIO mode for the PSR register to reflect the state of the corresponding signal.

8.3.5.1.5 GPIO interrupt configuration register1 (ICR1)

8.3.5.1.5.1 Offset

Register	Offset
ICR1	Ch

8.3.5.1.5.2 Function

The ICR1 register contains 16 two-bit fields, where each field specifies the interrupt configuration for a different input signal.

8.3.5.1.5.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

8.3.5.1.5.4 Fields

Field	Function
31-30 ICR15	Interrupt configuration field for GPIO interrupt 15 This bit field controls the active condition of the interrupt function for GPIO interrupt 15. 00b - Interrupt 15 is low-level sensitive. 01b - Interrupt 15 is high-level sensitive. 10b - Interrupt 15 is rising-edge sensitive. 11b - Interrupt 15 is falling-edge sensitive.
29-28 ICR14	Interrupt configuration field for GPIO interrupt 14 This bit field controls the active condition of the interrupt function for GPIO interrupt 14. 00b - Interrupt 14 is low-level sensitive. 01b - Interrupt 14 is high-level sensitive. 10b - Interrupt 14 is rising-edge sensitive. 11b - Interrupt 14 is falling-edge sensitive.
27-26 ICR13	Interrupt configuration field for GPIO interrupt 13 This bit field controls the active condition of the interrupt function for GPIO interrupt 13. 00b - Interrupt 13 is low-level sensitive. 01b - Interrupt 13 is high-level sensitive. 10b - Interrupt 13 is rising-edge sensitive. 11b - Interrupt 13 is falling-edge sensitive.
25-24 ICR12	Interrupt configuration field for GPIO interrupt 12 This bit field controls the active condition of the interrupt function for GPIO interrupt 12. 00b - Interrupt 12 is low-level sensitive. 01b - Interrupt 12 is high-level sensitive. 10b - Interrupt 12 is rising-edge sensitive. 11b - Interrupt 12 is falling-edge sensitive.
23-22 ICR11	Interrupt configuration field for GPIO interrupt 11 This bit field controls the active condition of the interrupt function for GPIO interrupt 11. 00b - Interrupt 11 is low-level sensitive. 01b - Interrupt 11 is high-level sensitive. 10b - Interrupt 11 is rising-edge sensitive.

Table continues on the next page...

Field	Function
	11b - Interrupt 11 is falling-edge sensitive.
21-20 ICR10	Interrupt configuration field for GPIO interrupt 10 This bit field controls the active condition of the interrupt function for GPIO interrupt 10. 00b - Interrupt 10 is low-level sensitive. 01b - Interrupt 10 is high-level sensitive. 10b - Interrupt 10 is rising-edge sensitive. 11b - Interrupt 10 is falling-edge sensitive.
19-18 ICR9	Interrupt configuration field for GPIO interrupt 9 This bit field controls the active condition of the interrupt function for GPIO interrupt 9. 00b - Interrupt 9 is low-level sensitive. 01b - Interrupt 9 is high-level sensitive. 10b - Interrupt 9 is rising-edge sensitive. 11b - Interrupt 9 is falling-edge sensitive.
17-16 ICR8	Interrupt configuration field for GPIO interrupt 8 This bit field controls the active condition of the interrupt function for GPIO interrupt 8. 00b - Interrupt 8 is low-level sensitive. 01b - Interrupt 8 is high-level sensitive. 10b - Interrupt 8 is rising-edge sensitive. 11b - Interrupt 8 is falling-edge sensitive.
15-14 ICR7	Interrupt configuration field for GPIO interrupt 7 This bit field controls the active condition of the interrupt function for GPIO interrupt 7. 00b - Interrupt 7 is low-level sensitive. 01b - Interrupt 7 is high-level sensitive. 10b - Interrupt 7 is rising-edge sensitive. 11b - Interrupt 7 is falling-edge sensitive.
13-12 ICR6	Interrupt configuration field for GPIO interrupt 6 This bit field controls the active condition of the interrupt function for GPIO interrupt 6. 00b - Interrupt 6 is low-level sensitive. 01b - Interrupt 6 is high-level sensitive. 10b - Interrupt 6 is rising-edge sensitive. 11b - Interrupt 6 is falling-edge sensitive.
11-10 ICR5	Interrupt configuration field for GPIO interrupt 5 This bit field controls the active condition of the interrupt function for GPIO interrupt 5. 00b - Interrupt 5 is low-level sensitive. 01b - Interrupt 5 is high-level sensitive. 10b - Interrupt 5 is rising-edge sensitive. 11b - Interrupt 5 is falling-edge sensitive.
9-8 ICR4	Interrupt configuration field for GPIO interrupt 4 This bit field controls the active condition of the interrupt function for GPIO interrupt 4. 00b - Interrupt 4 is low-level sensitive. 01b - Interrupt 4 is high-level sensitive. 10b - Interrupt 4 is rising-edge sensitive. 11b - Interrupt 4 is falling-edge sensitive.
7-6 ICR3	Interrupt configuration field for GPIO interrupt 3 This bit field controls the active condition of the interrupt function for GPIO interrupt 3. 00b - Interrupt 3 is low-level sensitive.

Table continues on the next page...

Field	Function
	01b - Interrupt 3 is high-level sensitive. 10b - Interrupt 3 is rising-edge sensitive. 11b - Interrupt 3 is falling-edge sensitive.
5-4 ICR2	Interrupt configuration field for GPIO interrupt 2 This bit field controls the active condition of the interrupt function for GPIO interrupt 2. 00b - Interrupt 2 is low-level sensitive. 01b - Interrupt 2 is high-level sensitive. 10b - Interrupt 2 is rising-edge sensitive. 11b - Interrupt 2 is falling-edge sensitive.
3-2 ICR1	Interrupt configuration field for GPIO interrupt 1 This bit field controls the active condition of the interrupt function for GPIO interrupt 1. 00b - Interrupt 1 is low-level sensitive. 01b - Interrupt 1 is high-level sensitive. 10b - Interrupt 1 is rising-edge sensitive. 11b - Interrupt 1 is falling-edge sensitive.
1-0 ICR0	Interrupt configuration field for GPIO interrupt 0 This bit field controls the active condition of the interrupt function for GPIO interrupt 0. 00b - Interrupt 0 is low-level sensitive. 01b - Interrupt 0 is high-level sensitive. 10b - Interrupt 0 is rising-edge sensitive. 11b - Interrupt 0 is falling-edge sensitive.

8.3.5.1.6 GPIO interrupt configuration register2 (ICR2)

8.3.5.1.6.1 Offset

Register	Offset
ICR2	10h

8.3.5.1.6.2 Function

The ICR2 register contains 16 two-bit fields, where each field specifies the interrupt configuration for a different input signal.

8.3.5.1.6.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

8.3.5.1.6.4 Fields

Field	Function
31-30 ICR31	Interrupt configuration field for GPIO interrupt 31 This bit field controls the active condition of the interrupt function for GPIO interrupt 31. 00b - Interrupt 31 is low-level sensitive. 01b - Interrupt 31 is high-level sensitive. 10b - Interrupt 31 is rising-edge sensitive. 11b - Interrupt 31 is falling-edge sensitive.
29-28 ICR30	Interrupt configuration field for GPIO interrupt 30 This bit field controls the active condition of the interrupt function for GPIO interrupt 30. 00b - Interrupt 30 is low-level sensitive. 01b - Interrupt 30 is high-level sensitive. 10b - Interrupt 30 is rising-edge sensitive. 11b - Interrupt 30 is falling-edge sensitive.
27-26 ICR29	Interrupt configuration field for GPIO interrupt 29 This bit field controls the active condition of the interrupt function for GPIO interrupt 29. 00b - Interrupt 29 is low-level sensitive. 01b - Interrupt 29 is high-level sensitive. 10b - Interrupt 29 is rising-edge sensitive. 11b - Interrupt 29 is falling-edge sensitive.
25-24 ICR28	Interrupt configuration field for GPIO interrupt 28 This bit field controls the active condition of the interrupt function for GPIO interrupt 28. 00b - Interrupt 28 is low-level sensitive. 01b - Interrupt 28 is high-level sensitive. 10b - Interrupt 28 is rising-edge sensitive. 11b - Interrupt 28 is falling-edge sensitive.
23-22 ICR27	Interrupt configuration field for GPIO interrupt 27 This bit field controls the active condition of the interrupt function for GPIO interrupt 27. 00b - Interrupt 27 is low-level sensitive. 01b - Interrupt 27 is high-level sensitive. 10b - Interrupt 27 is rising-edge sensitive. 11b - Interrupt 27 is falling-edge sensitive.

Table continues on the next page...

Field	Function
21-20	Interrupt configuration field for GPIO interrupt 26
ICR26	This bit field controls the active condition of the interrupt function for GPIO interrupt 26. 00b - Interrupt 26 is low-level sensitive. 01b - Interrupt 26 is high-level sensitive. 10b - Interrupt 26 is rising-edge sensitive. 11b - Interrupt 26 is falling-edge sensitive.
19-18	Interrupt configuration field for GPIO interrupt 25
ICR25	This bit field controls the active condition of the interrupt function for GPIO interrupt 25. 00b - Interrupt 25 is low-level sensitive. 01b - Interrupt 25 is high-level sensitive. 10b - Interrupt 25 is rising-edge sensitive. 11b - Interrupt 25 is falling-edge sensitive.
17-16	Interrupt configuration field for GPIO interrupt 24
ICR24	This bit field controls the active condition of the interrupt function for GPIO interrupt 24. 00b - Interrupt 24 is low-level sensitive. 01b - Interrupt 24 is high-level sensitive. 10b - Interrupt 24 is rising-edge sensitive. 11b - Interrupt 24 is falling-edge sensitive.
15-14	Interrupt configuration field for GPIO interrupt 23
ICR23	This bit field controls the active condition of the interrupt function for GPIO interrupt 23. 00b - Interrupt 23 is low-level sensitive. 01b - Interrupt 23 is high-level sensitive. 10b - Interrupt 23 is rising-edge sensitive. 11b - Interrupt 23 is falling-edge sensitive.
13-12	Interrupt configuration field for GPIO interrupt 22
ICR22	This bit field controls the active condition of the interrupt function for GPIO interrupt 22. 00b - Interrupt 22 is low-level sensitive. 01b - Interrupt 22 is high-level sensitive. 10b - Interrupt 22 is rising-edge sensitive. 11b - Interrupt 22 is falling-edge sensitive.
11-10	Interrupt configuration field for GPIO interrupt 21
ICR21	This bit field controls the active condition of the interrupt function for GPIO interrupt 21. 00b - Interrupt 21 is low-level sensitive. 01b - Interrupt 21 is high-level sensitive. 10b - Interrupt 21 is rising-edge sensitive. 11b - Interrupt 21 is falling-edge sensitive.
9-8	Interrupt configuration field for GPIO interrupt 20
ICR20	This bit field controls the active condition of the interrupt function for GPIO interrupt 20. 00b - Interrupt 20 is low-level sensitive. 01b - Interrupt 20 is high-level sensitive. 10b - Interrupt 20 is rising-edge sensitive. 11b - Interrupt 20 is falling-edge sensitive.
7-6	Interrupt configuration field for GPIO interrupt 19
ICR19	This bit field controls the active condition of the interrupt function for GPIO interrupt 19. 00b - Interrupt 19 is low-level sensitive. 01b - Interrupt 19 is high-level sensitive.

Table continues on the next page...

Field	Function
	10b - Interrupt 19 is rising-edge sensitive. 11b - Interrupt 19 is falling-edge sensitive.
5-4 ICR18	Interrupt configuration field for GPIO interrupt 18 This bit field controls the active condition of the interrupt function for GPIO interrupt 18. 00b - Interrupt 18 is low-level sensitive. 01b - Interrupt 18 is high-level sensitive. 10b - Interrupt 18 is rising-edge sensitive. 11b - Interrupt 18 is falling-edge sensitive.
3-2 ICR17	Interrupt configuration field for GPIO interrupt 17 This bit field controls the active condition of the interrupt function for GPIO interrupt 17. 00b - Interrupt 17 is low-level sensitive. 01b - Interrupt 17 is high-level sensitive. 10b - Interrupt 17 is rising-edge sensitive. 11b - Interrupt 17 is falling-edge sensitive.
1-0 ICR16	Interrupt configuration field for GPIO interrupt 16 This bit field controls the active condition of the interrupt function for GPIO interrupt 16. 00b - Interrupt 16 is low-level sensitive. 01b - Interrupt 16 is high-level sensitive. 10b - Interrupt 16 is rising-edge sensitive. 11b - Interrupt 16 is falling-edge sensitive.

8.3.5.1.7 GPIO interrupt mask register (IMR)

8.3.5.1.7.1 Offset

Register	Offset
IMR	14h

8.3.5.1.7.2 Function

The IMR register contains masking bits for each interrupt line.

8.3.5.1.7.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	IMR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	IMR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

8.3.5.1.7.4 Fields

Field	Function
31-0 IMR	Interrupt Mask bits This register is used to enable or disable the interrupt function on each of the 32 GPIO signals. Bit IMR[n] (n=0...31) controls interrupt n as follows: 0b - Interrupt n is disabled. 1b - Interrupt n is enabled.

8.3.5.1.8 GPIO interrupt status register (ISR)

8.3.5.1.8.1 Offset

Register	Offset
ISR	18h

8.3.5.1.8.2 Function

The ISR register functions as an interrupt status indicator. Each bit indicates whether an interrupt condition has been met for the corresponding input signal. When an interrupt condition is met (as determined by the corresponding interrupt condition register field), the corresponding bit in this register is set. Two wait states are required in read access for synchronization. One wait state is required for reset.

8.3.5.1.8.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	ISR															
W	W1C															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	ISR															
W	W1C															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

8.3.5.1.8.4 Fields

Field	Function
31-0 ISR	Interrupt status bits Bit n of this register is asserted (active high) when the active condition (as determined by the corresponding ICR bit) is detected on the GPIO input and is waiting for service. The value of this register is independent of the value in IMR register. When the active condition has been detected, the corresponding bit remains set until cleared by software. Status flags are cleared by writing a 1 to the corresponding bit position.

8.3.5.1.9 GPIO edge select register (EDGE_SEL)

8.3.5.1.9.1 Offset

Register	Offset
EDGE_SEL	1Ch

8.3.5.1.9.2 Function

The EDGE_SEL register may be used to override the ICR registers' configuration. If the GPIO_EDGE_SEL bit is set, then a rising edge or falling edge in the corresponding signal generates an interrupt. This register provides backward compatibility. On reset all bits are cleared (ICR is not overridden).

8.3.5.1.9.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	GPIO_EDGE_SEL															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	GPIO_EDGE_SEL															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

8.3.5.1.9.4 Fields

Field	Function
31-0 GPIO_EDGE_SEL	Edge select When EDGE_SEL[*n*] is set, the GPIO disregards the ICR[*n*] setting, and detects any edge on the corresponding input signal.

Chapter 9
External Memory

9.1 External Memory Overview

9.1.1 External Memory Overview

9.1.1.1 DRAM Interface

The SDRAM configurations supported by this chip are provided in the following table.

Table 9-1. DRAM controller supported SDRAM configurations

Parameter	LPDDR4	DDR4
Number of Controllers	1	1
Number of Channels	2	N/A
Number of Chip Selects	2	1
Bus Width	32-bit	32-bit
Maximum Clock Frequency	4000 MT/s	3200 MT/s

The DRAM controller and PHY also support the following:

- Inline ECC feature for LPDDR4 and DDR4
- Various low power modes, clock and power gated operations, that are defined for this chip. In addition, it can place the external DRAM into and out of its self-refresh mode as requested by different low-power operating modes.

9.1.1.2 SD/eMMC/SDIO Support

The chip has three Ultra Secured Digital Host Controller (uSDHC) modules for the SD/eMMC interface. It provides the interface between the host system and SD/SDIO/eMMC memory devices. The key features include:

- Supports SD/SDIO standard, up to version 3.0
- Supports eMMC standard, up to version 5.1
- Supports 3.3V and 1.8V operation, but does not support 1.2V operation
- Supports 1-bit / 4-bit SD and SDIO modes, 1-bit / 4-bit / 8-bit eMMC modes
  - Up to 400 Mbps of data transfer for SDIO cards using 4 parallel data lines in SDR mode
  - Up to 800 Mbps of data transfer for SDIO card using 4 parallel data lines in DDR mode
  - Up to 400 Mbps of data transfer for SDXC cards using 4 parallel data lines in SDR mode
  - Up to 800 Mbps of data transfer for SDXC card using 4 parallel data lines in DDR mode
  - Up to 1600 Mbps of data transfer for eMMC using 8 parallel data lines in SDR mode
  - Up to 3200 Mbps of data transfer for eMMC using 8 parallel data lines in DDR mode
- Two uSDHC controllers (SD1 and SD3) can support up to 8-bit interface, the other controller (SD2) can only support up to 4-bit interface.

9.1.1.3 Raw NAND Support

The Raw NAND Flash controller consists of three components:

- General Purpose Media Interface (GPMI) as the NAND controller pin interface
- AHB-to-APBH Bridge with DMA (APBH_DMA) as the DMA engine that drives the GPMI module
- 62-bit Correcting ECC Accelerator (BCH) as the 62-bit error correction hardware engine with an AXI bus master and a private connection to GPMI

The Raw NAND Flash controller support following key features:

- 8-bit NAND Flash, up to 4 devices supported by 4 chip-selects and 1 ganged ready/busy
- ONFI 3.2 complaint, synchronous clock rate of up to 100 MHz with data rate of up to 200 MB/s
- Supports ONFI NAND for Micron and SK Hynix, and Toggle NAND for Kioxia and Samsung[1]
- BCH62 for ECC, up to 200MB/s

1. Testing has been performed on select memory devices. Please contact your NXP representative for more details.

9.1.1.4 xSPI Interface

There is one Flexible Serial Peripheral Interface (FlexSPI) block that acts as an interface to one external Octal SPI serial flash device, or up to two external Quad SPI serial flash devices, each with up to four bidirectional data lines. The key features include:

- Channel A can be configured as 1/2/4/8-bit operation (Channel B is not usable when 8-bit operation is used)
- Channel B can be configured as 1/2/4-bit operation
- Support both dual-channel or single-channel operation
- Support both SDR mode and DDR mode
- Support up to 166MHz SDR Mode and 166MHz DDR Mode (with external Flash device DQS input)
- Support up to 133MHz SDR Mode and 66MHz DDR Mode (with internal DQS loopback mode)

9.2 DDR Controller (DDRC)

9.2.1 Overview

The DDRC (DDR Controller) is a memory controller that interfaces DDR based memories. The following types of SDRAMs are supported by the DDRC:

- DDR4
- LP-DDR4

NOTE

The information within this block guide is Synopsys Proprietary. Used with permission.

9.2.1.1 Block diagram

The block diagram for the DDR Controller is shown below.

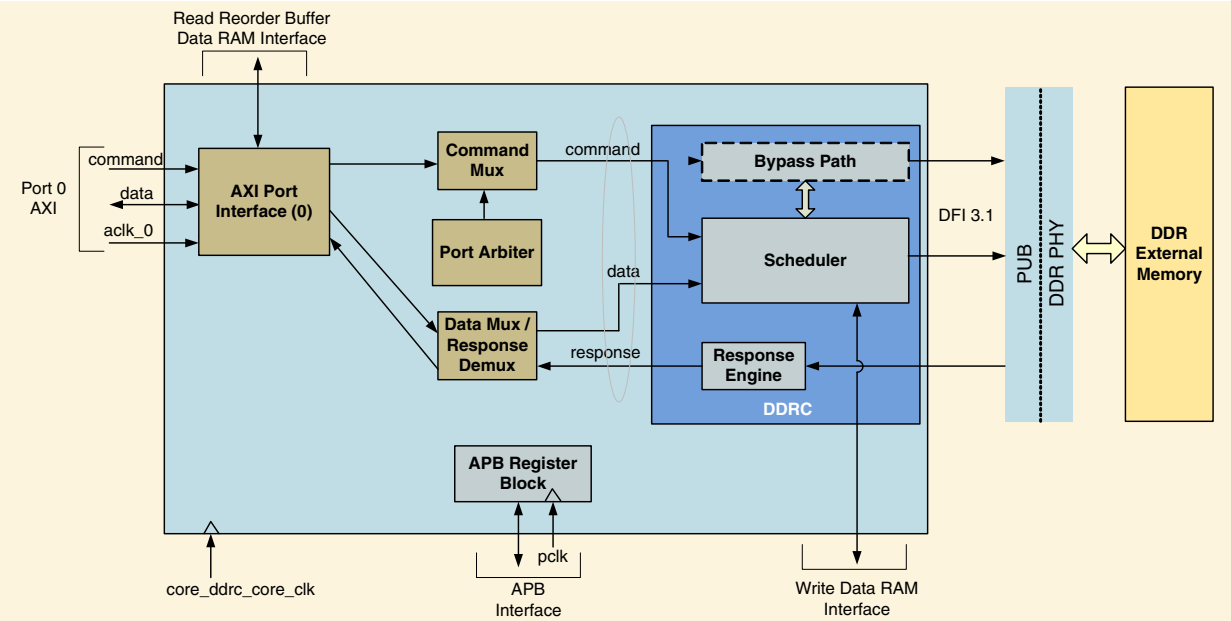

Figure 9-1. DDRC block diagram

The PHY Utility Block (PUB) is an adaption layer between the controller and the PHY, handling control function.

9.2.1.2 Features

The DDRC includes the following features:

- Direct software request control or programmable internal control for ZQ short calibration cycles
- Support for ZQ long calibration after self-refresh exit
- Direct software request control or programmable internal control for ZQ calibration cycles
- Support for ZQ Reset feature through software
- Dynamic scheduling to optimize bandwidth and latency
- Read and write buffers in fully associative CAMs, 32 each
- Delayed writes for optimum performance on SDRAM data bus
- Out of order execution of commands maximises the SDRAM efficiency
- Programmable SDRAM parameters
- Supports BL16 burst length
- Supports 1,2 memory ranks

- Control options to avoid starvation of lower priorities
- Guaranteed coherency for write-after-read (WAR) and read-after-write (RAW) hazards
- Write combine to allow multiple writes to the same address to be combined into a single write to SDRAM; supported for same starting address
- Paging policy selectable by configuration registers as any of the following:
  - Leave pages open after accesses, or
  - Close page when there are no further accesses available in the controller for that page, or
  - Auto-precharge with each access, with an optimization for page-close mode which leaves the page open after a flush for read-write and write-read collision cases
- Supports automatic SDRAM power-down entry and exit caused by lack of transaction arrival for programmable time
- Supports automatic Clock Stop entry and exit caused by lack of transaction arrival
- Supports automatic DDRC low power mode operation caused by lack of transaction arrival for programmable time via Hardware Low Power Interface
- Supports self-refresh entry and exit as follows:
  - Supports automatic self-refresh entry and exit caused by lack of transaction arrival for programmable time
  - Support for self-refresh entry and exit under software control
- Support for dynamically changing clock frequency while in self-refresh:
  - Shadow timing registers provided to allow fast frequency changing
- Support for explicit SDRAM mode register updates under software control
- Flexible address mapper logic to allow application specific mapping of row, column, bank, and rank bits
- User-selectable refresh control options:
  - Controller-generated auto-refreshes at programmable average intervals
  - In multi-rank designs, an offset can be applied to each rank's refresh timer to allow rank refreshes to expire at different times (this can increase efficiency by allowing traffic to continue to other ranks while a given rank is being refreshed)
  - Ability to group up to 8 controller-generated refreshes together to be issued consecutively (this reduces the frequency of page closings, increasing overall efficiency)
  - When controller-generated refreshes are grouped, some refreshes can be issued speculatively when the controller is idle for a programmable period of time
  - Ability to disable controller-generated auto-refreshes
  - Ability to issue a refresh through direct software request
  - When DDR4 is used, fine granularity refresh can be selected
- Optional ECC support, when controller is configured for 64-bit/32-bit/16-bit SDRAM data width, including the following:

    - Support for single error correction / double error detection (SEC/DED)
    - Automatic data scrubbing of correctable errors
    - Support for highly efficient read-modify-write when byte enables are used with ECC enabled
    - Automatic logging of both correctable and uncorrectable errors
    - Ability to “poison” the write data by adding uncorrectable errors, for use in testing ECC error handling
- DDR4 protocol up to DDR4-3200 speed grade is supported by the DDRC. The following features are supported:
    - Data Bus Inversion (DBI)
    - Geardown mode may be programmed where allowed by memory and PHY specification
    - Maximum power saving mode
    - Multi-purpose register (MPR) reads and writes
    - Per DRAM addressability
    - Fine granularity refresh
    - Cyclic redundancy check (CRC) with retry
    - Command/address latency
    - Programmable Preamble

9.2.2 Functional description

The DDRC converts system bus transactions into memory commands on the DFI interface that are compliant with the DDR protocols.

The main components of the block are:

- **AXI Port Interface (XPI) block**: This block provides the interface to the application ports. It provides bus protocol handling, data buffering and reordering for read data, data bus size conversion (upsizing or downsizing), and memory burst address alignment. Read data is stored in a SRAM, read re-order buffer and returned in order, to the AXI ports.
- **Port Arbiter (PA) block**: This block provides latency sensitive, priority based arbitration between the addresses issued by the XPIs (by the ports).
- **DDR Controller (DDRC) block**: This block contains a logical CAM (Content Addressable Memory). This holds information on the commands, which is used by the scheduling algorithms to optimally schedule commands to be sent to the PHY, based on priority, bank/rank status and DDR timing constraints. A bypass path is also provided (optionally).
- **APB Register Block**: This block contains the software accessible registers.

Please see Block diagram for the DDRC block diagram.

The details on DDRC are as follows:

- Write data is stored in DDRC until its associated command is issued to the PHY.
- Read data is handled by the response engine in the DDRC and is returned in the order of scheduled read commands on the HIF.
- ECC is handled by logic modules within the DDRC in the write data path and in the response engine.

1:2 frequency ratio term is used for the frequency ratio between the DDRC clock (core_ddrc_core_clk) and the memory clock.

In 1:2 frequency ratio mode, the DDRC clock rate is one half the memory clock rate (referred to as HDR, half data rate).

The terms “DFI clock” and “DFI PHY clock” are used in this document in accordance with the DFI specification:

- The DFI clock is the clock on which the DFI interface runs. It is the core_ddrc_core_clk.
- The DFI PHY clock is the SDRAM clock. In 1:2 frequency ratio, this has twice the frequency of the DFI clock.

9.2.2.1 AXI Port Interface (XPI)

The AXI protocol is burst-based with read and write request channels that specify the host ID for the request, start byte address, burst length, burst size, and burst type. This information is processed by the interface and is used subsequently by the DDRC.

The XPI interfaces the AXI application port to the DDRC and performs the following main functions:

- Read address generation
- Write address generation
- Read data generation
- Read data and response generation
- Write response generation

The XPI converts AXI bursts into read and write requests, which are forwarded to the Port Arbiter (PA). In the opposite direction, the XPI converts the responses from the DDRC into appropriate AXI responses.

The interface between XPI and PA is same as HIF (but with independent channels for read and write commands). Each AXI port can be independently configured to operate with a clock that is synchronous or asynchronous to the memory controller clock.

The AXI Specification requires that transactions must not cross a 4K address boundary. AXI compliant masters must meet this requirement.

9.2.2.1.1 Read Address Channel

The AXI read address channel has the following features:

- The read transaction can be of any length up to 256 for incremental bursts, 16 for wrapping bursts.
- The burst types supported are incremental and wrapping.
- The burst start address can be unaligned to the AXI data width boundaries
- The size of the burst can be less than the full width of the AXI data bus (also known as sub-sized transfers).

The signals on the read address channel are registered into the XPI in accordance with the AXI valid/ready handshaking protocol and are synchronous with the AXI clock (aclk).

Read requests are accepted if the request can be written into the Read Address Queue (RAQ). This is used to store all the read address requests. There are two address queues on a given port, named Blue and Red address queues. Clock domain crossing from aclk to DDRC clock (core_ddrc_core_clk) is performed in the RAQ block.

After registering the read address channel by the RAQ, the following operations are performed:

- Generation of new read requests is based on alignment (derived from AXI address and size), burst lengths (derived from AXI length and memory burst length), and burst type (derived from AXI incremental or wrapping). Each AXI burst is divided into packets of length equal to the memory burst length (BL2, BL4, BL8, BL16).
- Generation of new HIF address in the case of unaligned burst and burst expansion.

In general, realignment to a memory burst boundary potentially causes some data beats to be discarded (affecting bandwidth) and potentially introduces additional latency on the read data and response channel.

The aready output is defaulted to logic one and remains in logic one unless the RAQ becomes full or a WRAP burst is requested (aready is low on the next cycle after a WRAP burst is accepted). The read transaction is popped from the RAQ when it is not empty.

The XPI handles the generation of the token which is used by the DDRC for identifying the read command and corresponding data.

9.2.2.1.2 Write Address Channel

Write Address Queue (WAQ) is used to store all the addresses for write requests from a given port. There is a single queue for all AXI IDs from a given port. The write address channel behavior is similar to the read address channel.

Write address and read address channels are independent and the ordering between the write and read requests may not be preserved.

To preserve the sequence, a higher-level protocol needs to wait for read/write response before sending the next transaction.

Transactions across the ports are independent and can be issued in any order.

The write command is not forwarded to the DDRC until the write data is collected and the strobes are evaluated.

9.2.2.1.3 Read Data and Response Channel

The XPI handles the common response interface to the DDRC to process the read data from the memory.

AXI read data and response channel has a single data storage queue (RDQ - Read Data Queue) with two clocks—AXI clock for reading and DDRC clock for writing.

Data from different IDs are stored in the same queue and are returned in the order of read address acceptance.

The FSM handling the AXI handshake as well as the FIFO push and pop has the following features:

- Based on the information stored, filter the dummy beats
- Based on the signal hif_rdata_last, generate the rlast

SLVERR response may be returned for the read transactions for the following cases:

- ECC uncorrected error detected at the DFI
- InvalidLPDDR4 row address

9.2.2.1.3.1 Read Reorder Buffer

The read data can be returned from the DDRC in a different order from which the read commands are forwarded from the XPI. (due to the re-ordering of read commands in the DDRC to maximize SDRAM bandwidth). A read reorder buffer is implemented in each port to reorder the read data for that port to the same order as the order of the AXI read commands.

The AXI protocol allows the read data for transactions of different IDs to be interleaved. To reduce potential delays where read data for one ID is blocked waiting for data associated with another ID, the read reorder buffer is organized as number of virtual channels (See Figure 9-2). The Read Reorder Virtual Channel is a mechanism to allow independent read data reordering between multiple groups of AXI IDs.

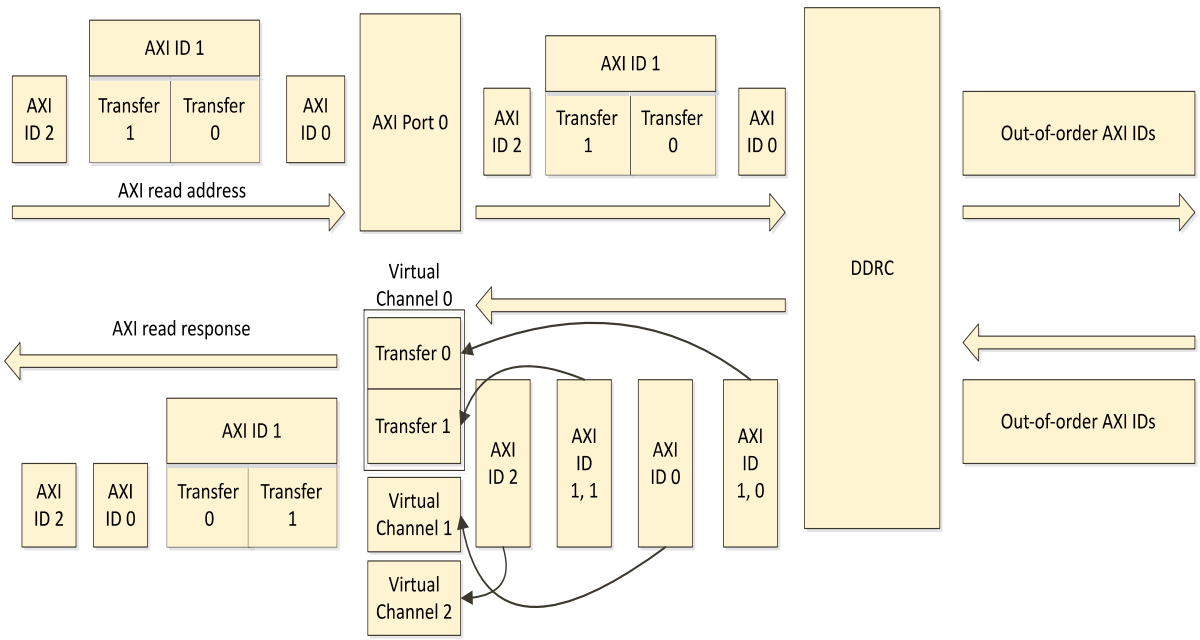

Figure 9-2. RRB Configured with Three Virtual Channels

9.2.2.1.4 Write data Channel

The AXI write data channel has a data storage queue (WDQ - Write Data Queue) with the following clocks:

- AXI clock (aclk_n) for writing and
- DDRC clock (core_ddrc_core_clk) for reading

This queue is used for the clock domain crossing between the AXI clock domain and the controller clock domain and acts as a registering layer in the case of a synchronous interface.

At the output of WDQ, some beats of a write data packet can be masked depending on alignment, burst size and burst length.

Write data from each port is forwarded to the DDRC, which forwards the data to a common data storage.

9.2.2.1.5 Write Response Channel

The write response is generated once the last beat of write data, for a given AXI burst, is accepted by the DDRC.

SLVERR response may be returned in the following cases:

- Invalid LPDDR4 row address

9.2.2.1.6 AXI Data Channel Interleaving

A given AXI port (XPI) can access both data channels and low granularity interleaving between the two data channels is possible by mapping a suitable LSB address bit which is at the memory burst boundary. In that case, for example, a long AXI burst can be expanded to HIF commands so that back to back accesses are to alternating data channels. This setting achieves the highest efficiency possible from a single AXI port.

On the read data path, data order - based on AXI ordering rules - has to be preserved within each channel and between both channels. The read reorder buffer reorders the data coming from a given channel. The data ordered from both channels is then reordered by the data channel reorder logic. Thus two separate data SRAMs are instantiated, one for each channel, whose outputs are combined to provide a single wide AXI read data channel.

By setting the correct system mapping, one port can be set to access one data channel and another port can be set to access the other data channel.

9.2.2.2 Host Interface (HIF)

HIF is an internal interface when the DDRC is configured to include a multi port arbiter. In this case, the AXI Port Interface and/or Port Arbiter handle all signals on this interface, effectively acting as the SoC core.

Read, write, as well as write data are received through the HIF. Following the receipt and acceptance of a write the DDRC requests write data from the interface. The interface subsequently provides the independently timed write data in the requested order (which matches the order in which requests are made to the DDRC). Both read and write requests can be reordered later, before being output on the DFI interface.

Requests to the DDRC are throttled in two ways:

- A credit mechanism that ensures that buffer space is available for any request the SoC core makes to the DDRC, prior to the request being made.
- An independent stall mechanism that throttles requests when address collisions take place or if entering self-refresh through the software self-refresh or hardware low power self-refresh.

Data is handled separately. The DDRC throttles data by potentially waiting after it receives a write before requesting the associated data. If there is collision, then the throttling lasts until the collision is cleared in the DDRC. Once write data is requested, it is always accepted by the DDRC.

9.2.2.2.1 Credit Mechanism

The DDRC employs a credit mechanism to ensure that buffers do not overflow. The interface making the request to the DDRC, can only request commands for which it has been granted “credits” to issue.

Credits are tracked seperately for the following three command types:

- High Priority read(HPR)
- Low Prioroity rad(LPR)
- Write

Credits are counted for each command type independently according to the following rules:

- Initially the interface has zero credits.
- The interface logic must include counters to track the number of credits granted by the DDRC and decremented due to commands issued by the interface logic to the DDRC. The interface logic must have separate credit counters for each individual command type.
- Following the de-assertion of reset to the DDRC, credits are issued to the interface for each command type. A given credit count increments every time the DDRC issues a credit, indicated by the assertion of the appropriate *_credit signal on the rising edge of core_ddrc_core_clk. The credit counting logic implemented externally to the DDRC must run on the same clock.
- When the credit count is greater than zero, the interface can issue requests of that type to the DDRC. Each time a request is issued to the DDRC, the associated credit count is decremented.
- The arbiter or the host can send Variable Priority Read (VPR) and Variable Priority Write (VPW) commands.

- VPR commands do not have a pre-allocated storage resource in the Read CAM (unlike HPR commands). VPR commands share the same resource with the LPR commands. As far as the credit mechanism is concerned, the VPR commands are counted in the LPR credit bucket.
- Similarly, VPW commands do not have a per-allocated storage resource in the Write CAM. VPW commands share the same resource with the Normal Write commands. As far as credit mechanism is concerned, the VPW commands are counted in the WR credit bucket.

- hif_cmd_valid
- hif_cmd_type
- hif_cmd_pri
- hif_lpr_credit
- hif_hpr_credit
- hif_wr_credit
- hif_cmd_stall

9.2.2.3 DFI Interface

The DDRC contains a DFI MC (Memory Controller) interface, which is used to connect to a DFIcompliant PHY, and to transfer address, control and data to the PHY. The DDRC interfaces to a PUB block which acts as the DFI PHY interface.

The DFI interface is sub-divided into the following interface groups:

- Control Interface
- Write Data Interface
- Read Data Interface
- Update Interface
- Status Interface
- Training Interface (PHY-independent mode supported by the DDRC)
- Low Power Control Interface

9.2.2.3.1 1:2 Frequency Ratio Mode Considerations

The DDRC, including its DFI interface runs at the half data rate (HDR) clock (referred to as 1:2 frequency ratio mode in the DFI Specification), so all DFI command and address signals are twice the width of the equivalent DDR SDRAM signals. DFI data signals are four times the width of the equivalent DDR SDRAM signals. The DDRC operates with

an HDR clock. The PHY handles HDR-to-SDR conversion on the address bus to memory and HDR/DDR conversion on the data buses. In 1:2 frequency ratio mode, core_ddrc_core_clk runs at half the frequency of CK/CK#.

9.2.2.3.2 Control Interface

The control interface is a reflection of the SDRAM control interface including address, bank, chip select, row strobe, column strobe, write enable, clock enable and ODT control, as applicable for the memory technology. This interface consists of the following signals:

- dfi_address
- dfi_bank
- dfi_cas_n
- dfi_cke
- dfi_cs
- dfi_odt
- dfi_ras_n
- dfi_reset_n
- dfi_we_n
- dfi_bg
- dfi_act_n

9.2.2.3.3 Write Data Interface

The write data interface handles the transmission of write data across the DFI interface. The DFI Specification defines signals and timing relationships. This interface consists of the following signals:

- dfi_wrdata
- dfi_wrdata_en
- dfi_wrdata_mask

The timing of this interface is user-configurable, to support all DFI-compliant PHYs through the DFITMG0[dfi_tphy_wrlat] and DFITMG0[dfi_tphy_wrdata] bits. For DFI 1:2, DFITMG0[dfi_wrdata_use_dfi_phy_clk] determines whether DFITMG0[dfi_tphy_wrlat] and DFITMG0[dfi_tphy_wrdata] are in terms of SDR or HDR clock cycles. If HDR, timing for dfi_wrdata* generation for write commands on phase 0/phase 1 are the same and dfi_wrdata* signals are aligned to HDR clock. If SDR, timing for dfi_wrdata* generation for write commands on phase 0/phase 1 are treated separately and dfi_wrdata* signals are not guaranteed to be aligned to HDR clock. Check your PHY requirements for correct programming.

In DDR4 configurations or LPDDR4 configurations, the signal dfi_wrdata_mask can act as Write DBI signal depending on the user programming of the SDRAM mode register.

Also, as per JEDEC Specification, the polarity of dfi_wrdata_mask is inverted when using DDR4 memories (if MSTR[ddr4] = 1). Therefore, for DDR4, if a bit of dfi_wrdata_mask is '0', the corresponding byte is masked.

9.2.2.3.3.1 Support for dfi_wrdata_cs/dfi_rddata_cs Signals (DFI 3.1)

The signal dfi_wrdata_cs is driven as follows:

- dfi_wrdata_cs is driven according to the relevant chip select tphy_wrcslat DFI PHY clock cycles after any command that generates dfi_wrdata. This includes a write, and in DDR4, a PDA (write). It is guaranteed to remain at this value for a minimum of tphy_wrcsgap plus the time for the write data (usually MSTR[burst_rdwr]).

Similarly, for dfi_rddata_c:

- dfi_rddata_cs is driven according to the relevant chip select tphy_rdcslat DFI PHY clock cycles after any command that generates dfi_rddata. This includes a Read, in LPDDR4, a MRR and in DDR4, a MPR (read). It is guaranteed to remain at this value for a minimum of tphy_rdcsgap plus the time for the read data (usually MSTR[burst_rdwr]).

The table outlines the DFI timing value and the equivalent register in the DDRC.

Table 9-2. DFI timing values for dfi_wrdata_cs/dfi_rddata_cs

DFI Timing Value	DDRC Register
$t_{phy_wrcslat}$	DFITMG2[dfi_tphy_wrcslat]
$t_{phy_wrcsgap}$	RANKCTL[diff_rank_wr_gap][1]
$t_{phy_rdcslat}$	DFITMG2[dfi_tphy_rdcslat]
$t_{phy_rdcsgap}$	RANKCTL[diff_rank_rd_gap][1]

NOTE

1. This register is in terms of DFI clocks (controller clocks), while tphy_wrcsgap is in terms of DFI PHY clocks.

9.2.2.3.4 Read Data Interface

The read data interface handles the return of read data across the DFI interface. The DFI Specification defines signals and timing relationships. This interface consists of the following signals:

- dfi_rddata
- dfi_rddata_en
- dfi_rddata_valid
- dfi_rddata_dbi

The timing of this interface is user-configurable, to support all DFI-compliant PHYs via the DFITMG0[t_rddata_en] bit.

For DFI 1:2, DFITMG0[dfi_rddata_use_dfi_phy_clk] determines whether DFITMG0[dfi_t_rddata_en] is in terms of SDR or HDR clock cycles. If HDR, timing for dfi_rddata_en generation for read commands on phase 0/phase 1 is the same and dfi_rddata* signals are aligned to HDR clock. If SDR, timing for dfi_rddata* generation for read commands on phase 0/phase 1 are treated separately and dfi_rddata* signals are not guaranteed to be aligned to HDR clock. Check the PHY requirements for correct programming.

In DDR4 configurations, the signal dfi_rddata_dbi is the read DBI signal.

The DDRC has been verified with the PHYs. It assumes that the DFI parameter tphy_rdlat does not exceed 48 cycles.It also assumes that the DFI parameter trddata_en does not exceed the SDRAM read latency (RL).

9.2.2.3.5 Update Interface

During system operation, the system may require updates to internal settings to compensate for environmental conditions. To ensure that updates do not interfere with signals on the SDRAM interface, the DFI interface supports update modes where the DFI read, write, and control interface are suspended from normal activity. The DFI Specification defines both MC-initiated and PHY-initiated updates.

9.2.2.3.5.1 MC-initiated Updates

This interface consists of the following signals:

- dfi_ctrlupd_req
- dfi_ctrlupd_ack
- dfi_ctrlupd_ack2

MC-initiated updates can be acknowledged or ignored by the PHY. DFI MC-initiated updates are performed periodically by DDRC.

9.2.2.3.5.2 PHY-initiated Updates

This interface consists of the following signals:

- dfi_phyupd_req
- dfi_phyupd_type
- dfi_phyupd_ack

9.2.2.3.6 Status Interface

The DFI interface requires status information for initialization and clock control to the SDRAM devices. These signals are used to convey information between the MC and PHY. This interface consists of the following signals:

- dfi_init_start
- dfi_init_complete
- dfi_frequency
- dfi_dram_clk_disable
- dfi_alert_n (this signal replaces dfi_parity_error).

The DDRC does not support the following signals (defined as optional in the DFI Specification):

- dfi_data_byte_disable
- dfi_freq_ratio

9.2.2.3.6.1 Initialization

The dfi_init_start signal is used to trigger the PHY initialization by setting it to 1. It is driven by the DDRC through the APB interface with the DFIMISC[dfi_init_start read-write] register field. The signal dfi_init_complete indicates that the PHY has completed its initialization. This information can be read/polled by the DDRC through the APB interface with the DFISTAT[dfi_init_complete] read-only register field.

9.2.2.3.6.2 Clock Disabling

The dfi_dram_clk_disable signal depends on setting of the PWRCTL[en_dfi_dram_clk_disable] bit.

9.2.2.3.6.3 Frequency Change

The interface consists of three signals:

- dfi_init_start: Output from the controller to the PHY
- dfi_init_complete: Output from the PHY to the controller
- dfi_frequency: Output from the controller to the PHY

The procedure is as follows:

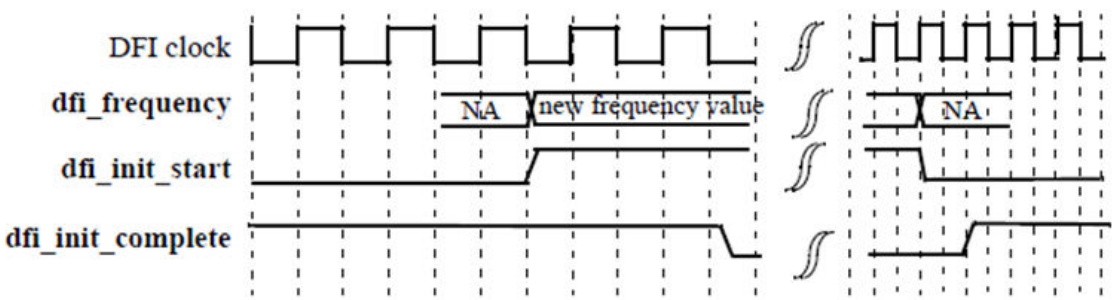

Figure 9-3. Frequency Change

dfi_frequency indicates the operating frequency of the system. This signal should change only at initialization, during a DFI frequency change operation, or other times that the system defines.This signal should be constant during normal operation.The number of supported frequencies and the mapping of signal values to clock frequencies are defined by the PHY, system, or both. For timing, the dfi_frequency signal must be set to a legal value and remain unchanged when dfi_init_start is asserted.The dfi_frequency signal can change any time when dfi_init_start is low and should be ignored at this time.

The behavior of the dfi_init_start signal is dependent on the dfi_init_complete signal.

If the PHY accepts the frequency change request, it must deassert the dfi_init_complete signal within tinit_start cycles of the dfi_init_start assertion. The MC continues to hold the dfi_init_start signal asserted until the clock frequency change has been completed. The de-assertion should be used by the PHY to reinitialize on the new clock frequency.

If the frequency change is not acknowledged (the dfi_init_complete signal remains asserted), the dfi_init_start signal must de-assert after tinit_start cycles. This requirement needs to be handled by the system as dfi_init_start is programmed through the software.

9.2.2.3.7 Low Power interface

In a DDR memory subsystem, it is advantageous to place the PHY in a low power state when the DDRC has knowledge that the memory subsystem remains idle for a period of time. Depending on the state of the system, the DDRC communicates state information to the PHY allowing the PHY to enter the appropriate power saving state. This interface consists of signals that are used to inform the PHY of a low power mode opportunity, as well as how quickly the DDRC requires the PHY to resume normal operation. This interface consists of the following signals:

- dfi_lp_req
- dfi_lp_wakeup
- dfi_lp_ack Software control is provided in DFILPCFG0/DFILPCFG1 registers for the following:
- This is an optional interface for a DFI-compliant PHY. The interface signals always exist in the DDRC. But the software can enable this interface in self-refresh and/or power-down and/or deep power-down mode and/or maximum power saving mode - DFILPCFG0[dfi_lp_en_pd], DFILPCFG0[dfi_lp_en_sr], DFILPCFG0[dfi_lp_en_dpd] and DFILPCFG1[dfi_lp_en_mpsm] respectively.
- Software control over what is driven on dfi_lp_wakeup signal (and its associated timing) in selfrefresh or power-down or deep power-down or maximum power saving mode - DFILPCFG0[dfi_lp_wakeup_pd], DFILPCFG0[dfi_lp_wakeup_sr], DFILPCFG0[dfi_lp_wakeup_dpd] and DFILPCFG1[dfi_lp_wakeup_mpsm] respectively.
- The timing of this DFI low power interface - DFILPCFG0[dfi_tlp_resp].
- ctl_idle output pin is a sideband signal (not specified in DFI). This is driven the same as dfi_lp_req if enabled via software (DFIMISC[ctl_idle_en]=1 and DFI Low Power Interface is also enabled via DFILPCFG0/DFILPCFG1 registers). If configured for Shared AC, dfi_lp_req signal of both data channels must be asserted for ctl_idle to be asserted.

9.2.2.3.8 PHY Master Interface

This interface consists of the following signals:

- dfi_phymstr_req
- dfi_phymstr_cs_state
- dfi_phymstr_state_sel
- dfi_phymstr_type
- dfi_phymstr_ack

9.2.2.4 APB Interface

The DDRC provides a dedicated APB 3.0 bus interface that is used to access the DDRC software programmable registers. The DDRC converts APB reads and writes into accesses to the internal register file.

9.2.2.4.1 Register Classes

There are three classes of registers in the DDRC:

- Dynamic Registers
- Quasi Dynamic Registers
- Static Registers

Dynamic registers can be written at any time during operation.

Static registers can be written only when the controller is in reset.

Quasi dynamic registers can be written when the controller is in reset and some specific conditions outside reset. To write them, SWCTL[sw_done] has to be set to 0 at the beginning of the programming sequence and set back to 1 at the end. After that, SWSTAT[sw_done_ack] has to be polled for acknowledge.

9.2.2.5 Clocks

An application port's clock (aclk_n/hclk_n) is considered synchronous when it is phase aligned and equal frequency to the DDRC core_ddrc_core_clk.

The following table provides the clocks for the DDRC module.

Table 9-3. Clocks

Clock	Description
core_ddrc_core_clk	DDRC clock
pclk	APB clock

9.2.2.6 Interrupts

The DDRC consists of the following interrupts:

- Interrupt for DRAM controller's performance monitor
- Error Interrupt for DFI error
- Scrubber Interrupt indicating one full address range sweep
- Error Interrupt for address protection fault
- Error Interrupt for correctable ECC error detected
- Error Interrupt for uncorrectable ECC error detected

Refer to the Interrupts chapter for details on the interrupt assignments.

9.2.3 External Signals

There are no external signals pinned out for the DDRC.

9.2.4 Initialization and Application Information

NXP provides a DDR Tool to help users perform LPDDR4/DDR4 training, stress test, and DDR initial code generation for u-boot SPL. Please refer to *i.MX 8M Family DDR Tools Release* on NXP Community for additional details.

9.2.5 Memory Map and register definition

This section includes the DDRC module memory map and detailed descriptions of all registers.

NOTE

The information within this block guide is Synopsys Proprietary. Used with permission.

9.2.5.1.2 Master Register0 (MSTR)

9.2.5.1.2.1 Offset

Register	Offset
MSTR	0h

9.2.5.1.2.2 Diagram

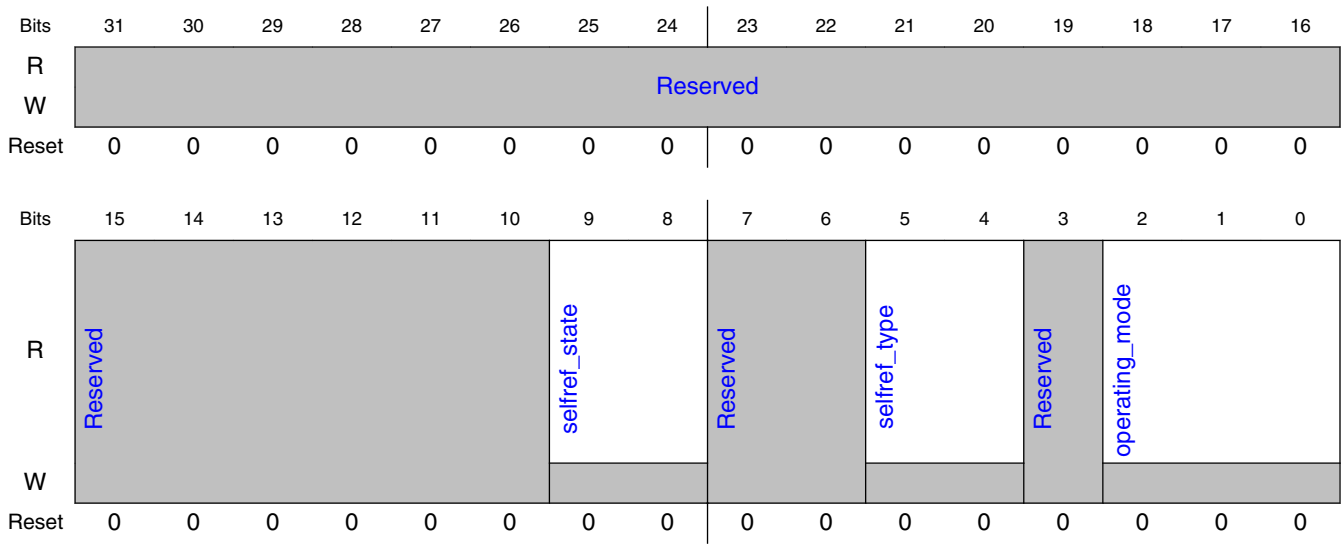
9.2.5.1.2.3 Fields

Field	Function
31-30 device_config	Indicates the configuration of the device used in the system. 00b - Reserved 01b - Reserved 10b - Reserved 11b - x32 device
29 frequency_mode	Choose which registers are used. 0b - Original Registers 1b - Shadow Registers
28-26 —	Reserved

Table continues on the next page...

Field	Function
25-24 active_ranks	Only present for multi-rank configurations. Each bit represents one rank. For two-rank configurations, only bits[25:24] are present. • 1 - populated • 0 - unpopulated LSB is the lowest rank number. For 2 ranks following combinations are legal • 01 - One rank • 11 - Two ranks • Others- Reserved For 4 ranks following combinations are legal: • 0001 - One rank • 0011 - Two ranks • 1111 - Four ranks
23 —	Reserved
22 —	Reserved
21-20 —	Reserved
19-16 burst_rdwr	SDRAM burst length used All other values are reserved. This controls the burst size used to access the SDRAM. This must match the burst length mode register setting in the SDRAM. (For BC4/8 on-the-fly mode of DDR4, set this field to 0x0100) 0001b - Reserved 0010b - Burst length of 4 0100b - Burst length of 8 1000b - Burst length of 16 (only supported for LPDDR4)
15 —	Reserved
14 —	Reserved
13-12 data_bus_width	Selects proportion of DQ bus width that is used by the SDRAM - 00 - Full DQ bus width to SDRAM - 01 - Half DQ bus width to SDRAM - 10 - Quarter DQ bus width to SDRAM - 11 - Reserved Note that half bus width mode is only supported when the SDRAM bus width is a multiple of 16, and quarter bus width mode is only supported when the SDRAM bus width is a multiple of 32 and the configuration parameter MEMC_QBUS_SUPPORT is set. Bus width refers to DQ bus width (excluding any ECC width).
11 geardown_mode	1 indicates put the DRAM in geardown mode (2N) and 0 indicates put the DRAM in normal mode (1N). This register can be changed, only when the Controller is in self-refresh mode. This signal must be set the same value as MR3 bit A3. Note: Geardown mode is not supported if the configuration parameter MEMC_CMD_RTN2IDLE is set Note: Geardown mode is not supported if the configuration parameter DDRC_SHARED_AC is set (in Shared-AC mode) and the register value is don't care
10 —	Reserved
9 burstchop	When set, enable burst-chop (BC4 or 8 on-the-fly) in DDR4. Burst Chop for Reads is exercised only in HIF configurations (DDRC_INCL_ARB not set) and if in full bus width mode (MSTR.data_bus_width = 00) and if MEMC_BURST_LENGTH=8 or 16. Burst Chop for Writes is exercised only if Partial Writes enabled

Table continues on the next page...



Field	Function
	(DDRC_PARTIAL_WR=1) and if CRC is disabled (CRCPARCTL1.crc_enable = 0). If DDR4 CRC/parity retry is enabled (CRCPARCTL1.crc_parity_retry_enable = 1), burst chop is not supported, and this bit must be set to '0'. BC4 (fixed) mode is not supported.
8-6 —	Reserved
5 lpddr4	Select LPDDR4 SDRAM - 1 - LPDDR4 SDRAM device in use. - 0 - non-LPDDR4 device in use Present only in designs configured to support LPDDR4.
4 ddr4	Select DDR4 SDRAM - 1 - DDR4 SDRAM device in use. - 0 - non-DDR4 device in use Present only in designs configured to support DDR4.
3 —	Reserved

1 —	Reserved
0 —	Reserved

9.2.5.1.3 Operating Mode Status Register (STAT)

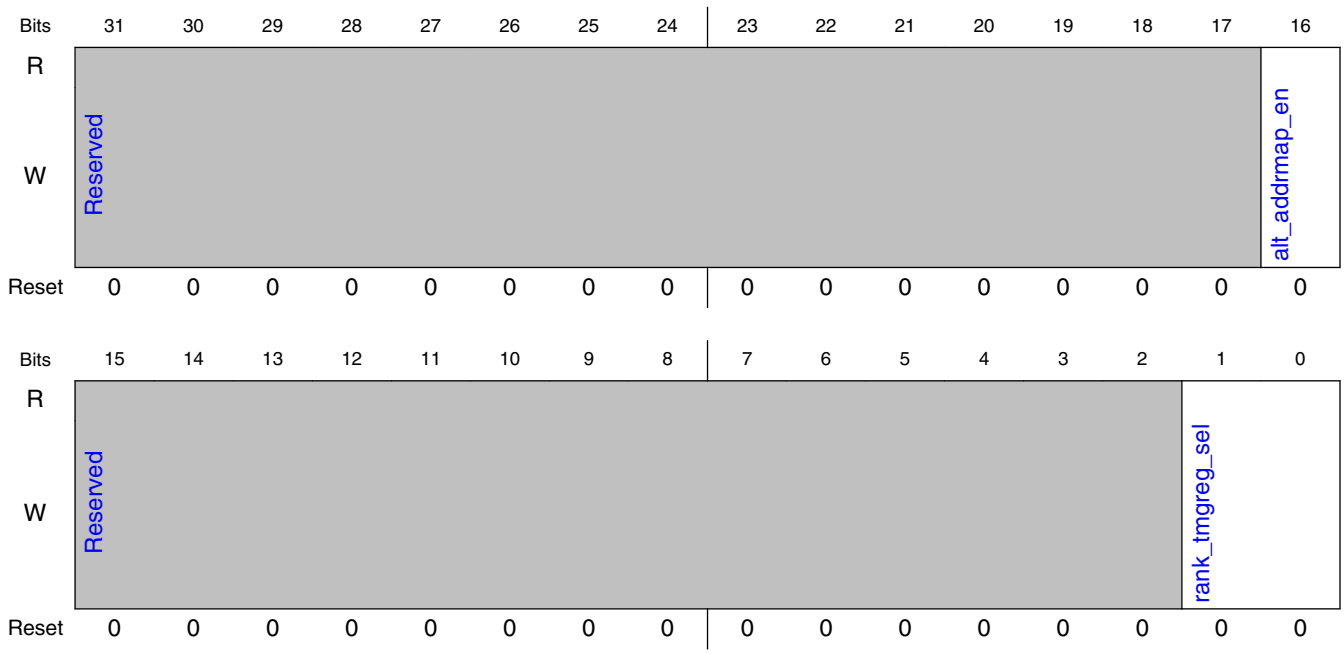
9.2.5.1.3.1 Offset

Register	Offset
STAT	4h

9.2.5.1.3.2 Diagram

9.2.5.1.3.3 Fields

Field	Function
31-10 —	Reserved
9-8 selfref_state	Self refresh state. This indicates self refresh or self refresh power down state for LPDDR4. This register is used for frequency change and MRR/MRW access during self refresh. 00b - SDRAM is not in Self Refresh. 01b - Self refresh 1 10b - Self refresh power down 11b - Self refresh
7-6 —	Reserved
5-4 selfref_type	Flags if Self Refresh (except LPDDR4) or SR-Powerdown (LPDDR4) is entered and if it was under Automatic Self Refresh control only or not. 00b - SDRAM is not in Self Refresh (except LPDDR4) or SR-Powerdown (LPDDR4). If retry is enabled by CRCPARCTRL1.crc_parity_retry_enable, this also indicates SRE command is still in parity error window or retry is in-progress. 10b - SDRAM is in Self Refresh (except LPDDR4) or SR-Powerdown (LPDDR4), which was not caused solely under Automatic Self Refresh control. It could have been caused by Hardware Low Power Interface and/or Software (reg_ddrc_selfref_sw). If retry is enabled, this guarantees SRE command is executed correctly without parity 11b - SDRAM is in Self Refresh (except LPDDR4) or SR-Powerdown (LPDDR4), which was caused by Automatic Self Refresh only. If retry is enabled, this guarantees SRE command is executed correctly without parity error.
3 —	Reserved
2-0 operating_mode	Operating mode This is 3-bits wide in configurations with LPDDR4/DDR4 support



Field	Function
	DDR4 designs: • 000 - Init • 001 - Normal • 010 - Power-down • 011 - Self refresh • 1XX - Deep power-down / Maximum Power Saving Mode LPDDR4 designs: • 000 - Init • 001 - Normal • 010 - Power-down • 011 - Self refresh / Self refresh power-down

16 alt_addrmap_en	Enable Alternative Address Map 0b - Disable Alternative Address Map 1b - Enable Alternative Address Map
15-2 —	Reserved
1-0 rank_tmgreg_sel	rank_tmgreg_sel Indicates which register set is used for each rank. Each bit represents one rank. (LSB is the lowest rank number.) **NOTE:** Only some of timing registers in DRAMTMGx are duplicated as MRAMTMGx for MRAM and its width is expanded for MRAM. This register can switch the duplicate registers, otherwise use DRAMTMGx. This register is only for DDR4 ST-MRAM rank, otherwise must be set to 0. This register must be set up while the Controller is in reset. 00b - USE DRAMTMGx registers for the rank 01b - USE MRAMTMGx registers for the rank

9.2.5.1.5 Operating Mode Status Register (MRCTRL3)

9.2.5.1.5.1 Offset

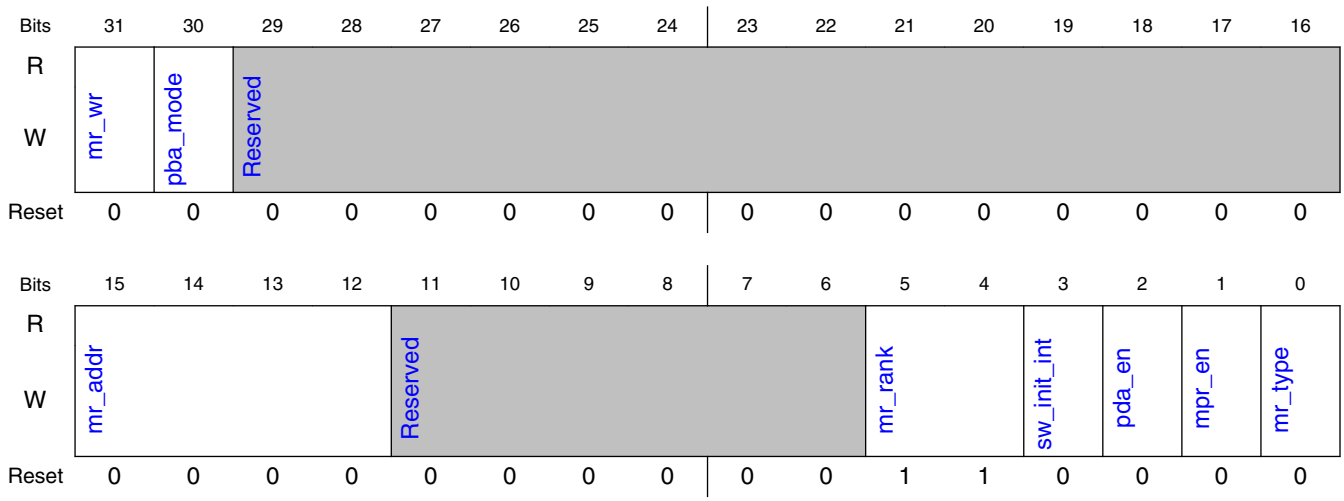
Register	Offset
MRCTRL3	Ch

9.2.5.1.5.2 Diagram

9.2.5.1.5.3 Fields

Field	Function
31-2 —	Reserved
1-0 mr_rank_sel	mr_rank_sel Controls which rank is accessed by MRCTRL0.mr_wr. Normally, it is desired to access all ranks, so all bits should be set to 1. Examples (assume uMCTL2 is configured for 8 ranks): • 0x01 - select rank 0 only • 0x02 - select rank 1 only • 0x05 - select ranks 0 and 2

9.2.5.1.6 Mode Register Read/Write Control Register 0. (MRCTRL0)



9.2.5.1.6.1 Offset

Register	Offset
MRCTRL0	10h

9.2.5.1.6.2 Function

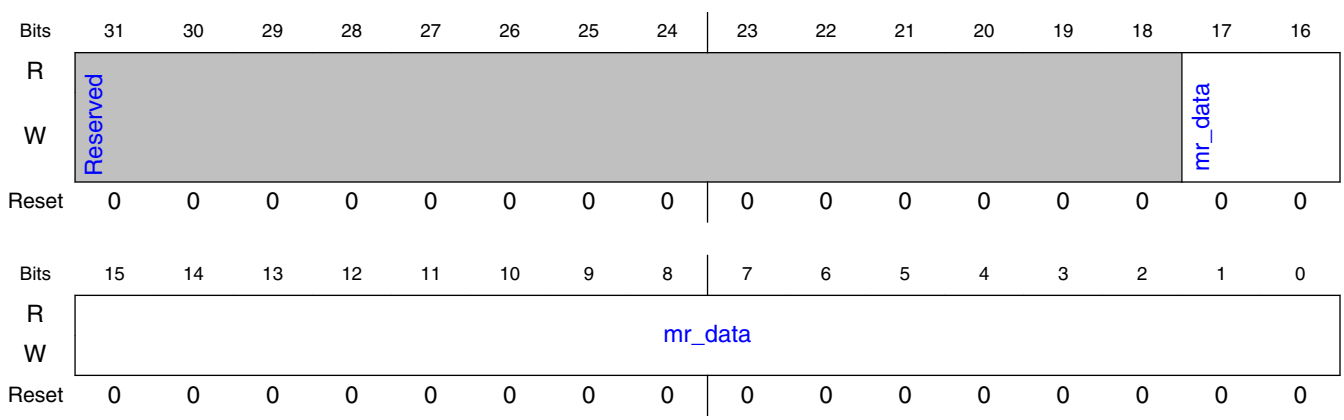
Mode Register Read/Write Control Register 0. Note: Do not enable more than one of the following fields simultaneously: - sw_init_int - pda_en - mpr_en

9.2.5.1.6.3 Diagram

9.2.5.1.6.4 Fields

Field	Function
31 mr_wr	Setting this register bit to 1 triggers a mode register read or write operation. When the MR operation is complete, the DDRC automatically clears this bit. The other register fields of this register must be written in a separate APB transaction, before setting this mr_wr bit. It is recommended NOT to set this signal if in Init, Deep power-down or MPSM operating modes.
30 pba_mode	Indicates whether PBA access is executed. When setting this bit to 1 along with setting pda_en to 1, DDRC initiates PBA access instead of PDA access. - 0 - Per DRAM Addressability mode - 1 - Per Buffer Addressability mode The completion of PBA access is confirmed by MRSTAT.pda_done in the same way as PDA.
29-16 —	Reserved
15-12 mr_addr	Address of the mode register that is to be written to. Don't Care for LPDDR4 (see MRCTRL1.mr_data for mode register addressing in LPDDR4).In case of DDR4, the bit[3:2] corresponds to the bank group bits. 0000b - MR0 0001b - MR1 0010b - MR2 0011b - MR3 0100b - MR4 0101b - MR5 0110b - MR6 0111b - MR7
11-6 —	Reserved
5-4 mr_rank	Controls which rank is accessed by MRCTRL0.mr_wr. Normally, it is desired to access all ranks, so all bits should be set to 1.Examples (assume DDRC is configured for 4 ranks): 0x1 - select rank 0 only 0x2 - select rank 1 only 0x5 - select ranks 0 and 2 0xA - select ranks 1 and 3 0xF - select ranks 0, 1, 2 and 3
3 sw_init_int	Indicates whether Software intervention is allowed via MRCTRL0/MRCTRL1 before automatic SDRAM initialization routine or not. For DDR4, this bit can be used to initialize the DDR4 RCD (MR7) before

Table continues on the next page...



Field	Function
	automatic SDRAM initialization. For LPDDR4, this bit can be used to program additional mode registers before automatic SDRAM initialization if necessary. In LPDDR4 independent channel mode, note that this must be programmed to both channels beforehand. Note that this must be cleared to 0 after completing Software operation. Otherwise, SDRAM initialization routine will not re-start. 0b - Software intervention is not allowed 1b - Software intervention is allowed
2 pda_en	Indicates whether the mode register operation is MRS in PDA mode or not. Note that when pba_mode=1, PBA access is initiated instead of PDA access. 0b - MRS 1b - MRS in Per DRAM Addressability
1 mpr_en	Indicates whether the mode register operation is MRS or WR/RD for MPR (only supported for DDR4). 0b - MRS 1b - WR/RD for MPR
0 mr_type	Indicates whether the mode register operation is read or write. 0b - Write 1b - Read

9.2.5.1.7 Mode Register Read/Write Control Register 1 (MRCTRL1)

9.2.5.1.7.1 Offset

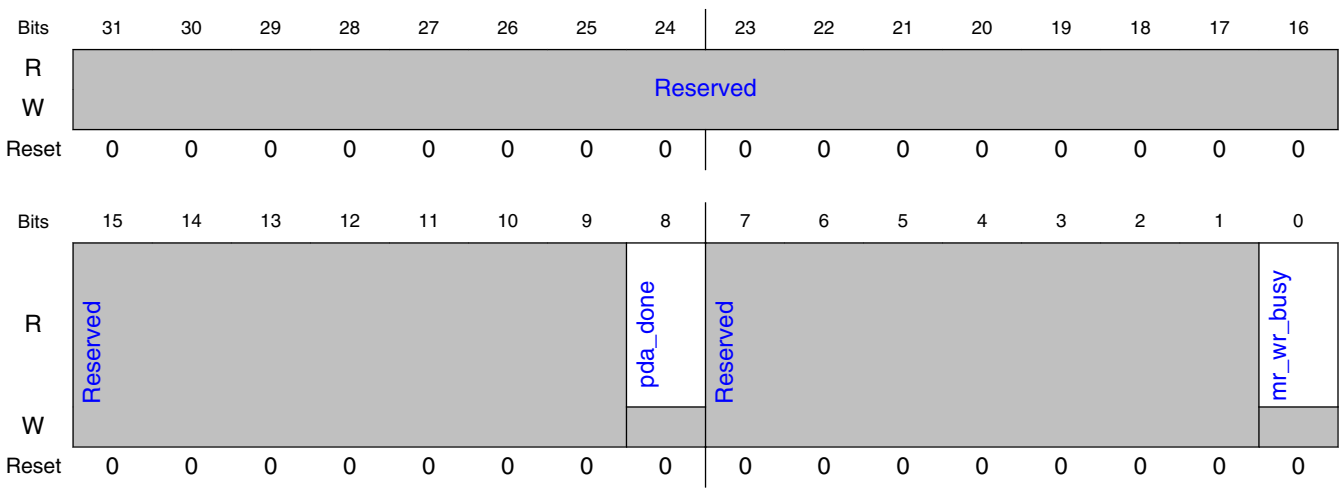
Register	Offset
MRCTRL1	14h

9.2.5.1.7.2 Diagram

9.2.5.1.7.3 Fields

Field	Function
31-18	Reserved

Table continues on the next page...



Field	Function
—	
17-0 mr_data	Mode register write data for all non-LPDDR4 modes. For LPDDR4, MRCTRL1[15:0] are interpreted as [15:8] MR Address [7:0] MR data for writes, don't care for reads. This is 18-bits wide in configurations with DDR4 support and 16-bits in all other configurations.

9.2.5.1.8 Mode Register Read/Write Status Register (MRSTAT)

9.2.5.1.8.1 Offset

Register	Offset
MRSTAT	18h

9.2.5.1.8.2 Diagram

9.2.5.1.8.3 Fields

Field	Function
31-9 —	Reserved
8 pda_done	The SoC core may initiate a MR write operation in PDA/PBA mode only if this signal is low. This signal goes high when three consecutive MRS commands related to the PDA/PBA mode are issued to the SDRAM. This signal goes low when MRCTRL0.pda_en becomes 0. Therefore, it is recommended to write MRCTRL0.pda_en to 0 after this signal goes high in order to prepare to perform PDA operation next time 0b - Indicates that mode register write operation related to PDA/PBA is in progress or has not started yet.

Table continues on the next page...

Field	Function
	1b - Indicates that mode register write operation related to PDA/PBA has competed.
7-1 —	Reserved
0 mr_wr_busy	The SoC core may initiate a MR write operation only if this signal is low. This signal goes high in the clock after the DDRC accepts the MRW/MRR request. It goes low when the MRW/MRR command is issued to the SDRAM. It is recommended not to perform MRW/MRR commands when 'MRSTAT.mr_wr_busy' is high. 0b - Indicates that the SoC core can initiate a mode register write operation 1b - Indicates that mode register write operation is in progress

9.2.5.1.9 Mode Register Read/Write Control Register 2 (MRCTRL2)

9.2.5.1.9.1 Offset

Register	Offset
MRCTRL2	1Ch

9.2.5.1.9.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	mr_device_sel

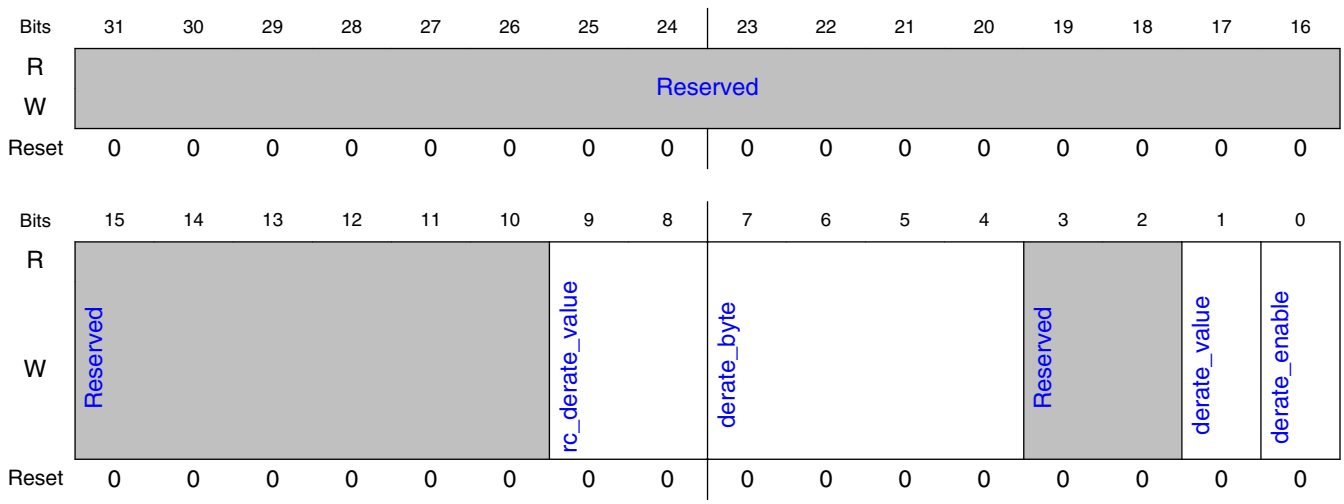
R W	mr_device_sel															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

9.2.5.1.9.3 Fields



Field	Function
31-0 mr_device_sel	Indicates the device(s) to be selected during the MRS that happens in PDA mode. Each bit is associated with one device. For example, bit[0] corresponds to Device 0, bit[1] to Device 1 etc. A '1' should be programmed to indicate that the MRS command should be applied to that device. A '0' indicates that the MRS commands should be skipped for that device.

9.2.5.1.10 Temperature Derate Enable Register (DERATEEN)

9.2.5.1.10.1 Offset

Register	Offset
DERATEEN	20h

9.2.5.1.10.2 Diagram

9.2.5.1.10.3 Fields

Field	Function
31-10 —	Reserved
9-8 rc_derate_value	Derate value of tRC for LPDDR4. Present only in designs configured to support LPDDR4. The required number of cycles for derating can be determined by dividing 3.75ns by the core_ddrc_core_clk period, and rounding up the next integer. 00b - Derating uses +1 01b - Derating uses +2 10b - Derating uses +3 11b - Derating uses +4
7-4 derate_byte	Derate byte Present only in designs configured to support LPDDR4. Indicates which byte of the MRR data is used for derating. The maximum valid value depends on MEMC_DRAM_TOTAL_DATA_WIDTH.
3-2 —	Reserved
1 derate_value	Derate value. Present only in designs configured to support LPDDR4. For LPDDR4, if the period of core_ddrc_core_clk is less than 1.875ns, this register field should be set to 1; otherwise it should be set to 0.

Table continues on the next page...

Field	Function
	0b - Derating uses +1 1b - Derating uses +2
0 derate_enable	Enables derating. Present only in designs configured to support LPDDR4. This field must be set to '0' for non-LPDDR4 mode. 0b - Timing parameter derating is disabled 1b - Timing parameter derating is enabled using MR4 read value.

9.2.5.1.11 Temperature Derate Interval Register (DERATEINT)

9.2.5.1.11.1 Offset

Register	Offset
DERATEINT	24h

9.2.5.1.11.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	mr4_read_interval															
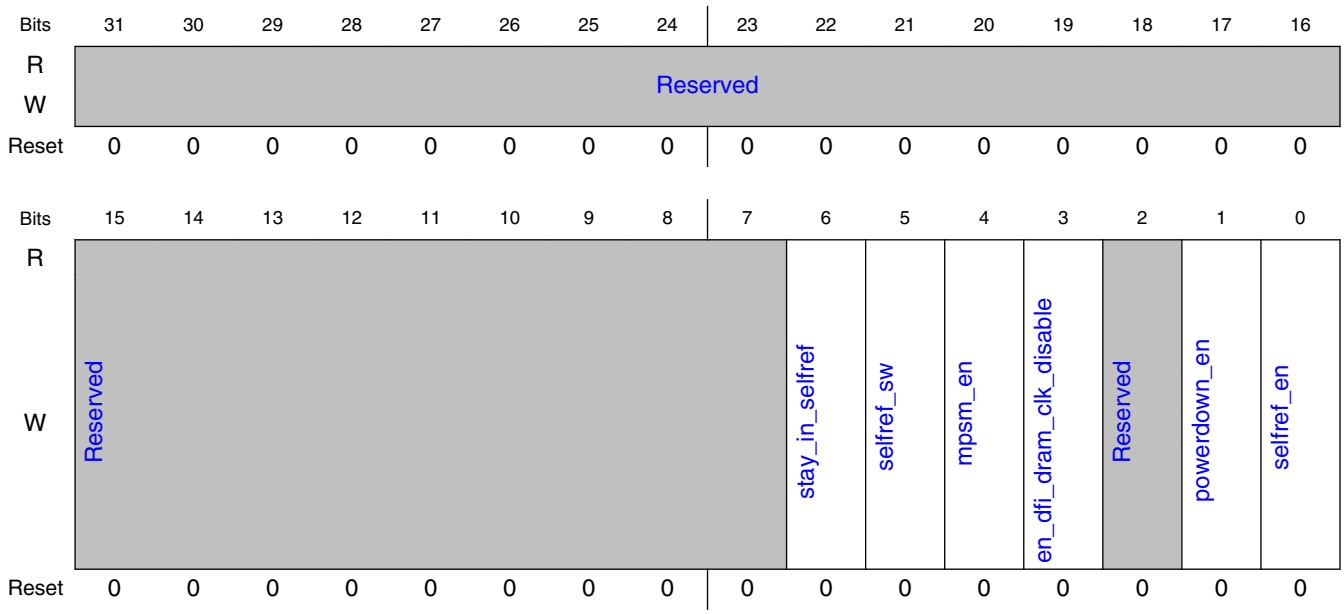
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

9.2.5.1.11.3 Fields



Field	Function
31-0 mr4_read_interval	Interval between two MR4 reads, used to derate the timing parameters. Present only in designs configured to support LPDDR4. This register must not be set to zero. Unit: DFI clock cycle.

9.2.5.1.12 Low Power Control Register (PWRCTL)

9.2.5.1.12.1 Offset

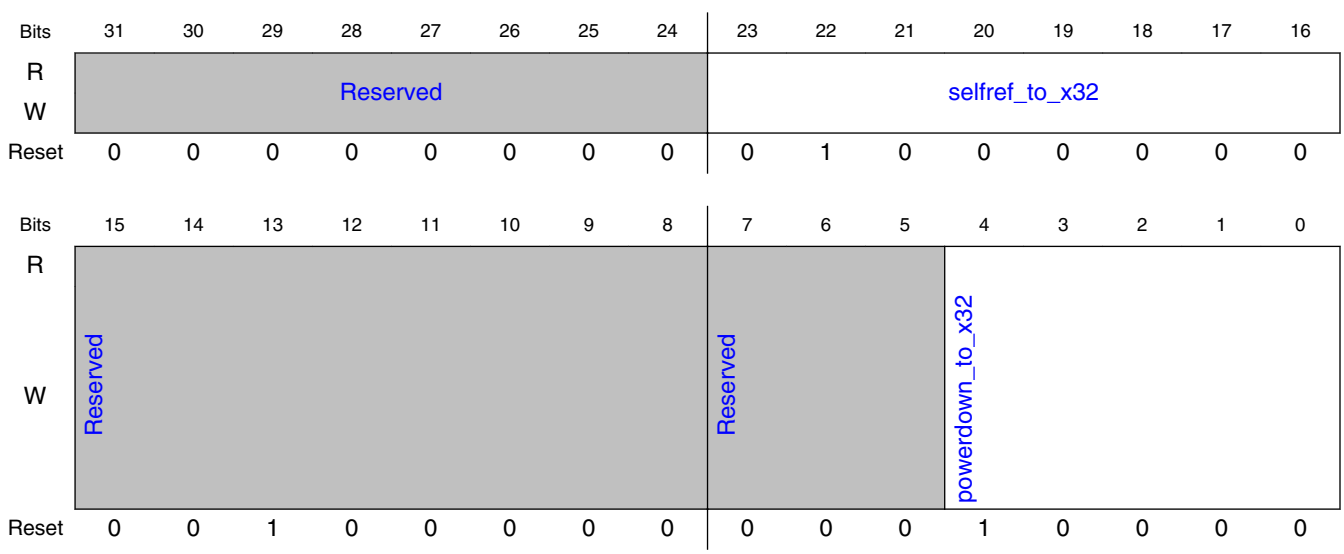
Register	Offset
PWRCTL	30h

9.2.5.1.12.2 Diagram

9.2.5.1.12.3 Fields

Field	Function
31-7 —	Reserved
6 stay_in_selfref	Self refresh state is an intermediate state to enter to Self refresh power down state or exit Self refresh power down state for LPDDR4. This register controls transition from the Self refresh state. - 1 - Prohibit transition from Self refresh state - 0 - Allow transition from Self refresh state 0b - 1b -
5 selfref_sw	A value of 1 to this register causes system to move to Self Refresh state immediately, as long as it is not in INIT or DPD/MPSM operating_mode. This is referred to as Software Entry/Exit to Self Refresh. 0b - Software Exit from Self Refresh 1b - Software Entry to Self Refresh
4 mpsm_en	When this is 1, the DDRC puts the SDRAM into maximum power saving mode when the transaction store is empty. This register must be reset to '0' to bring DDRC out of maximum power saving mode. Present only in designs configured to support DDR4. For non-DDR4, this register should not be set to 1. Note that MPSM is not supported when using a DDR PHY, if the PHY parameter DDRC_AC_CS_USE is disabled, as the MPSM exit sequence requires the chip-select signal to toggle. FOR PERFORMANCE ONLY.

Table continues on the next page...



Field	Function
3 en_dfi_dram_clk_disable	Enable the assertion of dfi_dram_clk_disable whenever a clock is not required by the SDRAM. If set to 0, dfi_dram_clk_disable is never asserted. Assertion of dfi_dram_clk_disable is as follows: In DDR4, can be asserted in following: in Self Refresh in Maximum Power Saving Mode In LPDDR4, can be asserted in following: in Self Refresh Power Down in Power Down during Normal operation (Clock Stop)
2 —	Reserved
1 powerdown_en	If true then the DDRC goes into power-down after a programmable number of cycles "maximum idle clocks before power down" (PWRTMG.powerdown_to_x32). This register bit may be re-programmed during the course of normal operation.
0 selfref_en	If true then the DDRC puts the SDRAM into Self Refresh after a programmable number of cycles "maximum idle clocks before Self Refresh (PWRTMG.selfref_to_x32)". This register bit may be re-programmed during the course of normal operation.

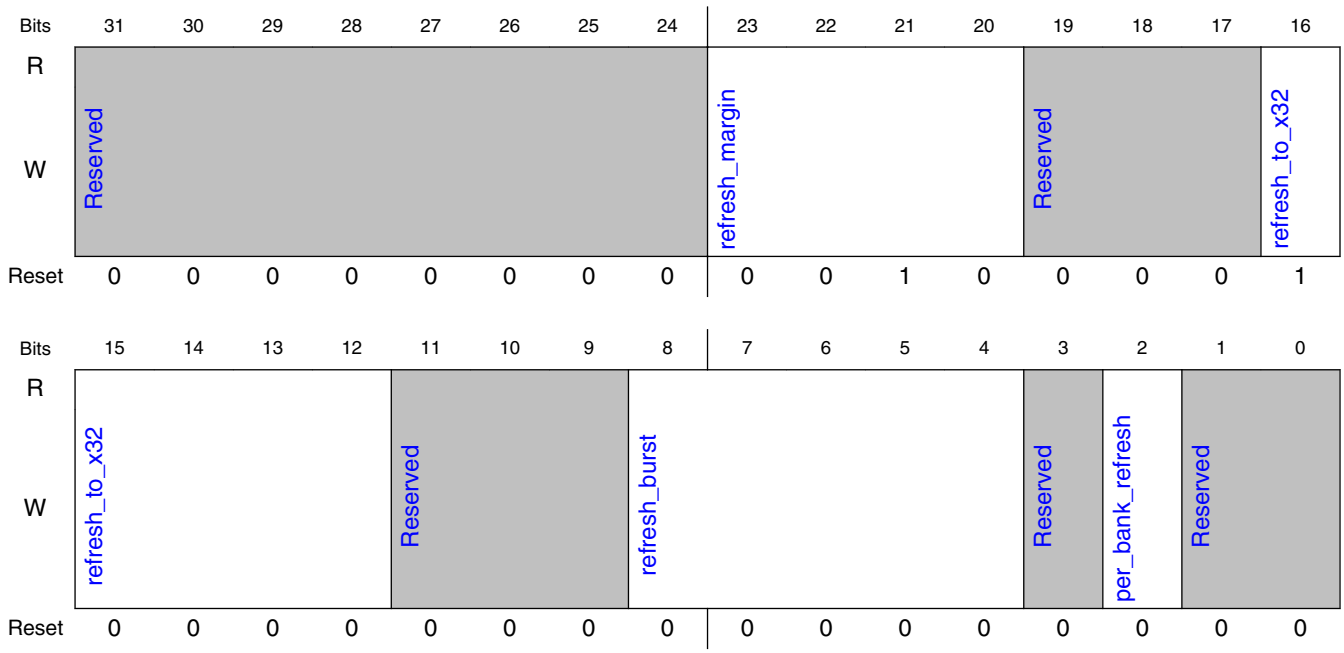
9.2.5.1.14.2 Diagram

9.2.5.1.14.3 Fields



Field	Function
31-28 —	Reserved
27-16 hw_lp_idle_x32	Hardware idle period. The cactive_ddrc output is driven low if the DDRC command channel is idle for hw_lp_idle * 32 cycles if not in INIT or DPD/MPSM operating_mode. The DDRC command channel is considered idle when there are no HIF commands outstanding. The hardware idle function is disabled when hw_lp_idle_x32=0. Unit: Multiples of 32 DFI clocks. FOR PERFORMANCE ONLY.
15-2 —	Reserved
1 hw_lp_exit_idle_en	When this bit is programmed to 1 the cactive_in_ddrc pin of the DDRC can be used to exit from the automatic clock stop, automatic power down or automatic self-refresh modes. Note, it will not cause exit of Self-Refresh that was caused by Hardware Low Power Interface and/or Software (PWRCTL.selfref_sw).
0 hw_lp_en	Enable for Hardware Low Power Interface.

9.2.5.1.15 Refresh Control Register 0 (RFSHCTL0)

9.2.5.1.15.1 Offset

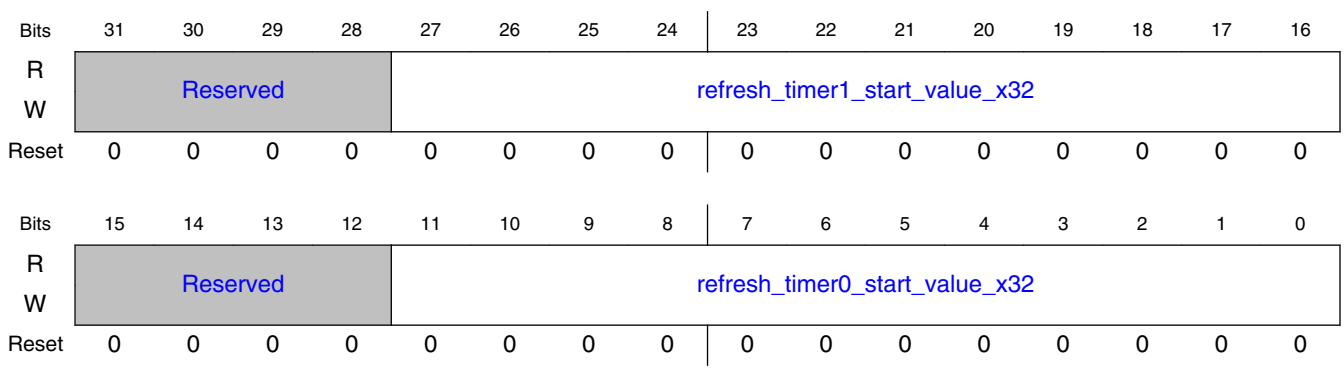
Register	Offset
RFSHCTL0	50h

9.2.5.1.15.2 Diagram

9.2.5.1.15.3 Fields

Field	Function
31-24 —	Reserved
23-20 refresh_margin	Threshold value in number of DFI clock cycles before the critical refresh or page timer expires. A critical refresh is to be issued before this threshold is reached. It is recommended that this not be changed from the default value, currently shown as 0x2. It must always be less than internally used t_rfc_nom_x32. Note that, in LPDDR4, internally used t_rfc_nom_x32 may be equal to RFSHTMG.t_rfc_nom_x32>>2 if derating is enabled (DERATEEN.derate_enable=1). Otherwise, internally used t_rfc_nom_x32 will be equal to RFSHTMG.t_rfc_nom_x32. Unit: Multiples of 32 DFI clocks.
19-17 —	Reserved
16-12 refresh_to_x32	If the refresh timer (tRFCnom, also known as tREFI) has expired at least once, but it has not expired (RFSHCTL0.refresh_burst+1) times yet, then a speculative refresh may be performed. A speculative refresh is a refresh performed at a time when refresh would be useful, but before it is absolutely required. When the SDRAM bus is idle for a period of time determined by this RFSHCTL0.refresh_to_x32 and the refresh timer has expired at least once since the last refresh, then a speculative refresh is performed. Speculative refreshes continues successively until there are no refreshes pending or until new reads or writes are issued to the DDRC. FOR PERFORMANCE ONLY. Unit: Multiples of 32 DFI clocks.
11-9 —	Reserved
8-4 refresh_burst	The programmed value + 1 is the number of refresh timeouts that is allowed to accumulate before traffic is blocked and the refreshes are forced to execute. Closing pages to perform a refresh is a one-time penalty that must be paid for each group of refreshes. Therefore, performing refreshes in a burst reduces the per-refresh penalty of these page closings. Higher numbers for RFSHCTL.refresh_burst slightly

Table continues on the next page...



Field	Function
	increases utilization; lower numbers decreases the worst-case latency associated with refreshes. - 0 - single refresh - 1 - burst-of-2 refresh - 7 - burst-of-8 refresh. In DDR4 mode, according to Fine Granularity feature, 8 refreshes can be postponed in 1X mode, 16 refreshes in 2X mode and 32 refreshes in 4X mode. If using PHY-initiated updates, care must be taken in the setting of RFSHCTL0.refresh_burst, to ensure that tRFCmax is not violated due to a PHY-initiated update occurring shortly before a refresh burst was due. In this situation, the refresh burst will be delayed until the PHY-initiated update is complete.
3 —	Reserved
2 per_bank_refresh	Per bank refresh allows traffic to flow to other banks. Present only in designs configured to support LPDDR4. 0b - All bank refresh 1b - Per bank refresh
1-0 —	Reserved

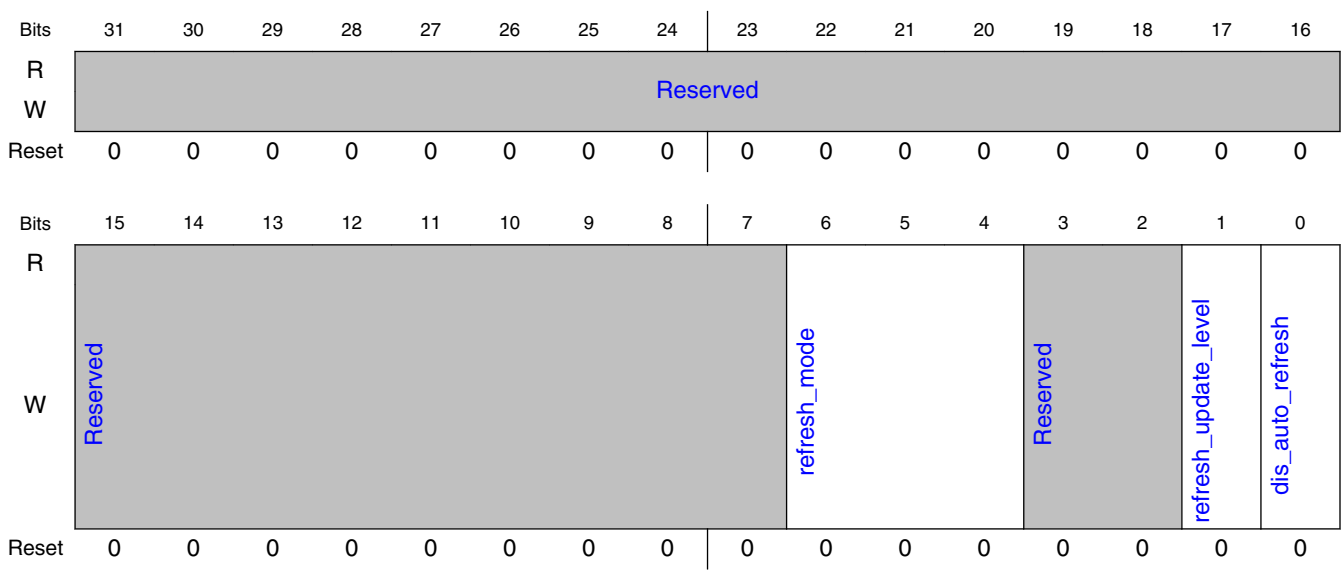
31-28 —	Reserved

Table continues on the next page...



Field	Function
27-16 refresh_timer1_start_value_x32	Refresh timer start for rank 1 (only present in multi-rank configurations). This is useful in staggering the refreshes to multiple ranks to help traffic to proceed. This is explained in Refresh Controls section of architecture chapter. Unit: Multiples of 32 DFI clock cycles. FOR PERFORMANCE ONLY.
15-12 —	Reserved
11-0 refresh_timer0_start_value_x32	Refresh timer start for rank 0 (only present in multi-rank configurations). This is useful in staggering the refreshes to multiple ranks to help traffic to proceed. This is explained in Refresh Controls section of architecture chapter. Unit: Multiples of 32 DFI clock cycles. FOR PERFORMANCE ONLY.

9.2.5.1.17 Refresh Control Register 3 (RFSHCTL3)

9.2.5.1.17.1 Offset

Register	Offset
RFSHCTL3	60h

9.2.5.1.17.2 Diagram

9.2.5.1.17.3 Fields

Field	Function
31-7	Reserved

Table continues on the next page...

Field	Function
—	
6-4 refresh_mode	Fine Granularity Refresh Mode - 000 - Fixed 1x (Normal mode) - 001 - Fixed 2x - 010 - Fixed 4x - 101 - Enable on the fly 2x (not supported) - 110 - Enable on the fly 4x (not supported) - Everything else - reserved Note: Only Fixed 1x mode is supported if RFSHCTL3.dis_auto_refresh = 1. Note: The on-the-fly modes are not supported in this version of the DDRC. Note: This must be set up while the Controller is in reset or while the Controller is in self-refresh mode. Changing this during normal operation is not allowed. Making this a dynamic register will be supported in future version of the DDRC. Note: This register field has effect only if a DDR4 SDRAM device is in use (MSTR.ddr4 = 1).
3-2 —	Reserved
1 refresh_update_level	Toggle this signal (either from 0 to 1 or from 1 to 0) to indicate that the refresh register(s) have been updated. refresh_update_level must not be toggled when the DDRC is in reset (core_ddrc_rstn = 0). The refresh register(s) are automatically updated when exiting reset.
0 dis_auto_refresh	When '1', disable auto-refresh generated by the DDRC. When auto-refresh is disabled, the SoC core must generate refreshes using the registers reg_ddrc_rank0_refresh, reg_ddrc_rank1_refresh, reg_ddrc_rank2_refresh and reg_ddrc_rank3_refresh. When dis_auto_refresh transitions from 0 to 1, any pending refreshes are immediately scheduled by the DDRC. If DDR4 CRC/parity retry is enabled (CRCPARCTL1.crc_parity_retry_enable = 1), disable auto-refresh is not supported, and this bit must be set to '0'. (DDR4 only) If FGR mode is enabled (RFSHCTL3.refresh_mode > 0), disable auto-refresh is not supported, and this bit must be set to '0'. This register field is changeable on the fly.

9.2.5.1.18 Refresh Timing Register (RFSHTMG)

9.2.5.1.18.1 Offset

Register	Offset
RFSHTMG	64h

9.2.5.1.18.2 Diagram

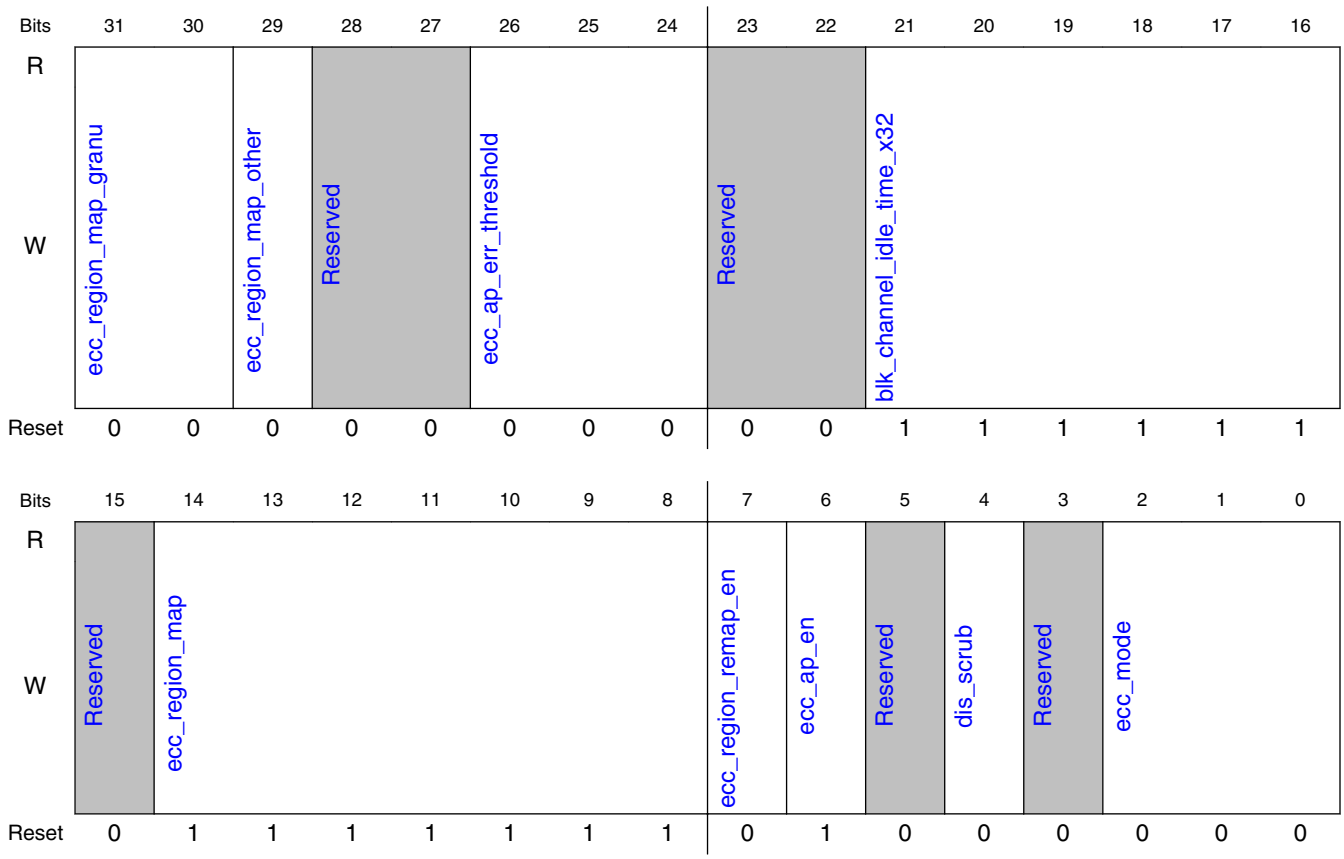
Reset	0	0	0	0	0	0	0	0	1	0	0	0	1	1	0	0

9.2.5.1.18.3 Fields



Field	Function
31-28 —	Reserved
27-16 t_rfc_nom_x32	tREFI: Average time interval between refreshes per rank (Specification: 7.8us for DDR4. See JEDEC specification for LPDDR4). For LPDDR4: - if using all-bank refreshes (RFSHCTL0.per_bank_refresh = 0), this register should be set to tREFIab - if using per-bank refreshes (RFSHCTL0.per_bank_refresh = 1), this register should be set to tREFIpb When the controller is operating in 1:2 frequency ratio mode, program this to (tREFI/2), no rounding up. In DDR4 mode, tREFI value is different depending on the refresh mode. The user should program the appropriate value from the spec based on the value programmed in the refresh mode register. Note that RFSHTMG.t_rfc_nom_x32 * 32 must be greater than RFSHTMG.t_rfc_min, and RFSHTMG.t_rfc_nom_x32 must be greater than 0x1. - Non-DDR4 or DDR4 Fixed 1x mode: RFSHTMG.t_rfc_nom_x32 must be less than or equal to 0xFFE. - DDR4 Fixed 2x mode: RFSHTMG.t_rfc_nom_x32 must be less than or equal to 0x7FF. - DDR4 Fixed 4x mode: RFSHTMG.t_rfc_nom_x32 must be less than or equal to 0x3FF. Unit: Multiples of 32 clocks.
15-10 —	Reserved
9-0 t_rfc_min	tRFC (min): Minimum time from refresh to refresh or activate. When the controller is operating in 1:1 mode, t_rfc_min should be set to RoundUp(tRFCmin/tCK). When the controller is operating in 1:2 mode, t_rfc_min should be set to RoundUp(RoundUp(tRFCmin/tCK)/2). In LPDDR4 mode: - if using all-bank refreshes, the tRFCmin value in the above equations is equal to tRFCab - if using per-bank refreshes, the tRFCmin value in the above equations is equal to tRFCpb. In DDR4 mode, the tRFCmin value in the above equations is different depending on the refresh mode (fixed 1X,2X,4X) and the device density. The user should program the appropriate value from the spec based on the 'refresh_mode' and the device density that is used. Unit: Clocks.

9.2.5.1.19 ECC Configuration Register 0 (ECCCFG0)

9.2.5.1.19.1 Offset

Register	Offset
ECCCFG0	70h

9.2.5.1.19.2 Diagram

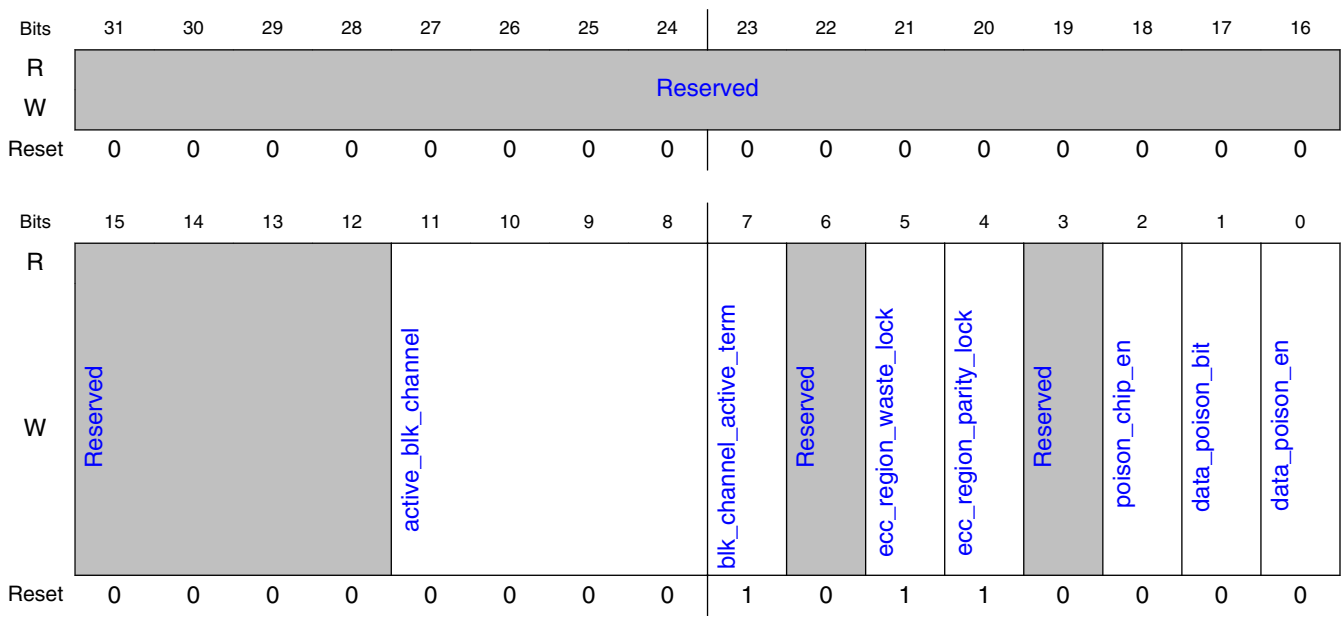
9.2.5.1.19.3 Fields

Field	Function
31-30 ecc_region_map_granu	Indicates granularity of selectable protected region Define one region size for ECCCFG0.ecc_region_map. 0 - 1/8 of memory spaces 1 - 1/16 of memory spaces 2 - 1/32 of memory spaces 3 - 1/64 of memory spaces
29 ecc_region_map_other	When ECCCFG0[ecc_region_map_granu] > 0, there is a region which is not controlled by ecc_region_map. This register defines the region to be protected or non-protected for Inline ECC. This register is valid only when ECCCFG0[ecc_region_map_granu]>0 && ECCCFG0[ecc_mode]=4. 0 - Non-Protected 1 - Protected
28-27 —	Reserved
26-24	Sets threshold for address parity error.

Table continues on the next page...

Field	Function
ecc_ap_err_threshold	ECCAPSTAT[ecc_ap_err] is asserted if number of ECC errors (correctable/uncorrectable) within one burst exceeds this threshold. This register value must be less than "Total number of ECC checks within one burst" when this feature is used, "Total number of ECC check within one burst" is calculated by (DRAM Data width) x (DRAM BL) / 64.
23-22 —	Reserved
21-16 blk_channel_idle_time_x32	Indicates the number of cycles on HIF interface with no access to protected regions which causes flush of all the block channels. In order to flush block channel, the controller injects write ECC command (when there is no incoming HIF command) if there is any write in the block and then stop tracking the block address. Unit: Multiples of 32 DFI clock cycles. 0 - Indicates no timeout (feature is disabled, not supported with this version) 1 - Indicates 32 cycles 2 - Indicates 2*32 cycles, and so on
15 —	Reserved
14-8 ecc_region_map	Selectable Protected Region setting. Memory space is divided to 8/16/32/64 regions which is determined by ECCCFG0.ecc_region_map_granu. Note: Highest 1/8 memory space is always ECC region. Lowest 7 regions are Selectable Protected Regions. The Selectable Protected Regions can be protected/non-protected selectively by ecc_region_map[6:0]. Other upper regions are non-protected region if any. Each bit of ecc_region_map[6:0] correspond to each of lowest 7 regions respectively. In order to protect a region with ECC, set the corresponding bit to 1, otherwise set to 0. All "0"s is invalid - there must be at least one protected region if inline ECC is enabled through ECCCFG0[ecc_mode] register. All regions are protected with the following setting. ecc_region_map=7'b1111111 ecc_region_map_granu=0 Only first 1/64 region is protected with the following setting. ecc_region_map=7'b0000001 ecc_region_map_granu=3
7 ecc_region_remap_en	Enables remapping ECC region feature. Only supported when inline ECC is enabled. 0 - Disable 1 - Enable
6 ecc_ap_en	Enables address protection feature. Only supported when inline ECC is enabled. 0 - Disable 1 - Enable
5 —	Reserved
4 dis_scrub	Disables ECC scrubs. Valid only when ECCCFG0[ecc_mode] = 3'b100 or 3'b101. **NOTE:** Scrub is not supported in inline ECC mode and the register value is don't care.
3 —	Reserved

Table continues on the next page...



Field	Function
2-0 ecc_mode	ECC mode indicator. 000 - ECC disabled 100 - ECC enabled - SEC/DED over 1 beat 101 - ECC enabled - Advanced ECC X4/X8 all other settings are reserved for future use

9.2.5.1.20 ECC Configuration Register 1 (ECCCFG1)

9.2.5.1.20.1 Offset

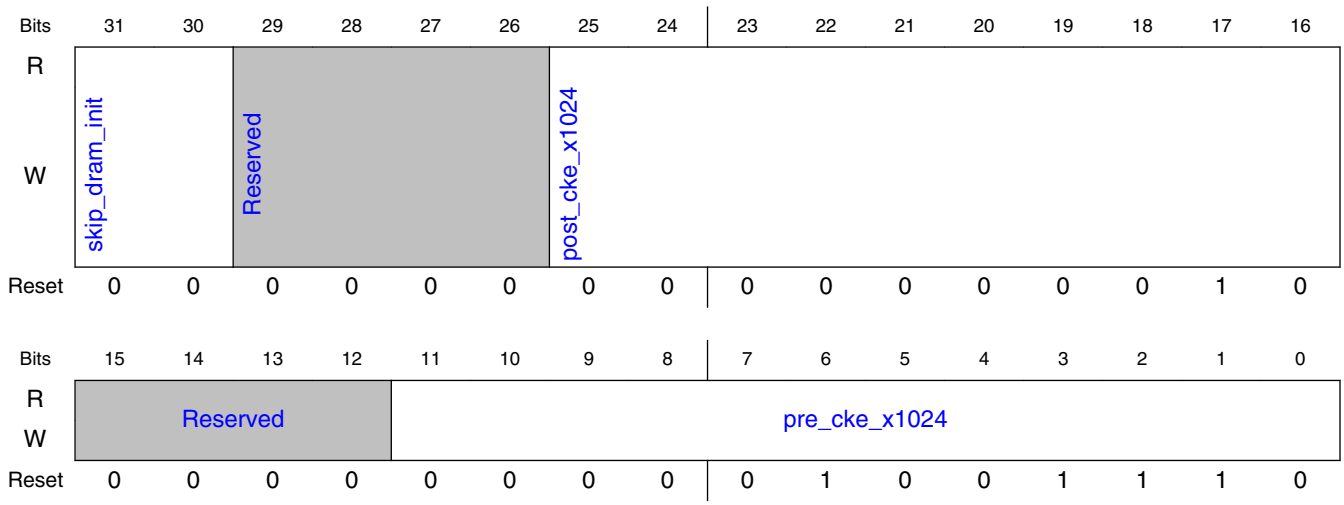
Register	Offset
ECCCFG1	74h

9.2.5.1.20.2 Diagram

9.2.5.1.20.3 Fields

Field	Function
31-12 —	Reserved

Table continues on the next page...



Field	Function
11-8 active_blk_channel	Indicated the number of active block channels. Total number of ECC block channels are defined by MEMC_NO_OF_BLK_CHANNEL hardware parameter. This register can limit the number of available channels. For example, if set to 0, only one channel is active and therefore block interleaving is disabled. The valid range is from 0 to MEMC_NO_OF_BLK_CHANNEL-1.
7 blk_channel_active_term	If enabled, block channel is terminated when full block write or full block read is performed (all address within block are written or read). This is debug register, and this must be set to 1 for normal operation. 0 - Disable (only for debug purpose) 1 - Enable (default)
6 —	Reserved
5 ecc_region_waste_lock	Locks the remaining waste parts of the ECC region (hole) that are not locked by ecc_region_parity_lock. 1 - Locked; if this region is accessed, error response is generated 0 - Unlocked; this region can be accessed normally, similar to non-ECC protected region
4 ecc_region_parity_lock	Locks the parity section of the ECC region (hole) which is the highest system address part of the memory that stores ECC parity for protected region. 1 - Locked; if this region is accessed, error response is generated 0 - Unlocked; this region can be accessed normally, similar to non-ECC protected region
3 —	Reserved
2 poison_chip_en	Indicates the data poison based on chip (that is, persistently poisons the DRAM data once its cs is selected to mimic chip failure). It is valid if ECCCFG1[data_poison_en]=1. 0 - Disable 1 - Enable. Persistently poison the write data to rank address that matches ECCPOISONADDR0[ecc_poison_rank].
1 data_poison_bit	Selects whether to poison 1 or 2 bits. 0 - 2-bit (uncorrectable) data poisoning 1 - 1-bit (correctable) data poisoning, if ECCCFG1[data_poison_en]=1
0 data_poison_en	Enables ECC data poisoning - introduces ECC errors on writes to address specified by the ECCPOISONADDR0/1 registers. This field must be set to 0 if ECC is disabled (ECCCFG0[ecc_mode] = 0).

9.2.5.1.21 SDRAM Initialization Register 0 (INIT0)

9.2.5.1.21.1 Offset

Register	Offset
INIT0	D0h

9.2.5.1.21.2 Diagram

9.2.5.1.21.3 Fields

Field	Function
31-30 skip_dram_init	If lower bit is enabled the SDRAM initialization routine is skipped. The upper bit decides what state the controller starts up in when reset is removed - 00 - SDRAM Intialization routine is run after power-up - 01 - SDRAM Initialization routine is skipped after power-up. Controller starts up in Normal Mode - 11 - SDRAM Initialization routine is skipped after power-up. Controller starts up in Self-refresh Mode - 10 - SDRAM Initialization routine is run after power-up. 00b - SDRAM Initialization routine is run after power-up 01b - SDRAM Initialization routine is skipped after power-up 10b - SDRAM Initialization routine is run after power-up 11b - SDRAM Initialization routine is skipped after power-up
29-26 —	Reserved
25-16 post_cke_x1024	Cycles to wait after driving CKE high to start the SDRAM initialization sequence. Unit: 1024 DFI clock cycles. LPDDR4 typically requires this to be programmed for a delay of 2 us. When the controller is operating in 1:2 frequency ratio mode, program this to JEDEC spec value divided by 2, and round it up to the next integer value.
15-12 —	Reserved
11-0 pre_cke_x1024	Cycles to wait after reset before driving CKE high to start the SDRAM initialization sequence. Unit: 1024 DFI clock cycles. LPDDR4: tINIT3 of 2 ms (min). When the controller is operating in 1:2 frequency ratio mode, program this to JEDEC spec value divided by 2, and round it up to the next integer value.

9.2.5.1.28 Rank Control Register (RANKCTL)

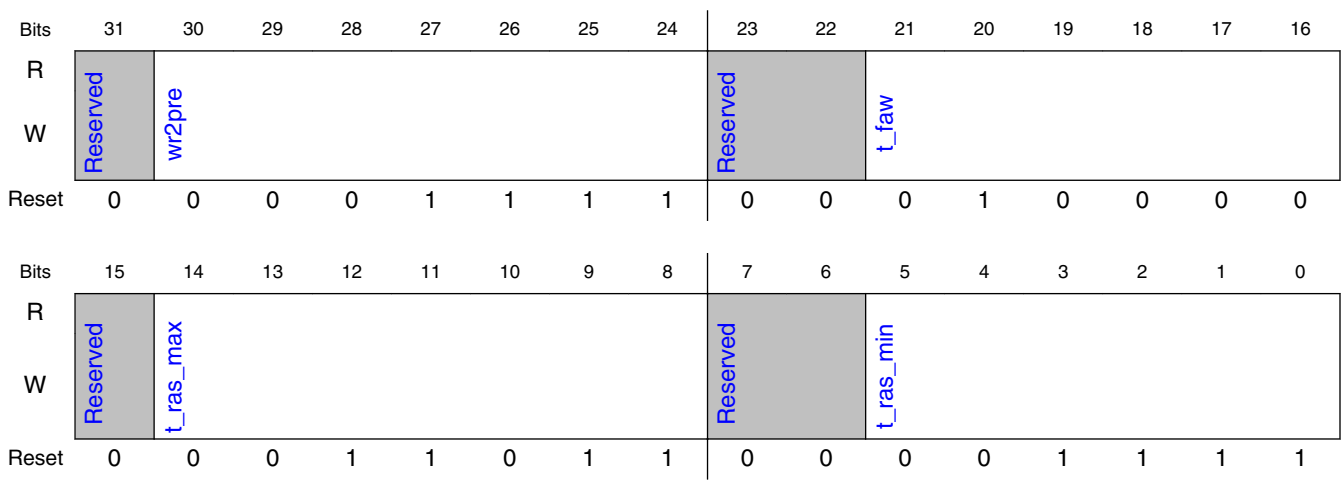
9.2.5.1.28.1 Offset

Register	Offset
RANKCTL	F4h

9.2.5.1.28.2 Diagram

9.2.5.1.28.3 Fields

Field	Function
31-12 —	Reserved
11-8 diff_rank_wr_gap	Only present for multi-rank configurations. Indicates the number of clocks of gap in data responses when performing consecutive writes to different ranks. This is used to switch the delays in the PHY to match the rank requirements. This value should consider both PHY requirement and ODT requirement. - PHY requirement: tphy_wrcsgap + 1 (see PHY databook for value of tphy_wrcsgap) If CRC feature is enabled, should be increased by 1. If write preamble is set to 2tCK(DDR4/LPDDR4 only), should be increased by 1. If write postamble is set to 1.5tCK(LPDDR4 only), should be increased by 1. - ODT requirement: The value programmed in this register takes care of the ODT switch off timing requirement when switching ranks during writes. For LPDDR4, the requirement is ODTLoff - ODTLon - BL/2 + 1 When the controller is operating in 1:1 mode, program this to the larger of PHY requirement or ODT requirement. When the controller is operating in 1:2 mode, program this to the larger value divided by two and round it up to the next integer.
7-4 diff_rank_rd_gap	Only present for multi-rank configurations. Indicates the number of clocks of gap in data responses when performing consecutive reads to different ranks. This is used to switch the delays in the PHY to match the rank requirements. This value should consider both PHY requirement and ODT requirement. - PHY requirement: tphy_rdcsgap + 1 (see PHY databook for value of tphy_rdcsgap) If read preamble is set to 2tCK(DDR4/LPDDR4 only), should be increased by 1. If read postamble is set to 1.5tCK(LPDDR4 only), should be increased by 1. - ODT requirement: The value programmed in this register takes care of the ODT switch off timing requirement when switching ranks during reads. When the controller is operating in 1:1 mode, program this to the larger of PHY requirement or ODT requirement. When the controller is operating in 1:2 mode, program this to the larger value divided by two and round it up to the next integer.
3-0 max_rank_rd	Only present for multi-rank configurations. Background: Reads to the same rank can be performed back-to-back. Reads to different ranks require additional gap dictated by the register RANKCTL.diff_rank_rd_gap. This is to avoid possible data bus contention as well as to give PHY enough time to switch the delay when changing ranks. The DDRC arbitrates for bus access on a cycle-by-cycle basis; therefore after a read is scheduled, there are few clock cycles (determined by the value on RANKCTL.diff_rank_rd_gap register) in which only reads from the same rank are eligible to be scheduled. This prevents reads from other ranks from having fair access to the data bus. This parameter represents the maximum number of reads that can be scheduled consecutively to the same rank. After



Field	Function
	this number is reached, a delay equal to RANKCTL.diff_rank_rd_gap is inserted by the scheduler to allow all ranks a fair opportunity to be scheduled. Higher numbers increase bandwidth utilization, lower numbers increase fairness. This feature can be DISABLED by setting this register to 0. When set to 0, the Controller will stay on the same rank as long as commands are available for it. Minimum programmable value is 0 (feature disabled) and maximum programmable value is 0xF. FOR PERFORMANCE ONLY.

9.2.5.1.29 SDRAM Timing Register 0 (DRAMTMG0)

9.2.5.1.29.1 Offset

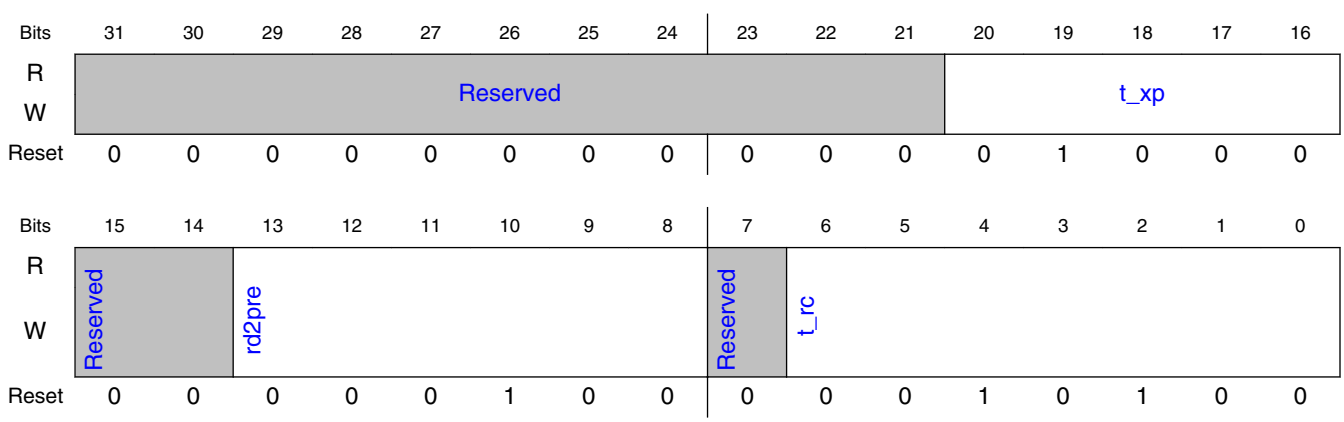
Register	Offset
DRAMTMG0	100h

9.2.5.1.29.2 Diagram

9.2.5.1.29.3 Fields

Field	Function
31 —	Reserved
30-24 wr2pre	Minimum time between write and precharge to same bank. Unit: Clocks Specifications: WL + BL/2 + tWR = approximately 8 cycles + 15 ns = 14 clocks @400MHz and less for lower frequencies where: - WL = write latency - BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM. BST (burst terminate) is not supported at present. - tWR = Write recovery time. This comes directly from the SDRAM specification. Add one extra cycle for LPDDR4 for this parameter. When the controller is operating in 1:2 frequency ratio mode, 1T mode, divide the above value by 2. No

Table continues on the next page...



Field	Function
	rounding up. When the controller is operating in 1:2 frequency ratio mode, 2T mode or LPDDR4 mode, divide the above value by 2 and round it up to the next integer value.
23-22 —	Reserved
21-16 t_faw	tFAW Valid only when 8 or more banks(or banks x bank groups) are present. In 8-bank design, at most 4 banks must be activated in a rolling window of tFAW cycles. When the controller is operating in 1:2 frequency ratio mode, program this to (tFAW/2) and round up to next integer value. In a 4-bank design, set this register to 0x1 independent of the 1:1/1:2 frequency mode. Unit: Clocks
15 —	Reserved
14-8 t_ras_max	tRAS(max): Maximum time between activate and precharge to same bank. This is the maximum time that a page can be kept open Minimum value of this register is 1. Zero is invalid. When the controller is operating in 1:2 frequency ratio mode, program this to (tRAS(max)-1)/2. No rounding up. Unit: Multiples of 1024 clocks.
7-6 —	Reserved
5-0 t_ras_min	tRAS(min): Minimum time between activate and precharge to the same bank. When the controller is operating in 1:2 frequency mode, 1T mode, program this to tRAS(min)/2. No rounding up. When the controller is operating in 1:2 frequency ratio mode, 2T mode or LPDDR4 mode, program this to (tRAS(min)/2) and round it up to the next integer value. Unit: Clocks

9.2.5.1.30 SDRAM Timing Register 1 (DRAMTMG1)

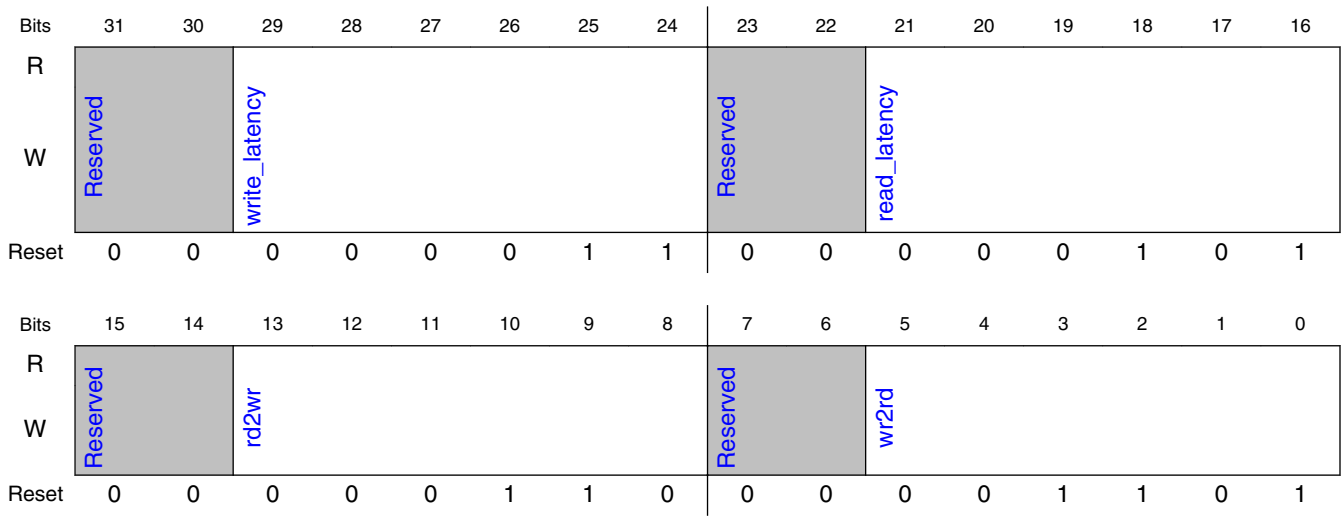
9.2.5.1.30.3 Fields



Field	Function
31-21 —	Reserved
20-16 t_xp	tXP: Minimum time after power-down exit to any operation. If C/A parity for DDR4 is used, set to (tXP +PL) instead. When the controller is operating in 1:2 frequency ratio mode, program this to (tXP/2) and round it up to the next integer value. Units: Clocks
15-14 —	Reserved
13-8 rd2pre	tRTP: Minimum time from read to precharge of same bank. DDR4: Max of following two equations: tAL + max (tRTP, 4) or, RL + BL/2 - tRP (*). LPDDR4: BL/2 + max(tRTP,8) - 8 (*). When both DDR4 SDRAM and ST-MRAM are used simultaneously, use SDRAM's tRP value for calculation. When the controller is operating in 1:2 mode, 1T mode, divide the above value by 2. No rounding up. When the controller is operating in 1:2 mode, 2T mode or LPDDR4 mode, divide the above value by 2 and round it up to the next integer value. Unit: Clocks.
7 —	Reserved
6-0 t_rc	tRC: Minimum time between activates to same bank. When the controller is operating in 1:2 frequency ratio mode, program this to (tRC/2) and round up to next integer value. Unit: Clocks.

9.2.5.1.31 SDRAM Timing Register 2 (DRAMTMG2)

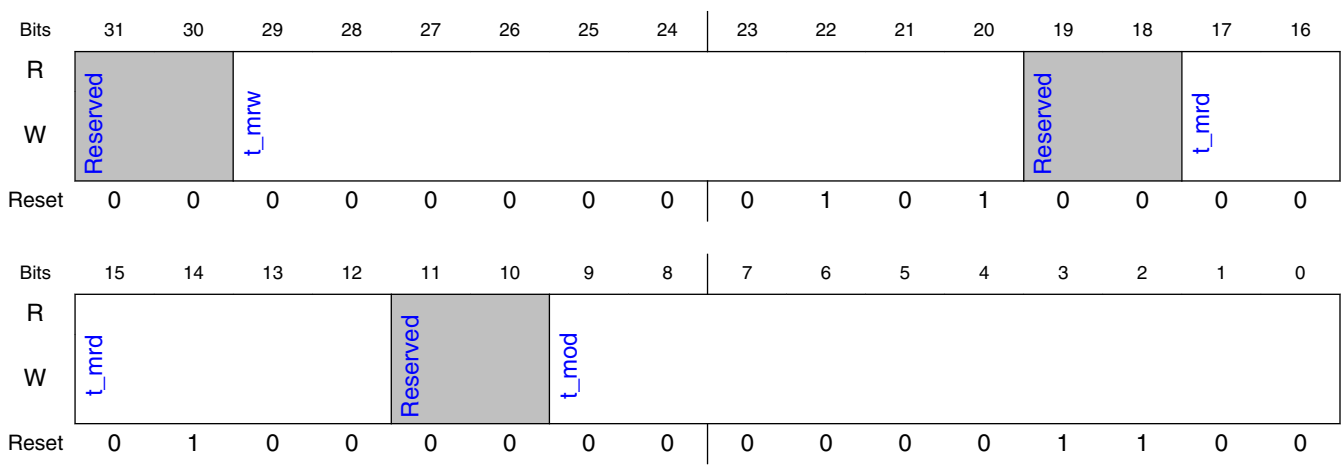
9.2.5.1.31.1 Offset

Register	Offset
DRAMTMG2	108h

9.2.5.1.31.2 Diagram

9.2.5.1.31.3 Fields

Field	Function
31-30 —	Reserved
29-24 write_latency	Set to WL Time from write command to write data on SDRAM interface. This must be set to WL. When the controller is operating in 1:2 frequency ratio mode, divide the value calculated using the above equation by 2, and round it up to next integer. Unit: clocks
23-22 —	Reserved
21-16 read_latency	Set to RL Time from read command to read data on SDRAM interface. This must be set to RL.When the controller is operating in 1:2 frequency ratio mode, divide the value calculated using the above equation by 2, and round it up to next integer. Unit: clocks
15-14 —	Reserved
13-8 rd2wr	DDR4: RL + BL/2 + 1 + WR_PREAMBLE - WL. LPDDR4(DQ ODT is Disabled): RL + BL/2 + RU(tDQSCKmax/tCK) + WR_PREAMBLE + RD_POSTAMBLE - WL. LPDDR4(DQ ODT is Enabled) : RL + BL/2 + RU(tDQSCKmax/tCK) + RD_POSTAMBLE - ODTLon - RU(tODTon(min)/tCK). Minimum time from read command to write command. Include time for bus turnaround and all per-bank, per-rank, and global constraints. Please see the relevant PHY databook for details of what should be included here. Unit: Clocks. Where: - WL = write latency - BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM - RL = read latency = CAS latency - WR_PREAMBLE = write preamble. This is unique to DDR4 and LPDDR4. - RD_POSTAMBLE = read postamble. This is unique to LPDDR4. For LPDDR4, if derating is enabled (DERATEEN.derate_enable=1), derated tDQSCKmax should be used. When the controller is operating in 1:2 frequency ratio mode, divide the value calculated using the above equation by 2, and round it up to next integer.
7-6 —	Reserved
5-0	DDR4: CWL + PL + BL/2 + tWTR_L Others: CWL + BL/2 + tWTR In DDR4, minimum time from write command to read command for same bank group. In others, minimum time from write command to read



Field	Function
wr2rd	command. Includes time for bus turnaround, recovery times, and all per-bank, per-rank, and global constraints. Unit: Clocks. Where: - CWL = CAS write latency - PL = Parity latency - BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM - tWTR_L = internal write to read command delay for same bank group. This comes directly from the SDRAM specification. - tWTR = internal write to read command delay. This comes directly from the SDRAM specification. Add one extra cycle for LPDDR4 operation. When the controller is operating in 1:2 mode, divide the value calculated using the above equation by 2, and round it up to next integer.

9.2.5.1.32 SDRAM Timing Register 3 (DRAMTMG3)

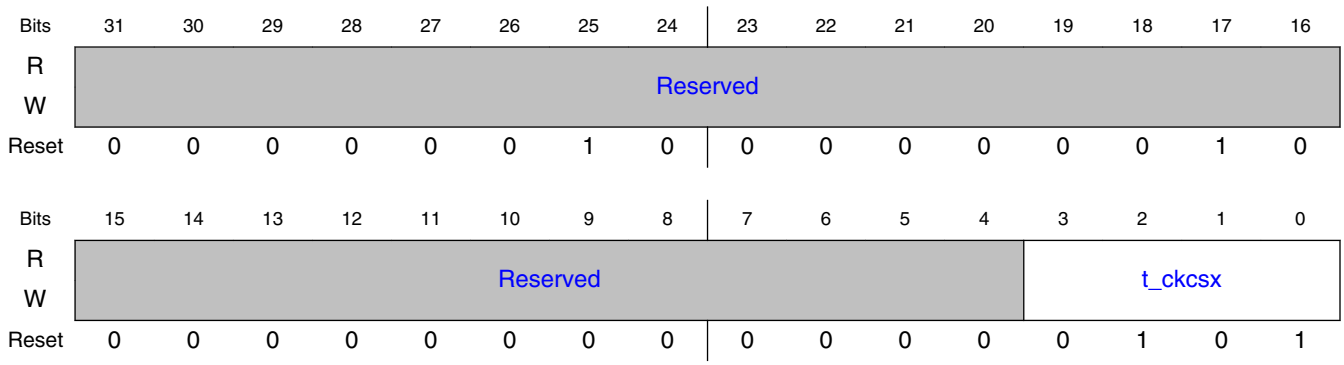
9.2.5.1.34.3 Fields



Field	Function
31-28 —	Reserved
27-24 t_cksrx	This is the time before Self Refresh Exit that CK is maintained as a valid clock before issuing SRX. Specifies the clock stable time before SRX. Recommended settings: - LPDDR4: tCKCKEH. - DDR4: tCKSRX When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.
23-20 —	Reserved
19-16 t_cksre	This is the time after Self Refresh Down Entry that CK is maintained as a valid clock. Specifies the clock disable delay after SRE. Recommended settings: LPDDR4: tCKCKEL. DDR4: max (10 ns, 5 tCK) (+ PL(parity latency)(*)) (*)Only if CRCPARCTL1.caparity_disable_before_sr=0, this register should be increased by PL. When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.
15-14 —	Reserved
13-8 t_ckesr	Minimum CKE low width for Self refresh or Self refresh power down entry to exit timing in memory clock cycles. Recommended settings: LPDDR4: max(tCKELPD, tSR). DDR4: tCKE + 1 (+ PL(parity latency)(*)) (*)Only if CRCPARCTL1.caparity_disable_before_sr=0, this register should be increased by PL. When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.
7-5 —	Reserved
4-0 t_cke	Minimum number of cycles of CKE HIGH/LOW during power-down and self refresh. LPDDR4 mode: Set this to the larger of tCKE, tCKELPD or tSR. - non-LPDDR4 designs: Set this to tCKE value. When the controller is operating in 1:2 frequency ratio mode, program this to (value described above)/2 and round it up to the next integer value. Unit: Clocks.

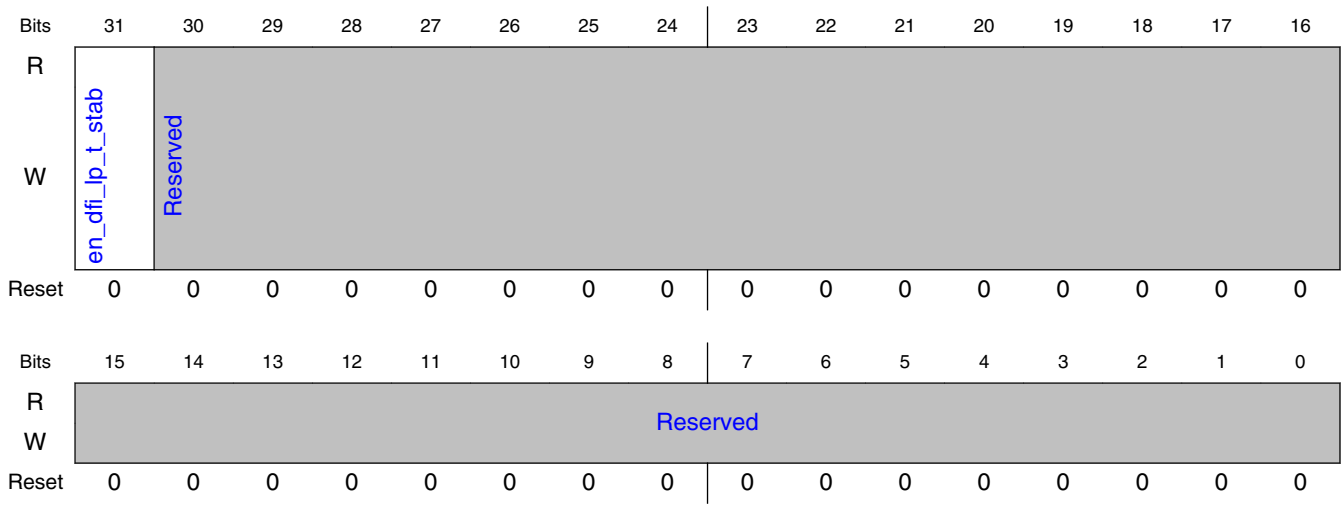
9.2.5.1.43.3 Fields



Field	Function
31-12 —	Reserved
11-0 t_xsr	tXSR: Exit Self Refresh to any command. When the controller is operating in 1:2 frequency ratio mode, program this to the above value divided by 2 and round up to next integer value. Note: Used only for LPDDR4 mode.

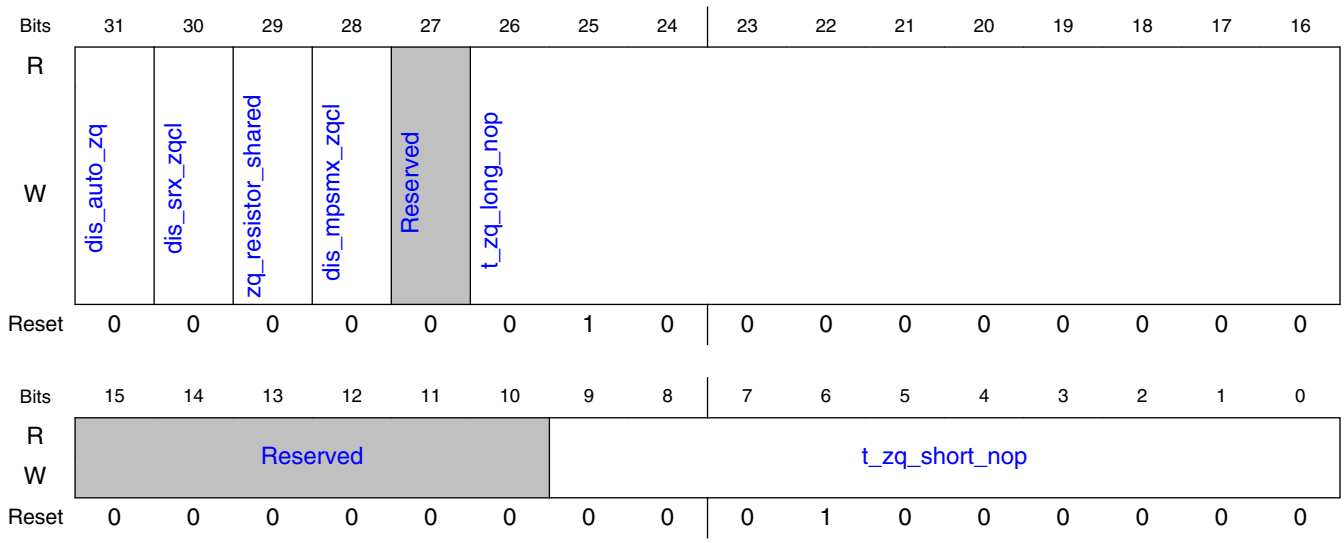
9.2.5.1.44 SDRAM Timing Register 15 (DRAMTMG15)

9.2.5.1.44.1 Offset

Register	Offset
DRAMTMG15	13Ch

9.2.5.1.44.2 Diagram

9.2.5.1.44.3 Fields



Field	Function
31 en_dfi_lp_t_stab	Enable DFI tSTAB 0b - Disable using tSTAB when exiting DFI LP 1b - Enable using tSTAB when exiting DFI LP. Needs to be set when the PHY is stopping the clock during DFI LP to save maximum power.
30-0 —	Reserved

9.2.5.1.45 ZQ Control Register 0 (ZQCTL0)

9.2.5.1.45.1 Offset

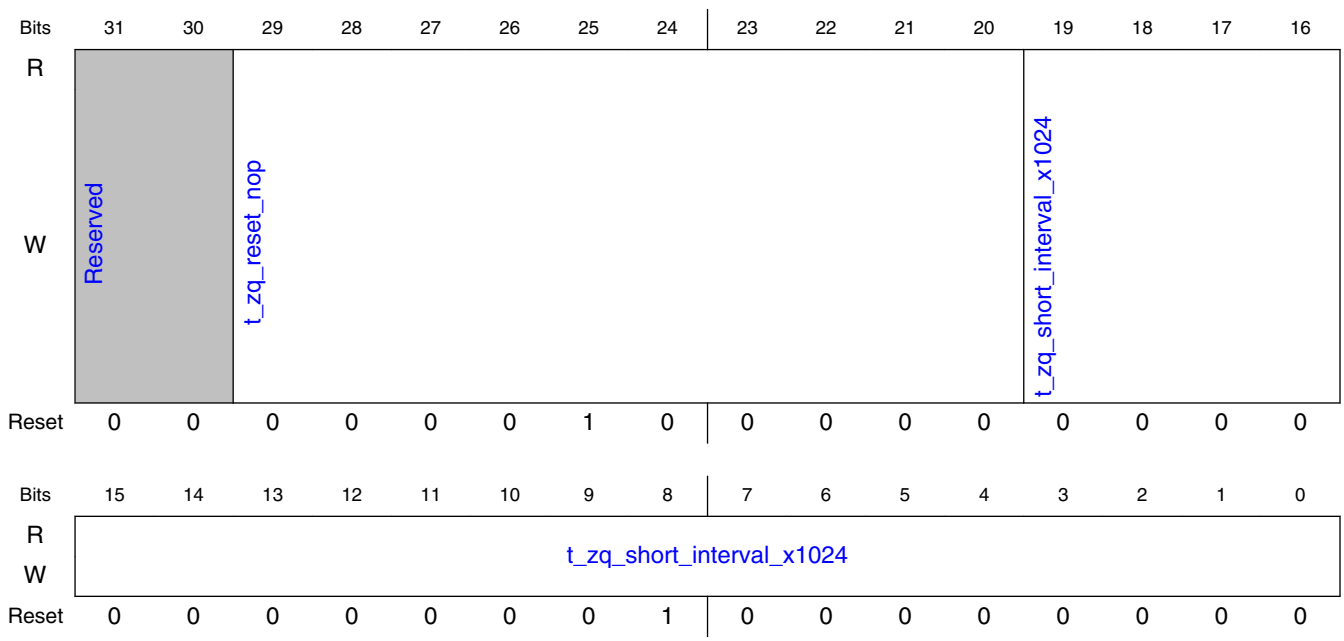
Register	Offset
ZQCTL0	180h

9.2.5.1.45.2 Diagram

9.2.5.1.45.3 Fields

Field	Function
31 dis_auto_zq	Disable Auto ZQCS/MPC 0b - Internally generate ZQCS/MPC(ZQ calibration) commands based on ZQCTL1.t_zq_short_interval_x1024. 1b - Disable DDRC generation of ZQCS/MPC(ZQ calibration) command. Register DBGCMD.zq_calib_short can be used instead to issue ZQ calibration request from APB module.
30 dis_srx_zqcl	Disable ZQCL/MPC 0b - Enable issuing of ZQCL/MPC(ZQ calibration) command at Self-Refresh/SR-Powerdown exit. 1b - Disable issuing of ZQCL/MPC(ZQ calibration) command at Self-Refresh/SR-Powerdown exit.
29 zq_resistor_shared	ZQ resistor sharing 0b - ZQ resistor is not shared. 1b - Denotes that ZQ resistor is shared between ranks. Means ZQinit/ZQCL/ZQCS/MPC(ZQ calibration) commands are sent to one rank at a time with tZQinit/tZQCL/tZQCS/tZQCAL/tZQLAT timing met between commands so that commands to different ranks do not overlap.
28 dis_mpsmx_zqcl	Do not issue ZQCL command at Maximum Power Save Mode exit if the DDRC_SHARED_AC configuration parameter is set. Program it to 1'b1. The software can send ZQCS after exiting MPSM mode. 0b - Enable issuing of ZQCL command at Maximum Power Saving Mode exit. Only applicable when run in DDR4 mode. This is only present for designs supporting DDR4 devices. 1b - Disable issuing of ZQCL command at Maximum Power Saving Mode exit. Only applicable when run in DDR4 mode.
27 —	Reserved
26-16 t_zq_long_nop	tZQoper for DDR4, tZQCAL for LPDDR4: Number of DFI clock cycles of NOP required after a ZQCL (ZQ calibration long)/MPC(ZQ Start) command is issued to SDRAM. When the controller is operating in 1:2 frequency ratio mode: DDR4: program this to tZQoper/2 and round it up to the next integer value. LPDDR4: program this to tZQCAL/2 and round it up to the next integer value.
15-10	Reserved

Table continues on the next page...



Field	Function
—	
9-0 t_zq_short_nop	tZQCS for DDR4, tZQLAT for LPDDR4: Number of DFI clock cycles of NOP required after a ZQCS (ZQ calibration short)/MPC(ZQ Latch) command is issued to SDRAM. When the controller is operating in 1:2 frequency ratio mode, program this to tZQCS/2 and round it up to the next integer value.

9.2.5.1.46 ZQ Control Register 1 (ZQCTL1)

9.2.5.1.46.1 Offset

Register	Offset
ZQCTL1	184h

9.2.5.1.46.2 Diagram

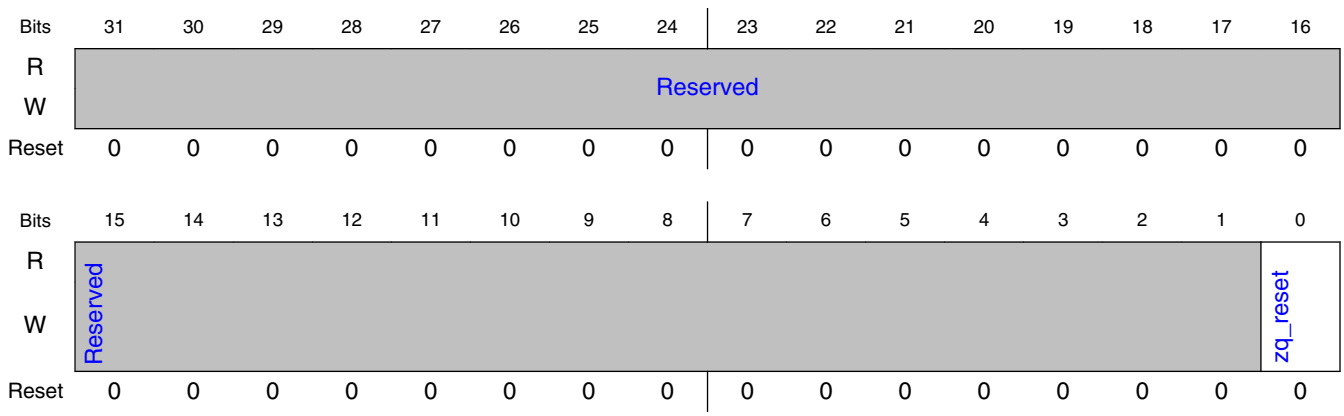
Field	Function
31-30 —	Reserved

Table continues on the next page...



Field	Function
29-20 t_zq_reset_nop	tZQReset: Number of DFI clock cycles of NOP required after a ZQReset (ZQ calibration Reset) command is issued to SDRAM. When the controller is operating in 1:2 frequency ratio mode, program this to tZQReset/2 and round it up to the next integer value. This is only present for LPDDR4.
19-0 t_zq_short_interval_x1024	Average interval to wait between automatically issuing ZQCS (ZQ calibration short)/MPC(ZQ calibration) commands to DDR4/LPDDR4 devices. Meaningless, if ZQCTL0.dis_auto_zq=1. Unit: 1024 DFI clock cycles.

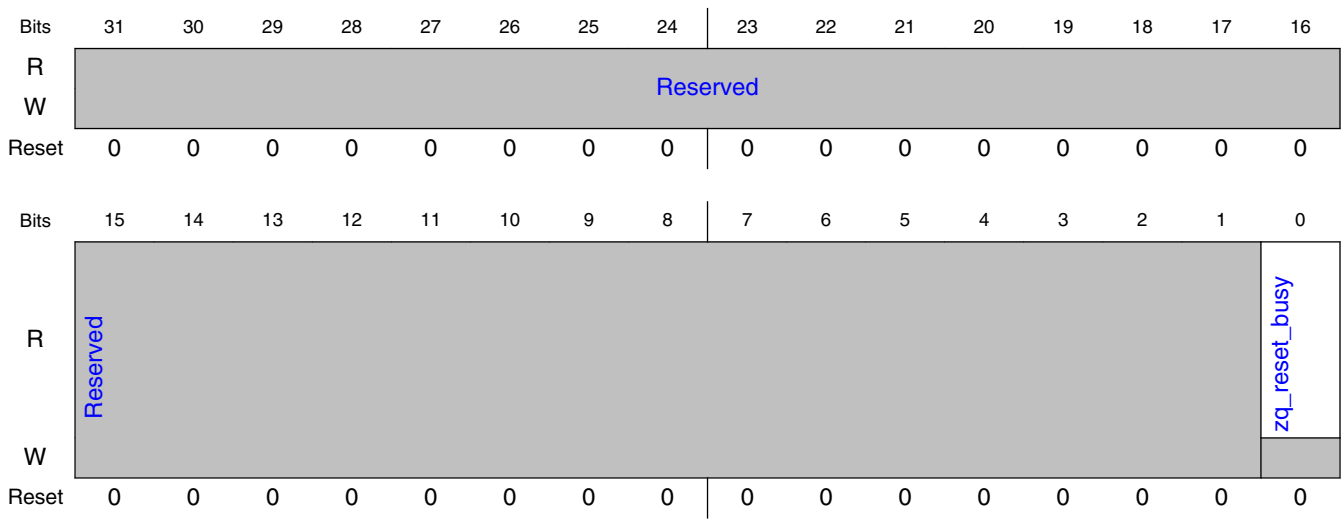
9.2.5.1.47 ZQ Control Register 2 (ZQCTL2)

9.2.5.1.47.1 Offset

Register	Offset
ZQCTL2	188h

9.2.5.1.47.2 Diagram

9.2.5.1.47.3 Fields



Field	Function
31-1 —	Reserved
0 zq_reset	Setting this register bit to 1 triggers a ZQ Reset operation. When the ZQ Reset operation is complete, the DDRC automatically clears this bit. It is recommended NOT to set this signal if in Init, Self-Refresh(except LPDDR4) or SR-Powerdown(LPDDR4) or Deep power-down operating modes. This is only present for LPDDR4.

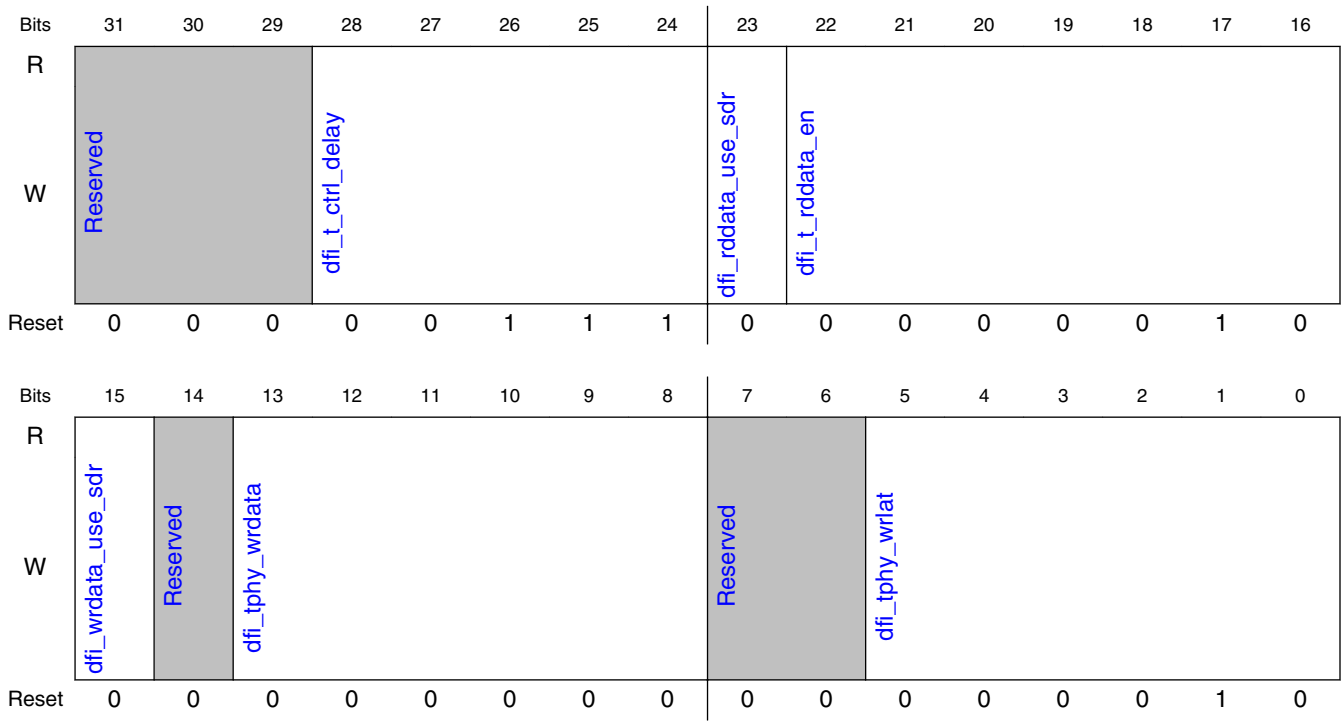
9.2.5.1.48 ZQ Status Register (ZQSTAT)

9.2.5.1.48.1 Offset

Register	Offset
ZQSTAT	18Ch

9.2.5.1.48.2 Diagram

9.2.5.1.48.3 Fields



Field	Function
31-1 —	Reserved
0 zq_reset_busy	SoC core may initiate a ZQ Reset operation only if this signal is low. This signal goes high in the clock after the DDRC accepts the ZQ Reset request. It goes low when the ZQ Reset command is issued to the SDRAM and the associated NOP period is over. It is recommended not to perform ZQ Reset commands when this signal is high. 0b - Indicates that the SoC core can initiate a ZQ Reset operation 1b - Indicates that ZQ Reset operation is in progress

9.2.5.1.49 DFI Timing Register 0 (DFITMG0)

9.2.5.1.49.1 Offset

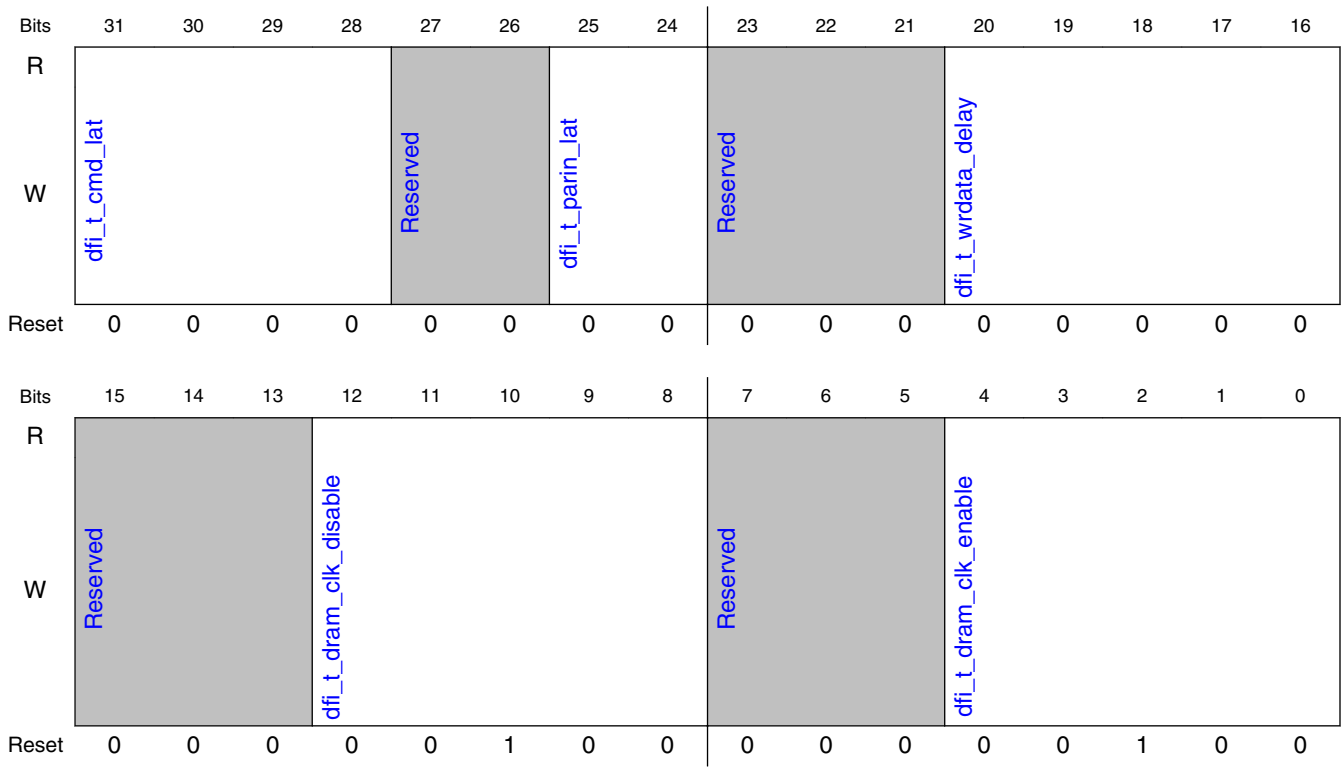
Register	Offset
DFITMG0	190h

9.2.5.1.49.2 Diagram

9.2.5.1.49.3 Fields

Field	Function
31-29 —	Reserved
28-24 dfi_t_ctrl_delay	Specifies the number of DFI clock cycles after an assertion or de-assertion of the DFI control signals that the control signals at the PHY-DRAM interface reflect the assertion or de-assertion. If the DFI clock and the memory clock are not phase-aligned, this timing parameter should be rounded up to the next integer value..
23 dfi_rddata_use_sdr	Defines whether dfi_rddata_en/dfi_rddata/dfi_rddata_valid is generated using HDR (DFI clock) or SDR (DFI PHY clock) values. Selects whether value in DFITMG0.dfi_t_rddata_en is in terms of HDR (DFI clock) or SDR (DFI PHY clock) cycles: - 0 in terms of HDR (DFI clock) cycles - 1 in terms of SDR (DFI PHY clock) cycles Refer to PHY specification for correct value.
22-16 dfi_t_rddata_en	Time from the assertion of a read command on the DFI interface to the assertion of the dfi_rddata_en signal. Refer to PHY specification for correct value. This corresponds to the DFI parameter trddata_en.Unit: DFI clock cycles or DFI PHY clock cycles, depending on DFITMG0.dfi_rddata_use_sdr.

Table continues on the next page...



Field	Function
15 dfi_wrdata_use_sdr	Defines whether dfi_wrdata_en/dfi_wrdata/dfi_wrdata_mask is generated using HDR (DFI clock) or SDR (DFI PHY clock) values Selects whether value in DFITMG0.dfi_tphy_wrlat is in terms of HDR (DFI clock) or SDR (DFI PHY clock) cycles Selects whether value in DFITMG0.dfi_tphy_wrdata is in terms of HDR (DFI clock) or SDR (DFI PHY clock) cycles - 0 in terms of HDR (DFI clock) cycles - 1 in terms of SDR (DFI PHY clock) cycles Refer to PHY specification for correct value.
14 —	Reserved
13-8 dfi_tphy_wrdata	Specifies the number of clock cycles between when dfi_wrdata_en is asserted to when the associated write data is driven on the dfi_wrdata signal. This corresponds to the DFI timing parameter tphy_wrdata. Refer to PHY specification for correct value. Note, max supported value is 8. Unit: DFI clock cycles or DFI PHY clock cycles, depending on DFITMG0.dfi_wrdata_use_sdr.
7-6 —	Reserved
5-0 dfi_tphy_wrlat	Write latency Number of clocks from the write command to write data enable (dfi_wrdata_en). This corresponds to the DFI timing parameter tphy_wrlat. Refer to PHY specification for correct value. Unit: DFI clock cycles or DFI PHY clock cycles, depending on DFITMG0.dfi_wrdata_use_sdr.

9.2.5.1.50 DFI Timing Register 1 (DFITMG1)

9.2.5.1.50.1 Offset

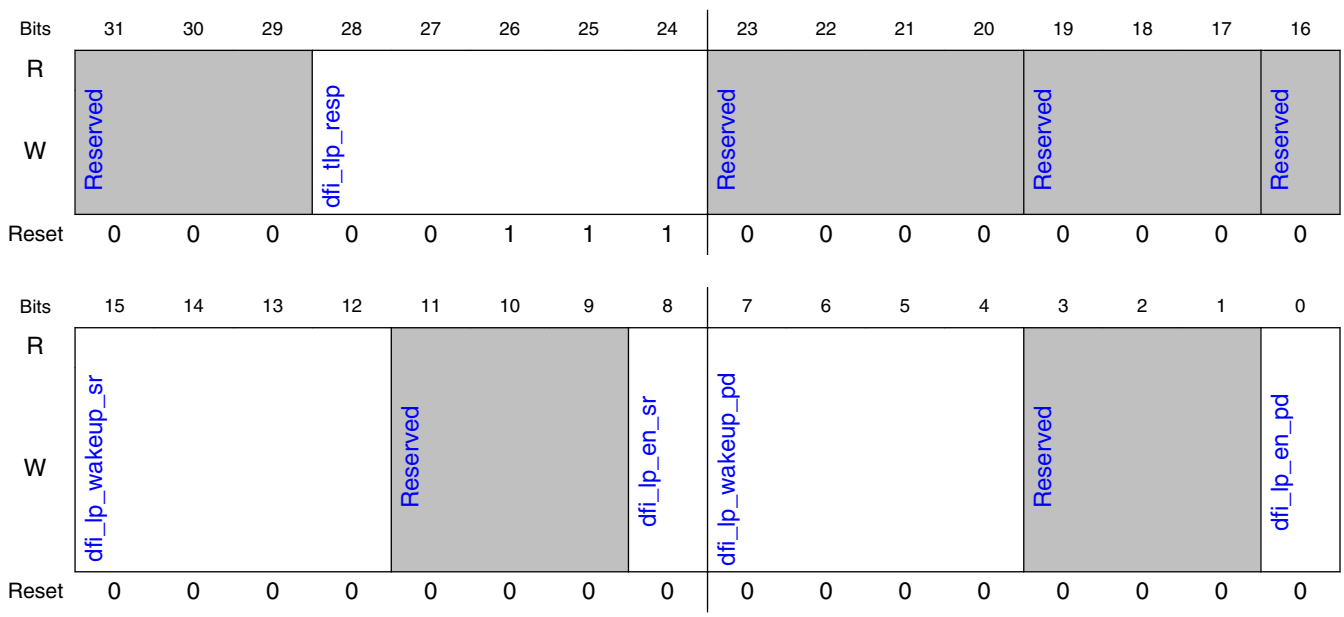
Register	Offset
DFITMG1	194h

9.2.5.1.50.2 Diagram

9.2.5.1.50.3 Fields

Field	Function
31-28 dfi_t_cmd_lat	Specifies the number of DFI PHY clock cycles between when the dfi_cs signal is asserted and when the associated command is driven. This field is used for CAL mode, should be set to '0' or the value which matches the CAL mode register setting in the DRAM. If the PHY can add the latency for CAL mode, this should be set to '0'. Valid Range: 0, 3, 4, 5, 6, and 8
27-26 —	Reserved
25-24 dfi_t_parin_lat	Specifies the number of DFI PHY clock cycles between when the dfi_cs signal is asserted and when the associated dfi_parity_in signal is driven.
23-21 —	Reserved
20-16 dfi_t_wrdata_delay	Specifies the number of DFI clock cycles between when the dfi_wrdata_en signal is asserted and when the corresponding write data transfer is completed on the DRAM bus. This corresponds to the DFI timing parameter twrdata_delay. Refer to PHY specification for correct value. For DFI 3.0 PHY, set to twrdata_delay, a new timing parameter introduced in DFI 3.0. For DFI 2.1 PHY, set to tphy_wrdata + (delay of DFI write data to the DRAM). Value to be programmed is in terms of DFI clocks, not PHY clocks. In FREQ_RATIO=2, divide PHY's value by 2 and round up to next integer. If using DFITMG0.dfi_wrdata_use_sdr=1, add 1 to the value. Unit: Clocks
15-13 —	Reserved

Table continues on the next page...



Field	Function
12-8 dfi_t_dram_clk_disable	Specifies the number of DFI clock cycles from the assertion of the dfi_dram_clk_disable signal on the DFI until the clock to the DRAM memory devices, at the PHY-DRAM boundary, maintains a low value. If the DFI clock and the memory clock are not phase aligned, this timing parameter should be rounded up to the next integer value.
7-5 —	Reserved
4-0 dfi_t_dram_clk_enable	Specifies the number of DFI clock cycles from the de-assertion of the dfi_dram_clk_disable signal on the DFI until the first valid rising edge of the clock to the DRAM memory devices, at the PHY-DRAM boundary. If the DFI clock and the memory clock are not phase aligned, this timing parameter should be rounded up to the next integer value.

9.2.5.1.51 DFI Low Power Configuration Register 0 (DFILPCFG0)

9.2.5.1.51.1 Offset

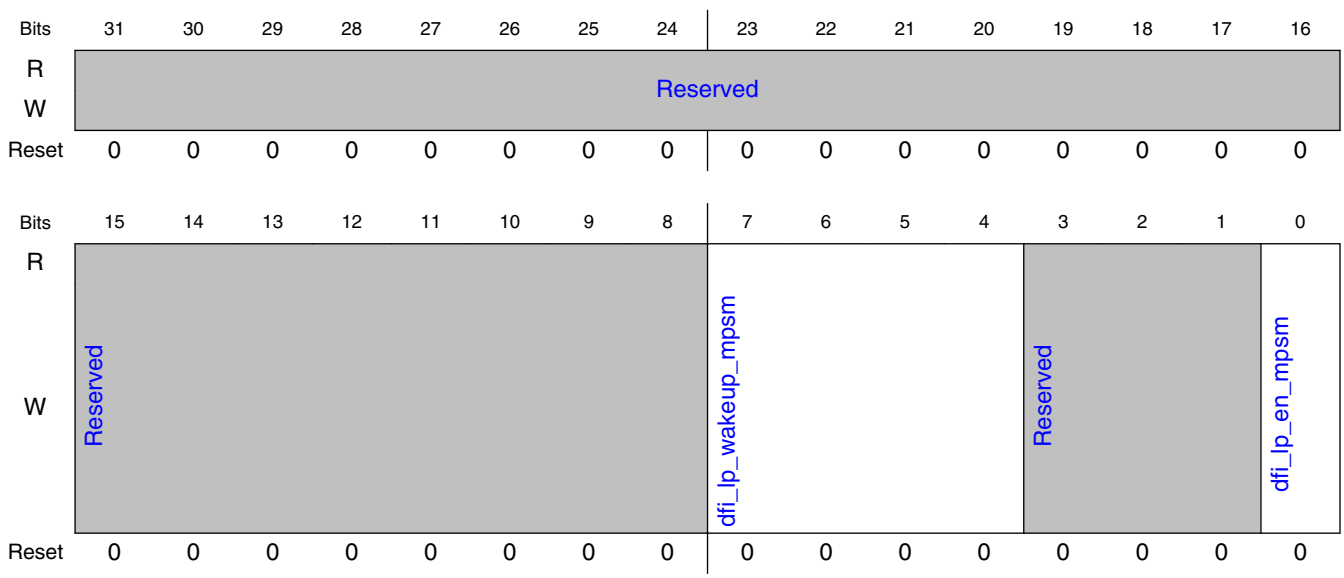
Register	Offset
DFILPCFG0	198h

9.2.5.1.51.2 Diagram

9.2.5.1.51.3 Fields

Field	Function
31-29 —	Reserved
28-24 dfi_tlp_resp	Setting in DFI clock cycles for DFI's tlp_resp time. Same value is used for both Power Down, Self Refresh, Deep Power Down and Maximum Power Saving modes. DFI 2.1 specification onwards, recommends using a fixed value of 7 always.
23-20 —	Reserved
19-17 —	Reserved
16 —	Reserved
15-12 dfi_lp_wakeup_sr	Value in DFI clpck cycles to drive on dfi_lp_wakeup signal when Self Refresh mode is entered. Determines the DFI's tlp_wakeup time: 0000b - 16 cycles 0001b - 32 cycles 0010b - 64 cycles 0011b - 128 cycles 0100b - 256 cycles 0101b - 512 cycles 0110b - 1024 cycles 0111b - 2048 cycles 1000b - 4096 cycles 1001b - 8192 cycles 1010b - 16384 cycles 1011b - 32768 cycles 1100b - 65536 cycles 1101b - 131072 cycles 1110b - 262144 cycles 1111b - Unlimited cycles
11-9 —	Reserved
8 dfi_lp_en_sr	Enables DFI Low Power interface handshaking during Self Refresh Entry/Exit. - 0 - Disabled - 1 - Enabled 0b - Disabled 1b - Enabled
7-4 dfi_lp_wakeup_pd	Value in DFI clock cycles to drive on dfi_lp_wakeup signal when Power Down mode is entered. Determines the DFI's tlp_wakeup time: 0000b - 16 cycles 0001b - 32 cycles 0010b - 64 cycles 0011b - 128 cycles 0100b - 256 cycles 0101b - 512 cycles 0110b - 1024 cycles 0111b - 2048 cycles 1000b - 4096 cycles 1001b - 8192 cycles 1010b - 16384 cycles 1011b - 32768 cycles 1100b - 65536 cycles

Table continues on the next page...



Field	Function
	1101b - 131072 cycles 1110b - 262144 cycles 1111b - Unlimited cycles
3-1 —	Reserved
0 dfi_lp_en_pd	Enables DFI Low Power interface handshaking during Power Down Entry/Exit. - 0 - Disabled - 1 - Enabled

9.2.5.1.52 DFI Low Power Configuration Register 1 (DFILPCFG1)

9.2.5.1.52.1 Offset

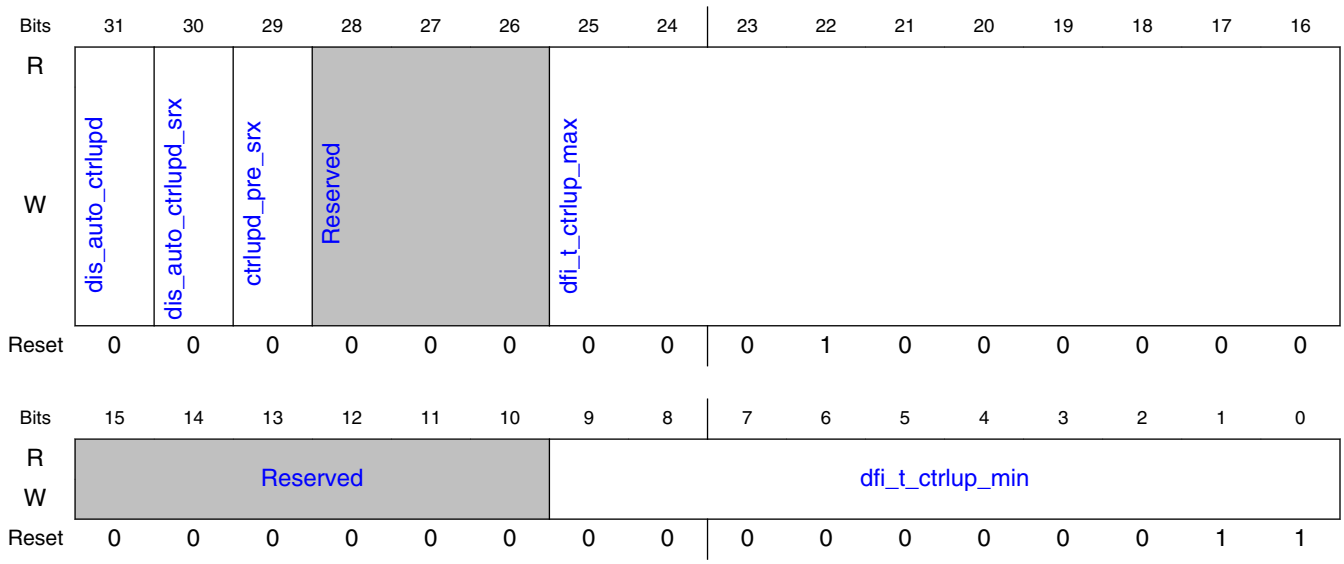
Register	Offset
DFILPCFG1	19Ch

9.2.5.1.52.2 Diagram

9.2.5.1.52.3 Fields

Field	Function
31-8 —	Reserved

Table continues on the next page...



Field	Function
7-4 dfi_lp_wakeup_mpsm	Value in DFI clock cycles to drive on dfi_lp_wakeup signal when Maximum Power Saving Mode is entered. Determines the DFI's tlp_wakeup time: 0000b - 16 cycles 0001b - 32 cycles 0010b - 64 cycles 0011b - 128 cycles 0100b - 256 cycles 0101b - 512 cycles 0110b - 1024 cycles 0111b - 2048 cycles 1000b - 4096 cycles 1001b - 8192 cycles 1010b - 16384 cycles 1011b - 32768 cycles 1100b - 65536 cycles 1101b - 131072 cycles 1110b - 262144 cycles 1111b - Unlimited cycles
3-1 —	Reserved
0 dfi_lp_en_mpsm	Enables DFI Low Power interface handshaking during Maximum Power Saving Mode Entry/Exit. - 0 - Disabled - 1 - Enabled This is only present for designs supporting DDR4 devices.

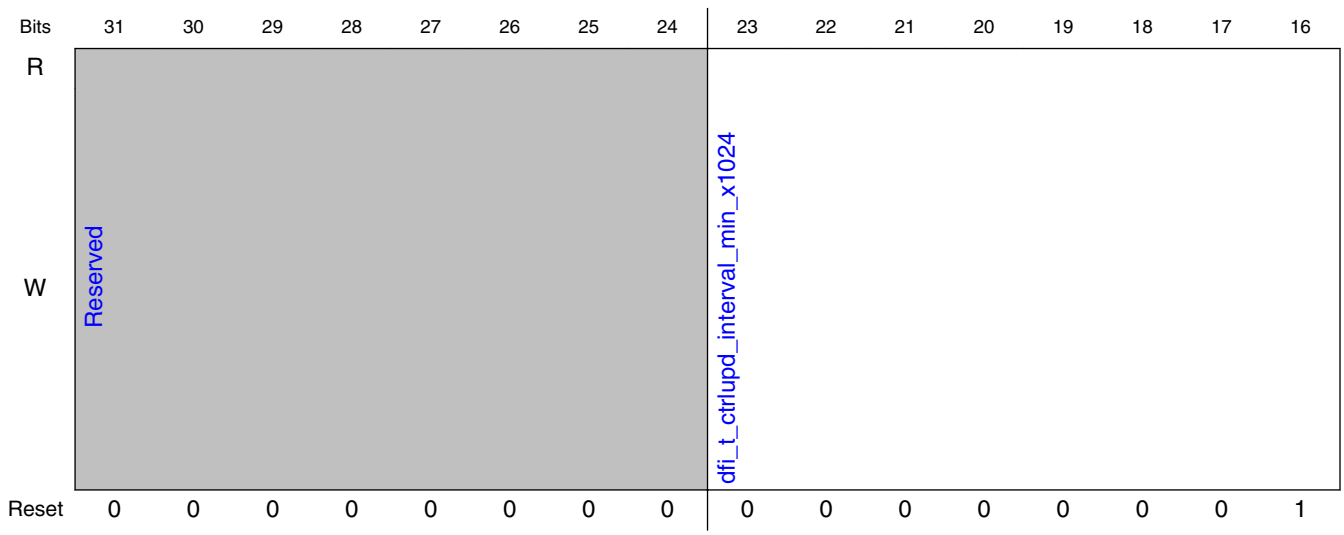
9.2.5.1.53 DFI Update Register 0 (DFIUPD0)

9.2.5.1.53.1 Offset

Register	Offset
DFIUPD0	1A0h

9.2.5.1.53.2 Diagram

9.2.5.1.53.3 Fields



Field	Function
31 dis_auto_ctrlupd	automatic dfi_ctrlupd_req generation by the DDRC 0b - DDRC issues dfi_ctrlupd_req periodically. 1b - disable the automatic dfi_ctrlupd_req generation by the DDRC. The core must issue the dfi_ctrlupd_req signal using register reg_ddrc_ctrlupd.
30 dis_auto_ctrlupd_srx	Auto ctrlupd request generation 0b - DDRC issues a dfi_ctrlupd_req before or after exiting self-refresh, depending on DFIUPD0.ctrlupd_pre_srx. 1b - disable the automatic dfi_ctrlupd_req generation by the DDRC at self-refresh exit.
29 ctrlupd_pre_srx	Selects dfi_ctrlupd_req requirements at SRX: - 0 : send ctrlupd after SRX - 1 : send ctrlupd before SRX If DFIUPD0.dis_auto_ctrlupd_srx=1, this register has no impact, because no dfi_ctrlupd_req will be issued when SRX. 0b - send ctrlupd after SRX 1b - send ctrlupd before SRX
28-26 —	Reserved
25-16 dfi_t_ctrlup_max	Specifies the maximum number of DFI clock cycles that the dfi_ctrlupd_req signal can assert. Lowest value to assign to this variable is 0x40.
15-10 —	Reserved
9-0 dfi_t_ctrlup_min	Specifies the minimum number of DFI clock cycles that the dfi_ctrlupd_req signal must be asserted. The DDRC expects the PHY to respond within this time. If the PHY does not respond, the DDRC will de-assert dfi_ctrlupd_req after dfi_t_ctrlup_min + 2 cycles. Lowest value to assign to this variable is 0x3.

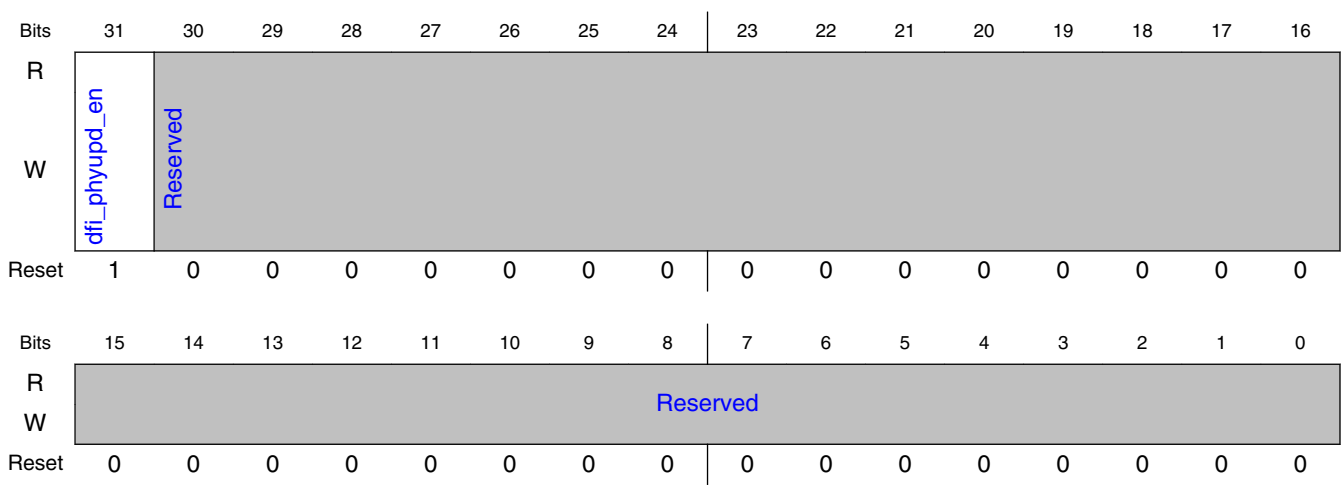
9.2.5.1.54 DFI Update Register 1 (DFIUPD1)

9.2.5.1.54.1 Offset

Register	Offset
DFIUPD1	1A4h

9.2.5.1.54.2 Diagram

9.2.5.1.54.3 Fields



Field	Function
31-24 —	Reserved
23-16 dfi_t_ctrlupd_interval_min_x1024	This is the minimum amount of time between DDRC initiated DFI update requests (which is executed whenever the DDRC is idle). Set this number higher to reduce the frequency of update requests, which can have a small impact on the latency of the first read request when the DDRC is idle. Minimum allowed value for this field is 1. Unit: 1024 DFI clock cycles
15-8 —	Reserved
7-0 dfi_t_ctrlupd_interval_max_x1024	This is the maximum amount of time between DDRC initiated DFI update requests. This timer resets with each update request; when the timer expires dfi_ctrlupd_req is sent and traffic is blocked until the dfi_ctrlupd_ackx is received. PHY can use this idle time to recalibrate the delay lines to the DLLs. The DFI controller update is also used to reset PHY FIFO pointers in case of data capture errors. Updates are required to maintain calibration over PVT, but frequent updates may impact performance. Minimum allowed value for this field is 1. Note: Value programmed for DFIUPD1.dfi_t_ctrlupd_interval_max_x1024 must be greater than DFIUPD1.dfi_t_ctrlupd_interval_min_x1024. Unit: 1024 DFI clock cycles

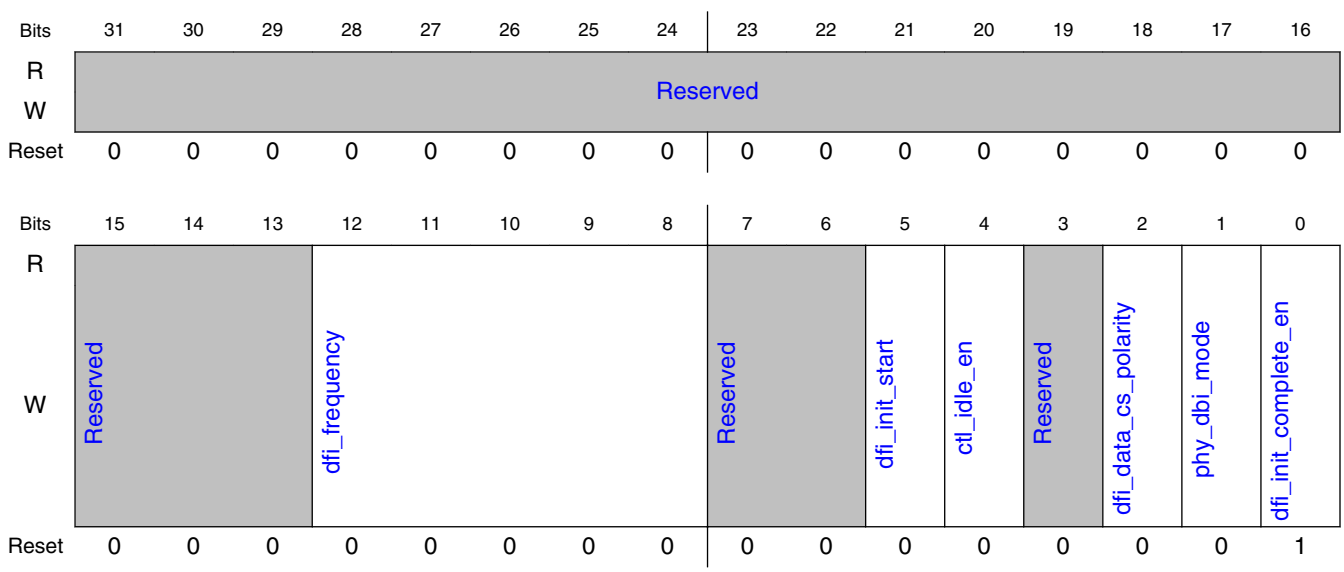
9.2.5.1.55 DFI Update Register 2 (DFIUPD2)

9.2.5.1.55.1 Offset

Register	Offset
DFIUPD2	1A8h

9.2.5.1.55.2 Diagram

9.2.5.1.55.3 Fields



Field	Function
31 dfi_phyupd_en	Enables the support for acknowledging PHY-initiated updates: 0b - Disabled 1b - Enabled
30-0 —	Reserved

9.2.5.1.56 DFI Miscellaneous Control Register (DFIMISC)

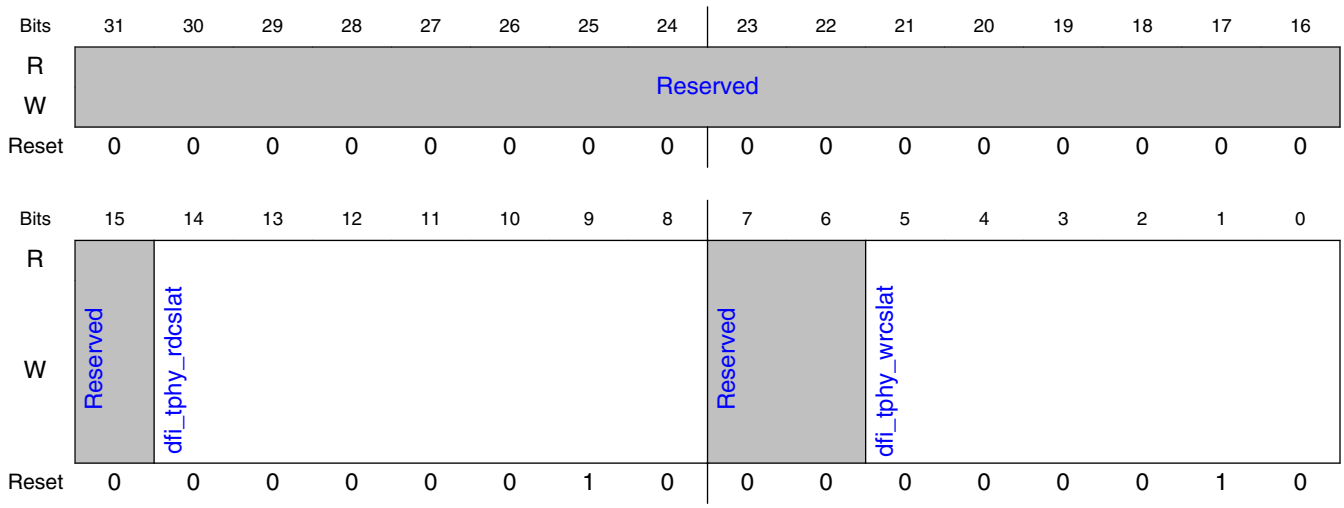
9.2.5.1.56.3 Fields

Field	Function
31-13 —	Reserved

Table continues on the next page...



Field	Function
12-8 dfi_frequency	Indicates the operating frequency of the system. The number of supported frequencies and the mapping of signal values to clock frequencies are defined by the PHY.
7-6 —	Reserved
5 dfi_init_start	PHY init start request signal.When asserted it triggers the PHY init start request
4 ctl_idle_en	Enables support of ctl_idle signal, which is non-DFI related pin specific to certain PHYs. See signal description of ctl_idle signal for further details of ctl_idle functionality.
3 —	Reserved
2 dfi_data_cs_polarity	Defines polarity of dfi_wrdata_cs and dfi_rddata_cs signals. 0b - Signals are active low 1b - Signals are active high
1 phy_dbi_mode	DBI implemented in DDRC or PHY. Present only in designs configured to support DDR4 and LPDDR4. 0b - DDRC implements DBI functionality. 1b - PHY implements DBI functionality.
0 dfi_init_complete_en	PHY initialization complete enable signal. When asserted the dfi_init_complete signal can be used to trigger SDRAM initialisation

9.2.5.1.57 DFI Timing Register 2 (DFITMG2)

9.2.5.1.57.1 Offset

Register	Offset

Field	Function
31-2 —	Reserved

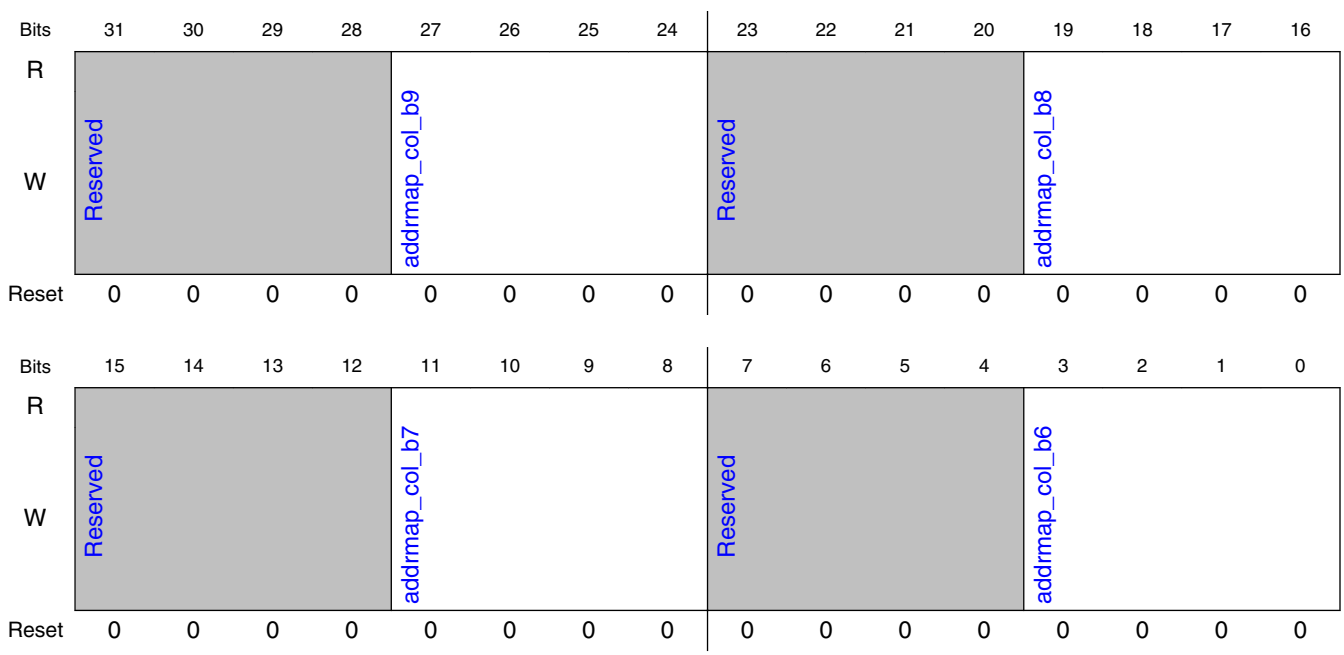
Table continues on the next page...



Field	Function
1 dis_hif	When 1, DDRC asserts the HIF command signal hif_cmd_stall. DDRC will ignore the hif_cmd_valid and all other associated request signals. This bit is intended to be switched on-the-fly.
0 dis_dq	When 1, DDRC will not de-queue any transactions from the CAM. Bypass is also disabled. All transactions are queued in the CAM. No reads or writes are issued to SDRAM as long as this is asserted. This bit may be used to prevent reads or writes being issued by the DDRC, which makes it safe to modify certain register fields associated with reads and writes (see User Guide for details). After setting this bit, it is strongly recommended to poll DBGCAM.wr_data_pipeline_empty and DBGCAM.rd_data_pipeline_empty, before making changes to any registers which affect reads and writes. This will ensure that the relevant logic in the DDRC is idle. This bit is intended to be switched on-the-fly.

	performed only when RFSHCTL3.dis_auto_refresh=1. It is recommended NOT to set this register bit if in Init or Deep power-down operating modes or Maximum Power Saving Mode.
0 rank0_refresh	Setting this register bit to 1 indicates to the DDRC to issue a refresh to rank 0. Writing to this bit causes DBGSTAT.rank0_refresh_busy to be set. When DBGSTAT.rank0_refresh_busy is cleared, the command has been stored in DDRC. For 3DS configuration, refresh is sent to rank index 0. This operation can be performed only when RFSHCTL3.dis_auto_refresh=1. It is recommended NOT to set this register bit if in Init or Deep power-down operating modes or Maximum Power Saving Mode.

9.2.5.1.79 Status Debug Register (DBGSTAT)

Field	Function
5 ctrlupd_busy	SoC core may initiate a ctrlupd operation only if this signal is low. This signal goes high in the clock after the DDRC accepts the ctrlupd request. It goes low when the ctrlupd operation is initiated in the DDRC. It is recommended not to perform ctrlupd operations when this signal is high. - 0 - Indicates that the SoC core can initiate a ctrlupd operation - 1 - Indicates that ctrlupd operation has not been initiated yet in the DDRC
4 zq_calib_short_busy	SoC core may initiate a ZQCS (ZQ calibration short) operation only if this signal is low. This signal goes high in the clock after the DDRC accepts the ZQCS request. It goes low when the ZQCS operation is initiated in the DDRC. It is recommended not to perform ZQCS operations when this signal is high. - 0 - Indicates that the SoC core can initiate a ZQCS operation - 1 - Indicates that ZQCS operation has not been initiated yet in the DDRC
3-2 —	Reserved
1 rank1_refresh_busy	SoC core may initiate a rank1_refresh operation (refresh operation to rank 1) only if this signal is low. This signal goes high in the clock after DBGCMD.rank1_refresh is set to one. It goes low when the rank1_refresh operation is stored in the DDRC. It is recommended not to perform rank1_refresh operations when this signal is high. - 0 - Indicates that the SoC core can initiate a rank1_refresh operation - 1 - Indicates that rank1_refresh operation has not been stored yet in the DDRC
0 rank0_refresh_busy	SoC core may initiate a rank0_refresh operation (refresh operation to rank 0) only if this signal is low. This signal goes high in the clock after DBGCMD.rank0_refresh is set to one. It goes low when the rank0_refresh operation is stored in the DDRC. It is recommended not to perform rank0_refresh operations when this signal is high. - 0 - Indicates that the SoC core can initiate a rank0_refresh operation - 1 - Indicates that rank0_refresh operation has not been stored yet in the DDRC

9.2.5.1.85.1 Offset

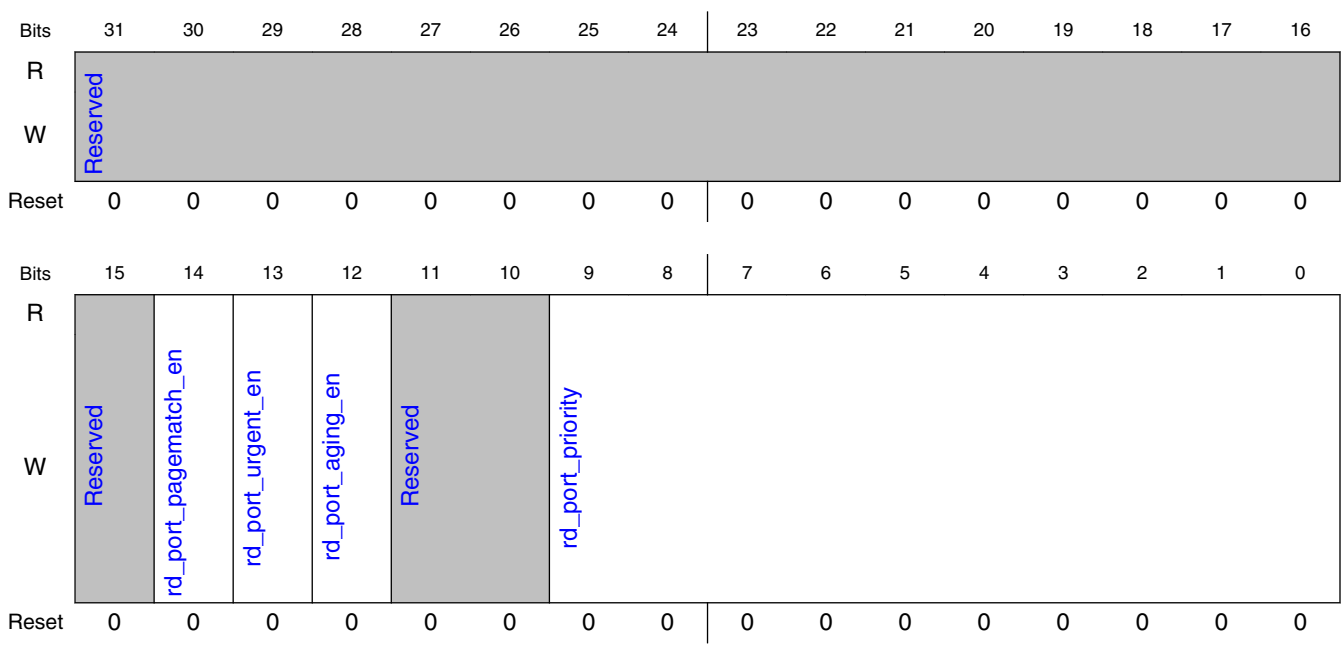
Register	Offset
PCCFG	400h

9.2.5.1.85.2 Diagram

9.2.5.1.85.3 Fields

Field	Function
31-9 —	Reserved
8 bl_exp_mode	Burst length expansion mode. By default (i.e. bl_exp_mode==0) XPI expands every AXI burst into multiple HIF commands, using the memory burst length as a unit. If set to 1, then XPI will use half of the memory burst length as a unit. This applies to both reads and writes. When MSTR.data_bus_width==00, setting bl_exp_mode to 1 has no effect. This can be used in cases where Partial Writes is enabled (DDRC_PARTIAL_WR=1), in order to avoid or minimize t_ccd_l penalty in DDR4 and t_ccd_mw penalty in LPDDR4. Hence, bl_exp_mode=1 is only recommended if DDR4 or LPDDR4. Note that if DBICTL.reg_ddrc_dm_en=0, functionality is not supported in the following cases: - DDRC_PARTIAL_WR=0 - DDRC_PARTIAL_WR=1, MSTR.data_bus_width=01, MEMC_BURST_LENGTH=8 and MSTR.burst_rdwr=1000 (LPDDR4 only) - DDRC_PARTIAL_WR=1, MSTR.data_bus_width=01, MEMC_BURST_LENGTH=4 and MSTR.burst_rdwr=0100 (DDR4 only), with either MSTR.reg_ddrc_burstchop=0 or CRCPARCTL1.reg_ddrc_crc_enable=1 Functionality is also not supported if Data Channel Interleave is enabled
7-5 —	Reserved

Table continues on the next page...



Field	Function
4 pagematch_limit	Page match four limit. If set to 1, limits the number of consecutive same page DDRC transactions that can be granted by the Port Arbiter to four when Page Match feature is enabled. If set to 0, there is no limit imposed on number of consecutive same page DDRC transactions.
3-1 —	Reserved
0 go2critical_en	If set to 1 (enabled), sets co_gs_go2critical_wr and co_gs_go2critical_lpr/co_gs_go2critical_hpr signals going to DDRC based on urgent input (awurgent, arurgent) coming from AXI master. If set to 0 (disabled), co_gs_go2critical_wr and co_gs_go2critical_lpr/co_gs_go2critical_hpr signals at DDRC are driven to 1b'0.

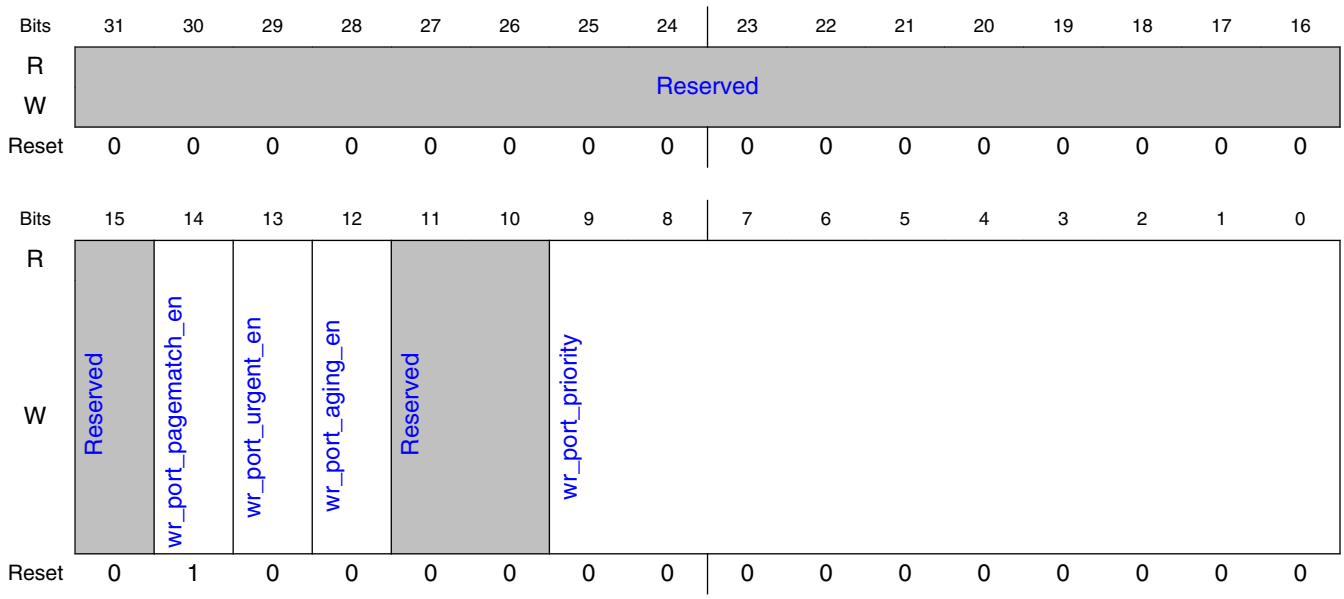
9.2.5.1.86 Port n Configuration Read Register (PCFGR_0)

9.2.5.1.86.1 Offset

Register	Offset
PCFGR_0	404h

9.2.5.1.86.2 Diagram

9.2.5.1.86.3 Fields



Field	Function
31-16 —	Reserved
15 —	Reserved
14 rd_port_pagematch_en	If set to 1, enables the Page Match feature. If enabled, once a requesting port is granted, the port is continued to be granted if the following immediate commands are to the same memory page (same bank and same row). See also related PCCFG.pagematch_limit register.
13 rd_port_urgent_en	If set to 1, enables the AXI urgent sideband signal (arurgent). When enabled and arurgent is asserted by the master, that port becomes the highest priority and co_gs_go2critical_lpr/co_gs_go2critical_hpr signal to DDRC is asserted if enabled in PCCFG.go2critical_en register. Note that arurgent signal can be asserted anytime and as long as required which is independent of address handshaking (it is not associated with any particular command).
12 rd_port_aging_en	If set to 1, enables aging function for the read channel of the port.
11-10 —	Reserved
9-0 rd_port_priority	Determines the initial load value of read aging counters. These counters will be parallel loaded after reset, or after each grant to the corresponding port. The aging counters down-count every clock cycle where the port is requesting but not granted. The higher significant 5-bits of the read aging counter sets the priority of the read channel of a given port. Port's priority will increase as the higher significant 5-bits of the counter starts to decrease. When the aging counter becomes 0, the corresponding port channel will have the highest priority level (timeout condition - Priority0). For multi-port configurations, the aging counters cannot be used to set port priorities when external dynamic priority inputs (arqos) are enabled (timeout is still applicable). For single port configurations, the aging counters are only used when they timeout (become 0) to force read-write direction switching. In this case, external dynamic priority input, arqos (for reads only) can still be used to set the DDRC read priority (2 priority levels: low priority read - LPR, high priority read - HPR) on a command by command basis. Note: The two LSBs of this register field are tied internally to 2'b00.

9.2.5.1.87 Port n Configuration Write Register (PCFGW_0)

Field	Function
31-0 mr4_read_interval	Interval between two MR4 reads, used to derate the timing parameters. Present only for LPDDR4. This register must not be set to zero. Unit: DFI clock cycle.

9.2.5.1.91 [SHADOW] Refresh Control Register 0 (RFSHCTL0_SHADOW)

9.2.5.1.91.1 Offset

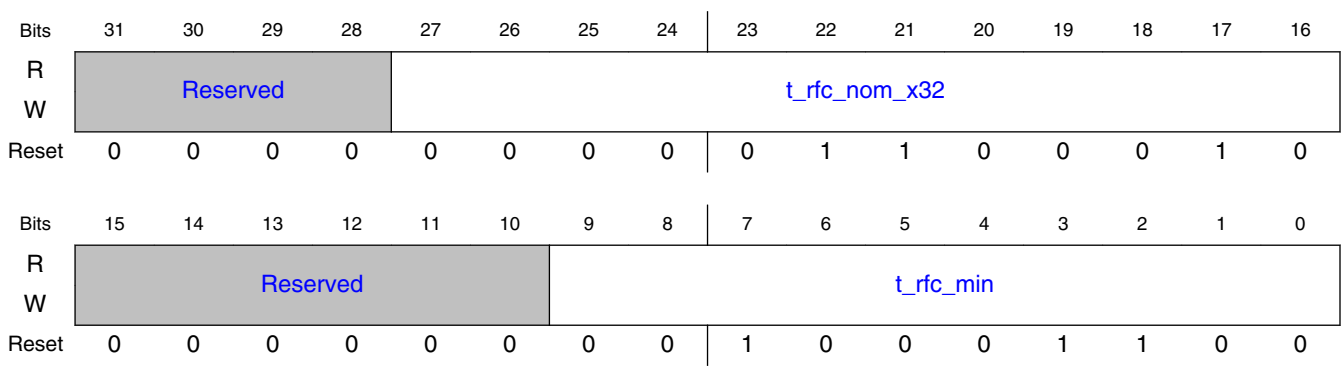
Register	Offset
RFSHCTL0_SHADOW	2050h

9.2.5.1.91.2 Diagram

9.2.5.1.91.3 Fields

Field	Function
31-24 —	Reserved
23-20 refresh_margin	Threshold value in number of DFI clock cycles before the critical refresh or page timer expires. A critical refresh is to be issued before this threshold is reached. It is recommended that this not be changed from the default value, currently shown as 0x2. It must always be less than internally used t_rfc_nom_x32. Note that, in LPDDR4, internally used t_rfc_nom_x32 may be equal to RFSHTMG.t_rfc_nom_x32>>2 if derating is enabled (DERATEEN.derate_enable=1). Otherwise, internally used t_rfc_nom_x32 will be equal to RFSHTMG.t_rfc_nom_x32. Unit: Multiples of 32 DFI clocks.
19-17 —	Reserved
16-12 refresh_to_x32	If the refresh timer (tRFCnom, also known as tREFI) has expired at least once, but it has not expired (RFSHCTL0.refresh_burst+1) times yet, then a speculative refresh may be performed. A speculative refresh is a refresh performed at a time when refresh would be useful, but before it is absolutely required. When the SDRAM bus is idle for a period of time determined by this RFSHCTL0.refresh_to_x32 and the refresh timer has expired at least once since the last refresh, then a speculative refresh is performed. Speculative refreshes continues successively until there are no refreshes pending or until new reads or writes are issued to the DDRC. FOR PERFORMANCE ONLY. Unit: Multiples of 32 DFI clocks.
11-9 —	Reserved
8-4 refresh_burst	The programmed value + 1 is the number of refresh timeouts that is allowed to accumulate before traffic is blocked and the refreshes are forced to execute. Closing pages to perform a refresh is a one-time penalty that must be paid for each group of refreshes. Therefore, performing refreshes in a burst reduces the per-refresh penalty of these page closings. Higher numbers for RFSHCTL.refresh_burst slightly

Table continues on the next page...



Field	Function
	increases utilization; lower numbers decreases the worst-case latency associated with refreshes. - 0 - single refresh - 1 - burst-of-2 refresh - 7 - burst-of-8 refresh. In DDR4 mode, according to Fine Granularity feature, 8 refreshes can be postponed in 1X mode, 16 refreshes in 2X mode and 32 refreshes in 4X mode. If using PHY-initiated updates, care must be taken in the setting of RFSHCTL0.refresh_burst, to ensure that tRFCmax is not violated due to a PHY-initiated update occurring shortly before a refresh burst was due. In this situation, the refresh burst will be delayed until the PHY-initiated update is complete.
3 —	Reserved
2 per_bank_refresh	- 1 - Per bank refresh; - 0 - All bank refresh. Per bank refresh allows traffic to flow to other banks. Present only for LPDDR4.
1-0 —	Reserved

9.2.5.1.92 [SHADOW] Refresh Timing Register (RFSHTMG_SHADOW)

9.2.5.1.92.1 Offset

Register	Offset
RFSHTMG_SHADOW	2064h

9.2.5.1.92.2 Diagram

9.2.5.1.92.3 Fields

Field	Function
31-28 —	Reserved

Table continues on the next page...

Field	Function
27-16 t_rfc_nom_x32	tREFI: Average time interval between refreshes per rank (Specification: 7.8us for DDR4. See JEDEC specification for LPDDR4). For LPDDR4: - if using all-bank refreshes (RFSHCTL0.per_bank_refresh = 0), this register should be set to tREFIab - if using per-bank refreshes (RFSHCTL0.per_bank_refresh = 1), this register should be set to tREFIpb When the controller is operating in 1:2 frequency ratio mode, program this to (tREFI/2), no rounding up. In DDR4 mode, tREFI value is different depending on the refresh mode. The user should program the appropriate value from the spec based on the value programmed in the refresh mode register. Note that RFSHTMG.t_rfc_nom_x32 * 32 must be greater than RFSHTMG.t_rfc_min, and RFSHTMG.t_rfc_nom_x32 must be greater than 0x1. - Non-DDR4 or DDR4 Fixed 1x mode: RFSHTMG.t_rfc_nom_x32 must be less than or equal to 0xFFE. - DDR4 Fixed 2x mode: RFSHTMG.t_rfc_nom_x32 must be less than or equal to 0x7FF. - DDR4 Fixed 4x mode: RFSHTMG.t_rfc_nom_x32 must be less than or equal to 0x3FF. Unit: Multiples of 32 clocks.
15-10 —	Reserved
9-0 t_rfc_min	tRFC (min): Minimum time from refresh to refresh or activate. When the controller is operating in 1:1 mode, t_rfc_min should be set to RoundUp(tRFCmin/tCK). When the controller is operating in 1:2 mode, t_rfc_min should be set to RoundUp(RoundUp(tRFCmin/tCK)/2). In LPDDR4 mode: - if using all-bank refreshes, the tRFCmin value in the above equations is equal to tRFCab - if using per-bank refreshes, the tRFCmin value in the above equations is equal to tRFCpb In DDR4 mode, the tRFCmin value in the above equations is different depending on the refresh mode (fixed 1X,2X,4X) and the device density. The user should program the appropriate value from the spec based on the 'refresh_mode' and the device density that is used. Unit: Clocks.

Field	Function
31 —	Reserved
30-24 wr2pre	Minimum time between write and precharge to same bank. Unit: Clocks Specifications: WL + BL/2 + tWR = approximately 8 cycles + 15 ns = 14 clocks @400MHz and less for lower frequencies where: - WL = write latency - BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM. BST (burst terminate) is not supported at present. - tWR = Write recovery time. This comes directly from the SDRAM specification. Add one extra cycle for LPDDR4 for this parameter. When the controller is operating in 1:2 frequency ratio mode, 1T mode, divide the above value by 2. No rounding up. When the controller is operating in 1:2 frequency ratio mode, 2T mode or LPDDR4 mode, divide the above value by 2 and round it up to the next integer value.
23-22 —	Reserved
21-16 t_faw	tFAW Valid only when 8 or more banks(or banks x bank groups) are present. In 8-bank design, at most 4 banks must be activated in a rolling window of tFAW cycles. When the controller is operating in 1:2 frequency ratio mode, program this to (tFAW/2) and round up to next integer value. In a 4-bank design, set this register to 0x1 independent of the 1:1/1:2 frequency mode. Unit: Clocks
15 —	Reserved
14-8 t_ras_max	tRAS(max): Maximum time between activate and precharge to same bank. This is the maximum time that a page can be kept open Minimum value of this register is 1. Zero is invalid. When the controller is operating in 1:2 frequency ratio mode, program this to (tRAS(max)-1)/2. No rounding up. Unit: Multiples of 1024 clocks.
7-6 —	Reserved
5-0 t_ras_min	tRAS(min): Minimum time between activate and precharge to the same bank. When the controller is operating in 1:2 frequency mode, 1T mode, program this to tRAS(min)/2. No rounding up. When the controller is operating in 1:2 frequency ratio mode, 2T mode or LPDDR4 mode, program this to (tRAS(min)/2) and round it up to the next integer value. Unit: Clocks

9.2.5.1.98 [SHADOW] SDRAM Timing Register 1 (DRAMTMG1_SHADOW)

Field	Function
31-21 —	Reserved
20-16 t_xp	tXP: Minimum time after power-down exit to any operation. If C/A parity for DDR4 is used, set to (tXP +PL) instead. When the controller is operating in 1:2 frequency ratio mode, program this to (tXP/2) and round it up to the next integer value. Units: Clocks
15-14 —	Reserved
13-8 rd2pre	tRTP: Minimum time from read to precharge of same bank. - DDR4: Max of following two equations: tAL + max (tRTP, 4) or, RL + BL/2 - tRP (*). - LPDDR4: BL/2 + max(tRTP,8) - 8 (*). When both DDR4 SDRAM and ST-MRAM are used simultaneously, use SDRAM's tRP value for calculation. When the controller is operating in 1:2 mode, 1T mode, divide the above value by 2. No rounding up. When the controller is operating in 1:2 mode, 2T mode or LPDDR4 mode, divide the above value by 2 and round it up to the next integer value. Unit: Clocks.
7 —	Reserved
6-0 t_rc	tRC: Minimum time between activates to same bank. When the controller is operating in 1:2 frequency ratio mode, program this to (tRC/2) and round up to next integer value. Unit: Clocks.

9.2.5.1.99 [SHADOW] SDRAM Timing Register 2 (DRAMTMG2_SHADOW)

9.2.5.1.99.1 Offset

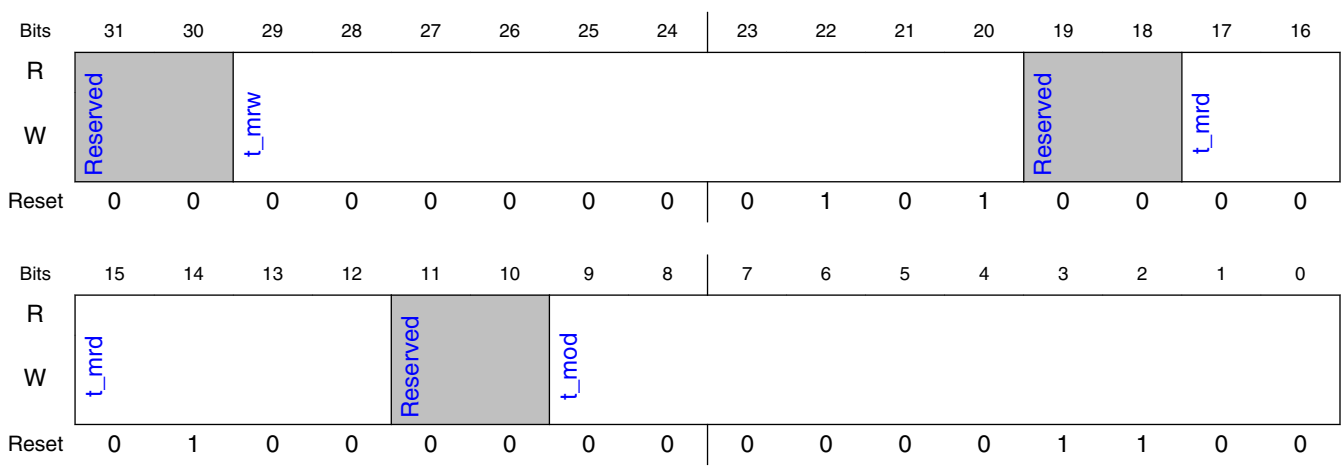
Register	Offset
DRAMTMG2_SHADOW	2108h

9.2.5.1.99.2 Diagram

9.2.5.1.99.3 Fields

Field	Function
31-30 —	Reserved
29-24 write_latency	Set to WL Time from write command to write data on SDRAM interface. This must be set to WL. When the controller is operating in 1:2 frequency ratio mode, divide the value calculated using the above equation by 2, and round it up to next integer. Unit: clocks
23-22 —	Reserved
21-16 read_latency	Set to RL Time from read command to read data on SDRAM interface. This must be set to RL.When the controller is operating in 1:2 frequency ratio mode, divide the value calculated using the above equation by 2, and round it up to next integer. Unit: clocks
15-14 —	Reserved
13-8	DDR4: RL + BL/2 + 1 + WR_PREAMBLE - WL. LPDDR4(DQ ODT is Disabled): RL + BL/2 + RU(tDQSCKmax/tCK) + WR_PREAMBLE + RD_POSTAMBLE - WL. LPDDR4(DQ ODT is Enabled) : RL

Table continues on the next page...



Field	Function
rd2wr	+ BL/2 + RU(tDQSCKmax/tCK) + RD_POSTAMBLE - ODTLon - RU(tODTon(min)/tCK). Minimum time from read command to write command. Include time for bus turnaround and all per-bank, per-rank, and global constraints. Please see the relevant PHY databook for details of what should be included here. Unit: Clocks. Where: - WL = write latency - BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM - RL = read latency = CAS latency - WR_PREAMBLE = write preamble. This is unique to DDR4 and LPDDR4. - RD_POSTAMBLE = read postamble. This is unique to LPDDR4. For LPDDR4, if derating is enabled (DERATEEN.derate_enable=1), derated tDQSCKmax should be used. When the controller is operating in 1:2 frequency ratio mode, divide the value calculated using the above equation by 2, and round it up to next integer.
7-6 —	Reserved
5-0 wr2rd	DDR4: CWL + PL + BL/2 + tWTR_L Others: CWL + BL/2 + tWTR In DDR4, minimum time from write command to read command for same bank group. In others, minimum time from write command to read command. Includes time for bus turnaround, recovery times, and all per-bank, per-rank, and global constraints. Unit: Clocks. Where: - CWL = CAS write latency - PL = Parity latency - BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM - tWTR_L = internal write to read command delay for same bank group. This comes directly from the SDRAM specification. - tWTR = internal write to read command delay. This comes directly from the SDRAM specification. Add one extra cycle for LPDDR4 operation. When the controller is operating in 1:2 mode, divide the value calculated using the above equation by 2, and round it up to next integer.

9.2.5.1.100 [SHADOW] SDRAM Timing Register 3 (DRAMTMG3_SHADOW)

9.2.5.1.100.1 Offset

Register	Offset
DRAMTMG3_SHADOW	210Ch

9.2.5.1.100.2 Diagram

9.2.5.1.100.3 Fields

Field	Function
31-30 —	Reserved
29-20 t_mrw	Time to wait after a mode register write or read (MRW or MRR). Present only for LPDDR4. LPDDR4: Set this to the larger of tMRW and tMRWCKEL. When the controller is operating in 1:2 frequency ratio mode, program this to the above values divided by 2 and round it up to the next integer value.
19-18 —	Reserved
17-12 t_mrd	tMRD: Cycles to wait after a mode register write or read. Depending on the connected SDRAM, tMRD represents: DDR4: Time from MRS to MRS command. LPDDR4: Time from MRS to non-MRS command. When the controller is operating in 1:2 frequency ratio mode, program this to (tMRD/2) and round it up to the next integer value. If C/A parity for DDR4 is used, set to tMRD_PAR(tMOD+PL) instead.
11-10 —	Reserved
9-0 t_mod	tMOD: Parameter used only in DDR4. Cycles between load mode command and following non-load mode command. If C/A parity for DDR4 is used, set to tMOD_PAR(tMOD+PL) instead. Set to tMOD if controller is operating in 1:1 frequency ratio mode, or tMOD/2 (rounded up to next integer) if controller is operating in 1:2 frequency ratio mode.

Field	Function
31-29 —	Reserved
28-24 t_rcd	tRCD - tAL: Minimum time from activate to read or write command to same bank. When the controller is operating in 1:2 frequency ratio mode, program this to ((tRCD - tAL)/2) and round it up to the next integer value. Minimum value allowed for this register is 1, which implies minimum (tRCD - tAL) value to be 2 when the controller is operating in 1:2 frequency ratio mode. Unit: Clocks.
23-20 —	Reserved
19-16 t_ccd	DDR4: tCCD_L: This is the minimum time between two reads or two writes for same bank group. Others: tCCD: This is the minimum time between two reads or two writes. When the controller is operating in 1:2 frequency ratio mode, program this to (tCCD_L/2 or tCCD/2) and round it up to the next integer value. Unit: clocks.
15-12 —	Reserved
11-8 t_rrd	DDR4: tRRD_L: Minimum time between activates from bank "a" to bank "b" for same bank group. Others: tRRD: Minimum time between activates from bank "a" to bank "b" When the controller is operating in 1:2 frequency ratio mode, program this to (tRRD_L/2 or tRRD/2) and round it up to the next integer value. Unit: Clocks.
7-5 —	Reserved
4-0 t_rp	tRP: Minimum time from precharge to activate of same bank. When the controller is operating in 1:1 frequency ratio mode, t_rp should be set to RoundUp(tRP/tCK). When the controller is operating in 1:2 frequency ratio mode, t_rp should be set to RoundDown(RoundUp(tRP/tCK)/2) + 1. When the controller is operating in 1:2 frequency ratio mode in LPDDR4, t_rp should be set to RoundUp(RoundUp(tRP/tCK)/2). Unit: Clocks.

DRAMTMG5_SHADOW	2114h

9.2.5.1.102.2 Diagram

9.2.5.1.102.3 Fields

Field	Function
31-28 —	Reserved
27-24 t_cksrx	This is the time before Self Refresh Exit that CK is maintained as a valid clock before issuing SRX. Specifies the clock stable time before SRX. Recommended settings: LPDDR4: tCKCKEH. DDR4: tCKSRX When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.
23-20 —	Reserved
19-16 t_cksre	This is the time after Self Refresh Down Entry that CK is maintained as a valid clock. Specifies the clock disable delay after SRE. Recommended settings: LPDDR4: tCKCKEL. DDR4: max (10 ns, 5 tCK) (+ PL(parity latency)(*)) (*)Only if CRCPARCTL1.caparity_disable_before_sr=0, this register should be increased by PL. When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.
15-14 —	Reserved
13-8 t_ckesr	Minimum CKE low width for Self refresh or Self refresh power down entry to exit timing in memory clock cycles. Recommended settings: LPDDR4: max(tCKELPD, tSR). DDR4: tCKE + 1 (+ PL(parity latency)(*)) (*)Only if CRCPARCTL1.caparity_disable_before_sr=0, this register should be increased by PL. When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.
7-5 —	Reserved
4-0 t_cke	Minimum number of cycles of CKE HIGH/LOW during power-down and self refresh. - LPDDR4 mode: Set this to the larger of tCKE, tCKELPD or tSR. - non-LPDDR4 designs: Set this to tCKE value. When the controller is operating in 1:2 frequency ratio mode, program this to (value described above)/2 and round it up to the next integer value. Unit: Clocks.

Field	Function
31 dis_auto_zq	- 1 - Disable DDRC generation of ZQCS/MPC(ZQ calibration) command. Register DBGCMD.zq_calib_short can be used instead to issue ZQ calibration request from APB module. - 0 - Internally generate ZQCS/MPC(ZQ calibration) commands based on ZQCTL1.t_zq_short_interval_x1024.
30 dis_srx_zqcl	1 - Disable issuing of ZQCL/MPC(ZQ calibration) command at Self-Refresh/SR-Powerdown exit. 0 - Enable issuing of ZQCL/MPC(ZQ calibration) command at Self-Refresh/SR-Powerdown exit.
29 zq_resistor_shared	- 1 - Denotes that ZQ resistor is shared between ranks. Means ZQinit/ZQCL/ZQCS/MPC(ZQ calibration) commands are sent to one rank at a time with tZQinit/tZQCL/tZQCS/tZQCAL/tZQLAT timing met between commands so that commands to different ranks do not overlap. - 0 - ZQ resistor is not shared.
28 dis_mpsmx_zqcl	- 1 - Disable issuing of ZQCL command at Maximum Power Saving Mode exit. Only applicable when run in DDR4 mode. - 0 - Enable issuing of ZQCL command at Maximum Power Saving Mode exit. Only applicable when run in DDR4 mode. This is only present for designs supporting DDR4 devices. Note: Do not issue ZQCL command at Maximum Power Save Mode exit if the DDRC_SHARED_AC configuration parameter is set. Program it to 1'b1. The software can send ZQCS after exiting MPSM mode.
27 —	Reserved
26-16 t_zq_long_nop	tZQoper for DDR4, tZQCAL for LPDDR4: Number of DFI clock cycles of NOP required after a ZQCL (ZQ calibration long)/MPC(ZQ Start) command is issued to SDRAM. When the controller is operating in 1:2 frequency ratio mode: DDR4: program this to tZQoper/2 and round it up to the next integer value. LPDDR4: program this to tZQCAL/2 and round it up to the next integer value.
15-10 —	Reserved
9-0 t_zq_short_nop	tZQCS for DDR4, tZQLAT for LPDDR4: Number of DFI clock cycles of NOP required after a ZQCS (ZQ calibration short)/MPC(ZQ Latch) command is issued to SDRAM. When the controller is operating in 1:2 frequency ratio mode, program this to tZQCS/2 and round it up to the next integer value.

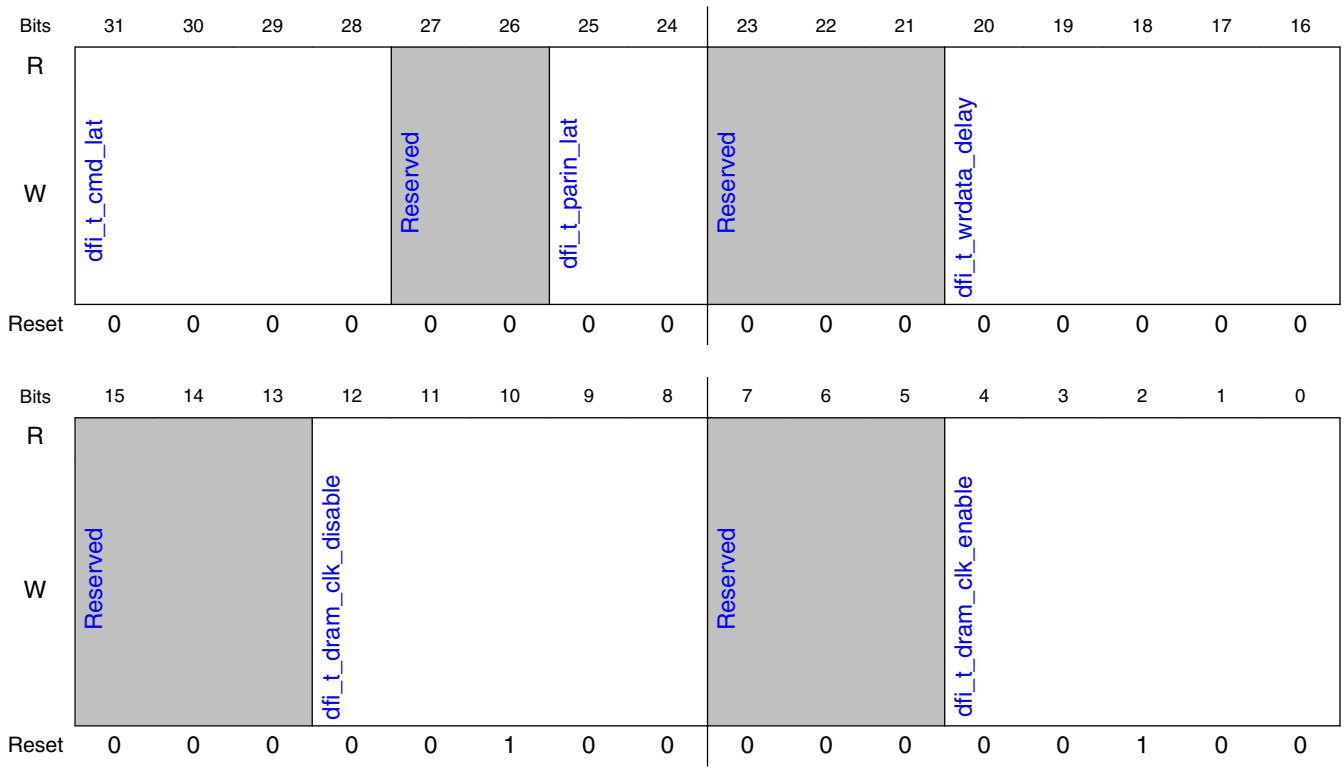
Field	Function
31-29 —	Reserved
28-24 dfi_t_ctrl_delay	Specifies the number of DFI clock cycles after an assertion or de-assertion of the DFI control signals that the control signals at the PHY-DRAM interface reflect the assertion or de-assertion. If the DFI clock and the memory clock are not phase-aligned, this timing parameter should be rounded up to the next integer value.
23 dfi_rddata_use_sdr	Defines whether dfi_rddata_en/dfi_rddata/dfi_rddata_valid is generated using HDR (DFI clock) or SDR (DFI PHY clock) values. Selects whether value in DFITMG0.dfi_t_rddata_en is in terms of HDR (DFI clock) or SDR (DFI PHY clock) cycles: - 0 in terms of HDR (DFI clock) cycles - 1 in terms of SDR (DFI PHY clock) cycles Refer to PHY specification for correct value.

Table continues on the next page...



Field	Function
22-16 dfi_t_rddata_en	Time from the assertion of a read command on the DFI interface to the assertion of the dfi_rddata_en signal. Refer to PHY specification for correct value. This corresponds to the DFI parameter trddata_en.Unit: DFI clock cycles or DFI PHY clock cycles, depending on DFITMG0.dfi_rddata_use_sdr.
15 dfi_wrdata_use_sdr	Defines whether dfi_wrdata_en/dfi_wrdata/dfi_wrdata_mask is generated using HDR (DFI clock) or SDR (DFI PHY clock) values Selects whether value in DFITMG0.dfi_tphy_wrlat is in terms of HDR (DFI clock) or SDR (DFI PHY clock) cycles Selects whether value in DFITMG0.dfi_tphy_wrdata is in terms of HDR (DFI clock) or SDR (DFI PHY clock) cycles - 0 in terms of HDR (DFI clock) cycles - 1 in terms of SDR (DFI PHY clock) cycles Refer to PHY specification for correct value.
14 —	Reserved
13-8 dfi_tphy_wrdata	Specifies the number of clock cycles between when dfi_wrdata_en is asserted to when the associated write data is driven on the dfi_wrdata signal. This corresponds to the DFI timing parameter tphy_wrdata. Refer to PHY specification for correct value. Note, max supported value is 8. Unit: DFI clock cycles or DFI PHY clock cycles, depending on DFITMG0.dfi_wrdata_use_sdr.
7-6 —	Reserved
5-0 dfi_tphy_wrlat	Write latency Number of clocks from the write command to write data enable (dfi_wrdata_en). This corresponds to the DFI timing parameter tphy_wrlat. Refer to PHY specification for correct value.Unit: DFI clock cycles or DFI PHY clock cycles, depending on DFITMG0.dfi_wrdata_use_sdr.

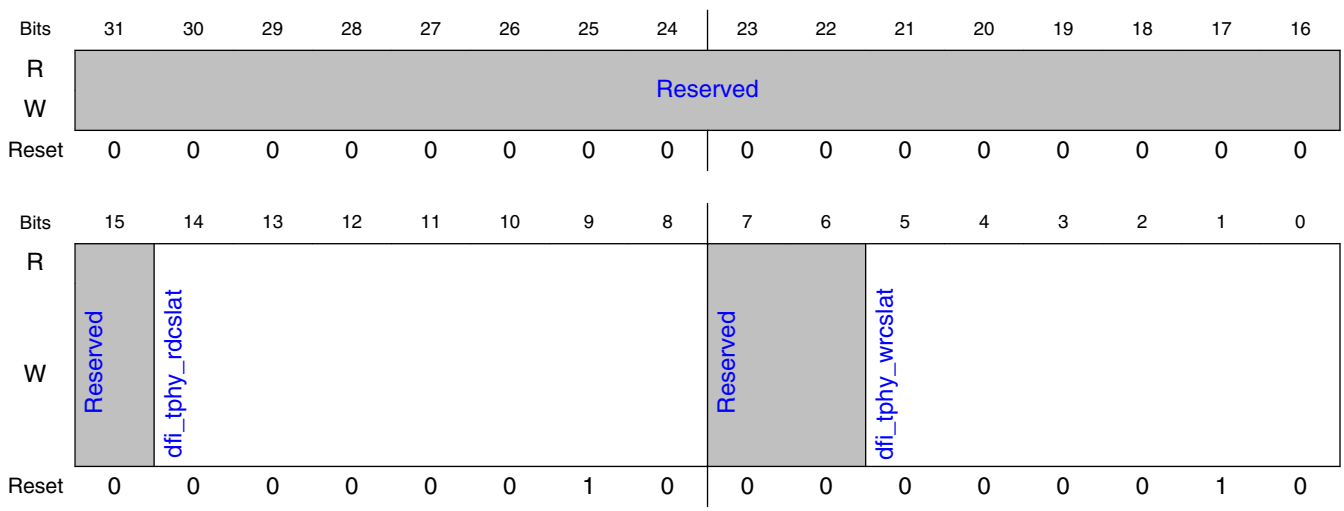
9.2.5.1.115.3 Fields

Field	Function
31-28 dfi_t_cmd_lat	Specifies the number of DFI PHY clock cycles between when the dfi_cs signal is asserted and when the associated command is driven. This field is used for CAL mode, should be set to '0' or the value which matches the CAL mode register setting in the DRAM. If the PHY can add the latency for CAL mode, this should be set to '0'. Valid Range: 0, 3, 4, 5, 6, and 8
27-26 —	Reserved
25-24 dfi_t_parin_lat	Specifies the number of DFI PHY clock cycles between when the dfi_cs signal is asserted and when the associated dfi_parity_in signal is driven.
23-21 —	Reserved
20-16 dfi_t_wrdata_delay	Specifies the number of DFI clock cycles between when the dfi_wrdata_en signal is asserted and when the corresponding write data transfer is completed on the DRAM bus. This corresponds to the DFI timing parameter twrdata_delay. Refer to PHY specification for correct value. For DFI 3.0 PHY, set to twrdata_delay, a new timing parameter introduced in DFI 3.0. For DFI 2.1 PHY, set to tphy_wrdata + (delay of DFI write data to the DRAM). Value to be programmed is in terms of DFI clocks, not PHY clocks. In FREQ_RATIO=2, divide PHY's value by 2 and round up to next integer. If using DFITMG0.dfi_wrdata_use_sdr=1, add 1 to the value. Unit: Clocks
15-13 —	Reserved

Table continues on the next page...



Field	Function
12-8 dfi_t_dram_clk_disable	Specifies the number of DFI clock cycles from the assertion of the dfi_dram_clk_disable signal on the DFI until the clock to the DRAM memory devices, at the PHY-DRAM boundary, maintains a low value. If the DFI clock and the memory clock are not phase aligned, this timing parameter should be rounded up to the next integer value.
7-5 —	Reserved
4-0 dfi_t_dram_clk_enable	Specifies the number of DFI clock cycles from the de-assertion of the dfi_dram_clk_disable signal on the DFI until the first valid rising edge of the clock to the DRAM memory devices, at the PHY-DRAM boundary. If the DFI clock and the memory clock are not phase aligned, this timing parameter should be rounded up to the next integer value.

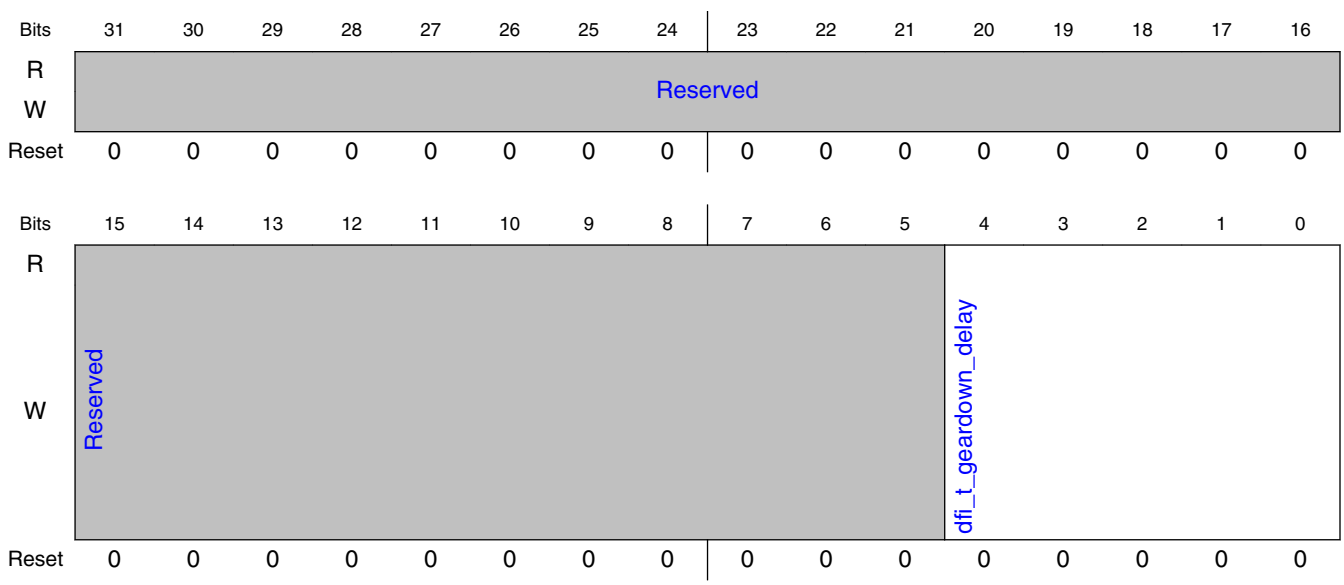
Table continues on the next page...



Field	Function
20-16 wr_odt_delay	The delay, in DFI PHY clock cycles, from issuing a write command to setting ODT values associated with that command. ODT setting must remain constant for the entire time that DQS is driven by the DDRC. Recommended values: DDR4: - DFITMG1.dfi_t_cmd_lat (to adjust for CAL mode).
15-12 —	Reserved
11-8 rd_odt_hold	DFI PHY clock cycles to hold ODT for a read command. The minimum supported value is 2. Recommended values: DDR4: - BL8: 5 + RD_PREAMBLE RD_PREAMBLE = 1 (1tCK write preamble), 2 (2tCK write preamble)
7 —	Reserved
6-2 rd_odt_delay	The delay, in DFI PHY clock cycles, from issuing a read command to setting ODT values associated with that command. ODT setting must remain constant for the entire time that DQS is driven by the DDRC. Recommended values: DDR4: - CL - CWL - RD_PREAMBLE + WR_PREAMBLE + DFITMG1.dfi_t_cmd_lat (to adjust for CAL mode) WR_PREAMBLE = 1 (1tCK write preamble), 2 (2tCK write preamble) RD_PREAMBLE = 1 (1tCK write preamble), 2 (2tCK write preamble). If (CL - CWL - RD_PREAMBLE + WR_PREAMBLE) < 0, DDRC does not support ODT for read operation.
1-0 —	Reserved

9.3 DDR BLK_CTRL

9.3.1 Overview

The DDRMIX domain contains a control register known as DDR Block Control (DDR BLK_CTRL). This register controls the DDR device selection for supported DDR devices.

9.3.1.1 Block Diagram

The DDR BLK_CTRL interface connects to the DDRMIX domain peripherals. A block diagram illustrating the DDRMIX domain is shown below.

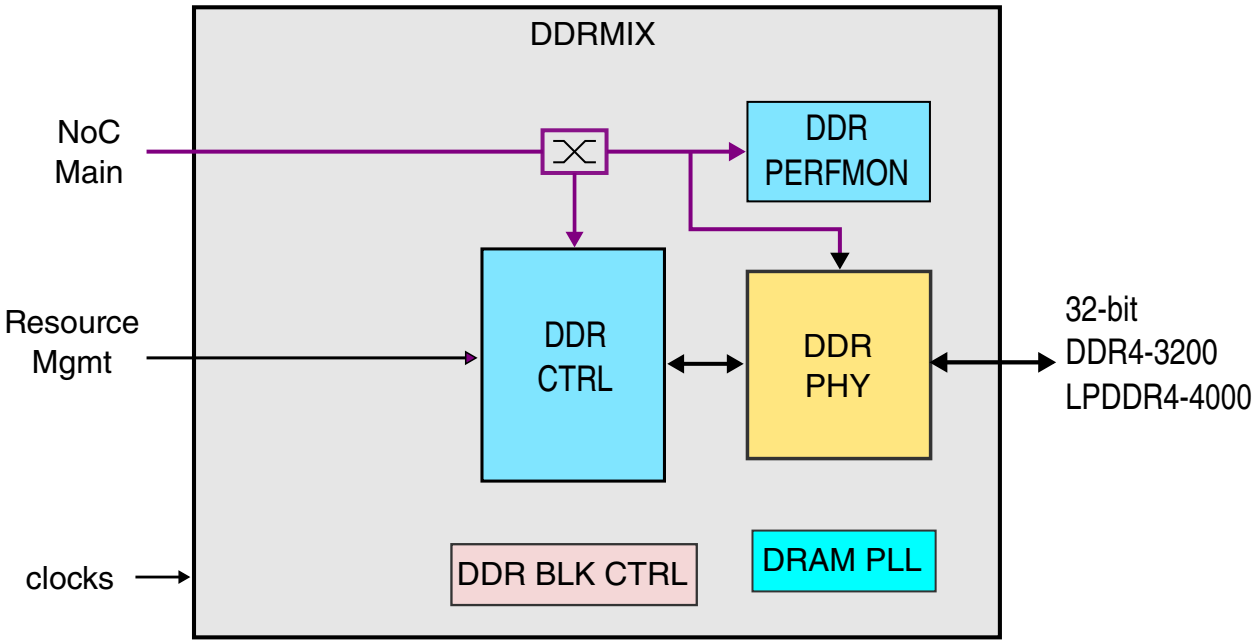

Figure 9-4. DDRMIX Block Diagram

9.3.2 Memory Map and register definition

This section includes the DDR BLK_CTRL module memory map and detailed descriptions of all registers.

9.4 DDR PHY (DDR_PHY)

9.4.1 Overview

The Double Data Rate Physical Layer (DDR PHY), provides an interface between universal controllers and external DDR4/LPDDR4 SDRAM devices.

NOTE

The information within this block guide is Synopsys Proprietary. Used with permission.

9.4.1.1 Block Diagram

The block diagram of the DDR PHY is provided below.

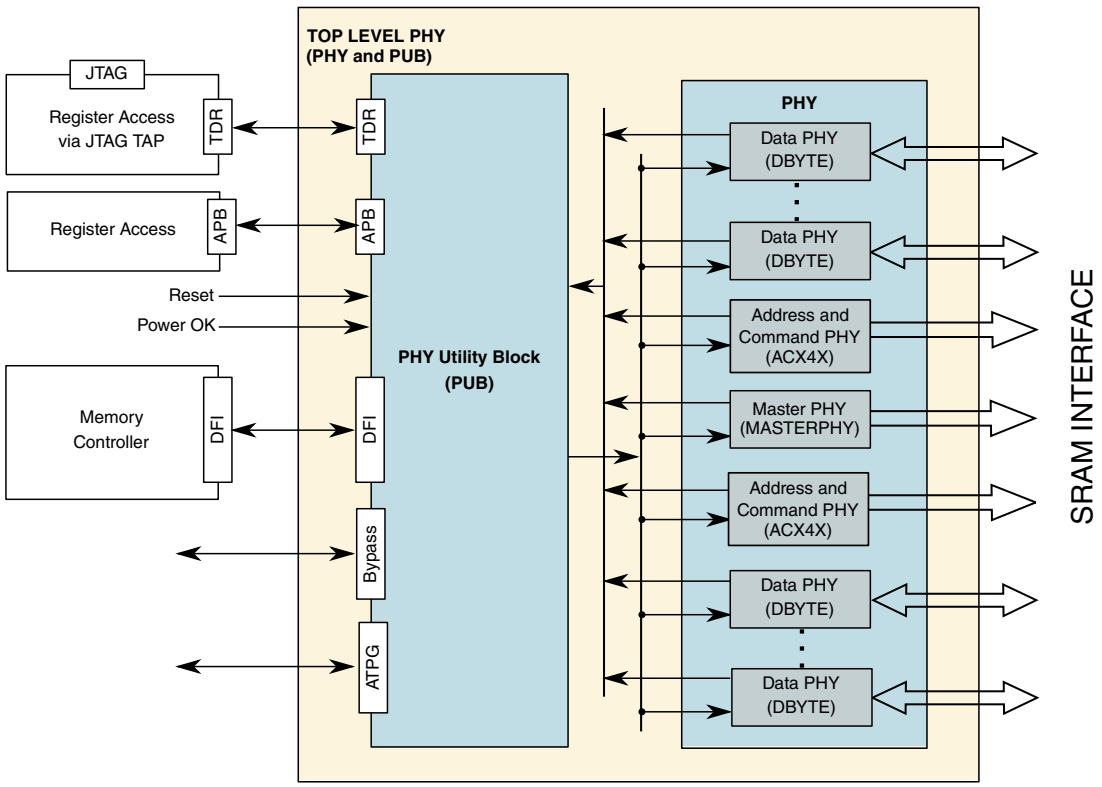

Figure 9-5. DDR PHYBlock Diagram

9.4.1.2 Features

The following features are supported in the DDR PHY:

- DDR4 and LPDDR4 operation
- Multiple memory rank support:
  - Four ranks supported for DDR4
  - Two ranks supported for LPDDR4
- DFI interface (DFI v4.0 Addendum 2, March 2015)
- At-speed loopback testing on both the address and data channels
- Mux-scan ATPG
- High-speed PLL used to generate the high speed clock for data transmit and high speed digital pipelines
- PHY Utility Block (PUB), which provides configuration and control
- Power on reset (POR) circuit, DRAM reset, DRAM alert and PHY debug
- A global voltage reference generation and observation circuit
- Impedance calibration circuits

9.4.2 Functional Description

The DDR PHY is composed of the following:

- DBYTE - The eight-lane data IO unit
- ACX4 - The four-lane address/command hard IP unit
- MASTERPHY - Contains the PLL, the voltage reference, thermal calibration, and reset
- PUB - PHY Utility Block

9.4.2.1 DDR Address/Command PHY (ACX4)

The DDR SDRAM address/command PHY (DDRPHYACX4) provides an address and command interface to the external SDRAM memories. A memory interface typically contains a single address/command PHY and one or more data PHYs (one for each byte lane).

The AC consists of multiple design slices. The address/command (AC) slice is used for all address and command and clk/cs/odt signals. Each slice contains all logic required for both the output (address/command) and input (loopback) paths of the respective signals.

All clocking inside the AC is derived from an input clock, which is generated by the PLL in the MASTERPHY. The PLL generates the higher frequency clocks that are is used inside the macro and minimizes input clock jitter.

9.4.2.1.1 ACX4 Transmit Lanes

The ACX4 component contains 4 transmit only lanes which are grouped as follows:

- Clock group: {CK_t, CK_c}
- CA group: {ras_n, cas_n, we_n, addr…}
- CKE,CS,ODT group{CKE, CS_n, ODT…}

In DDR4 systems, 12 ACs are required to control one 72b/64b channel with four independent ranks.

In LPDDR4 systems, the 12 ACs are broken up into two independently controllable groups, enabling up to two independent 32b channels (each with a maximum of two ranks.

9.4.2.1.2 ACX4 Command Path

Each SDRAM address and command signal is driven from the memory controller to the SDRAM through an address/command slice. Controlled address/command pipeline logic inside the AC slice converts the DFI-rate signals from the controller to single data rate (SDR) Address/Command signals going to the SDRAM. The last launching register inside the address/command slice is clocked by a delay-shifted DDR clock. For SDR operation, all outputs remain constants for two cycles at a time.

The path for the SDRAM clock (CK) is through a standard AC slice which is configured to act as a dedicated clock (CK) slice. This shifted address/command output makes the CK centered into the data eye of the address/command signals.

All AC outputs going to the SDRAM have a LCDL, which can be used to align or shift the outputs of the data PHY. This delay element can also be used to provide delay adjustment during functional or loopback modes.

9.4.2.1.3 ACX4 Loopback/DFT Paths

For every lane there will be a loopback-only receive path. The loopback path is stimulated and checked by utilizing a FirmWare image.

9.4.2.2 DDR Data PHY (DBYTE)

The DDR SDRAM Data PHY (DBYTE) provides data interface to external SDRAM memory. Features of the DBYTE include:

- High speed digital logic pipeline for transmit datapaths to the SDRAM
- High speed digital logic pipeline for receive datapaths from the SDRAM
- Drivers and receivers for the DQ and DQS signals as well as all the necessary high voltage analog macros to interface off chip
- I/O component that includes PVT-compensated on-die termination (ODT) and output impedance
- Loop-back test mode and PRBS checkers to help verify the integrity of the internal datapath of all DBYTE I/O lanes

9.4.2.2.1 DBYTE Write Path

Each SDRAM data is driven from the PUB to the SDRAM through a data (DQ) slice. Controlled data pipeline logic inside the DBYTE slice converts the DFI-rate signals from the PUB to double-data rate (DDR) signals going to the SDRAM. The last launching register inside the data slice is clocked by the DDR clock.

The path for the SDRAM write strobe is through a dedicated data strobe (DQS) slice. The output register of the DQS slice is clocked by a delayed version of PclkIn. PclkIn drives the output register in the DQ slice is shifted using the DLL in training mode. This centers the write data strobe signal in the write data eye.

All DBYTE outputs going to the SDRAM, including write data, write data strobe read DQS gate, driver power down, receiver power down, on-die termination enable, and output enable have a DLL that is used to deskew the outputs in order to maximize the write data eye.

Apart from the DQS pipeline, the DQS slice also contains a similar pipeline for output enables, on-die termination enable, driver power down, and receiver power down. This matches the I/O control signals to the corresponding data and data strobe.

9.4.2.2.2 DBYTE Read and Loopback Path

Read data from the SDRAM is written into a four-deep asynchronous FIFO that is implemented inside the DQ slice.

NOTE

The FIFO is 16 deep in terms of the DRAM DQS writing into the FIFO; it is 8 deep on the core side when a half-speed DFICLK is employed and it is 8 deep on the core side when a full speed DFICLK is employed.

The FIFO is written using the DQS clock and read using the Controller clock. A per-bit delay line at the input of the DQ slice is used to optionally de-skew read data with respect to the read strobe in order to maximize the read data eye.

The read data strobe path and a read DQS gate path is implemented inside the DQS slice. A delay line at the input of the slice shifts the read DQS by nominal 90 degrees (with the actual value arrived at through training) so that the strobe is centered into the read data eye before clocking the data into the FIFO. A Bit- Wise Delay Line (BDL) in the read DQS path is used to match a corresponding bit de-skew BDL in the DQ slice.

The DQS slice also generates the write pointers for the data FIFO. These pointers, together with the strobe, are then distributed to all DQ slices. The PUB generates a trained read-valid signal to read the data from the PHY.

The DBI uses DQS Slice 1, configured to behave as a DQ slice in x8 mode only.

9.4.2.2.2.1 DBYTE Loopback/DFT Paths

High speed loopback is implemented on all DBYTE I/Os. The DBYTE read path also doubles as the loopback path. During loopback, the PUB enables the gating of the DQS signal in the same way as it would normally gate the DQS during reads. This allows the looped back data to be clocked into the read data FIFO using the looped back DQS signal.

9.4.2.2.2.2 Memory Controller based DBYTE Loopback

This high speed PHY loopback mode uses all the DBYTE control and data paths in mission mode like operation modes. In this mode, the memory controller issues simultaneous Read/Write commands to the PHY, resulting in transmitting and receiving the same data on each DQ pad.

9.4.2.3 Master PHY (MASTERPHY)

The Master block contains the PLL, the Primary Voltage Reference, thermal calibration, reset, and I/O cells for test and control.

9.4.2.3.1 PLL

The PLL in the MASTER is a simplified PLL that has DFICLK as an input and creates an internal clock by quadrupling the DFICLK frequency. The PLL in the MASTER can only multiply the input clock frequency to produce an output clock that is four times the frequency of the input clock. The internal clock is the output of the MASTER to the ACX4 and DBYTE.

9.4.2.3.1.1 Optimal PLL Settings for Mission Mode Frequency Bins

Table 9-4. Optimal PLL Settings for Mission Mode Frequency Bins (PLL Max Bandwidth = 2 MHz)

pllin min (MHz)	pllin max (MHz)	Input div. ratio	Fbk min (MHz)	Fbk max (MHz)	Fbk div. ratio	VCO min (MHz)	VCO max (MHz)	PllCtrl2 PllFreqSel[4:0]	PLLTestMode int_half[8] prop_half[5] vco_mode[2] overflow[1]	PllCtrl1 PllCpPropCtrl[8:5]	PllCtrl1 PllCpIntCtrl[4:0]	PllCtrl4 PllCpPropGsCtrl[8:5]	PllCtrl4 PllCpIntGsCtrl[4:0]

9.4.2.3.2 Voltage Reference

This primary voltage reference generates the VREF global out used by the receivers in the ACX4 and DBYTE.

9.4.2.3.3 Calibration

The MASTER contains the analog blocks to perform output drive and input termination impedance calibration. Through the use of a digital control state machine, located in the PUB, the full mixed-signal calibration loop matches the impedance of the driver and termination with that of an external precision resistor. The resulting digital calibration code is fed to the address/command, DQ, and DQS blocks to control their impedance.

9.4.2.3.4 Reset

Reset takes the asynchronous reset bump, the PwrOk bump, and dfi_reset_n signal and combines them and synchronizes to the DFI clock. This is used by the ACX4 and DBYTE.

9.4.2.4 PHY Utility Block (PUB)

The following is an overview of the different functionality of the PHY Utility Block (PUB):

- Registers required to configure, control, train and self-test the PHY. Also contains registers required to initialize the DRAM.
- Initialization - this includes locking of the PLL, delay line calibration and calibration of I/O impedances.
- Data Training- train the PHY for optimum timing margins. This includes finding the best positioning of the DQS gating window during reads, write leveling, data bit deskew, and optimizing the read and write data eye.
- Implements a DFI-compliant interface between the external controller and the PHY.

9.4.2.4.1 DDR PHY Control and Configuration

The DDR PHY's PUB registers provide the required configuration, control, training and self-testing of the PHY. Also contains registers required to initialize the DRAM.

Refer to the DDR PHY register descriptions for more information.

9.4.2.4.2 DFI Interface

The DDR PHY and the DDR Controller both require a standard interface to transfer address, data, and control between these two blocks. These interfaces are DFI compliant. The PUB contains the DFI interface for the PHY.

For more information regarding the DFI specification, refer to the following:

- DDR PHY Interface (DFI) Specification, Revision 3.1 (Preliminary), 21, March 2014
- DDR PHY Interface (DFI) Specification Preliminary DFI 4.0 Specification - Addendum to DFI 3.1, 2 April 2014

9.4.2.5 Clocks

The following table provides the clocks for the DDR PHY module.

Table 9-5. Clocks

Clock	Description
DFICLK	DFI Clock
APBCLK	APB Clock
DfiCtlClk	DFI Controller Clock
BypassPclk	PHY High speed Bypass Clock

9.4.3 External Signals

The following table provides the external signals for the DDR PHY module.

Table 9-6. External Signals

Signal	Description
ACn	Address and Command signals
ALERT_N	DDR4 alert
DMn	Data mask
DQn	Data
DQSn_N/P	Data strobe
RESET_N	Reset
VREF	Voltage reference for receivers
ZN	Calibration external reference resistor

9.4.4 Initialization and Training Sequence

The following outlines the general initialization and training sequence. Unless otherwise stated, these functions occur within the DDR PHY.

1. Bring up VDD, VDDQ, and VAA. This occurs outside of the DDR PHY.
2. Start the clocks and reset the PHY. This also occurs outside of the PHY.

3. Initialize PHY configuration.
4. Load the PHY training firmware into instruction memory SRAM.
5. Set the PHY input clocks to the desired frequency. This occurs outside of the PHY.
6. Write the Message Block parameters for the training firmware.There are several locations in the data memory that must be written for the training firmware to have these parameters.
7. Execute the training firmware.
8. Once the training firmware completes, the results are returned to the data memory in the message block structure. This message block can be read. The result may be that another frequency needs to be trained (return to step 5).
9. Load the PHY Initialization Engine registers with the provided initialization sequence.
10. Initialize the PHY to mission mode by performing a DFI initialization sequence per the DFI specification.
11. The PHY is now in mission mode.

9.4.5 Memory Map and Register Definition

This section includes the DDRC PHY module memory map and detailed descriptions of all registers.

NOTE

The information within this block guide is Synopsys Proprietary. Used with permission.

NOTE

Only LPDDR4 and DDR4 operation is supported.

Field	Function
15-3 —	Reserved
2-0 DqLnSel	Supports mapping of PHY dq to dram dq within a byte (swizzle). Supports mapping of PHY dq to dram dq within a byte (swizzle). Intended to undo the swizzle of board-level phy-to-dram connections. such that MRR operations of binary counters may be return correct values. Note that this register is per-dbyte such that the sizzle may be different per dbyte. Each register in a byte's set of DqLnSel must have a unique value within the set. For example, if, on this dbyte, PHY lane 3 is connected to memory dq0 (on this dbyte), then Register Dq0LnSel for this dbyte should be 3.

9.5 AHB-to-APBH Bridge with DMA (APBH-Bridge-DMA)

9.5.1 Overview

The AHB-to-APBH bridge provides the chip with an inexpensive peripheral attachment bus running on the AHB's HCLK. (The H in APBH denotes that the APB*H* is synchronous to HCLK .)

As shown in the figure below, the AHB-to-APBH bridge includes the AHB-to-APB PIO bridge for a memory-mapped I/O to the APB devices, as well as a central DMA facility for devices on this bus and a vectored interrupt controller for the ARM core. Each one of the APB peripherals, including the vectored interrupt controller, is documented in their respective chapters.

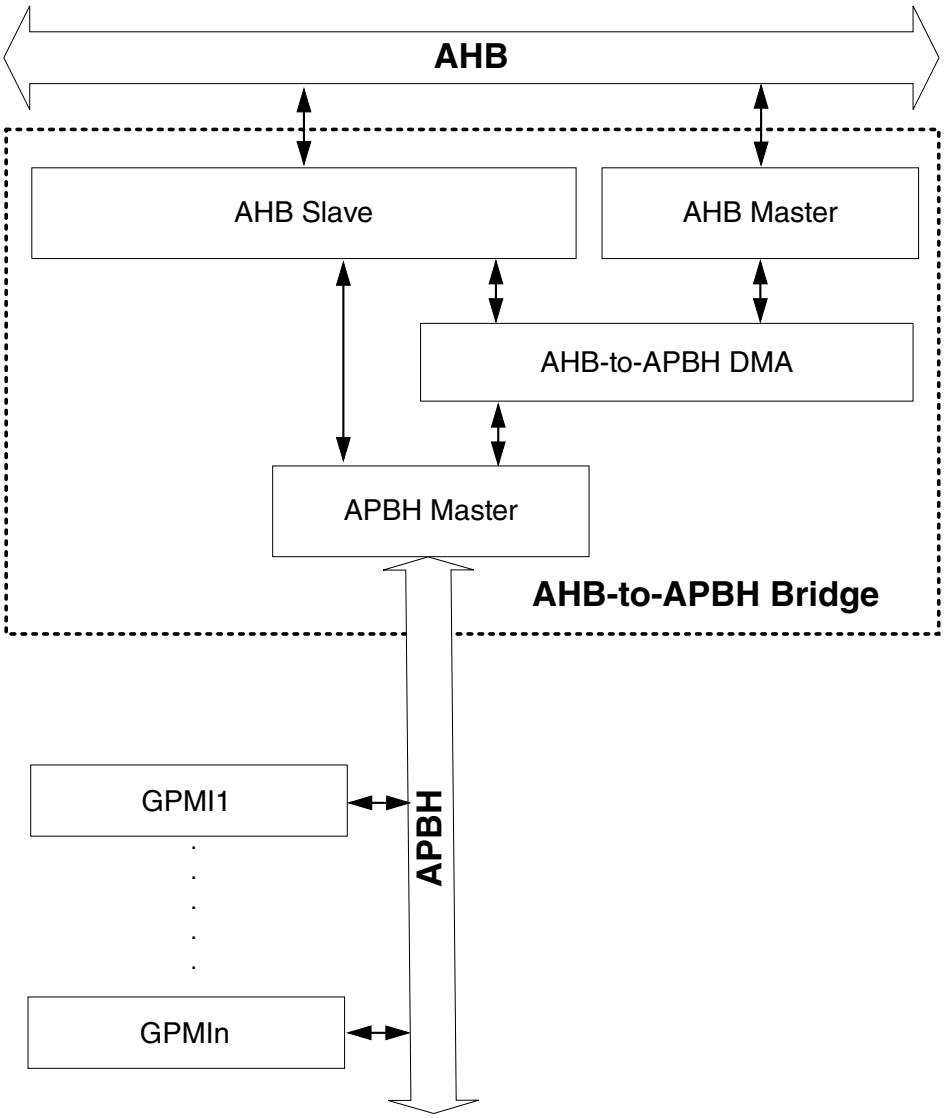

Figure 9-6. AHB-to-APBH Bridge DMA Block Diagram

The DMA controller uses the APBH bus to transfer read and write data to and from each peripheral. There is no separate DMA bus for these devices. Contention between the DMA's use of the APBH bus and the AHB-to-APB bridge functions' use of the APBH is mediated by an internal arbitration logic. For contention between these two units, the DMA is favored and the AHB slave will report "not ready" through its HREADY output until the bridge transfer can complete. The arbiter tracks repeated lockouts and inverts the priority, guaranteeing the ARM platform every fourth transfer on the APB.

9.5.2 Functional Description

9.5.2.1 Clocks

The table found here describes the clock sources for APBH. Please see clock control block for clock setting, configuration and gating information.

Table 9-7. APBH Clocks

Clock name	Description
hclk	Module clock

9.5.2.2 APBH DMA

The DMA supports four channels of DMA services, as shown in the following table. The shared DMA resource allows each independent channel to follow a simple chained command list. Command chains are built up using the general structure, as shown in Figure 9-7.

Table 9-8. APBH DMA channel assignments

APBH DMA Channel #	Usage
0	GPMI0
1	GPMI1
2	GPMI2
3	GPMI3

A single command structure or channel command word specifies a number of operations to be performed by the DMA in support of a given device. Thus, the ARM platform can set up large units of work, chaining together many DMA channel command words, pass them off to the DMA, and have no further concern for the device until the DMA completion interrupt occurs. The goal is to have enough intelligence in the DMA and the devices to keep the interrupt frequency from any device below 1 KHz (arrival intervals longer than 1 ms).

A single command structure can issue 32-bit PIO write operations to key registers in the associated device using the same APB bus and controls that it uses to write DMA data bytes to the device. For example, this allows a chain of operations to be issued to the GPMI controller to send NAND command bytes, address bytes, and data transfers where the command and the address structure is completely under software control, but the

administration of that transfer is handled autonomously by the DMA. Each DMA structure can have 0–15 PIO words appended to it. The CMDPIOWORDS field, if non-zero, instructs the DMA engine to copy these words to the APB, beginning at the first register address offset for the peripheral and and incrementing the register offset each cycle.

The DMA master generates only normal read/write transfers to the APBH. It does *not* generate set, clear, or toggle (SCT) transfers.

After any requested PIO words have been transferred to the peripheral, the DMA examines the two-bit command field in the channel command structure. Table 9-9 shows the four commands implemented by the DMA.

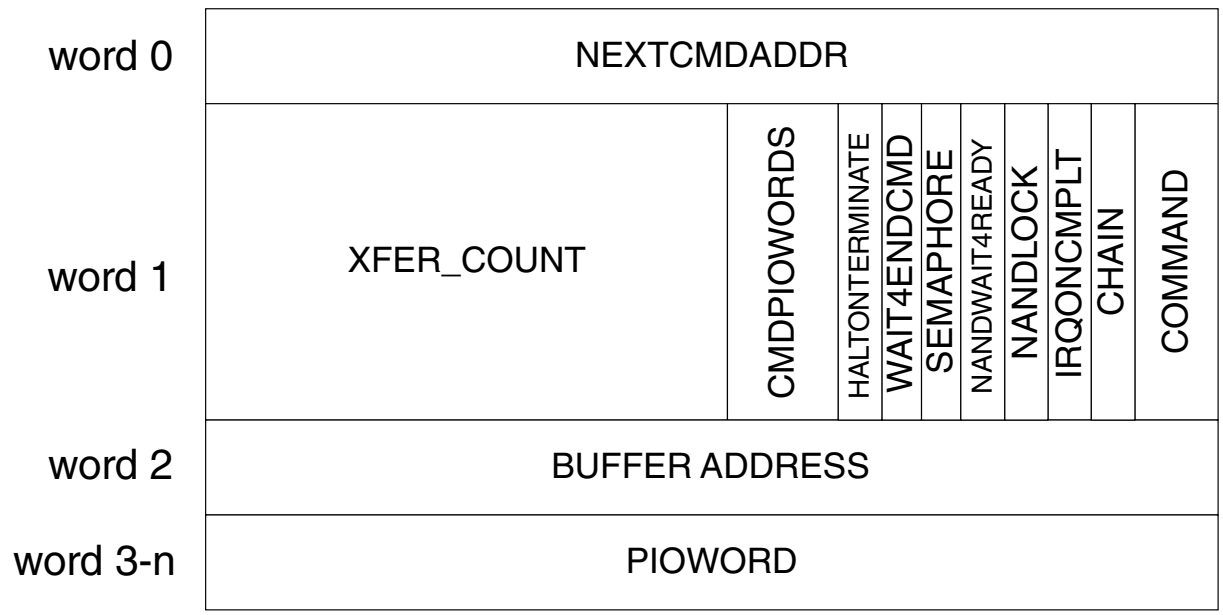

Figure 9-7. AHB-to-APBH Bridge DMA channel command structure

Table 9-9. APBH DMA commands

DMA Command	Usage
00	NO_DMA_XFER. Perform any requested PIO word transfers, but terminate the command before any DMA transfer.
01	DMA_WRITE. Perform any requested PIO word transfers, then perform a DMA transfer from the peripheral for the specified number of bytes.
10	DMA_READ. Perform any requested PIO word transfers and then perform a DMA transfer to the peripheral for the specified number of bytes.
11	DMA_SENSE. Perform any requested PIO word transfers, then perform a conditional branch to the next chained device. Follow the NEXTCMD_ADDR pointer if the peripheral sense is false. Follow the BUFFER_ADDRESS as a chain pointer if the peripheral sense line is true. This command becomes a no-operation for any channel other than a GPMI channel.

DMA_WRITE operations copy data bytes to the system memory (on-chip RAM or SDRAM) from the associated peripheral.

DMA_READ operations copy data bytes to the APB peripheral from the system memory. The DMA engine contains a shared byte aligner that aligns bytes from system memory to or from the peripherals. Peripherals always assume little-endian-aligned data arrives or departs on their 32-bit APB. The DMA_READ transfer uses the BUFFER_ADDRESS word in the command structure to point to the DMA data buffer to be read by the DMA_READ command.

The NO_DMA_XFER command is used to write PIO words to a device without performing any DMA data byte transfers. This command is useful in such applications as activating the NAND devices CHECKSTATUS operation. The check status command reads a status byte from the NAND device, performs an XOR and MASK against an expected value supplied as part of the PIO transfer. Once the read check completes (see NAND Read Status Polling Example), the NO_DMA_XFER command completes. The result in the peripheral is that its sense line is driven by the results of the comparison. The sense flip-flop is only updated by CHECKSTATUS for the device that is executed. At some future point, the chain contains a DMA command structure with the fourth and final command value, that is, the DMA_SENSE command.

As each DMA command completes, it triggers the DMA to load the next DMA command structure in the chain. The normal flow list of DMA commands is found by following the NEXTCMD_ADDR pointer in the DMA command structure. The DMA_SENSE command uses the DMA buffer pointer word of the command structure to point to an alternate DMA command structure chain or list. The DMA_SENSE command examines the sense line of the associated peripheral. If the sense line is false, then the DMA follows the standard list found whose next command is found from the pointer in the NEXTCMD_ADDR word of the command structure. If the sense line is true, then the DMA follows the alternate list whose next command is found from the pointer in the DMA Buffer Pointer word of the DMA_SENSE command structure (see Figure 9-7). The sense command ignores the CHAIN bit, so that both pointers must be valid when the DMA comes to a sense command.

If the wait-for-end-command bit (WAIT4ENDCMD) is set in a command structure, the DMA channel waits for the device to signal completion of a command by toggling the endcmd signal before proceeding to load and execute the next command structure. Then, if DECREMENT_SEMAPHORE is set, the semaphore is decremented after the end command is seen.

A detailed bit-field view of the DMA command structure is shown in the following table, which shows a field that specifies the number of bytes to be transferred by this DMA command. The transfer-count mechanism is duplicated in the associated peripheral, either as an implied or as a specified count in the peripheral.

Table 9-10. DMA channel command word in system memory

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	09	08	07	06	05	04	03	02	01	00
NEXT_COMMAND_ADDRESS																															
Number DMA Bytes to Transfer																Number PIO Words to Write							HALTONTERMINATE	WAIT4ENDCMD	DECREMENT SEMAPHORE	NANDwAIT4READY	NANDLOCK	IRQ_COMPLETE	CHAIN	COMMAND	
DMA Buffer or Alternate CCW																															
Zero or More PIO Words to Write to the Associated Peripheral Starting at its Base Address on the APBH Bus																															

Figure 9-7 also shows the CHAIN bit in bit 2 of the second word of the command structure. This bit is set to 1, if the NEXT_COMMAND_ADDRESS contains a pointer to another DMA command structure. If a null pointer (0) is loaded into the NEXT_COMMAND_ADDRESS, it is not detected by the DMA hardware. Only the CHAIN bit indicates whether a valid list exists beyond the current structure.

If the IRQ_COMPLETE bit is set in the command structure, then the last act of the DMA before loading the next command is to set the interrupt-status bit corresponding to the current channel. The sticky interrupt request bit in the DMA CSR remains set until cleared by the software. It can be used to interrupt the ARM platform.

The NAND_LOCK bit is monitored by the DMA channel arbiter. Once a NAND channel (from channel 0 to channel 3) succeeds in the arbiter with its NAND_LOCK bit set, then the arbiter ignores the other NAND channels until a command is completed in which the NAND_LOCK is not set. Notice that the semantic here is that the NAND_LOCK state is to limit scheduling of a non-locked DMA. A DMA channel can go from unlocked to locked in the arbiter at the beginning of a command when the NAND_LOCK bit is set. When the last DMA command of an atomic sequence is completed, the lock should be removed. To accomplish this, the last command does not have the NAND_LOCK bit. It is still locked in the atomic state within the arbiter when the command starts, so that it is the only NAND command that can be executed. At the end, it drops from the atomic state within the arbiter.

The NAND_WAIT4READY bit also has a special use for GPMI channels (from channel 0 to channel 3), i.e., the NAND device channels. The GPMI peripheral supplies a sample of the ready line from the NAND device. This ready value is used to hold off of a command with this bit set until the ready line is asserted to 1. Once the arbiter sees a command with a wait-for-ready set, it holds off that channel until ready is asserted.

Receiving an IRQ for HALTONTERMINATE (HOT) is a feature in the APBH DMA descriptor that allows GPMI to signal to the DMA engine that an error has occurred. If a commmand is stalled due to an error, a HOT signal is sent from the peripheral to the DMA engine and causes an IRQ after terminating the DMA descriptor being executed.

Therefore, it is recommended that software use this signal as follows:

- Always set HALTONTERMINATE to 1 in a DMA descriptor. That way, if a peripheral signals HOT, the transfer will end, leaving the peripheral block and the DMA engine synchronized (but at the end of a command).
- When an IRQ from an APBH channel is received, and the IRQ is determined to be due to an error (as opposed to an IRQONCOMPLETE interrupt) the software should:
  - Reset the channel.
  - Determine the error from error reporting in the peripheral block, then manage the error in the peripheral that is attached to that channel in whatever appropriate way exists for that device (software recovery, device reset, block reset, etc).

Each channel has an eight-bit counting semaphore that controls whether it is in the idle state. When the semaphore is non-zero, the channel is ready to run, process commands and perform DMA transfers. Whenever a command finishes its DMA transfer, it checks the DECREMENT_SEMAPHORE bit. If set, it decrements the counting semaphore. If the semaphore goes to 0 as a result, then the channel enters the idle state and remains there until the semaphore is incremented by the software. When the semaphore goes to non-zero and the channel is in its idle state, then it uses the value in the APBH_CHn_NXTCMDAR register (next command address register) to fetch a pointer to the next command to process.

NOTE

This is a double indirect case. This method allows the software to append to a running command list under the protection of the counting semaphore.

To start processing the first time, software creates the command list to be processed. It writes the address of the first command into the APBH_CHn_NXTCMDAR register, and then writes 1 to the counting semaphore in APBH_CHn_SEMA. The DMA channel loads APBH_CHn_CURCMDAR register and then enters the normal state machine processing for the next command. When the software writes a value to the counting semaphore, it is added to the semaphore count by hardware, protecting the case where both hardware and software are trying to change the semaphore on the same clock edge.

Software can examine the value of APBH_CHn_CURCMDAR at any time to determine the location of the command structure currently being processed.

9.5.2.3 NAND Read Status Polling Example

The following figure shows a more complicated scenario.

This subset of a NAND device workload shows that the first two command structures are used during the data-write phase of an NAND device write operation (CLE and ALE transfers omitted for clarity).

- After writing the data, one must wait until the NAND device status register indicates that the write charge has been transferred. This is built into the workload using a check status command in the NAND in a loop created from the next two DMA command structures.
- The NO_DMA_TRANSFER command is shown here performing the read check, followed by a DMA_SENSE command to branch the DMA command structure list, based on the status of a bit in the external NAND device.

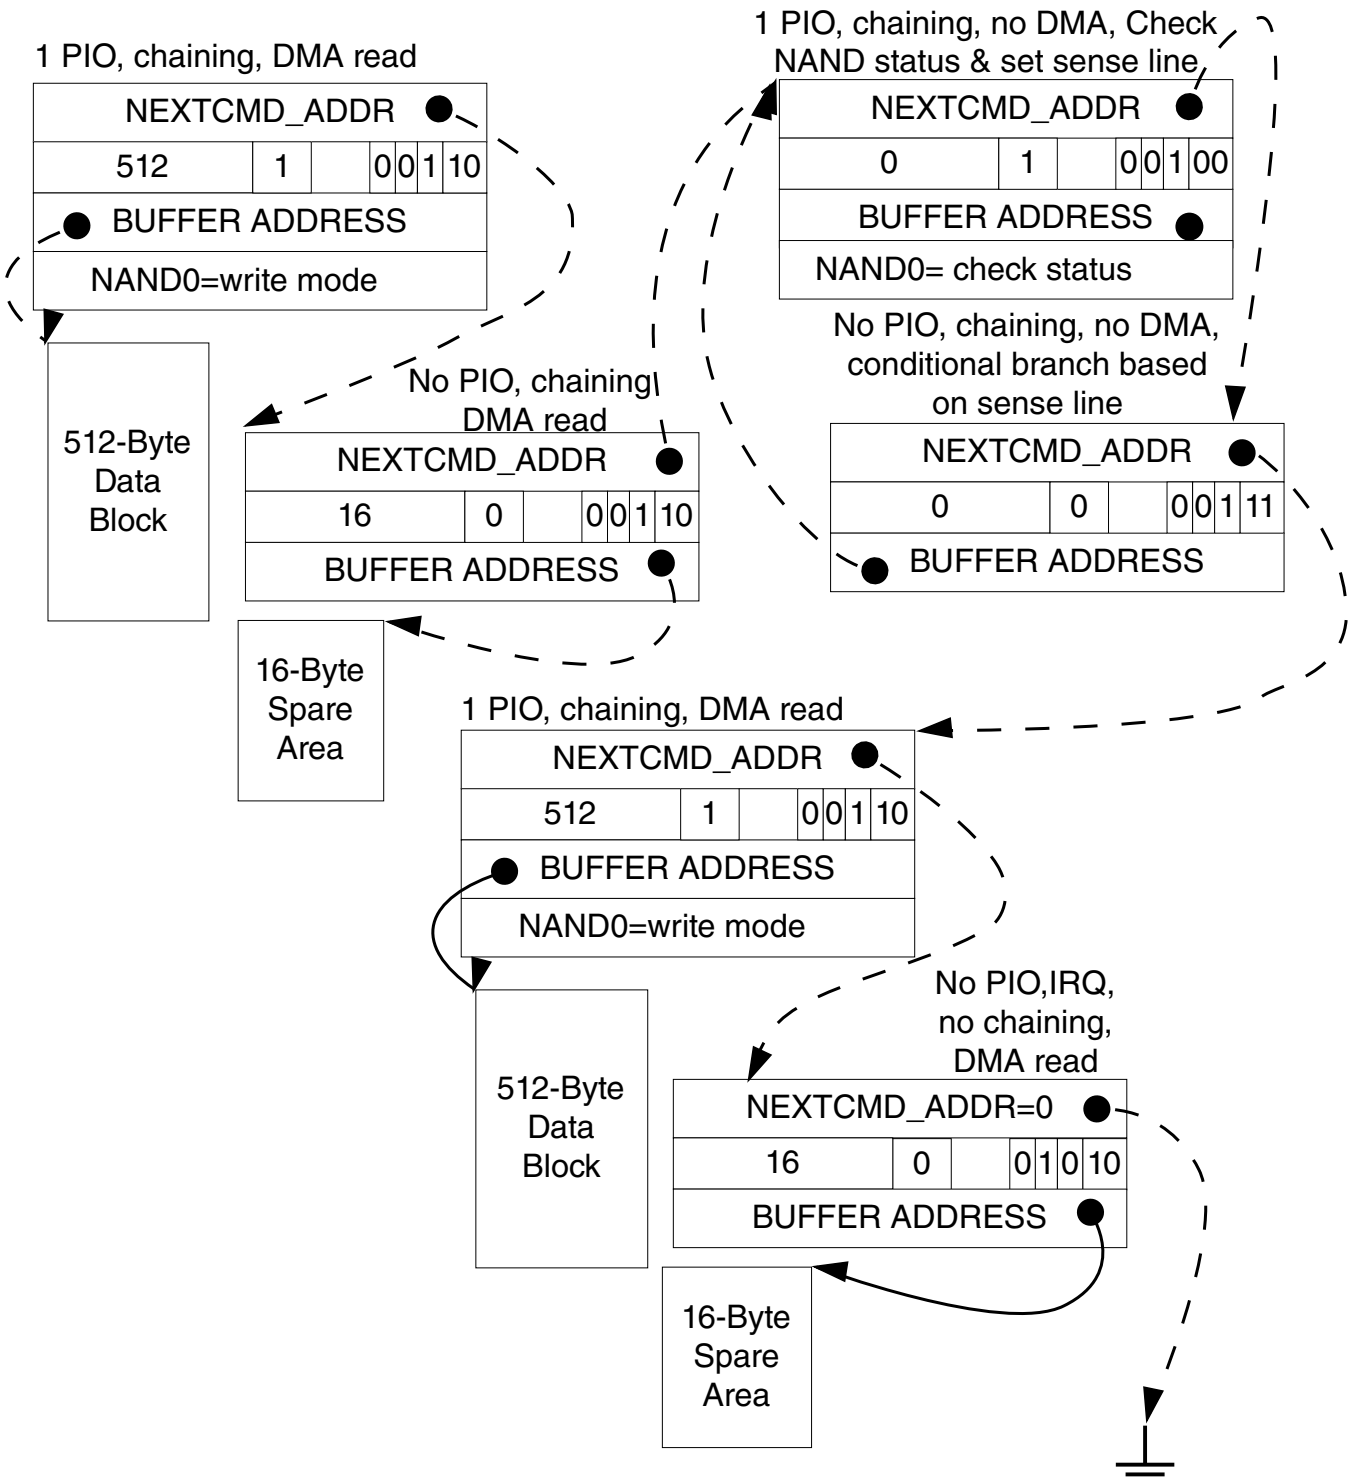

Figure 9-8. AHB-to-APBH Bridge DMA NAND Read Status Polling with DMA Sense Command

The example in the above figure shows the workload continuing immediately to the next NAND page transfer. However, one could perform a second sense operation to see if an error has occurred after the write. One could then point the sense command alternate branch at a NO_DMA_XFER command with the interrupt bit set. If the CHAIN bit is not

set on this failure branch, then the ARM platform is interrupted immediately, and the channel process is also immediately terminated in the presence of a workload-detected NAND error bit.

Note that each word of the three-word DMA command structure corresponds to a PIO register of the DMA that is accessible on the APBH bus. Normally, the DMA copies the next command structure onto these registers for processing at the start of each command by following the value of the pointer previously loaded into the NEXTCMD_ADDR register.

To start DMA processing for the first command, initialize the PIO registers of the desired channel, as follows:

- First, load the next command address register with a pointer to the first command to be loaded.
- Then, write 1 to the counting semaphore register. This causes the DMA to schedule the targeted channel for the DMA command structure load, just as if it had finished its previous command.

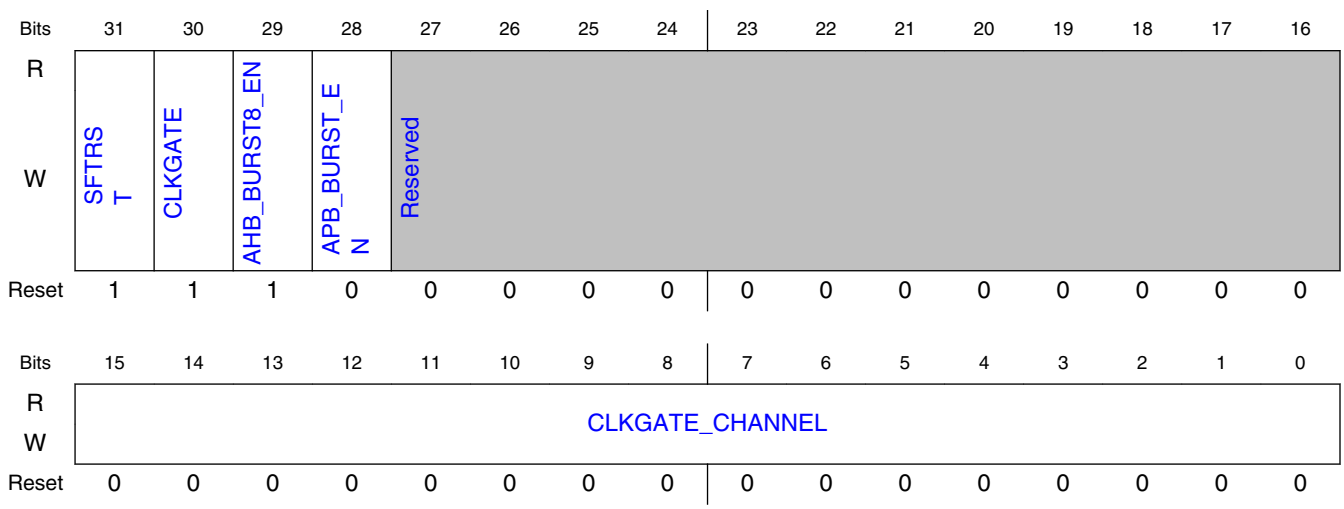
9.5.3.2 AHB to APBH Bridge Control and Status Register 0 (CTRL0)

9.5.3.2.1 Offset

Register	Offset	Description
CTRL0	0h	AHB to APBH Bridge Control and Status Register 0
CTRL0_SET	4h	Writing a 1 to a bit in this register sets the corresponding bit in CTRL0

Table continues on the next page...



Register	Offset	Description
CTRL0_CLR	8h	Writing a 1 to a bit in this register clears the corresponding bit in CTRL0
CTRL0_TOG	Ch	Writing a 1 to a bit in this register toggles the corresponding bit in CTRL0

9.5.3.2.2 Function

The APBH CTRL 0 provides overall control of the AHB to APBH bridge and DMA.

This register contains module softreset, clock gating, channel clock gating/freeze bits.

9.5.3.2.3 Diagram

9.5.3.2.4 Fields

Field	Function
31 SFTRST	SFTRST Set this bit to zero to enable normal APBH DMA operation. Set this bit to one (default) to disable clocking with the APBH DMA and hold it in its reset (lowest power) state. This bit can be turned on and then off to reset the APBH DMA block to its default state.
30 CLKGATE	CLKGATE This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.
29 AHB_BURST8_EN	AHB_BURST8_EN Set this bit to one (default) to enable AHB 8-beat burst. Set to zero to disable 8-beat burst on AHB interface.
28	APB_BURST_EN

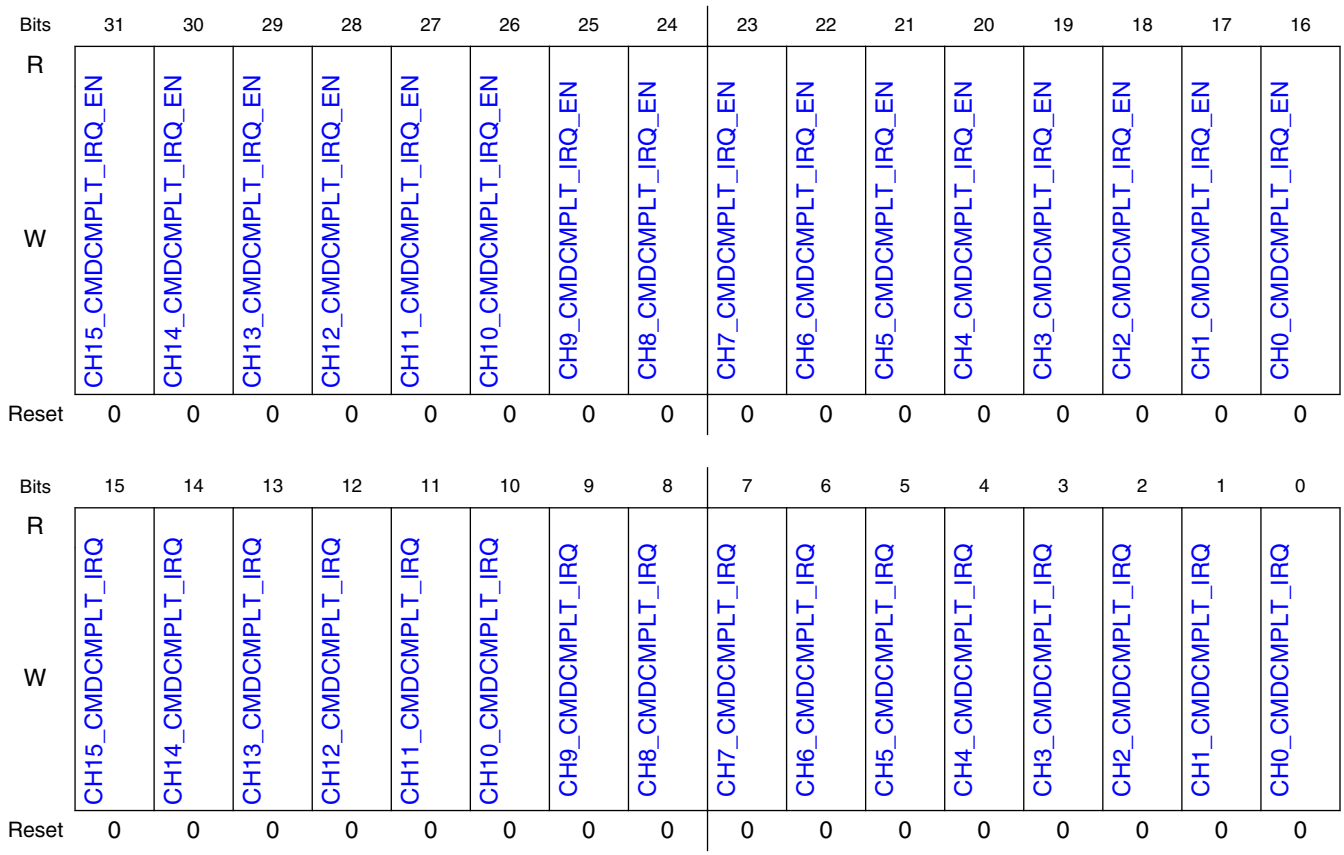
Table continues on the next page...

Field	Function
APB_BURST_EN	Set this bit to one to enable apb master do a continous transfers when a device request a burst dma. Set to zero will treat a burst dma request as 4/8 individual requests.
27-16 —	RSVD0 Reserved, always set to zero.
15-0 CLKGATE_CHANNEL	CLKGATE_CHANNEL These bits must be set to zero for normal operation of each channel. When set to one they gate off the individual clocks to the channels. 0000000000000001b - 0000000000000010b - 0000000000000100b - 0000000000001000b - 0000000000010000b - 0000000000100000b - 0000000001000000b - 0000000010000000b - 0000000100000000b -

9.5.3.3 AHB to APBH Bridge Control and Status Register 1 (CTRL1)

9.5.3.3.1 Offset

Register	Offset	Description
CTRL1	10h	AHB to APBH Bridge Control and Status Register 1
CTRL1_SET	14h	Writing a 1 to a bit in this register sets the corresponding bit in CTRL1
CTRL1_CLR	18h	Writing a 1 to a bit in this register clears the corresponding bit in CTRL1
CTRL1_TOG	1Ch	Writing a 1 to a bit in this register toggles the corresponding bit in CTRL1



9.5.3.3.2 Function

The APBH CTRL one provides overall control of the interrupts generated by the AHB to APBH DMA. This register contains the per channel interrupt status bits and the per channel interrupt enable bits. Each channel has a dedicated interrupt vector in the vectored interrupt controller.

EXAMPLE

```
// use bitfield write macro
BF_WR(APBH_CTRL1, CH5_CMDCMPLT_IRQ, 0);
// or, assign to register struct's bitfield
BF_APBH_CTRL1.CH5_CMDCMPLT_IRQ = 0;
```

9.5.3.3.3 Diagram

9.5.3.3.4 Fields

Field	Function
31 CH15_CMDCMPLT_IRQ_EN	CH15_CMDCMPLT_IRQ_EN Setting this bit enables the generation of an interrupt request for APBH DMA channel 15.
30 CH14_CMDCMPLT_IRQ_EN	CH14_CMDCMPLT_IRQ_EN Setting this bit enables the generation of an interrupt request for APBH DMA channel 14.
29 CH13_CMDCMPLT_IRQ_EN	CH13_CMDCMPLT_IRQ_EN Setting this bit enables the generation of an interrupt request for APBH DMA channel 13.
28 CH12_CMDCMPLT_IRQ_EN	CH12_CMDCMPLT_IRQ_EN Setting this bit enables the generation of an interrupt request for APBH DMA channel 12.
27	CH11_CMDCMPLT_IRQ_EN Setting this bit enables the generation of an interrupt request for APBH DMA channel 11.

Table continues on the next page...

Field	Function
CH11_CMDCMPLT_IRQ_EN	
26 CH10_CMDCMPLT_IRQ_EN	CH10_CMDCMPLT_IRQ_EN Setting this bit enables the generation of an interrupt request for APBH DMA channel 10.
25 CH9_CMDCMPLT_IRQ_EN	CH9_CMDCMPLT_IRQ_EN Setting this bit enables the generation of an interrupt request for APBH DMA channel 9.
24 CH8_CMDCMPLT_IRQ_EN	CH8_CMDCMPLT_IRQ_EN Setting this bit enables the generation of an interrupt request for APBH DMA channel 8.
23 CH7_CMDCMPLT_IRQ_EN	CH7_CMDCMPLT_IRQ_EN Setting this bit enables the generation of an interrupt request for APBH DMA channel 7.
22 CH6_CMDCMPLT_IRQ_EN	CH6_CMDCMPLT_IRQ_EN Setting this bit enables the generation of an interrupt request for APBH DMA channel 6.
21 CH5_CMDCMPLT_IRQ_EN	CH5_CMDCMPLT_IRQ_EN Setting this bit enables the generation of an interrupt request for APBH DMA channel 5.
20 CH4_CMDCMPLT_IRQ_EN	CH4_CMDCMPLT_IRQ_EN Setting this bit enables the generation of an interrupt request for APBH DMA channel 4.
19 CH3_CMDCMPLT_IRQ_EN	CH3_CMDCMPLT_IRQ_EN Setting this bit enables the generation of an interrupt request for APBH DMA channel 3.
18 CH2_CMDCMPLT_IRQ_EN	CH2_CMDCMPLT_IRQ_EN Setting this bit enables the generation of an interrupt request for APBH DMA channel 2.
17 CH1_CMDCMPLT_IRQ_EN	CH1_CMDCMPLT_IRQ_EN Setting this bit enables the generation of an interrupt request for APBH DMA channel 1.
16 CH0_CMDCMPLT_IRQ_EN	CH0_CMDCMPLT_IRQ_EN Setting this bit enables the generation of an interrupt request for APBH DMA channel 0.
15 CH15_CMDCMPLT_IRQ	CH15_CMDCMPLT_IRQ Interrupt request status bit for APBH DMA Channel 15. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
14 CH14_CMDCMPLT_IRQ	CH14_CMDCMPLT_IRQ Interrupt request status bit for APBH DMA Channel 14. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
13 CH13_CMDCMPLT_IRQ	CH13_CMDCMPLT_IRQ Interrupt request status bit for APBH DMA Channel 13. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.

Table continues on the next page...

Field	Function
12 CH12_CMDCMPLT_IRQ	CH12_CMDCMPLT_IRQ Interrupt request status bit for APBH DMA Channel 12. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
11 CH11_CMDCMPLT_IRQ	CH11_CMDCMPLT_IRQ Interrupt request status bit for APBH DMA Channel 11. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
10 CH10_CMDCMPLT_IRQ	CH10_CMDCMPLT_IRQ Interrupt request status bit for APBH DMA Channel 10. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
9 CH9_CMDCMPLT_IRQ	CH9_CMDCMPLT_IRQ Interrupt request status bit for APBH DMA Channel 9. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
8 CH8_CMDCMPLT_IRQ	CH8_CMDCMPLT_IRQ Interrupt request status bit for APBH DMA Channel 8. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
7 CH7_CMDCMPLT_IRQ	CH7_CMDCMPLT_IRQ Interrupt request status bit for APBH DMA channel 7. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
6 CH6_CMDCMPLT_IRQ	CH6_CMDCMPLT_IRQ Interrupt request status bit for APBH DMA channel 6. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
5 CH5_CMDCMPLT_IRQ	CH5_CMDCMPLT_IRQ Interrupt request status bit for APBH DMA channel 5. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
4 CH4_CMDCMPLT_IRQ	CH4_CMDCMPLT_IRQ Interrupt request status bit for APBH DMA channel 4. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
3 CH3_CMDCMPLT_IRQ	CH3_CMDCMPLT_IRQ Interrupt request status bit for APBH DMA channel 3. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
2 CH2_CMDCMPLT_IRQ	CH2_CMDCMPLT_IRQ Interrupt request status bit for APBH DMA channel 2. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
1 CH1_CMDCMPLT_IRQ	CH1_CMDCMPLT_IRQ Interrupt request status bit for APBH DMA channel 1. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
0 CH0_CMDCMPLT_IRQ	CH0_CMDCMPLT_IRQ Interrupt request status bit for APBH DMA channel 0. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.

9.5.3.4 AHB to APBH Bridge Control and Status Register 2 (CTRL2)

9.5.3.4.1 Offset

Register	Offset	Description
CTRL2	20h	AHB to APBH Bridge Control and Status Register 2
CTRL2_SET	24h	Writing a 1 to a bit in this register sets the corresponding bit in CTRL2
CTRL2_CLR	28h	Writing a 1 to a bit in this register clears the corresponding bit in CTRL2
CTRL2_TOG	2Ch	Writing a 1 to a bit in this register toggles the corresponding bit in CTRL2

9.5.3.4.2 Function

The APBH CTRL 2 provides channel error interrupts generated by the AHB to APBH DMA. This register contains the per channel interrupt status bits and the per channel interrupt enable bits. Each channel has a dedicated interrupt vector in the vectored interrupt controller.

EXAMPLE

```
// use bitfield write macro
BF_WR(APBH_CTRL1, CH5_CMDCMPLT_IRQ, 0);
// or, assign to register struct's bitfield
BF_APBH_CTRL1.CH5_CMDCMPLT_IRQ = 0;
```

	0 - channel early termination. 0b - An early termination from the device causes error IRQ. 1b - An AHB bus error causes error IRQ.
21 CH5_ERROR_STATUS	CH5_ERROR_STATUS Error status bit for APBX DMA Channel 5. Valid when corresponding Error IRQ is set. 1 - AHB bus error 0 - channel early termination. 0b - An early termination from the device causes error IRQ. 1b - An AHB bus error causes error IRQ.
20 CH4_ERROR_STATUS	CH4_ERROR_STATUS Error status bit for APBX DMA Channel 4. Valid when corresponding Error IRQ is set. 1 - AHB bus error 0 - channel early termination. 0b - An early termination from the device causes error IRQ. 1b - An AHB bus error causes error IRQ.
19 CH3_ERROR_STATUS	CH3_ERROR_STATUS Error status bit for APBX DMA Channel 3. Valid when corresponding Error IRQ is set. 1 - AHB bus error 0 - channel early termination. 0b - An early termination from the device causes error IRQ. 1b - An AHB bus error causes error IRQ.
18 CH2_ERROR_STATUS	CH2_ERROR_STATUS Error status bit for APBX DMA Channel 2. Valid when corresponding Error IRQ is set. 1 - AHB bus error 0 - channel early termination. 0b - An early termination from the device causes error IRQ. 1b - An AHB bus error causes error IRQ.
17 CH1_ERROR_STATUS	CH1_ERROR_STATUS Error status bit for APBX DMA Channel 1. Valid when corresponding Error IRQ is set. 1 - AHB bus error 0 - channel early termination. 0b - An early termination from the device causes error IRQ. 1b - An AHB bus error causes error IRQ.
16 CH0_ERROR_STATUS	CH0_ERROR_STATUS Error status bit for APBX DMA Channel 0. Valid when corresponding Error IRQ is set. 1 - AHB bus error 0 - channel early termination. 0b - An early termination from the device causes error IRQ. 1b - An AHB bus error causes error IRQ.
15 CH15_ERROR_IRQ	CH15_ERROR_IRQ Error interrupt status bit for APBH DMA Channel 15. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.

Table continues on the next page...

Field	Function
14 CH14_ERROR_IRQ	CH14_ERROR_IRQ Error interrupt status bit for APBH DMA Channel 14. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
13 CH13_ERROR_IRQ	CH13_ERROR_IRQ Error interrupt status bit for APBH DMA Channel 13. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
12 CH12_ERROR_IRQ	CH12_ERROR_IRQ Error interrupt status bit for APBH DMA Channel 12. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
11 CH11_ERROR_IRQ	CH11_ERROR_IRQ Error interrupt status bit for APBH DMA Channel 11. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
10 CH10_ERROR_IRQ	CH10_ERROR_IRQ Error interrupt status bit for APBH DMA Channel 10. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
9 CH9_ERROR_IRQ	CH9_ERROR_IRQ Error interrupt status bit for APBH DMA Channel 9. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
8 CH8_ERROR_IRQ	CH8_ERROR_IRQ Error interrupt status bit for APBH DMA Channel 8. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
7 CH7_ERROR_IRQ	CH7_ERROR_IRQ Error interrupt status bit for APBX DMA Channel 7. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
6 CH6_ERROR_IRQ	CH6_ERROR_IRQ Error interrupt status bit for APBX DMA Channel 6. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
5 CH5_ERROR_IRQ	CH5_ERROR_IRQ Error interrupt status bit for APBX DMA Channel 5. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
4 CH4_ERROR_IRQ	CH4_ERROR_IRQ Error interrupt status bit for APBX DMA Channel 4. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
3 CH3_ERROR_IRQ	CH3_ERROR_IRQ Error interrupt status bit for APBX DMA Channel 3. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
2 CH2_ERROR_IRQ	CH2_ERROR_IRQ Error interrupt status bit for APBX DMA Channel 2. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
1 CH1_ERROR_IRQ	CH1_ERROR_IRQ Error interrupt status bit for APBX DMA Channel 1. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
0 CH0_ERROR_IRQ	CH0_ERROR_IRQ Error interrupt status bit for APBX DMA Channel 0. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.

9.5.3.5 AHB to APBH Bridge Channel Register (CHANNEL_CTRL)

9.5.3.5.1 Offset

Register	Offset	Description
CHANNEL_CTRL	30h	AHB to APBH Bridge Channel Register
CHANNEL_CTRL_SET	34h	Writing a 1 to a bit in this register sets the corresponding bit in CHANNEL_CTRL
CHANNEL_CTRL_CLR	38h	Writing a 1 to a bit in this register clears the corresponding bit in CHANNEL_CTRL
CHANNEL_CTRL_TOG	3Ch	Writing a 1 to a bit in this register toggles the corresponding bit in CHANNEL_CTRL

9.5.3.5.2 Function

The APBH CHANNEL CTRL provides reset/freeze control of each DMA channel. This register contains individual channel reset/freeze bits.

9.5.3.5.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table continues on the next page...

Field	Function
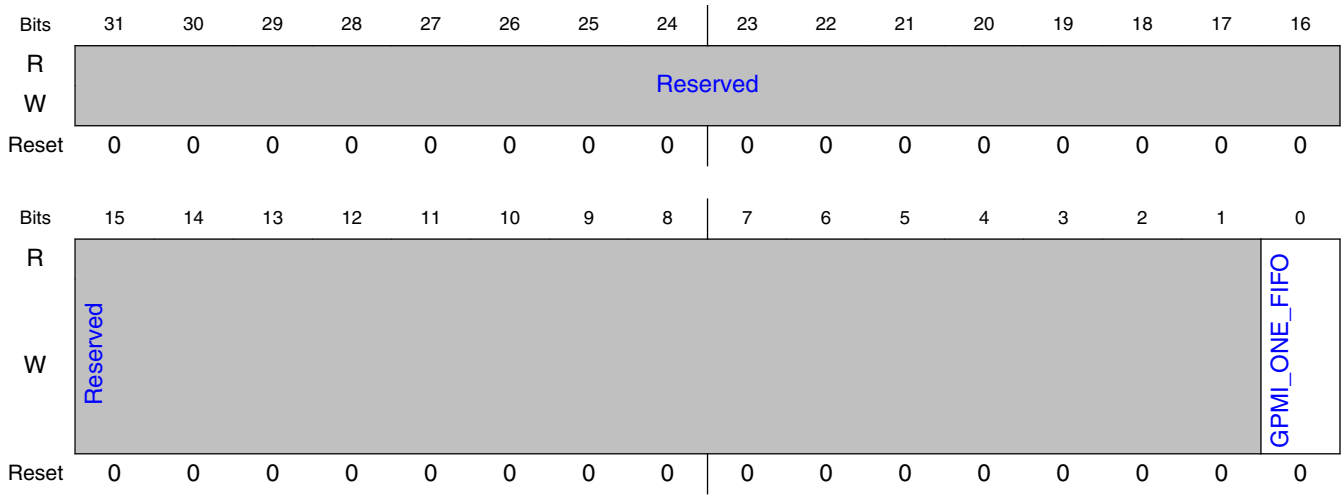
9-8 CH4	CH4 DMA burst size for GPMI channel 4. Do not change. GPMI only support burst size 4.
7-6 CH3	CH3 DMA burst size for GPMI channel 3. Do not change. GPMI only support burst size 4.
5-4 CH2	CH2 DMA burst size for GPMI channel 2. Do not change. GPMI only support burst size 4.
3-2 CH1	CH1 DMA burst size for GPMI channel 1. Do not change. GPMI only support burst size 4.
1-0 CH0	CH0 DMA burst size for GPMI channel 0. Do not change. GPMI only support burst size 4.

9.5.3.7 AHB to APBH DMA Debug Register (DEBUG)

9.5.3.7.1 Offset



Register	Offset
DEBUG	60h

9.5.3.7.2 Function

This register is for debug purpose.

The debug register is for internal use only. Not recommend for customer useage.

9.5.3.7.3 Diagram

9.5.3.7.4 Fields

Field	Function
31-1 —	- Reserved, always set to zero.
0 GPMI_ONE_FIFO	GPMI_ONE_FIFO Set to 0ne and the 8 GPMI channels will share the DMA FIFO, and when set to zero, the 8 GPMI channels will use its own DMA FIFO.

9.5.3.8 APBH DMA Channel n Current Command Address Register (CH0_CURCMDAR - CH15_CURCMDAR)

9.5.3.8.1 Offset

For a = 0 to 15:

Register	Offset
CHa_CURCMDAR	100h + (a × 70h)

9.5.3.8.2 Function

The APBH DMA channel n current command address register points to the multiword command that is currently being executed. Commands are threaded on the command address.

APBH DMA Channel n is controlled by a variable sized command structure. This register points to the command structure currently being executed.

EXAMPLE

```
// read the whole register, since there is only one field
pCurCmd = (apbh_chn_cmd_t *) APBH_CHn_CURCMDAR_RD(0);
// or, use multi-register bitfield read macro
pCurCmd = (apbh_chn_cmd_t *) BF_RDn(APBH_CHn_CURCMDAR, 0, CMD_ADDR);
// or, assign from bitfield of indexed register's struct
pCurCmd = (apbh_chn_cmd_t *) APBH_CHn_CURCMDAR(0).CMD_ADDR;
```

9.5.3.8.3 Diagram

9.5.3.8.4 Fields

Field	Function
31-0 CMD_ADDR	CMD_ADDR Pointer to command structure currently being processed for channel n.

9.5.3.9 APBH DMA Channel n Next Command Address Register (CH0_NXTCMDAR - CH15_NXTCMDAR)

9.5.3.9.1 Offset

For a = 0 to 15:

Register	Offset
CHa_NXTCMDAR	110h + (a × 70h)

9.5.3.9.2 Function

The APBH DMA Channel n Next Command Address register contains the address of the next multiword command to be executed. Commands are threaded on the command address. Set CHAIN to 1 in the DMA command word to process command lists.

APBH DMA Channel n is controlled by a variable sized command structure. Software loads this register with the address of the first command structure to process and increments the Channel n semaphore to start processing. This register points to the next command structure to be executed when the current command is completed.

EXAMPLE

```
// write the entire register, since there is only one field
APBH_CHn_NXTCMDAR_WR(0, (reg32_t) pCommandTwoStructure);
// or, use multi-registerbitfield write macro
BF_WRn(APBH_CHn_NXTCMDAR, 0, (reg32_t) pCommandTwoStructure);
// or, assign to bitfield of indexed register's struct
APBH_CHn_NXTCMDAR(0).CMD_ADDR = (reg32_t) pCommandTwoStructure;
```

9.5.3.9.3 Diagram

9.5.3.9.4 Fields

Field	Function
31-0 CMD_ADDR	CMD_ADDR Pointer to next command structure for channel n.

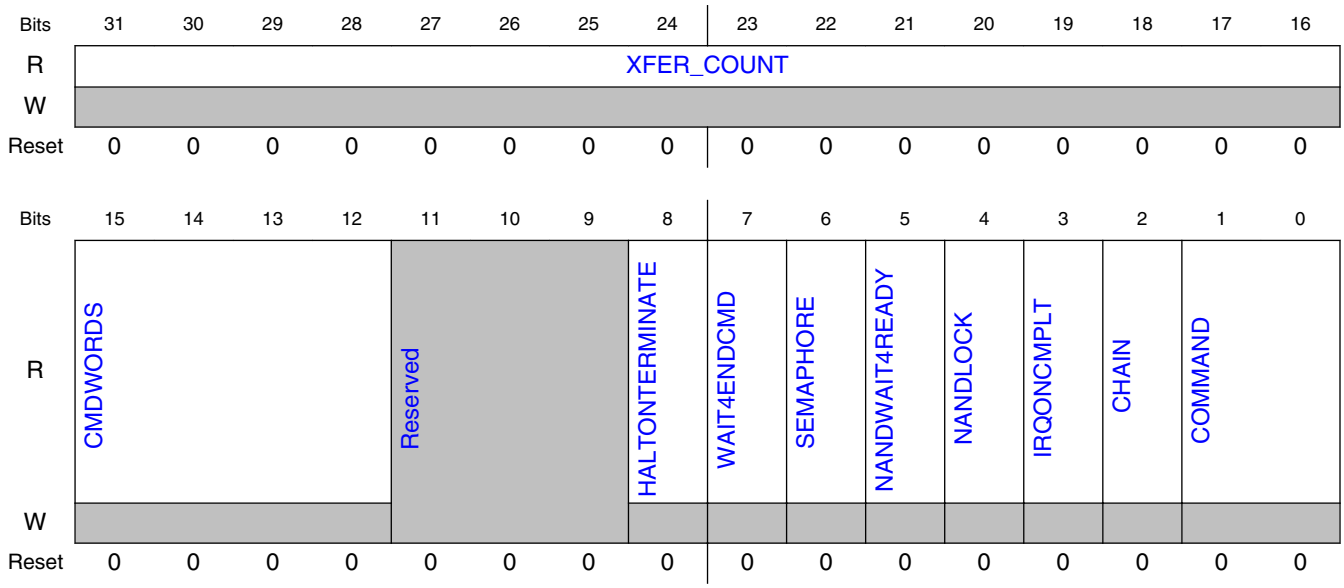
9.5.3.10 APBH DMA Channel n Command Register (CH0_CMD - CH15_CMD)

9.5.3.10.1 Offset

For a = 0 to 15:

Register	Offset
CHa_CMD	120h + (a × 70h)

9.5.3.10.2 Function



The APBH DMA Channel n command register specifies the DMA transaction to perform for the current command chain item.

The command register controls the overall operation of each DMA command for this channel. It includes the number of bytes to transfer to or from the device, the number of APB PIO command words included with this command structure, whether to interrupt at command completion, whether to chain an additional command to the end of this one and whether this transfer is a read or write DMA transfer.

EXAMPLE

```
apbh_chn_cmd_t dma_cmd;
// transfer 512 bytes
dma_cmd.XFER_COUNT = 512;
// transfer to system memory from peripheral device
dma_cmd.COMMAND = BV_APBH_CHn_CMD_COMMAND__DMA_WRITE;
// chain an additional command structure on to the list
dma_cmd.CHAIN = 1;
// generate an interrupt on completion of this command structure
dma_cmd.IRQONCMPLT = 1;
```

9.5.3.10.3 Diagram

9.5.3.10.4 Fields

Field	Function
31-16 XFER_COUNT	XFER_COUNT This field indicates the number of bytes to transfer to or from the appropriate PIO register in the GPMI0 device. A value of 0 indicates a 64 KBytes transfer.
15-12 CMDWORDS	CMDWORDS This field indicates the number of command words to send to the GPMI0, starting with the base PIO address of the GPMI0 control register and incrementing from there. Zero means transfer NO command words
11-9 —	- Reserved, always set to zero.
8 HALTONTERMINATE	HALTONTERMINATE A value of one indicates that the channel will immeditately terminate the current descriptor and halt the DMA channel if a terminate signal is set. A value of 0 will still cause an immediate terminate of the channel if the terminate signal is set, but the channel will continue as if the count had been exhausted, meaning it will honor IRQONCMPLT, CHAIN, SEMAPHORE, and WAIT4ENDCMD.
7 WAIT4ENDCMD	WAIT4ENDCMD A value of one indicates that the channel will wait for the end of command signal to be sent from the APBH device to the DMA before starting the next DMA command.
6 SEMAPHORE	SEMAPHORE A value of one indicates that the channel will decrement its semaphore at the completion of the current command structure. If the semaphore decrements to zero, then this channel stalls until software increments it again.
5	NANDWAIT4READY

Table continues on the next page...

Field	Function
NANDWAIT4READY	A value of one indicates that the NAND DMA channel will will wait until the NAND device reports "ready" before executing the command. It is ignored for non-NAND DMA channels.
4 NANDLOCK	NANDLOCK A value of one indicates that the NAND DMA channel will remain "locked" in the arbiter at the expense of other NAND DMA channels. It is ignored for non-NAND DMA channels.
3 IRQONCMPLT	IRQONCMPLT A value of one indicates that the channel will cause the interrupt status bit to be set upon completion of the current command, i.e. after the DMA transfer is complete.
2 CHAIN	CHAIN A value of one indicates that another command is chained onto the end of the current command structure. At the completion of the current command, this channel will follow the pointer in APBH_CHn_CMDAR to find the next command.
1-0 COMMAND	COMMAND This bitfield indicates the type of current command: 00b - Perform any requested PIO word transfers but terminate command before any DMA transfer. 01b - Perform any requested PIO word transfers and then perform a DMA transfer from the peripheral for the specified number of bytes. 10b - Perform any requested PIO word transfers and then perform a DMA transfer to the peripheral for the specified number of bytes. 11b - Perform any requested PIO word transfers and then perform a conditional branch to the next chained device. Follow the NEXCMD_ADDR pointer if the perpheral sense is true. Follow the BUFFER_ADDRESS as a chain pointer if the peripheral sense line is false.

9.5.3.11 APBH DMA Channel n Buffer Address Register (CH0_BAR - CH15_BAR)

9.5.3.11.1 Offset

For a = 0 to 15:

Register	Offset
CHa_BAR	130h + (a × 70h)

9.5.3.11.2 Function

The APBH DMA Channel n buffer address register contains a pointer to the data buffer for the transfer. For immediate forms, the data is taken from this register. This is a byte address which means transfers can start on any byte boundary.

This register holds a pointer to the data buffer in system memory. After the command values have been read into the DMA controller and the device controlled by this channel, then the DMA transfer will begin, to or from the buffer pointed to by this register.

EXAMPLE

```
apbh_chn_bar_t dma_data;
dma_data.ADDRESS = (reg32_t) pDataBuffer;
```

9.5.3.11.3 Diagram

9.5.3.11.4 Fields

Field	Function
31-0 ADDRESS	ADDRESS Address of system memory buffer to be read or written over the AHB bus.

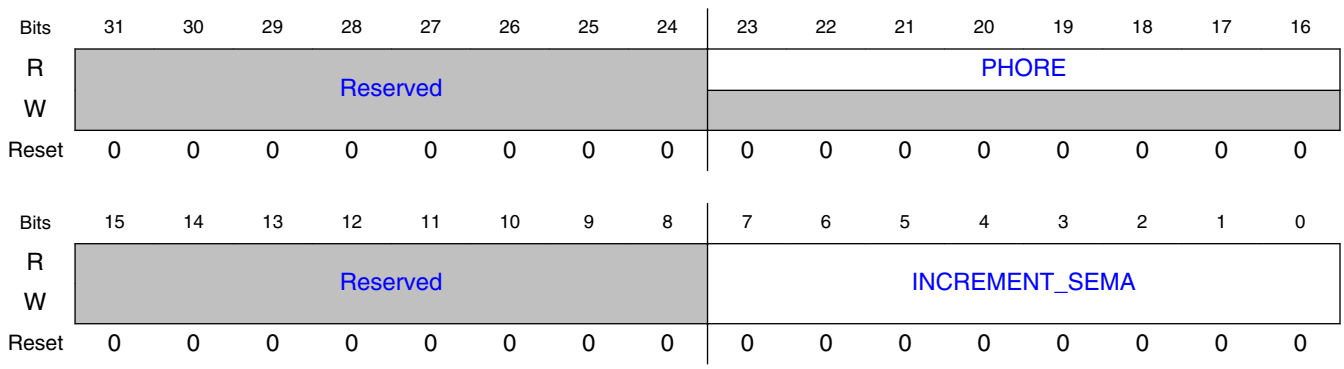
9.5.3.12 APBH DMA Channel n Semaphore Register (CH0_SEMA - CH15_SEMA)

9.5.3.12.1 Offset

For a = 0 to 15:

Register	Offset
CHa_SEMA	140h + (a × 70h)

9.5.3.12.2 Function



The APBH DMA Channel n semaphore register is used to synchronize the ARM platform instruction stream and the DMA chain processing state.

Each DMA channel has an 8 bit counting semaphore that is used to synchronize between the program stream and and the DMA chain processing. DMA processing continues until the DMA attempts to decrement a semaphore that has already reached a value of zero. When the attempt is made, the DMA channel is stalled until software increments the semaphore count.

EXAMPLE

```
// increment semaphore by two
BF_WR(APBH_CHn_SEMA, 0, INCREMENT_SEMA, 2);
// get instantaneous value
current_sema = BF_RD(APBH_CHn_SEMA, 0, PHORE);
```

9.5.3.12.3 Diagram

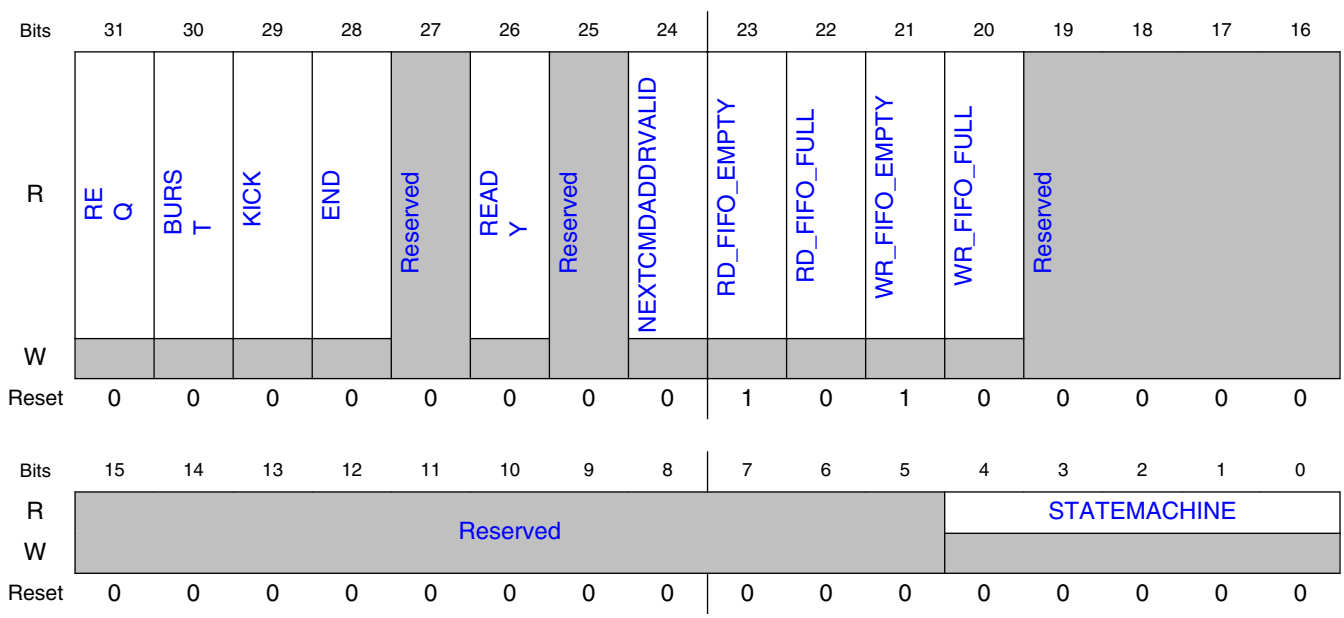
9.5.3.12.4 Fields

Field	Function
31-24 —	- Reserved, always set to zero.
23-16 PHORE	PHORE This read-only field shows the current (instantaneous) value of the semaphore counter.
15-8 —	- Reserved, always set to zero.
7-0 INCREMENT_SEMA	INCREMENT_SEMA The value written to this field is added to the semaphore count in an atomic way such that simultaneous software adds and DMA hardware substracts happening on the same clock are protected. This bit field reads back a value of 0x00. Writing a value of 0x02 increments the semaphore count by two, unless the DMA channel decrements the count on the same clock, then the count is incremented by a net one.

9.5.3.13 AHB to APBH DMA Channel n Debug Information (CH0_DEBUG1 - CH15_DEBUG1)

9.5.3.13.1 Offset

For a = 0 to 15:



Register	Offset
CHa_DEBUG1	150h + (a × 70h)

9.5.3.13.2 Function

This register gives debug visibility into the APBH DMA Channel n state machine and controls.

This register allows debug visibility of the APBH DMA Channel n.

9.5.3.13.3 Diagram

9.5.3.13.4 Fields

Field	Function
31 REQ	REQ This bit reflects the current state of the DMA Request Signal from the APB device
30 BURST	BURST This bit reflects the current state of the DMA Burst Signal from the APB device
29 KICK	KICK This bit reflects the current state of the DMA Kick Signal sent to the APB Device
28 END	END This bit reflects the current state of the DMA End Command Signal sent from the APB Device
27 —	SENSE This bit is reserved for this DMA Channel and always reads 0.
26 READY	READY This bit is reserved for this DMA Channel and always reads 0.
25 —	LOCK This bit is reserved for this Channel and always reads 0.
24 NEXTCMDADDRVALID	NEXTCMDADDRVALID This bit reflects the internal bit which indicates whether the channel's next command address is valid.
23 RD_FIFO_EMPTY	RD_FIFO_EMPTY This bit reflects the current state of the DMA Channel's Read FIFO Empty signal.
22 RD_FIFO_FULL	RD_FIFO_FULL This bit reflects the current state of the DMA Channel's Read FIFO Full signal.
21 WR_FIFO_EMPTY	WR_FIFO_EMPTY This bit reflects the current state of the DMA Channel's Write FIFO Empty signal.
20 WR_FIFO_FULL	WR_FIFO_FULL This bit reflects the current state of the DMA Channel's Write FIFO Full signal.
19-5 —	RSVD1 Reserved
4-0 STATEMACHINE	STATEMACHINE PIO Display of the DMA Channel n state machine state. 00000b - This is the idle state of the DMA state machine. 00001b - State in which the DMA is waiting to receive the first word of a command. 00010b - State in which the DMA is waiting to receive the third word of a command. 00011b - State in which the DMA is waiting to receive the second word of a command. 00100b - The state machine processes the descriptor command field in this state and branches accordingly. 00101b - The state machine waits in this state for the PIO APB cycles to complete. 00110b - State in which the DMA is waiting to receive the fourth word of a command, or waiting to receive the PIO words when PIO count is greater than 1.

Field	Function
	00111b - This state determines whether another PIO cycle needs to occur before starting DMA transfers. 01000b - During a read transfers, the state machine enters this state waiting for the last bytes to be pushed out on the APB. 01001b - When an AHB read request occurs, the state machine waits in this state for the AHB transfer to complete. 01100b - During DMA Write transfers, the state machine waits in this state until the AHB master arbiter accepts the request from this channel. 01101b - During DMA Read transfers, the state machine waits in this state until the AHB master arbiter accepts the request from this channel. 01110b - Upon completion of the DMA transfers, this state checks the value of the Chain bit and branches accordingly. 01111b - The state machine goes to this state after the DMA transfers are complete, and determines what step to take next. 10100b - When a terminate signal is set, the state machine enters this state until the current AHB transfer is completed. 10101b - When the Wait for Command End bit is set, the state machine enters this state until the DMA device indicates that the command is complete. 11100b - During DMA Write transfers, the state machine waits in this state until the AHB master completes the write to the AHB memory space. 11101b - If HALTONTERMINATE is set and a terminate signal is set, the state machine enters this state and effectively halts. A channel reset is required to exit this state 11110b - If the Chain bit is a 0, the state machine enters this state and effectively halts. 11111b - When the NAND Wait for Ready bit is set, the state machine enters this state until the GPMI device indicates that the external device is ready.

9.5.3.14 AHB to APBH DMA Channel n Debug Information (CH0_DEBUG2 - CH15_DEBUG2)

9.5.3.14.1 Offset

For a = 0 to 15:

Register	Offset
CHa_DEBUG2	160h + (a × 70h)

9.5.3.14.2 Function

This register gives debug visibility for the APB and AHB byte counts for DMA Channel n.

This register allows debug visibility of the APBH DMA Channel n.

9.5.3.14.3 Diagram

23-16 MINOR	MINOR Fixed read-only value reflecting the MINOR field of the RTL version.
15-0 STEP	STEP Fixed read-only value reflecting the stepping of the RTL version.

9.6 62BIT Correcting ECC Accelerator (BCH)

9.6.1 Overview

The hardware ECC accelerator provides a forward error-correction function for improving the reliability of various storage media that may be attached to the device.

For example, NAND flash devices use a spare area to store ECC codes to correct some hard bit errors in data stored within the device, allowing higher device yields and, therefore, lower NAND device costs.

The Bose, Ray-Chaudhuri, Hocquenghem (BCH) Encoder and Decoder module is capable of correcting from 2 to 62 single bit errors within a block of data no larger than about 1900 bytes (512 bytes or 1024 bytes are typical) in applications such as protecting data and resources stored on modern NAND flash devices. The correction level in the BCH block is programmable to provide flexibility for varying applications and configurations of flash page size. The design can be programmed to encode protection of

2 to 62 bit errors when writing flash and to correct the corresponding number of errors on decode. The correction level when decoding MUST be programmed to the same correction level as was used during the encode phase.

BCH-codes are a type of block-code, which implies that all error-correction is performed over a block of N-symbols. The BCH operation will be performed over GF(2^{13} = 8192) or GF(2^{14} = 16384), which is the Galois Field consisting of 8191 or 16383 one-bit symbols. BCH-encoding (or encode for any block-code) can be performed by two algorithms: systematic encoding or multiplicative encoding. Systematic encoding is the process of reading all the symbols which constitute a block, dividing continuously these symbols by the generator polynomial for the GF(8192) or GF(16384) and appending the resulting ***t*** parity symbols to the block to create a BCH codeword (where ***t*** is the number of correctable bits).

The BCH encode process creates *t**13 (or *t**14)-bit parity symbols for each data block when the data is written to the flash device. The parity symbols are written to the flash device after the corresponding data block, and together these are collectively called the codeword. The codeword can be used during the decode process to correct errors that occur in either the data or parity blocks.

The BCH decoder processes code words in a 4-step fashion:

1. Syndrome Calculation (SC): This is the process of reading in all of the symbols of the codeword and continuously dividing by the generator polynomial for the field. 2**t* syndromes must be calculated for each codeword and inspection of the syndromes determines if there are errors: a non-zero set of syndromes indicates one or more errors. This process is implemented parallel hardware to minimize processing time since it must be done every time the decode is performed.
2. Key Equation Solver (KES): The syndromes represent 2t-linear equations with 2t-unknown variables. The process of solving these equations and selecting from the numerous solutions constitutes the KES module. When the KES block completes its operations, it generates an error locator polynomial (sigma) that is used in the proceeding block to determine the locations and values of the errors.
3. Chien Search (CS): This block takes input from the KES block and uses the Chien Algorithm for finding the locations of the errors based on the error locator polynomial. The method basically involves substituting all 8191 symbols from the GF(8192) or 16383 symbols from the GF(16383) into the locator polynomial. All evaluations that produce a zero solution indicate locations of the various errors. Since each located error corresponds to a single bit, the bit in the original data may be corrected by simply flipping the polarity of the incorrect location.

4. Correction: this block has to convert the symbol index and mask information to memory byte indexes and masks.

The BCH block, shown in the figure, was designed to operate in a pipelined fashion to maximize throughput. Aside from the initial latency to fill the pipeline stages, the BCH throughput is about 7/4 cycles/byte. Thus, the bottleneck in performing NAND reads and error corrections is the BCH rate. Current GPMI read rates are approximately 1/2 cycles/byte maximally for the current generation of NAND flash. Fortunately, BCH has a different master clock from GPMI, this gives some flexibility to match the throughput rate. The CPU is not directly involved in generating parity symbols, checking for errors, or correcting them.

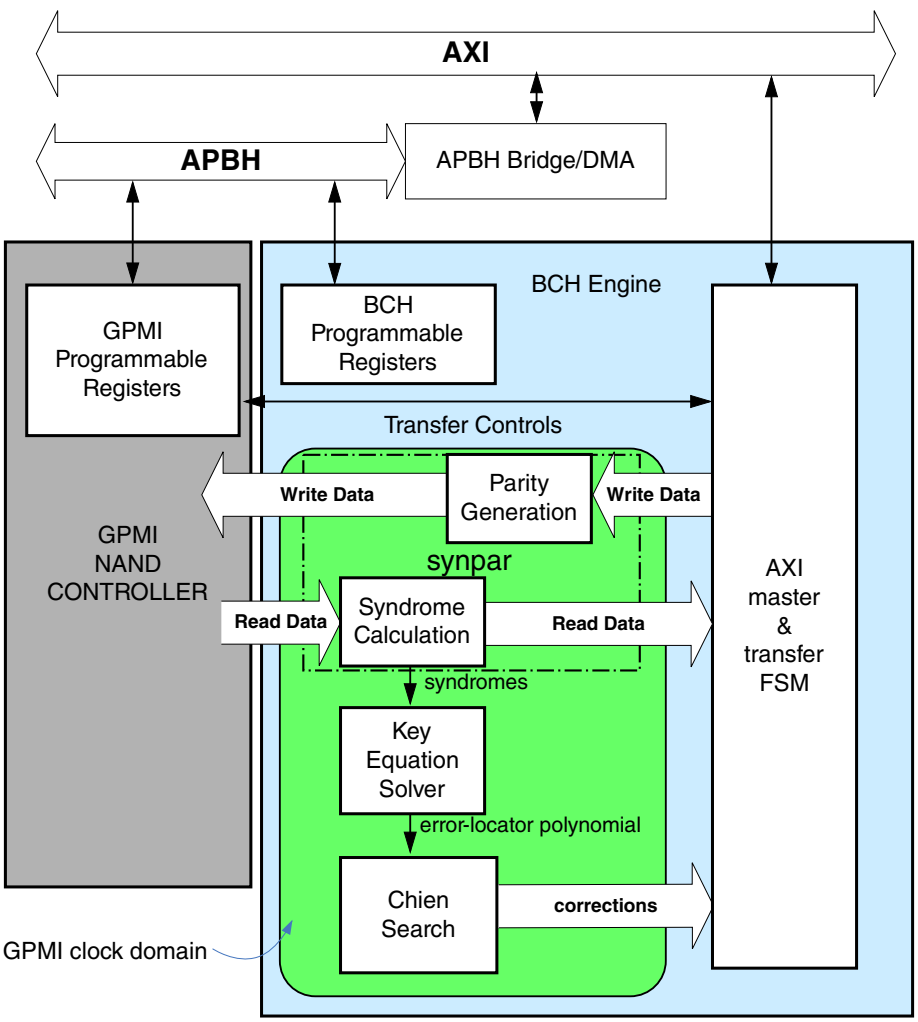

Figure 9-9. Hardware BCH Accelerator

9.6.2 Functional Description

9.6.2.1 Operation

Before performing any NAND flash read or write operations, software should first program the BCH's flash layout registers (see Flash Page Layout) to specify how data is to be formatted on the flash device. The BCH hardware allows full programmability over the flash page layout to enable users flexibility in balancing ECC correction levels and ever-changing flash page sizes.

To initiate a NAND Flash write, software will program a GPMI DMA operation. The DMA need only program the GPMI control registers (and handle the requisite flash addressing handshakes) since the BCH will handle all data operations using its AXI bus interface. The BCH will then send the data to the GPMI controller to be written to flash as it computes the parity symbols. At the end of each data block the BCH will insert the parity symbols into the data stream so that the GPMI sees only a continuous stream of data to be written.

NAND Flash read operations operate in a similar manner. As the GPMI controller reads the device, all data is sent to the BCH hardware for error detection/correction. The BCH controller writes all incoming read data to system memory and in parallel computes the syndromes used to detect bit errors. If errors are detected within a block, the BCH hardware activates the error correction logic to determine where bit errors have occurred and ultimately correct them in the data buffer in system memory. After an entire flash page has been read and corrected, the BCH will signal an interrupt to the CPU.

The figure below indicates how data read from the GPMI is operated on within the BCH hardware. As the BCH receives data from the GPMI (top row), it is written to memory by the BCH's Bus Interface Unit (BIU) (second row). For blocks requiring correction, the KES logic will be activated after the entire block has been received. Once the error locator polynomial has been computed, the corrections are determined by the Chien Search and fed back to the BIU, which performs a read, modify, write operation on the buffer in memory to correct the data.

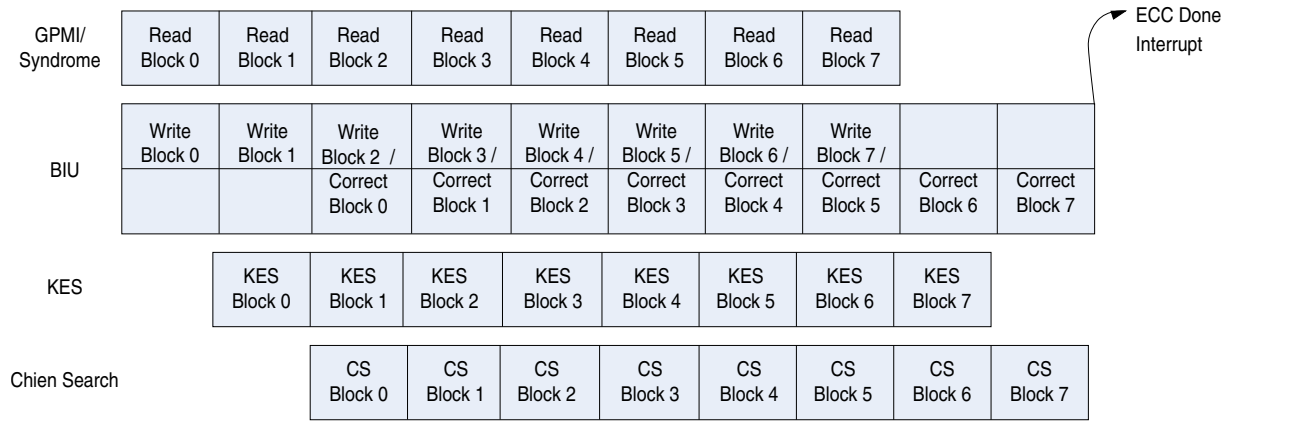

Figure 9-10. Block Pipeline while Reading Flash

9.6.2.1.1 BCH Limitations and Assumptions

- The BCH is programmable to support 2 to 62 bit error correction. ECC0 is supported as a pass-through, non-correcting mode.
- Data block sizes must be a multiple of 4 bytes and be aligned in system memory.
- The BCH supports a programmable number of metadata/auxiliary data bytes, from 0 to 255.
- Metadata will be written at the beginning of the flash page to facilitate fast access for filesystem operations.
- Metadata may be treated as an independent block for ECC purposes or combined with the first data block to conserve bits in the flash.
- The BCH does not support a partial page write (this can be accomplished by programming the BCH layout registers such that the BCH only sees a portion of the page).
- Flash read operations can read the entire page or the first block on the page.
- The BCH also supports a memory-to-memory mode of operation that does not require the use of DMA or the GPMI.

9.6.2.1.2 Flash Page Layout

The BCH supports a fully programmable flash page layout. The BCH maintains four independent layout registers that can describe four completely different NAND devices or layouts.

When the BCH initiates an operation, it selects one of the layouts by using the chip select as an index into the BCH_LAYOUTSELECT register that determines which layout should be used for the operation.

Three possible (generic) flash layout schemes are supported, as indicated in the figure below. (In each case, the metadata size may also be programmed to 0 bytes). Metadata may either be combined with the first block of data or the size of the first data block can be programmed to 0 to allow the metadata to be protected by its own ECC parity bits.

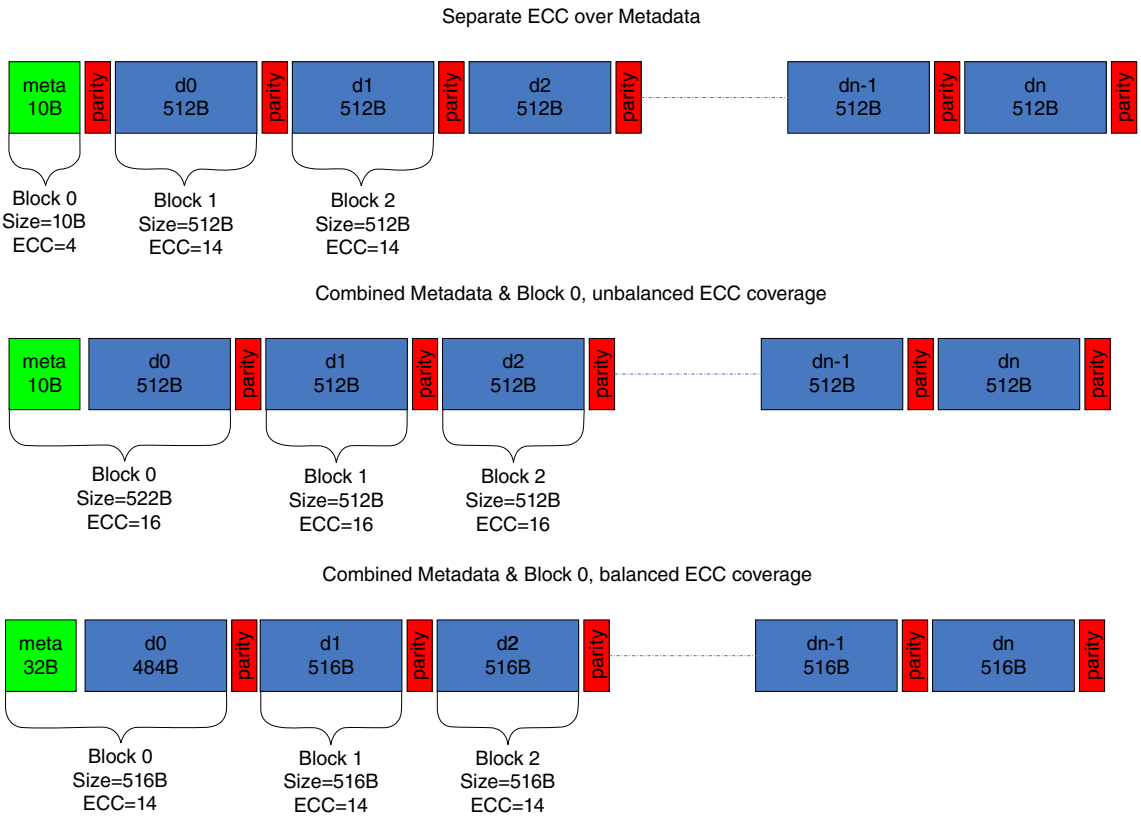

Figure 9-11. FLASH Page Layout Options

Each layout is determined by a pair of registers that define the following parameters:

- DATA0_SIZE: Indicates the number of data bytes in the first block on the page (this should not include parity or metadata bytes). This should be set to 0 when the metadata is to be covered separately with its own ECC. This must be a multiple of 4 bytes.
- ECC0: Indicates the ECC level to be used for the first block on the flash (data0+metadata).
- META_SIZE: Indicates the number of bytes (from 0-255) that are stored as metadata.

- NBLOCKS: Indicates the number of subsequent DATAN blocks on the flash, or the number of blocks following the DATA0 block.
- DATAN_SIZE: Indicates the number of data bytes in all subsequent data blocks. This MUST be a multiple of 4 bytes.
- ECCN: Indicates the ECC level to be used for the subsequent data blocks.
- GF0 or GFN: Indicates the Galois field the meta / data blocks are using
- PAGE_SIZE: Indicates the total number of bytes available per page on the physical flash device. This includes the spare area and is typically 4096+128, 4096+218, or 2048+64 bytes.

9.6.2.1.3 Determining the ECC layout for a device

Since the BCH is programmable, a system can trade off ECC levels for flash size and layout configurations.

The following examples indicate how to determine a valid layout based on the required storage space and flash size. For all cases, the size of the parity will be 13 (or 14 for GF(2^{14}))×ECC level ***bits***-- so for ECC8, 13 (or 14) bytes are required (per block).

9.6.2.1.3.1 4K+218 flash, 10 bytes metadata, 512 byte data blocks, separate metadata, Assuming GF(2^{13})

In this case, we have 8 data blocks each consisting of 512 bytes. Since the flash has 218 spare bytes (1744 bits), first estimate an ECC level for the data blocks by first subtracting the number of metadata bytes from the spare bytes (218 - 10 = 208 bytes = 1664 bits) then dividing the number of bits by 8 (number of blocks) and then by 13 (bits per ECC level).

(218 - 10) × 8 = 1664/13(8) = 16

Therefore all the data blocks could be covered by ECC16 if the metadata had no parity. This isn't acceptable, so assume ECC14 for all the data blocks. Now calculate the number of free bits for the metadata parity as

1664 - (14) × 13 × 8 = 208

Therefore, 208 bits remain for metadata parity. Dividing by 13 (bits/ECC) gives 16, so the metadata can be covered with ECC16. The settings for this device would then be

Table 9-11. Settings for 4K+218 FLASH

Setting	Value
PAGE_SIZE	4096+218=4314=0x10DA
META_SIZE	10=0x0A
DATA0_SIZE	0
ECC0	16=0x10
GF0	GF(2^{13})
DATAN_SIZE	512=0x200 (in register interface, assigned as 0x80)
ECCN	14=0x0E
GFN	GF(2^{13})
NBLOCKS	8

9.6.2.1.3.2 4K+128 flash, 10 bytes metadata, 1024 byte data blocks, separate metadata, assuming GF(2^{13}) for data and GF(2^{14}) for metadata

This flash will have 118 bytes available for ECC (after subtracting the metadata size), therefore, 994 bits.

Dividing by 4×14 (number of blocks × ECC level) we get 17.75, therefore we can support ECC16 on the data blocks. The number of free spare bits becomes 944 - 16 × 4 × 14 = 944 - 896 = 48, divided by 13 = 3.69, therefore the metadata can be also covered by ECC2.

Table 9-12. Settings for 4K+128 FLASH

Setting	Value
PAGE_SIZE	4096+128=4224=0x1080
META_SIZE	10=0x0A
DATA0_SIZE	0
ECC0	2
GF0	GF(2^{13})
DATAN_SIZE	1024=0x400 (in register interface, assigned as 0x100)
ECCN	16
GFN	GF(2^{14})
NBLOCKS	4

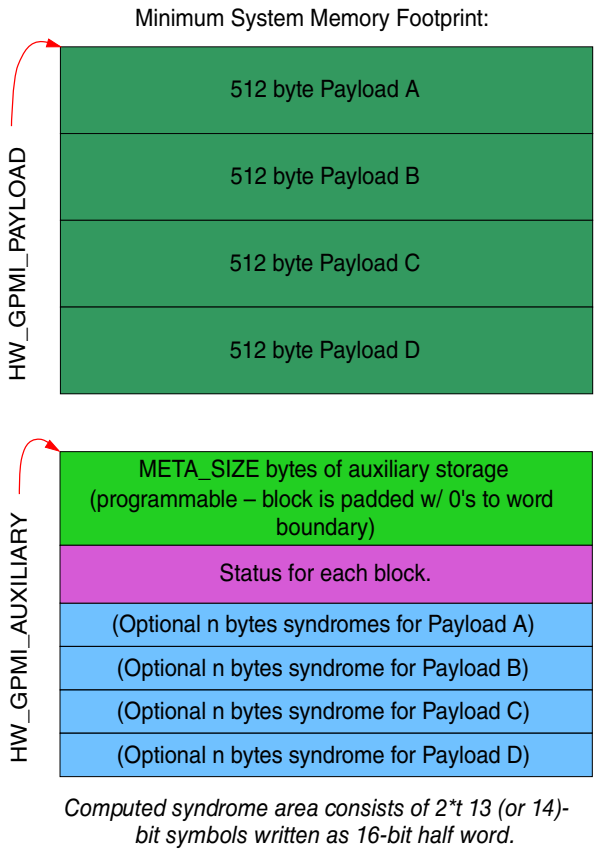
In this case, there will be additional unused spare bits, with the BCH will pad out with zeros.

9.6.2.1.4 Data Buffers in System Memory

While the data on the flash is interleaved with parity symbols, the BCH assumes that the data buffers in memory are contiguous.

Metadata read from the flash will be stored to the location pointed to by the GPMI_AUXILIARY register and data will be written to the address specified in the GPMI_PAYLOAD register as is shown in the following figure where the block length is 512 bytes for example. Since the number of blocks on a flash page is programmable, the BCH also writes individual block correction status to the auxiliary pointer at the word-aligned address following the end of the metadata. Optionally, the computed syndromes may also be written to the auxiliary area if the DEBUGSYNDROME bit is set in the control register.

As blocks complete processing, the bus master will accumulate the status for each block and write it to the auxiliary data buffer following the metadata. The metadata area will be padded with 0's until the next word boundary and the status for blocks 0-3 will be written to the next word. The status for subsequent blocks will then be written to the buffer. The status for the first block (metadata block) is also stored in the STATUS_BLK0 register in the BCH_STATUS register. The completion codes for the blocks are indicated in the Table 9-13. Note that the definition of the bytes and their ordering in the auxiliary and payload storage areas are user defined. When this data is read back from the flash and put into memory, it will resemble the original buffer that was written out to the flash.



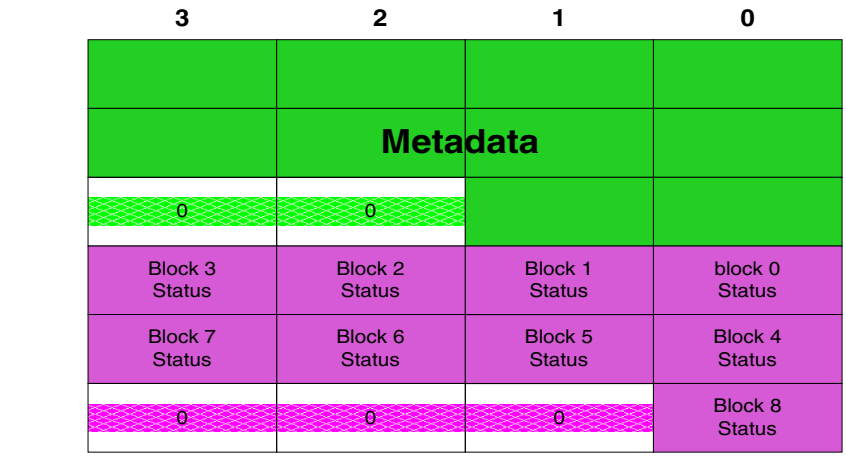


Figure 9-12. BCH Data Buffers in Memory

Table 9-13. Status Block Completion Codes

Code	Description
0xFF	Block is erased
0xFE	Block is uncorrectable
0x00	No errors found
0x01-0x3E	Number of errors corrected

The following figure shows the layout of the bytes within the status field.

Status bytes are allocated based on the NBLOCKS programmed into the flash format register. The number of status bytes are computed by NBLOCK+1. The status area will be padded with zeros to the next word boundary.

Syndrome data written for debug purposes follows the end of the status block.

Figure 9-13. Memory-to-Memory Operations

9.6.2.2 Memory to Memory (Loopback) Operation

The BCH supports a memory-to-memory mode of operation where both the encoded and decoded buffers reside in system memory.

This can be useful for applications where data must be protected by ECC, but the storage device does not reside on the GPMI bus.

The BCH operation in memory to memory mode is much simpler than in GPMI mode since DMAs are not required to manage the operation. Instead, software simply writes the BCH_DATAPTR and BCH_METAPTR with the addresses of the data and metadata (auxiliary) buffers and the BCH_ENCODEPTR with the address of the buffer for encoded data. To initiate the operation, software simply sets the M2M_ENCODE and M2M_ENABLE bits in the control register. The BCH can be programmed to either issue an interrupt at the end of the operation or software may poll the status bits for completion.

Memory to memory decode operations work in a similar manner. The encoded data address is written to the BCH_ENCODEPTR and the data and meta pointers are written to buffers that correspond to the desired decoded data addresses. To initiate a decode, software must set the M2M_ENCODE bit to 0 while writing the M2M_ENABLE bit. Note that the addresses written to the BCH_DATAPTR, BCH_METAPTR and BCH_ENCODEPTR registers should always be aligned on a 4 byte boundary. In other words, the 2 lower bits of the address should always be written with zeros.

9.6.2.3 Programming the BCH/GPMI Interfaces

Programming the BCH for NAND operations consists largely of disabling the soft reset and clock bits (SFTRST and CLKGATE) from the BCH_CTRL register and then programming the flash layout registers to correspond to the format of the attached NAND device(s).

The BCH_LAYOUTSELECT register should also be programmed to map the chip select of each attached device into one of the four layout registers.

The bulk of the programming is actually applied to the GPMI through PIO operations embedded in DMA command structures. The DMA will perform all the requisite handshaking with the GPMI interface to negotiate the address portion of the transfer, then the BCH will handle all the movement of data from memory to the GPMI (writes) or the GPMI to memory (reads). The BCH will direct all data blocks to the buffer pointed to by the PAYLOAD_BUFFER and the metadata will be written to the AUXILIARY_BUFFER. Both of these registers are located in the GPMI PIO data space and are communicated to the BCH hardware at the beginning of the transfer. Thus, the normal multi-NAND DMA based device interleaving is preserved, that is, four NANDs on four separate chip selects can be scheduled for read or write operations using the BCH. Whichever channel finishes its ready wait first and enters the DMA arbiter with its lock bit set owns the GPMI command interface and through it owns the BCH resources for the duration of its processing.

9.6.2.3.1 BCH Encoding for NAND Writes

The BCH encoder flowchart in Figure 9-14 shows the detailed steps involved in programming and using the BCH encoder. This flowchart shows how to use the BCH block with the GPMI.

To use the BCH encoder with the GPMI's DMA, create a DMA command chain containing ten descriptor structures, as shown in Figure 9-16 and detailed in the DMA structure code example that follows it in DMA Structure Code Example. The ten descriptors perform the following tasks:

1. Disable the BCH block (in case it was enabled) and issue NAND write setup command byte (under CLE) and address bytes (under ALE).
2. Configure and enable the BCH and GPMI blocks to perform the NAND write.
3. Disable the BCH block and issue NAND write execute command byte (under CLE).
4. Wait for the NAND device to finish writing the data by watching the ready signal.

5. Check for NAND timeout through PSENSE.
6. Issue NAND status command byte (under CLE).
7. Read the status and compare against expected.
8. If status is incorrect or incomplete, branch to error handling descriptor chain.
9. Otherwise, write is complete and emit GPMI interrupt.

```

9.6.2.3.1.2 Using the BCH Encoder

To use the BCH encoder, first turn off the module-wide soft reset bit in both the GPMI and BCH blocks before starting any DMA activity.

Turning off the soft reset must take place by itself, prior to programming the rest of the control registers. Turn off the BCH bus master soft reset bit. Turn off the clock gate bits.

Program the remainder of the GPMI, BCH and APBH DMA as follows:

```
// bring APBH out of reset
APBH_CTRL0_CLR(BM_APBH_CTRL0_SFRST);
APBH_CTRL0_CLR(BM_APBH_CTRL0_CLKGATE);

// bring BCH out of reset
BCH_CTRL_CLR(BM_BCH_CTRL_SFTRST);
BCH_CTRL_CLR(BM_BCH_CTRL_CLKGATE);

// bring gpmi out of reset
GPMI_CTRL0_CLR(BM_GPMI_CTRL0_SFTRST);
GPMI_CTRL0_CLR(BM_GPMI_CTRL0_CLKGATE);
GPMI_CTRL1_SET(BM_GPMI_CTRL1_DEV_RESET | // deassert reset
                   BM_GPMI_CTRL1_BCH_MODE  );    // enable BCH mode

// enable pinctrl
PINCTRL_CTRL_WR(0x00000000);

// enable gpmi pins
PINCTRL_MUXSEL0_CLR(0x0000ffff);    // data bits
PINCTRL_MUXSEL1_CLR(0x03ffffff);    // control bits
PINCTRL_MUXSEL8_CLR(0x0003f3ff);    // control bits
PINCTRL_MUXSEL8_SET(0x00015155);    // control bits
```

Note that for writing NANDs (ECC encoding), only GPMI DMA command complete interrupts are used. The BCH engine is used for writing to the NAND but may optionally produces an interrupt. From the sample code in DMA Structure Code Example :

- DMA descriptor 1 prepares the NAND for data write by using the GPMI to issue a write setup command byte under CLE, then sends a 5-byte address under ALE. The BCH engine is disabled and not used for these commands.
- DMA descriptor 2 enables the BCH engine for encoding to begin the initial writing of the NAND data by specifying where the data and auxiliary payload are coming from in system memory.

- DMA descriptor 3 issues the write commit command byte under CLE to the NAND.
- DMA descriptor 4 waits for the NAND to complete the write commit/transfer by watching the NAND's ready line status. This descriptor relinquishes the NANDLOCK on the GPMI to enable the other DMA channels to initiate NAND transactions on different NAND CS lines.
- DMA descriptor 6 issues a NAND status command byte under "CLE" to check the status of the NAND device following the page write.
- DMA descriptor 7 reads back the NAND status and compares the status with an expected value. If there are differences, then the DMA processing engine follows an error-handling DMA descriptor path.
- DMA descriptor 8 disables the BCH engine and emits a GPMI interrupt to indicate that the NAND write has been completed.

9.6.2.3.2 BCH Decoding for NAND Reads

When a page is read from NAND flash, BCH syndromes will be computed and, if correctable errors are found, they will be corrected on a per block basis within the NAND page. This decoding process is fully overlapped with other NAND data reads and with CPU execution. The BCH decoder flowchart in the figure below shows the steps involved in programming the decoder. The hardware flow of reading and decoding a 4096-byte page is shown in Figure 9-18.

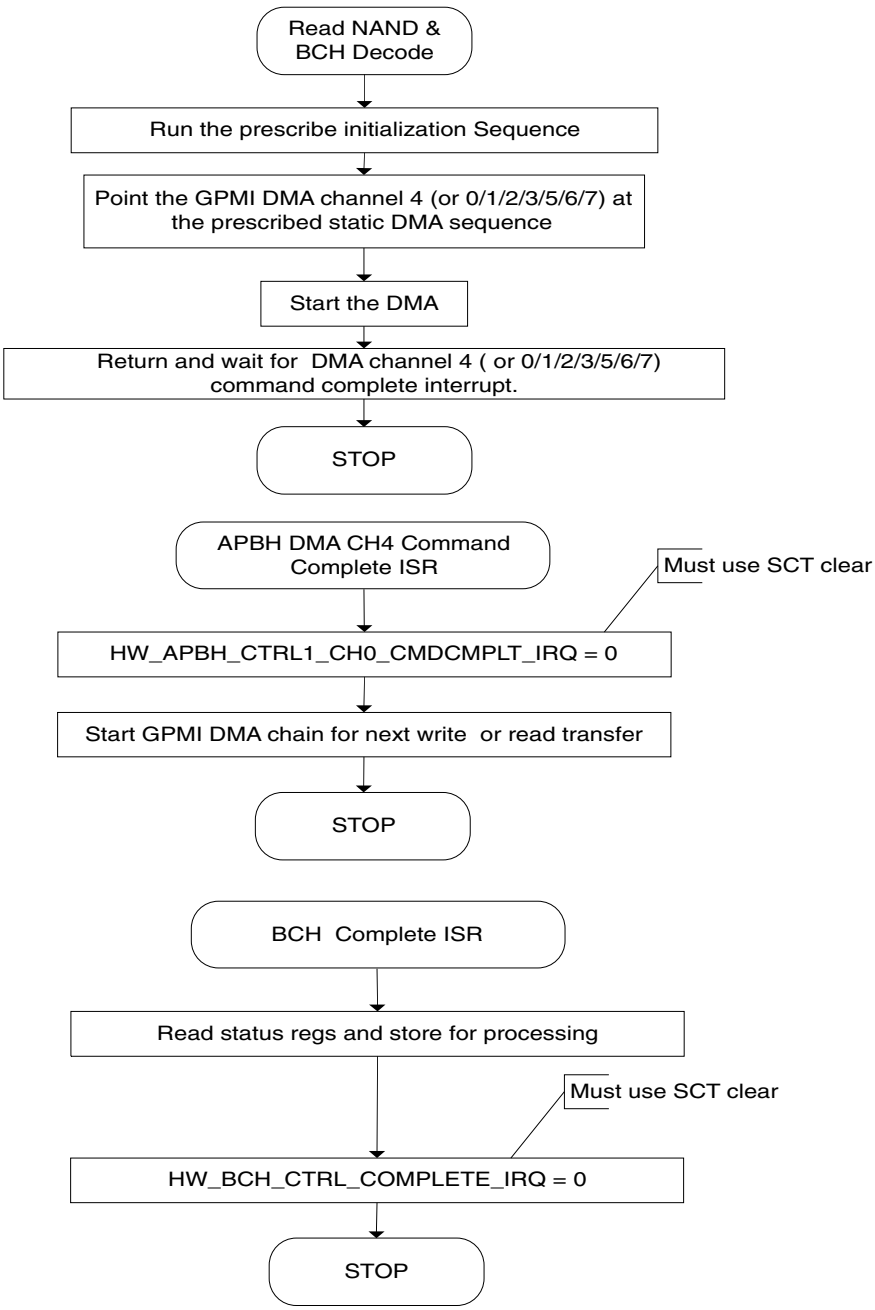

Figure 9-17. BCH Decode Flowchart

Conceptually, an APHB DMA Channel (0,1,2 or 3) command chain with seven command structures linked together is used to perform the BCH decode operation (as shown in Figure 9-18).

Note

The GPMI's DMA command structures controls the BCH decode operation.

To use the BCH decoder with the GPMI's DMA, create a DMA command chain containing seven descriptor structures, as shown in the figure below and detailed in the DMA structure code example that follows it in DMA Structure Code Example. The seven DMA descriptors perform the following tasks:

1. Issue NAND read setup command byte (under "CLE") and address bytes (under "ALE").
2. Issue NAND read execute command byte (under "CLE").
3. Wait for the NAND device to complete accessing the block data by watching the ready signal.
4. Check for NAND timeout through "PSENSE".
5. Configure and enable the BCH block and read the NAND block data.
6. Disable the BCH block.
7. Descriptor NOP to allow NANDLOCK in the previous descriptor to the thread-safe.

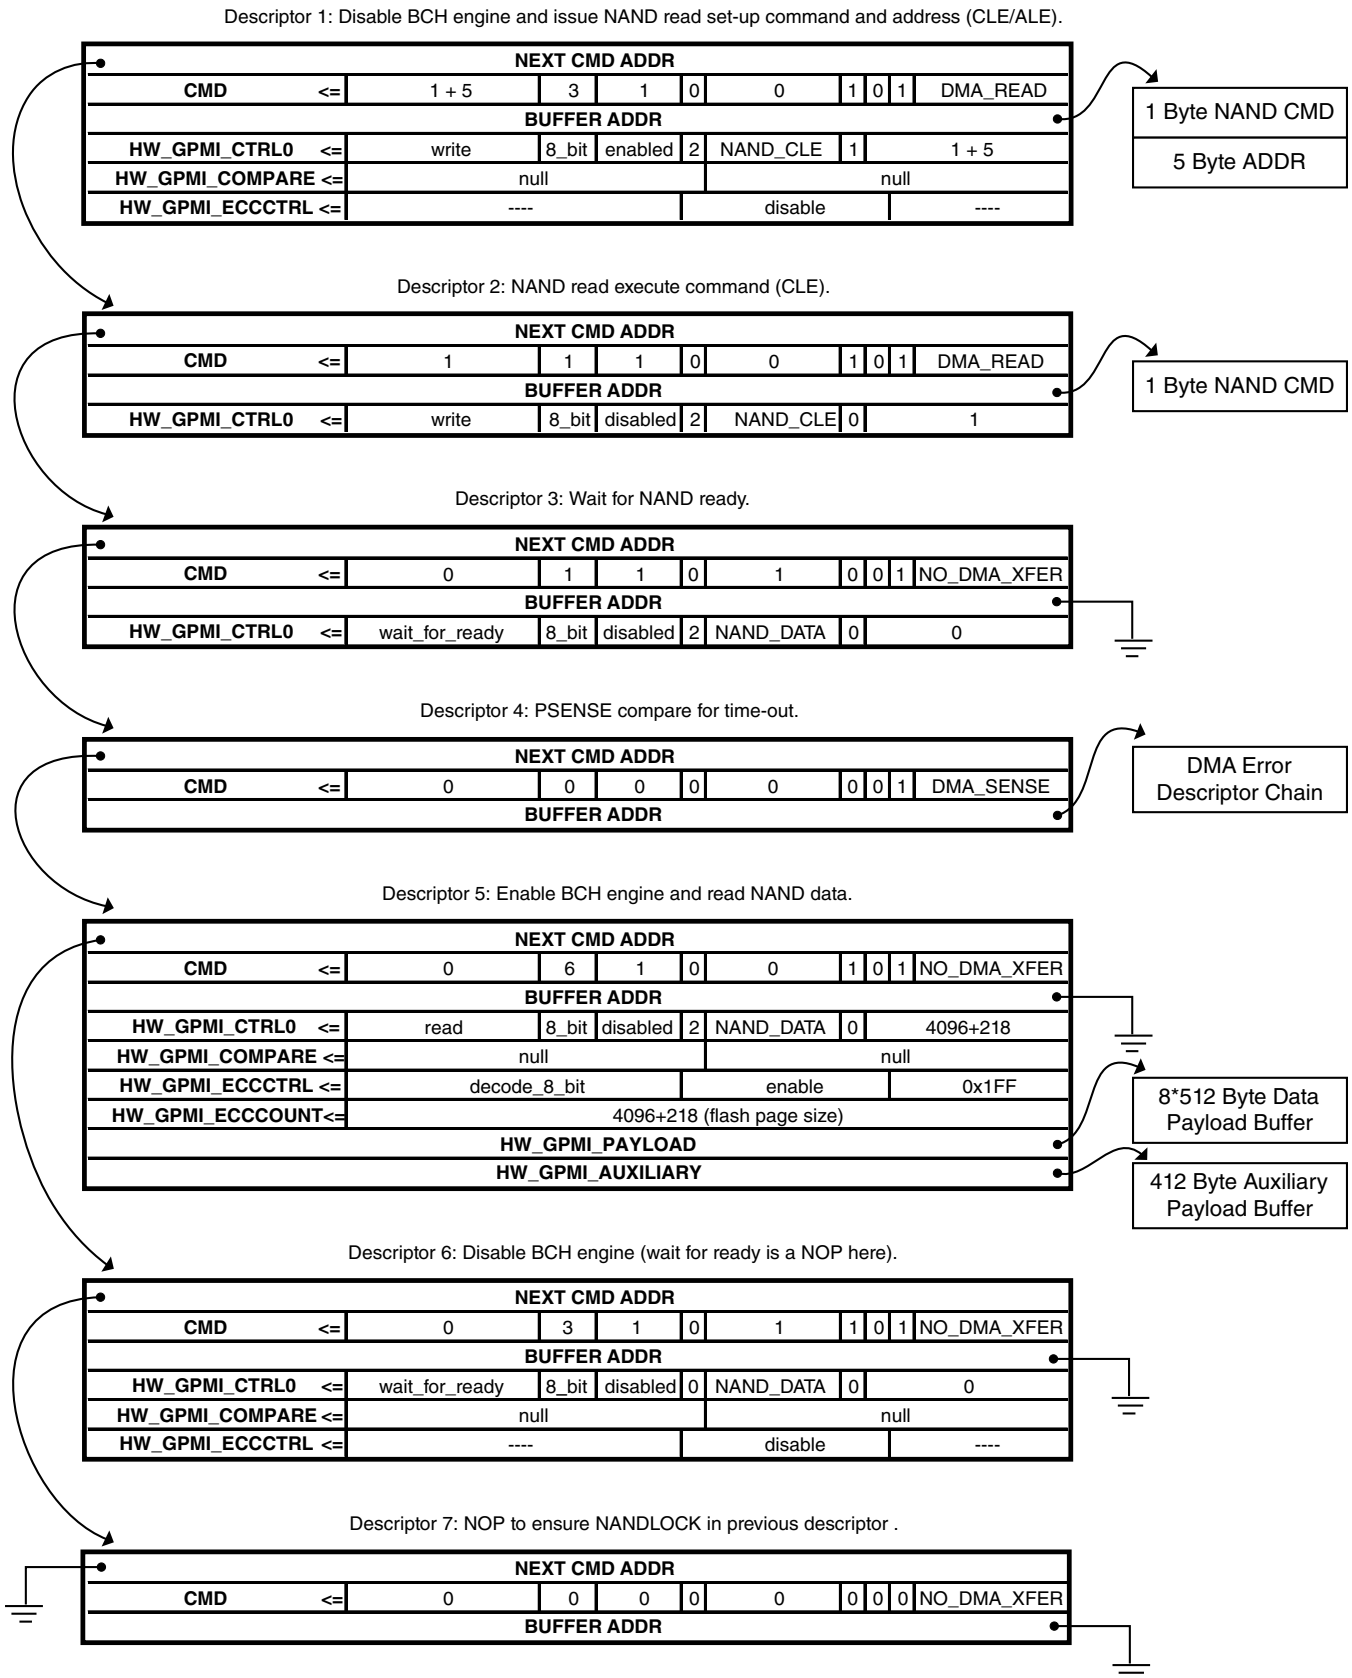

Figure 9-18. BCH Decode DMA Descriptor Chain

9.6.2.3.2.1 DMA Structure Code Example

The following sample code illustrates the coding for one read transaction, consisting of a seven DMA command structure chain for reading all 4096 bytes of payload data (eight 512-byte blocks) and 65 bytes of metadata with the associative parity bytes (8 * (18) + 9) from a 4K NAND page sitting on GPMI CS2.

```

9.6.2.3.2.2 Using the Decoder

As illustrated in Figure 9-18 and the sample code in DMA Structure Code Example :

- DMA descriptor 1 prepares the NAND for data read by using the GPMI to issue a NAND read setup command byte under CLE, then sends a 5-byte address under ALE. The BCH engine is not used for these commands.
- DMA descriptor 2 issues a one-byte read execute command to the NAND device that triggers its read access. The NAND then goes not ready.
- DMA descriptor 3 performs a wait for ready operation allowing the DMA chain to remain dormant until the NAND device completes its read access time.

- DMA descriptor 5 handles the reading and error correction of the NAND data. This command's PIOs activate the BCH engine to write the read NAND data to system memory and to process it for any errors that need to be corrected. This DMA descriptor contains two PIO values that are system memory addresses pointing to the PAYLOAD data area and to the AUXILIARY data area. These addresses are used by the BCH engine's AHB master to move data into system memory and to correct it. While this example is reading an entire 4K page—payload plus metadata—it is equally possible to read just one 512-byte payload block or just the uniquely protected metadata block in a single 7 DMA structure transfer.
- DMA descriptor 6 disables the BCH engine with the NANDLOCK asserted. This is necessary to ensure that the GPMI resource is not arbitrated to another DMA channel when multiple DMA channels are active concurrently.
- DMA descriptor 7 de-asserts the NANDLOCK to free up the GPMI resource to another channel.

As the BCH block receives data from the GPMI:

- The decoder transforms the read NAND data block into a BCH code word and computes the codeword syndrome.
- If no errors are present, then the BCH block can immediately report back to firmware. This report is passed as the BCH_CTRL_COMPLETE_IRQ interrupt status bit and the associated status registers in BCH_STATUS0/1 registers.
- If an error is present, then the BCH block corrects the necessary data block or parity block bytes, if possible (not all errors are correctable).

As the BCH decoder reads the data and parity blocks, it records a special condition, i.e., that all of the bits of a payload data block or metadata block are one, including any associated parity bytes. The all-ones case for both parity and data indicates an erased block in the NAND device.

The BCH_STATUS0 register contains a 4-bit field that indicates the final status of the auxiliary block. A value of 0x0 indicates no errors found for a block.

- A value of 1 to 20 inclusive indicates that many correctable errors were found and fixed.
- A value of 0xFE indicates uncorrectable errors detected on the block.

- A value of 0xFF indicates that the block was in the special ALL ONES state and is therefore considered to be an ERASED block.
- All other values are disallowed by the hardware design.

Recall that up to eight NAND devices can have DMA chains in-flight at once, i.e. they can all be contending for access to the GPMI data bus. It is impossible to predict which NAND device will enter the BCH engine with a transfer first, because each chain includes a wait4ready command structure. As a result, firmware should look at the BCH_STATUS0_COMPLETED_CE bit field to determine which block is being reported in the status register. There is also a 16-bit HANDLE field in the GPMI_ECCCTRL register that is passed down the pipeline with each transaction. This handle field can be used to speed firmware's detection of which transaction is being reported.

These examples of reading and writing have focused on full page transfers of 4K page NAND devices. Other device configurations can be specified by changing the ECCOUNT field in the GPMI registers and reprogramming the BCH's FLASHnLAYOUTm registers.

The BCH and GPMI blocks are designed to be very efficient at reading single 512 (or 1024)-byte pages in one transaction. With no errors, the transaction takes less than 20 HCLKs longer than the time to read the raw data from the NAND.

To summarize, the APBH DMA command chain for a BCH decode operation is shown in Figure 9-18. Seven DMA command structures must be present for each NAND read transaction decoded by the BCH. The seven DMA command structures for multiple NAND read transaction blocks can be chained together to make larger units of work for the BCH, and each will produce an appropriate error report in the BCH PIO space. Multiple NAND devices can have such multiple chains scheduled. The results can come back out of order with respect to the multiple chains.

9.6.2.3.3 Interrupts

There are two interrupt sources used in processing BCH protected NAND read and write transfers.

Since all BCH operations are initiated by GPMI DMA command structures, the DMA completion interrupt for the GPMI is an important ISR. Both of the flow charts of Figure 9-14 and Figure 9-17 show the GPMI DMA complete ISR skeleton. In both reads and writes, the GPMI DMA completion interrupt is used to schedule work ***INTO*** the error correction pipeline. As the front end processing completes, the DMA interrupt is generated and additional work, such as DMA chains, are passed to the GPMI DMA to keep it *fed*. For write operations, this is the only interrupt that is generated for processing the NAND write transfer.

For reads, however, two interrupts are needed. Every read is started by a GPMI DMA command chain and the front end queue is fed as described above. The back end of the read pipeline is drained by monitoring the BCH completion interrupt found int HW_BCH_CTRL_COMPLETE_IRQ.

BCH transaction consists of reading or writing all of the blocks requested in the HW_GPMI_ECCCTRL_BUFFER_MASK bit field. As every read transaction completes, it posts the status of all of the blocks to the HW_BCH_STATUS0 and HW_BCH_STATUS1 registers and sets the completion interrupt. The five stages of the BCH read pipeline completes, one in the GPMI and four in the BCH, are independently stalled as they complete and try to deliver to the next stage in the data flow. Several of these stages can be skipped if no-errors are found or once an uncorrectable error is found in a block.

In any case, the final stage will stall if the status register is busy waiting for the CPU to take status register results. The hardware monitors the state of the HW_BCH_CTRL_COMPLETE_IRQ bit. If it is still set when the last pipeline stage is ready to post data, then the stage will stall. It follows that the next previous stage will stall when it is ready to hand off work to the final stage, and so on up the pipeline.

CAUTION

It is important that firmware read the STATUS0/1 results and save them before clearing the interrupt request bit. Otherwise, a transaction and its results could be completely lost.

9.6.2.3.4 Randomizer

BCH ECC has a Randomizer module that is interfaced through the GPMI APBHDMA chain. The Randomizer can generate random data based on BCH ECC encoded/decoded data. It can be employed to reduce the disturbances caused by a neighboring cell in the NAND chip, thus reducing bit errors.

To enable the Randomizer module, set GPMI_ECCCTRL[RANDOMIZER_ENABLE] to 1, then set GPMI_ECCCOUNT[RANDOMIZER_PAGE] to select randomizer page number needed to be randomized. All these registers can be programmed by the DMA chain. The randomized data should start from the zero column address and be the size of the whole NAND page. If the randomizer function is enabled, GPMI_ECCCTRL[ENABLE_ECC] should also be enabled. To bypass BCH error correction function, set BCH_FLASHxLAYOUT0[ECC0] and BCH_FLASHxLAYOUT1[ECCN] to 0.

9.6.2.4 Behavior During Reset

A soft reset (SFTRST) can take multiple clock periods to complete, so do NOT set CLKGATE when setting SFTRST.

The reset process gates the clocks automatically. The exemplary code is shown below.

```
// A soft reset can take multiple clocks to complete, so do NOT gate the
// clock when setting soft reset. The reset process will gate the clock
// automatically. Poll until this has happened before subsequently
// preparing soft-reset and clock gate
  BCH_CTRL_CLR(BM_BCH_CTRL_SFTRST);
  BCH_CTRL_CLR(BM_BCH_CTRL_CLKGATE);
// asserting soft-reset
  BCH_CTRL_SET(BM_BCH_CTRL_SFTRST);
// waiting for confirmation of soft-reset
  while (!BCH_CTRL.B.CLKGATE)
  {
// busy wait
  }
// Done.
  BCH_CTRL_CLR(BM_BCH_CTRL_SFTRST);
  BCH_CTRL_CLR(BM_BCH_CTRL_CLKGATE);
```

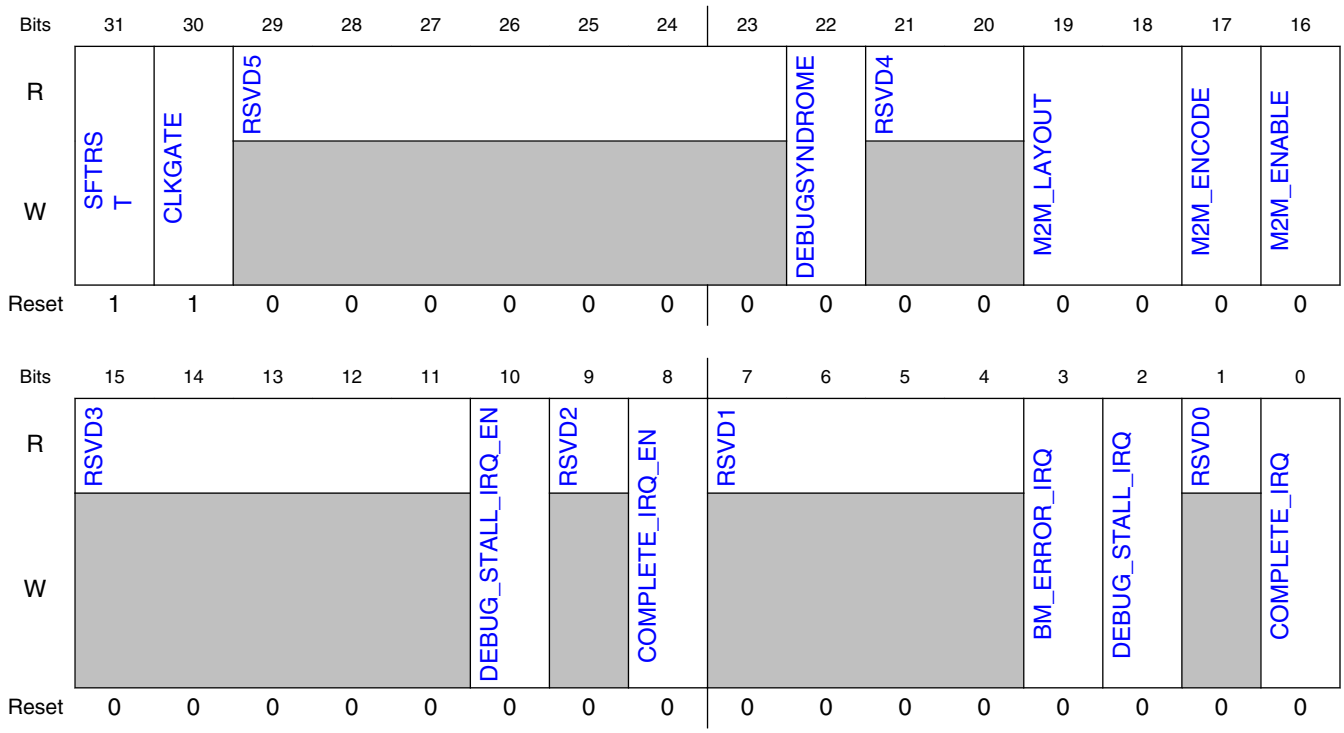
9.6.3.2 Hardware BCH ECC Accelerator Control Register (CTRL)



9.6.3.2.1 Offset

Register	Offset	Description
CTRL	0h	Hardware BCH ECC Accelerator Control Register
CTRL_SET	4h	Writing a 1 to a bit in this register sets the corresponding bit in CTRL
CTRL_CLR	8h	Writing a 1 to a bit in this register clears the corresponding bit in CTRL
CTRL_TOG	Ch	Writing a 1 to a bit in this register toggles the corresponding bit in CTRL

9.6.3.2.2 Function

The BCH CTRL provides overall control of the hardware ECC accelerator

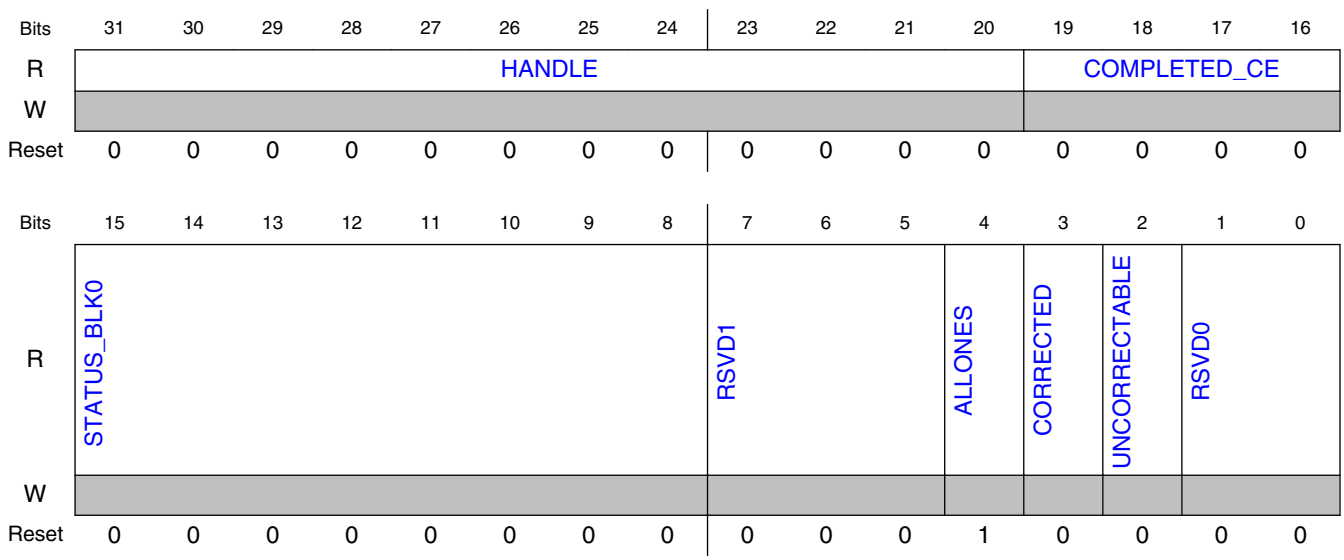
9.6.3.2.4 Fields

Field	Function
31 SFTRST	SFTRST Set this bit to 0 to enable normal BCH operation. Set this bit to 1 (default) to disable clocking with the BCH and hold it in its reset (lowest power) state. This bit can be turned on and then off to reset the BCH block to its default state. This bit resets all state machines except for the AHB master state machine 0b - Allow BCH to operate normally. 1b - Hold BCH in reset.
30 CLKGATE	CLKGATE This bit must be set to 0 for normal operation. When set to 1 it gates off the clocks to the block. 0b - Allow BCH to operate normally. 1b - Do not clock BCH gates in order to minimize power consumption.
29-23 RSVD5	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

Field	Function
22 DEBUGSYNDROME	DEBUGSYNDROME (For debug purposes only). Enable write of computed syndromes to memory on BCH decode operations. Computed syndromes will be written to the auxiliary buffer after the status block. Syndromes will be written as padded 16-bit values.
21-20 RSVD4	This field is reserved. This read-only field is reserved and always has the value 0
19-18 M2M_LAYOUT	M2M_LAYOUT Selects the flash page format for memory-to-memory operations.
17 M2M_ENCODE	M2M_ENCODE Selects encode (parity generation) or decode (correction) mode for memory-to-memory operations.
16 M2M_ENABLE	M2M_ENABLE NOTE! WRITING THIS BIT INITIATES A MEMORY-TO-MEMORY OPERATION. The BCH module must be inactive (not processing data from the GPMI) when this bit is set. The M2M_ENCODE and M2M_LAYOUT bits as well as the ENCODEPTR, DATAPTR, and METAPTR registers are used for memory-to-memory operations and must be correctly programmed before writing this bit.
15-11 RSVD3	This field is reserved. This read-only field is reserved and always has the value 0
10 DEBUG_STALL_IRQ_EN	DEBUG_STALL_IRQ_EN 1 = interrupt on debug stall mode is enabled. The IRQ is raised on every block
9 RSVD2	This field is reserved. This read-only field is reserved and always has the value 0.
8 COMPLETE_IRQ_EN	COMPLETE_IRQ_EN 1 = interrupt on completion of correction is enabled.
7-4 RSVD1	This field is reserved. This read-only field is reserved and always has the value 0.
3 BM_ERROR_IRQ	BM_ERROR_IRQ AHB Bus interface Error Interrupt Status. Write a 1 to the SCT clear address to clear the interrupt status bit.
2 DEBUG_STALL_IRQ	DEBUG_STALL_IRQ DEBUG STALL Interrupt Status. Write a 1 to the SCT clear address to clear the interrupt status bit.
1 RSVD0	This field is reserved. This read-only field is reserved and always has the value 0.
0 COMPLETE_IRQ	COMPLETE_IRQ This bit indicates the state of the external interrupt line. Write a 1 to the SCT clear address to clear the interrupt status bit. NOTE: subsequent ECC completions will be held off as long as this bit is set. Be sure to read the data from BCH_STATUS0, 1 before clearing this interrupt bit.

9.6.3.3 Hardware ECC Accelerator Status Register 0 (STATUS0)



9.6.3.3.1 Offset

Register	Offset
STATUS0	10h

9.6.3.3.2 Function

The BCH STAT register provides visibility into the run-time status of the BCH and status information when processing is complete. It provides overall status of the hardware ECC accelerator.

9.6.3.3.3 Diagram

9.6.3.3.4 Fields

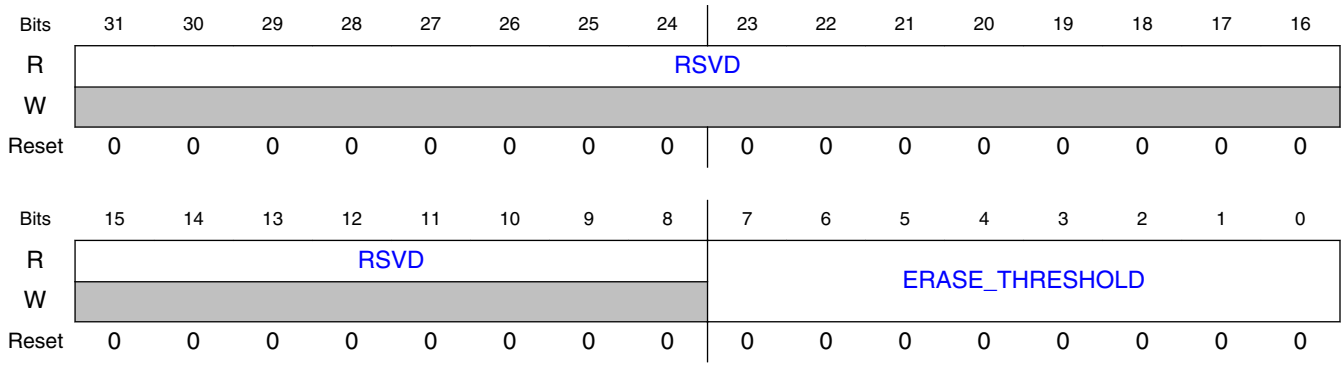
Field	Function
31-20 HANDLE	HANDLE Software supplies a 12 bit handle for this transfer as part of the GPMI DMA PIO operation that started the transaction. That handle passes down the pipeline and ends up here at the time the BCH interrupt is signaled.
19-16	COMPLETED_CE This is the chip enable number corresponding to the NAND device from which this data came.

Table continues on the next page...

Field	Function
COMPLETED_CE	
15-8 STATUS_BLK0	STATUS_BLK0 Count of symbols in error during processing of first block of flash (metadata block). The number of errors reported will be in the range of 0 to the ECC correction level for block 0. 00000000b - No errors found on block. 00000001b - One error found on block. 00000010b - One errors found on block. 00000011b - One errors found on block. 00000100b - One errors found on block. 11111110b - Block exhibited uncorrectable errors. 11111111b - Page is erased.
7-5 RSVD1	This field is reserved. This read-only field is reserved and always has the value 0.
4 ALLONES	ALLONES 1 = All data bits of this transaction are ONE.
3 CORRECTED	CORRECTED 1 = At least one correctable error encountered during last processing cycle.
2 UNCORRECTABLE	UNCORRECTABLE 1 = Uncorrectable error encountered during last processing cycle.
1-0 RSVD0	This field is reserved. This read-only field is reserved and always has the value 0.

9.6.3.4 Hardware ECC Accelerator Mode Register (MODE)

9.6.3.4.1 Offset



Register	Offset
MODE	20h

9.6.3.4.2 Function

The BCH MODE register provides additional mode controls.

Contains additional global mode controls for the BCH engine.

9.6.3.4.3 Diagram

9.6.3.4.4 Fields

Field	Function
31-8 RSVD	This field is reserved. This read-only field is reserved and always has the value 0.
7-0 ERASE_THRESHOLD	ERASE_THRESHOLD This value indicates the maximum number of zero bits on a flash subpage for it to be considered erased. For SLC NAND devices, this value should be programmed to 0 (meaning that the entire page should consist of bytes of 0xFF. For MLC NAND devices, bit errors may occur on reads (even on blank pages), so this threshold can be used to tune the erased page checking algorithm.

9.6.3.5 Hardware BCH ECC Loopback Encode Buffer Register (ENCODEPTR)

9.6.3.5.1 Offset

Register	Offset
ENCODEPTR	30h

9.6.3.5.2 Function

When performing memory to memory operations, indicates the address of the encode buffer. This register should be programmed before writing a 1 to the M2M_ENABLE bit in the CTRL register.

For memory to memory operations, this register is used as the pointer to the encoded data, which is an output when encoding and an input while decoding.

9.6.3.5.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	ADDR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

9.6.3.5.4 Fields

Field	Function
31-0 ADDR	ADDR Address pointer to encode buffer. This is the source for decode operations and the destination for encode operations. This value must be aligned on a 4 bytes boundary.

9.6.3.6 Hardware BCH ECC Loopback Data Buffer Register (DATAPTR)

9.6.3.6.1 Offset

Register	Offset
DATAPTR	40h

9.6.3.6.2 Function

When performing memory to memory operations, indicates the address of the data buffer.

For memory to memory operations, this register is used as the pointer to the data to encode or the destination buffer for decode operations.

9.6.3.6.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	ADDR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

9.6.3.6.4 Fields

Field	Function
31-0 ADDR	ADDR Address pointer to data buffer. This is the source for encode operations and the destination for decode operations. This register should be programmed before writing a 1 to the M2M_ENABLE bit in the CTRL register. This value must be aligned on a 4 byte boundary.

9.6.3.7 Hardware BCH ECC Loopback Metadata Buffer Register (METAPTR)

9.6.3.7.1 Offset

Register	Offset
METAPTR	50h

9.6.3.7.2 Function

When performing memory to memory operations, indicates the address of the metadata buffer.

For memory to memory operations, this register is used as the pointer to the metadata to encode or the extracted metadata for decode operations.

9.6.3.7.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	ADDR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

9.6.3.7.4 Fields

Field	Function
31-0 ADDR	ADDR Address pointer to metadata buffer. This is the source for encode metadata read operations and the destination for metadata decode operations. This register should be programmed before writing a 1 to the M2M_ENABLE bit in the CTRL register. This value must be aligned on a 4 bytes boundary.

9.6.3.8 Hardware ECC Accelerator Layout Select Register (LAYOUTSELECT)

9.6.3.8.1 Offset

Register	Offset
LAYOUTSELECT	70h

9.6.3.8.2 Function

The BCH LAYOUTSELECT register provides a mapping of chip selects to layout registers.

When the BCH engine receives a request to process a data block from the GPMI interface, it will use this register to map the incoming chip select to one of the four possible flash layout registers

9.6.3.8.3 Diagram

9.6.3.8.4 Fields

Field	Function
31-30 CS15_SELECT	CS15_SELECT Selects which layout is used for chip select 15.
29-28 CS14_SELECT	CS14_SELECT Selects which layout is used for chip select 14.
27-26 CS13_SELECT	CS13_SELECT Selects which layout is used for chip select 13.
25-24 CS12_SELECT	CS12_SELECT Selects which layout is used for chip select 12.
23-22 CS11_SELECT	CS11_SELECT Selects which layout is used for chip select 11.
21-20 CS10_SELECT	CS10_SELECT Selects which layout is used for chip select 10.
19-18 CS9_SELECT	CS9_SELECT Selects which layout is used for chip select 9.
17-16 CS8_SELECT	CS8_SELECT Selects which layout is used for chip select 8.
15-14 CS7_SELECT	CS7_SELECT Selects which layout is used for chip select 7.
13-12 CS6_SELECT	CS6_SELECT Selects which layout is used for chip select 6.
11-10	CS5_SELECT

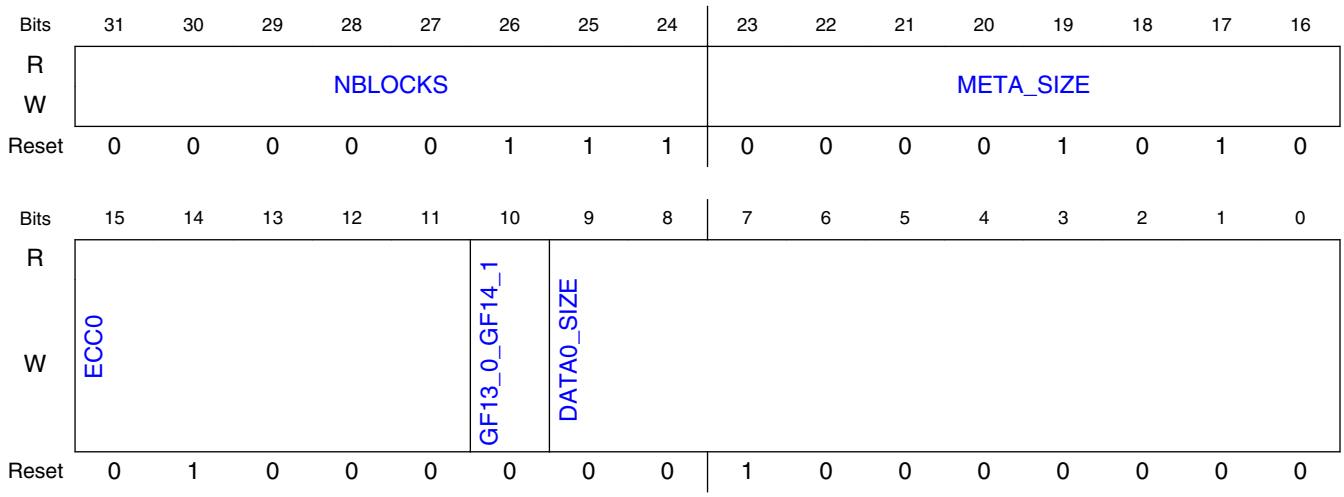
Table continues on the next page...

Field	Function
CS5_SELECT	Selects which layout is used for chip select 5.
9-8 CS4_SELECT	CS4_SELECT Selects which layout is used for chip select 4.
7-6 CS3_SELECT	CS3_SELECT Selects which layout is used for chip select 3.
5-4 CS2_SELECT	CS2_SELECT Selects which layout is used for chip select 2.
3-2 CS1_SELECT	CS1_SELECT Selects which layout is used for chip select 1.
1-0 CS0_SELECT	CS0_SELECT Selects which layout is used for chip select 0.

9.6.3.9 Hardware BCH ECC Flash 0 Layout 0 Register (FLASH0LAYOUT0)

9.6.3.9.1 Offset

Register	Offset
FLASH0LAYOUT0	80h



9.6.3.9.2 Function

The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjunction with the FLASH0LAYOUT1 register to control the format for the devices selecting layout 0 in the LAYOUTSELECT register.

Each pair of layout registers describes one of four supported flash configurations. Software should program the LAYOUTSELECT register for each supported GPMI chip select to select from one of the four layout values. Each pair of registers contains settings that are used by the BCH block while reading / writing the flash page to control data, metadata, and flash page sizes as well as the ECC correction level. The first block written to flash can be programmed to have different ECC, metadata, and data sizes from subsequent data blocks on the device. In addition, the number of blocks stored on a page of flash is not fixed, but instead is determined by the number of bytes consumed by the initial (block 0) and subsequent data blocks.

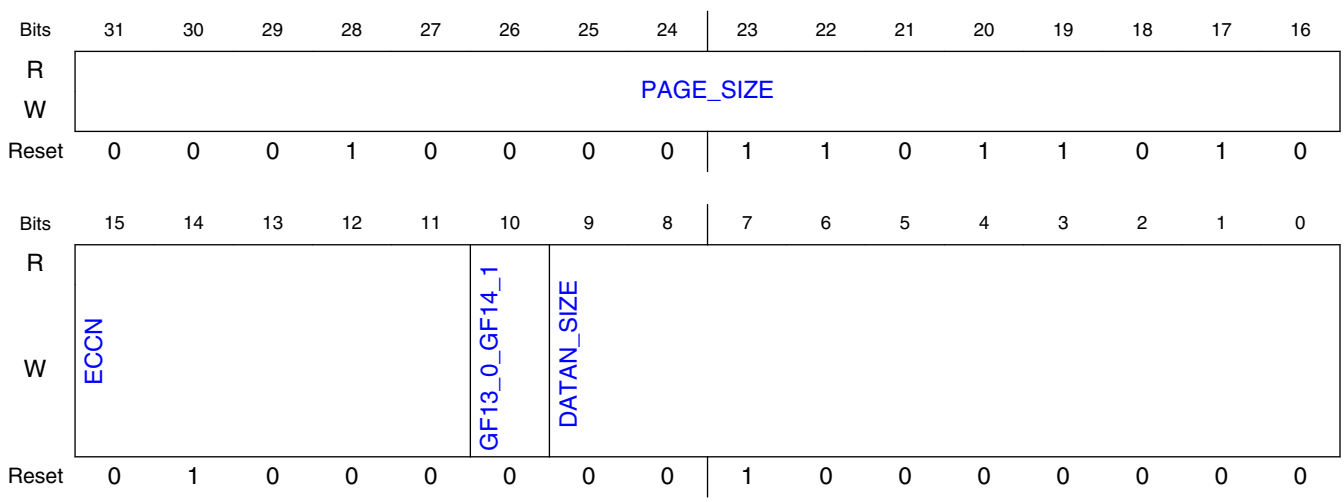
See sections Flash Page Layout and Determining the ECC layout for a device for more detail information on setting up the flash layout registers.

9.6.3.9.3 Diagram

9.6.3.9.4 Fields

Field	Function
31-24 NBLOCKS	NBLOCKS Number of subsequent blocks on the flash page (excluding the data0 block). A value of 0 indicates that only the DATA0 block is present and a value of 8 indicates that 8 subsequent blocks are present for a total of 9 blocks on the flash (including the DATA0 block). Any values from 0 to 255 are supported by the hardware.
23-16 META_SIZE	META_SIZE Indicates the size of the metadata (in bytes) to be stored on a flash page. The BCH design support from 0 to 255 bytes for metadata—if set to 0, no metadata will be stored. Metadata is stored before the associated data in block 0. If the DATA0_SIZE field is programmed to a 0, then metadata effectively be stored with its own parity. When both the metadata and data0 fields are programmed with non-zero values, the first block will contain both portions of data and covered by a single parity block.
15-11 ECC0	ECC0 Indicates the ECC level for the first block on the flash page. The first block covers metadata plus the associated data from the DATA0_SIZE field. 00000b - No ECC to be performed 00001b - ECC 2 to be performed 00010b - ECC 4 to be performed 11110b - ECC 60 to be performed 11111b - ECC 62 to be performed
10 GF13_0_GF14_1	GF13_0_GF14_1 Select GF13 or GF14: 0-GF13; 1-GF14
9-0 DATA0_SIZE	DATA0_SIZE Indicates the size of the data 0 block (in DWORDS / four bytes) to be stored on the flash page. If set to 0, the first block only contains metadata.

9.6.3.10 Hardware BCH ECC Flash 0 Layout 1 Register (FLASH0LAYOUT1)



9.6.3.10.1 Offset

Register	Offset
FLASH0LAYOUT1	90h

9.6.3.10.2 Function

The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjunction with the FLASH0LAYOUT0 register to control the format for the device selecting layout 0 in the LAYOUTSELECT register.

9.6.3.10.3 Diagram

9.6.3.10.4 Fields

Field	Function
31-16 PAGE_SIZE	PAGE_SIZE Indicates the total size of the flash page (in bytes). This should be set to the page size including spare area. The page size is programmable to accomodate different flash configurations that may be available in the future.
15-11	ECCN

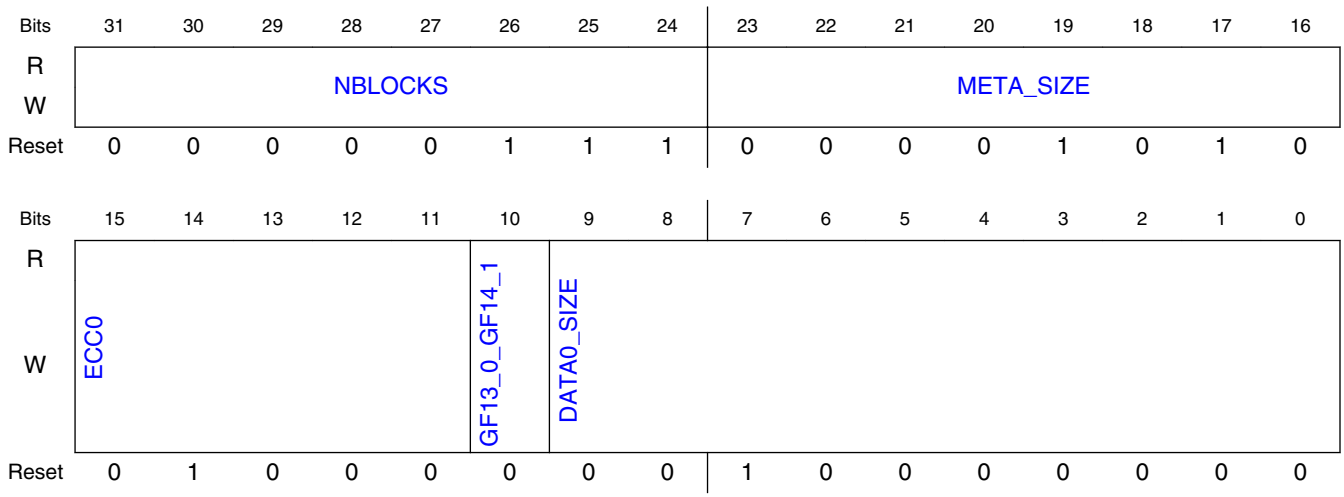
Table continues on the next page...

Field	Function
ECCN	Indicates the ECC level for the subsequent blocks on the flash page (blocks 1-n). Subsequent blocks only contain data (no metadata). 00000b - No ECC to be performed 00001b - ECC 2 to be performed 00010b - ECC 4 to be performed 11110b - ECC 60 to be performed 11111b - ECC 62 to be performed
10 GF13_0_GF14_1	GF13_0_GF14_1 Select GF13 or GF14: 0-GF13; 1-GF14
9-0 DATAN_SIZE	DATAN_SIZE Indicates the size of the subsequent data blocks (in DWORDS / four bytes) to be stored on the flash page. The size of subsequent data blocks does not have to match the data size for block 0, which is important when metadata is stored separately or for balancing the amount of data stored in each block.

9.6.3.11 Hardware BCH ECC Flash 1 Layout 0 Register (FLASH1LAYOUT0)

9.6.3.11.1 Offset

Register	Offset
FLASH1LAYOUT0	A0h



9.6.3.11.2 Function

The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjunction with the FLASH1LAYOUT1 register to control the format for the devices selecting layout 1 in the LAYOUTSELECT register.

Each pair of layout registers describes one of four supported flash configurations. Software should program the LAYOUTSELECT register for each supported GPMI chip select to select from one of the four layout values. Each pair of registers contains settings that are used by the BCH block while reading / writing the flash page to control data, metadata, and flash page sizes as well as the ECC correction level. The first block written to flash can be programmed to have different ECC, metadata, and data sizes from subsequent data blocks on the device. In addition, the number of blocks stored on a page of flash is not fixed, but instead is determined by the number of bytes consumed by the initial (block 0) and subsequent data blocks.

See sections Flash Page Layout and Determining the ECC layout for a device for more detail information on setting up the flash layout registers.

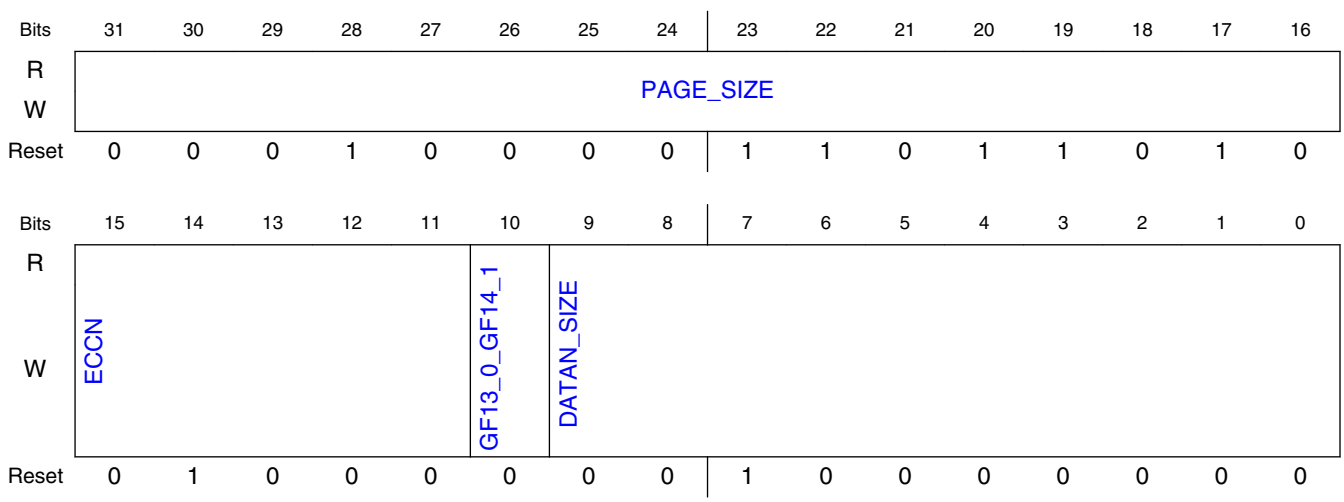
9.6.3.11.3 Diagram

9.6.3.11.4 Fields

Field	Function
31-24 NBLOCKS	NBLOCKS Number of subsequent blocks on the flash page (excluding the data0 block). A value of 0 indicates that only the DATA0 block is present and a value of 8 indicates that 8 subsequent blocks are present for a total of 9 blocks on the flash (including the DATA0 block). Any values from 0 to 255 are supported by the hardware.
23-16 META_SIZE	META_SIZE Indicates the size of the metadata (in bytes) to be stored on a flash page. The BCH design supports from 0 to 255 bytes for metadata—if set to 0, no metadata will be stored. Metadata is stored before the associated data is in block 0. If the DATA0_SIZE field is programmed to a 0, then metadata effectively be stored with its own parity. When both the metadata and data0 fields are programmed with non-zero values, the first block will contain both portions of data and covered by a single parity block.
15-11 ECC0	ECC0 Indicates the ECC level for the first block on the flash page. The first block covers metadata plus the associated data from the DATA0_SIZE field. 00000b - No ECC to be performed 00001b - ECC 2 to be performed 00010b - ECC 4 to be performed 11110b - ECC 60 to be performed 11111b - ECC 62 to be performed
10 GF13_0_GF14_1	GF13_0_GF14_1 Select GF13 or GF14: 0-GF13; 1-GF14
9-0	DATA0_SIZE

Field	Function
DATA0_SIZE	Indicates the size of the data 0 block (in DWORDS / four bytes) to be stored on the flash page. If set to 0, the first block will contains metadata.

9.6.3.12 Hardware BCH ECC Flash 1 Layout 1 Register (FLASH1LAYOUT1)



9.6.3.12.1 Offset

Register	Offset
FLASH1LAYOUT1	B0h

9.6.3.12.2 Function

The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjunction with the FLASH1LAYOUT0 register to control the format for the device selecting layout 1 in the LAYOUTSELECT register.

9.6.3.12.3 Diagram

9.6.3.12.4 Fields

Field	Function
31-16	PAGE_SIZE

Table continues on the next page...

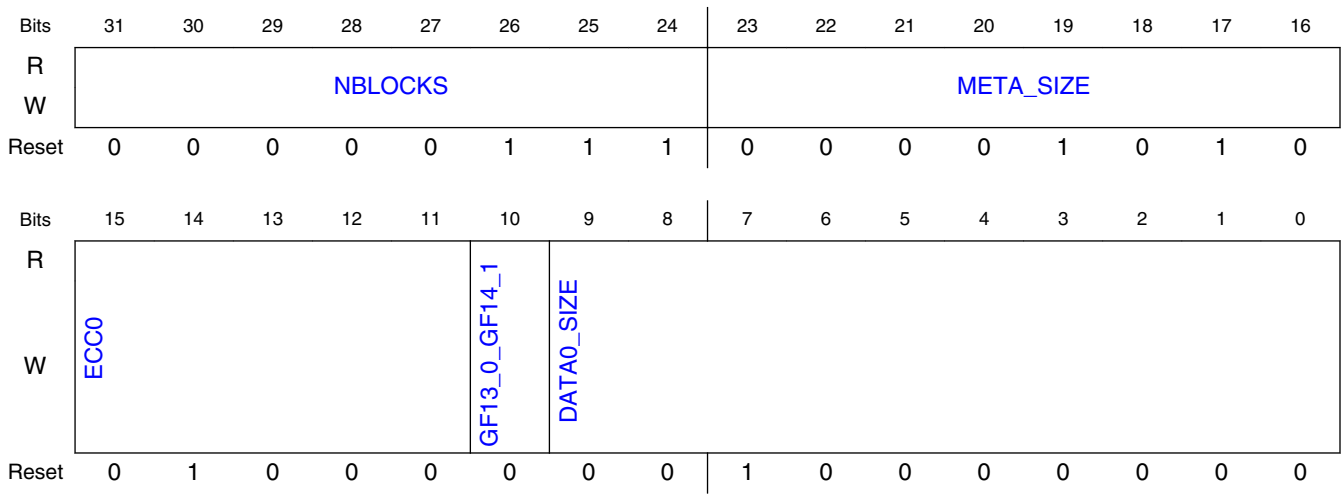
Field	Function
PAGE_SIZE	Indicates the total size of the flash page (in bytes). This should be set to the page size including spare area. The page size is programmable to accomodate different flash configurations that may be available in the future.
15-11 ECCN	ECCN Indicates the ECC level for the subsequent blocks on the flash page (blocks 1-n). Subsequent blocks only contain data (no metadata). 00000b - No ECC to be performed 00001b - ECC 2 to be performed 00010b - ECC 4 to be performed 11110b - ECC 60 to be performed 11111b - ECC 62 to be performed
10 GF13_0_GF14_1	GF13_0_GF14_1 Select GF13 or GF14: 0-GF13; 1-GF14
9-0 DATAN_SIZE	DATAN_SIZE Indicates the size of the subsequent data blocks (in DWORDS / four bytes) to be stored on the flash page. The size of subsequent data blocks does not have to match the data size for block 0, which is important when metadata is stored separately or for balancing the amount of data stored in each block.

9.6.3.13 Hardware BCH ECC Flash 2 Layout 0 Register (FLASH2LAYOUT0)

9.6.3.13.1 Offset

Register	Offset
FLASH2LAYOUT0	C0h

9.6.3.13.2 Function



The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjunction with the FLASH2LAYOUT1 register to control the format for the devices selecting layout 2 in the LAYOUTSELECT register.

Each pair of layout registers describes one of four supported flash configurations. Software should program the LAYOUTSELECT register for each supported GPMI chip select to select from one of the four layout values. Each pair of registers contains settings that are used by the BCH block while reading / writing the flash page to control data, metadata, and flash page sizes as well as the ECC correction level. The first block written to flash can be programmed to have different ECC, metadata, and data sizes from

subsequent data blocks on the device. In addition, the number of blocks stored on a page of flash is not fixed, but instead is determined by the number of bytes consumed by the initial (block 0) and subsequent data blocks.

See sections Flash Page Layout and Determining the ECC layout for a device for more detail information on setting up the flash layout registers.

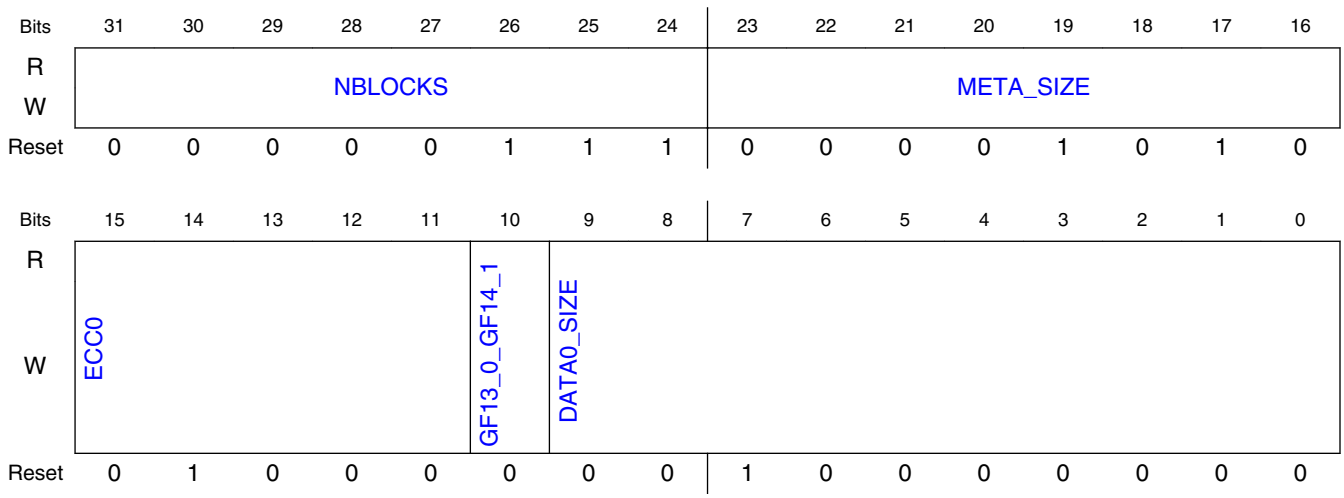
9.6.3.15 Hardware BCH ECC Flash 3 Layout 0 Register (FLASH3LAYOUT0)

9.6.3.15.1 Offset

Register	Offset
FLASH3LAYOUT0	E0h

9.6.3.15.2 Function



The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjunction with the FLASH3LAYOUT1 register to control the format for the devices selecting layout 3 in the LAYOUTSELECT register.

Each pair of layout registers describes one of four supported flash configurations. Software should program the LAYOUTSELECT register for each supported GPMI chip select to select from one of the four layout values. Each pair of registers contains settings that are used by the BCH block while reading / writing the flash page to control data,

metadata, and flash page sizes as well as the ECC correction level. The first block written to flash can be programmed to have different ECC, metadata, and data sizes from subsequent data blocks on the device. In addition, the number of blocks stored on a page of flash is not fixed, but instead is determined by the number of bytes consumed by the initial (block 0) and subsequent data blocks.

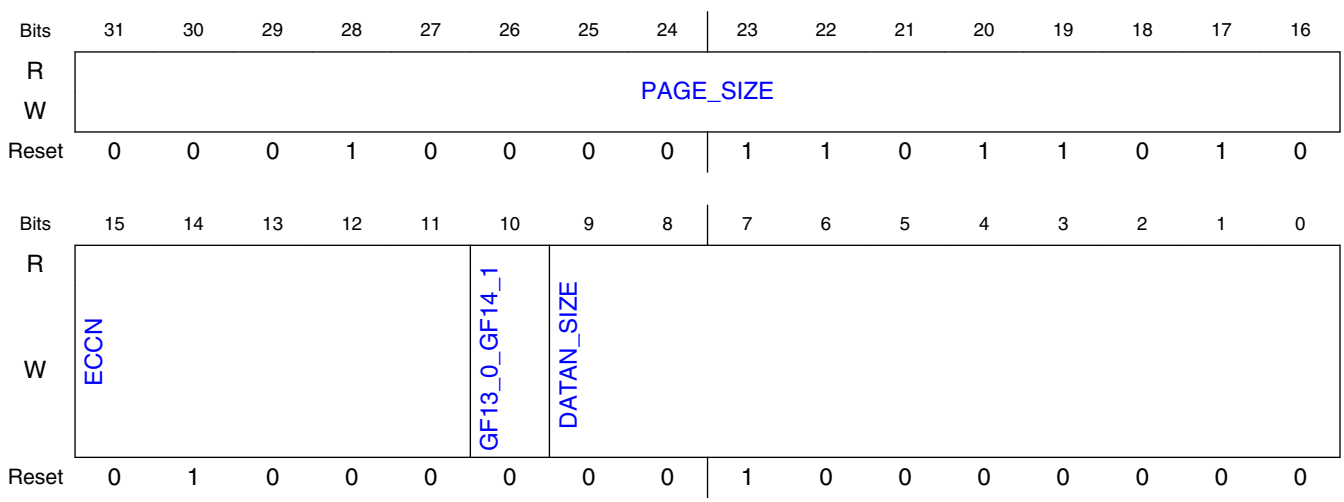
	00010b - ECC 4 to be performed 11110b - ECC 60 to be performed 11111b - ECC 62 to be performed
10 GF13_0_GF14_1	GF13_0_GF14_1 Select GF13 or GF14: 0-GF13; 1-GF14
9-0 DATA0_SIZE	DATA0_SIZE Indicates the size of the data 0 block (in DWORDS / four bytes) to be stored on the flash page. If set to 0, the first block will only contain metadata.

9.6.3.16 Hardware BCH ECC Flash 3 Layout 1 Register (FLASH3LAYOUT1)



9.6.3.16.1 Offset

Register	Offset
FLASH3LAYOUT1	F0h

9.6.3.16.2 Function

The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjunction with the FLASH3LAYOUT0 register to control the format for the device selecting layout 3 in the LAYOUTSELECT register.

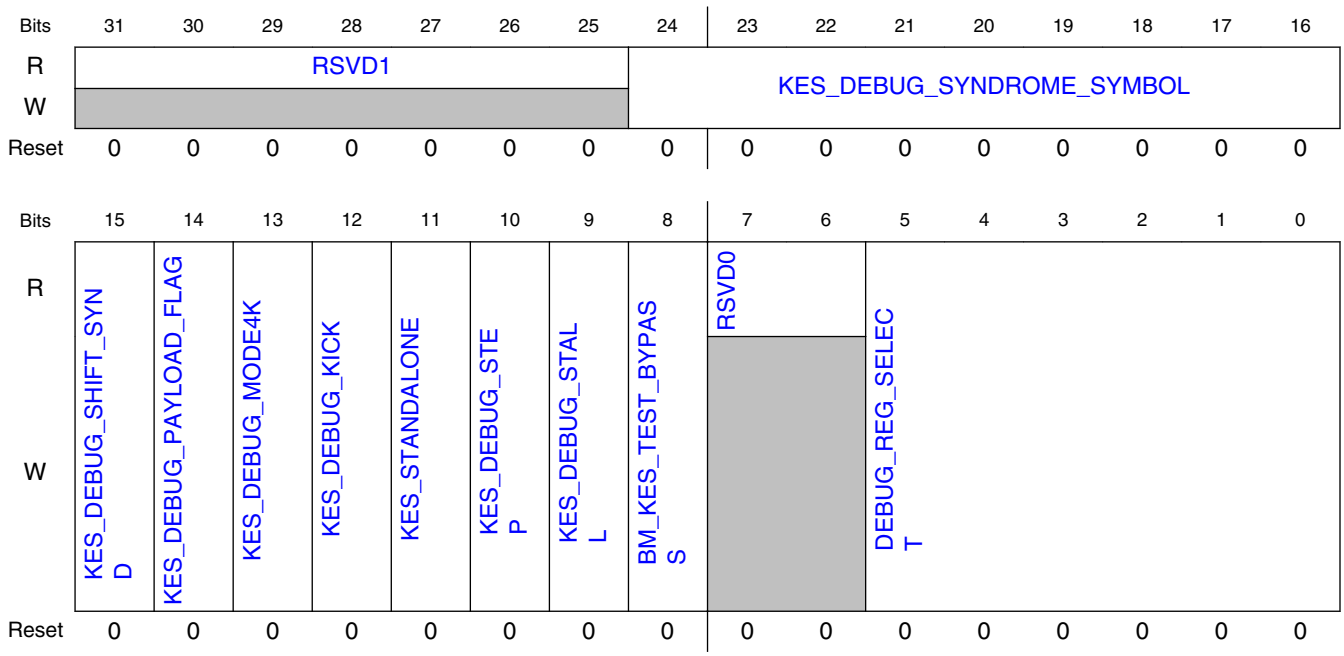
9.6.3.16.3 Diagram

9.6.3.16.4 Fields

Field	Function
31-16 PAGE_SIZE	PAGE_SIZE Indicates the total size of the flash page (in bytes). This should be set to the page size including spare area. The page size is programmable to accomodate different flash configurations that may be available in the future.
15-11 ECCN	ECCN Indicates the ECC level for the subsequent blocks on the flash page (blocks 1-n). Subsequent blocks only contain data (no metadata). 00000b - No ECC to be performed 00001b - ECC 2 to be performed 00010b - ECC 4 to be performed 11110b - ECC 60 to be performed 11111b - ECC 62 to be performed
10 GF13_0_GF14_1	GF13_0_GF14_1 Select GF13 or GF14: 0-GF13; 1-GF14
9-0 DATAN_SIZE	DATAN_SIZE Indicates the size of the subsequent data blocks (in DWORDS / four bytes) to be stored on the flash page. The size of subsequent data blocks does not have to match the data size for block 0, which is important when metadata is stored separately or for balancing the amount of data stored in each block.

9.6.3.17 Hardware BCH ECC Debug Register0 (DEBUG0)

9.6.3.17.1 Offset



Register	Offset	Description
DEBUG0	100h	Hardware BCH ECC Debug Register0
DEBUG0_SET	104h	Writing a 1 to a bit in this register sets the corresponding bit in DEBUG0
DEBUG0_CLR	108h	Writing a 1 to a bit in this register clears the corresponding bit in DEBUG0
DEBUG0_TOG	10Ch	Writing a 1 to a bit in this register toggles the corresponding bit in DEBUG0

9.6.3.17.2 Function

The hardware BCH accelerator internal state machines and signals can be seen in the ECC debug register.

The BCH_DEBUG0 register provides access to various internal state information which might prove useful during hardware debug and validation.

9.6.3.17.4 Fields

Field	Function
31-25 RSVD1	This field is reserved. This read-only field is reserved and always has the value 0.
24-16 KES_DEBUG_SYNDROME_SYMBOL	KES_DEBUG_SYNDROME_SYMBOL The 9 bit value in this bit field shifts into the syndrome register array at the input of the KES engine whenever BCH_DEBUG0_KES_DEBUG_SHIFT_SYND is toggled. 000000000b - Bus master address generator for SYND_GEN writes operates normally. 000000001b - Bus master address generator always addresses last four bytes in Auxiliary block.
15 KES_DEBUG_SHIFT_SYND	KES_DEBUG_SHIFT_SYND Toggling this bit causes the value in BCH_DEBUG0_KES_SYNDROME_SYMBOL to be shift into the syndrome register array at the input to the KES engine. After shifting in 16 symbols, one can kick off both KES and CF cycles by toggling BCH_DEBUG0_KES_DEBUG_KICK. Make sure that set KES_BCH_DEBUG0_KES_STANDALONE mode to 1 before kicking.
14 KES_DEBUG_PAYLOAD_FLAG	KES_DEBUG_PAYLOAD_FLAG When running the stand alone debug mode on the error calculator, the state of this bit is presented to the KES engine as the input payload flag. 1b - Payload is set for 512 bytes data block.
13	KES_DEBUG_MODE4K

Table continues on the next page...

Field	Function
KES_DEBUG_MODE4K	When running the stand alone debug mode on the error calculator, the state of this bit is presented to the KES engine as the input mode (4K or 2K pages). 1b - Mode is set for 4K NAND pages.
12 KES_DEBUG_KICK	KES_DEBUG_KICK Toggling causes KES engine FSM to start as if kick by the Bus Master. This allows stand alone testing of the KES and Chien Search engines. Be sure to set KES_BCH_DEBUG0_KES_STANDALONE mode to 1 before kicking.
11 KES_STANDALONE	KES_STANDALONE Set to one, cause the KES engine to suppress toggling the KES_BM_DONE signal to the bus master and suppress toggling the CF_BM_DONE signal by the CF engine. 0b - Bus master address generator for SYND_GEN writes operates normally. 1b - Bus master address generator always addresses last four bytes in Auxiliary block.
10 KES_DEBUG_STEP	KES_DEBUG_STEP Toggling this bit causes the KES FSM to skip passed the stall state if it is in DEBUG_STALL mode and completed processing a block.
9 KES_DEBUG_STALL	KES_DEBUG_STALL Set to one to cause KES FSM to stall after notifying Chien search engine to start processing its block but before notifying the bus master that the KES computation is complete. This allows a diagnostic to stall the FSM after each blocks key equations are solved. This also has the effect of stalling the CSFE search engine so it's state can be examined after it finishes processing the KES stalled block. 0b - KES FSM proceeds to next block supplied by bus master. 1b - KES FSM waits after current equations are solved and the search engine is started.
8 BM_KES_TEST_BYPASS	BM_KES_TEST_BYPASS 1 = Point all SYND_GEN writes to dummy area at the end of the AUXILLIARY block so that diagnostics can preload all payload, parity bytes and computed syndrome bytes for test the KES engine. 0b - Bus master address generator for SYND_GEN writes operates normally. 1b - Bus master address generator always addresses last four bytes in Auxiliary block.
7-6 RSVD0	This field is reserved. This read-only field is reserved and always has the value 0.
5-0 DEBUG_REG_SELECT	DEBUG_REG_SELECT The value loaded in this bit field is used to select the internal register state view of KES engine or the Chien search engine.

9.7 General Purpose Media Interface (GPMI)

9.7.1 Overview

The GPMI controller is a flexible interface to supporting up to four NAND flash chip selects.

- ONFI 3.2, DDR mode, Samsung / Toshiba Toggle NAND protocol compatible.
- Fully configurable address and command behavior, providing support for future devices not yet specified.

The GPMI resides on the APBH. The GPMI also provides an interface to the BCH module to allow direct parity processing.

Registers are clocked on the HCLK domain. The I/O and pin timing are clocked on a dedicated GPMICLK domain. GPMICLK can be set to maximize I/O performance.

The following figure shows a block diagram of the GPMI controller.

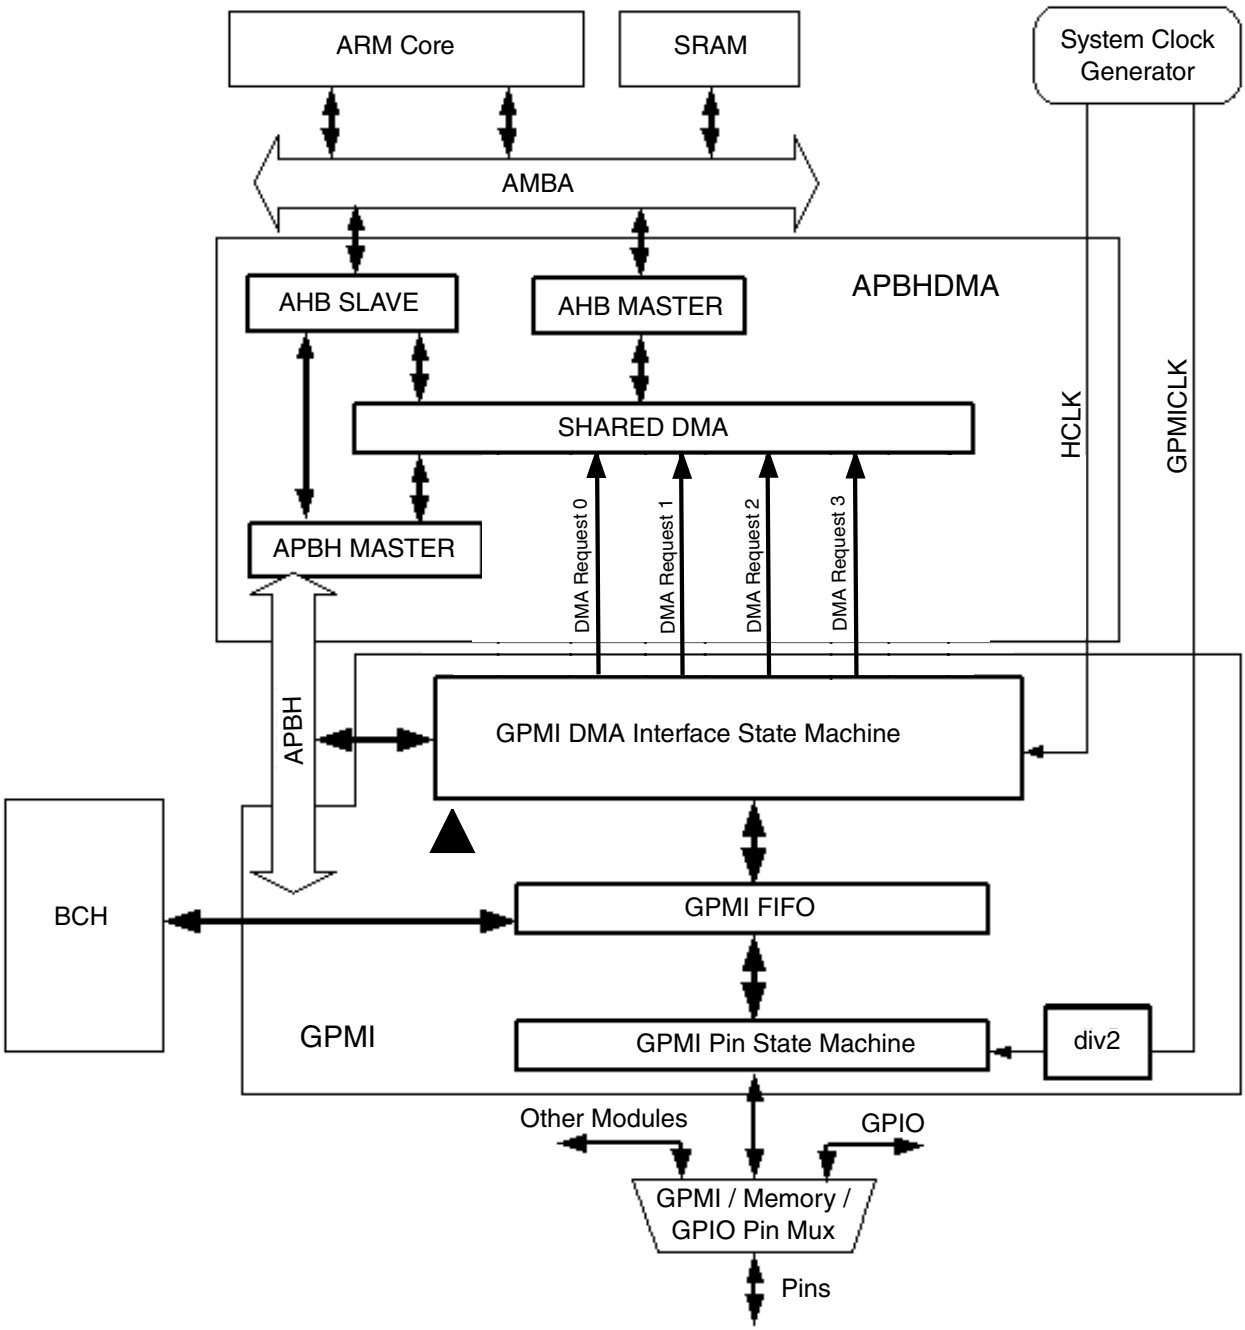

Figure 9-19. General-Purpose Media Interface Controller Block Diagram

9.7.2 Functional Description

9.7.2.1 GPMI NAND Mode

The general-purpose media interface has several features to efficiently support NAND:

- Individual chip select pins and ganged ready/busy pin for up to four NANDs.
- Individual state machine and DMA channel for each chip select.
- Special command modes work with DMA controller to perform all normal NAND functions without CPU intervention.
- Configurable timing based on a dedicated clock allows optimal balance of high NAND performance and low system power.

GPMI and DMA have been designed to handle complex multi-page operations without CPU intervention. The DMA uses a linked descriptor function with branching capability to automatically handle all of the operations needed to read/write multiple pages:

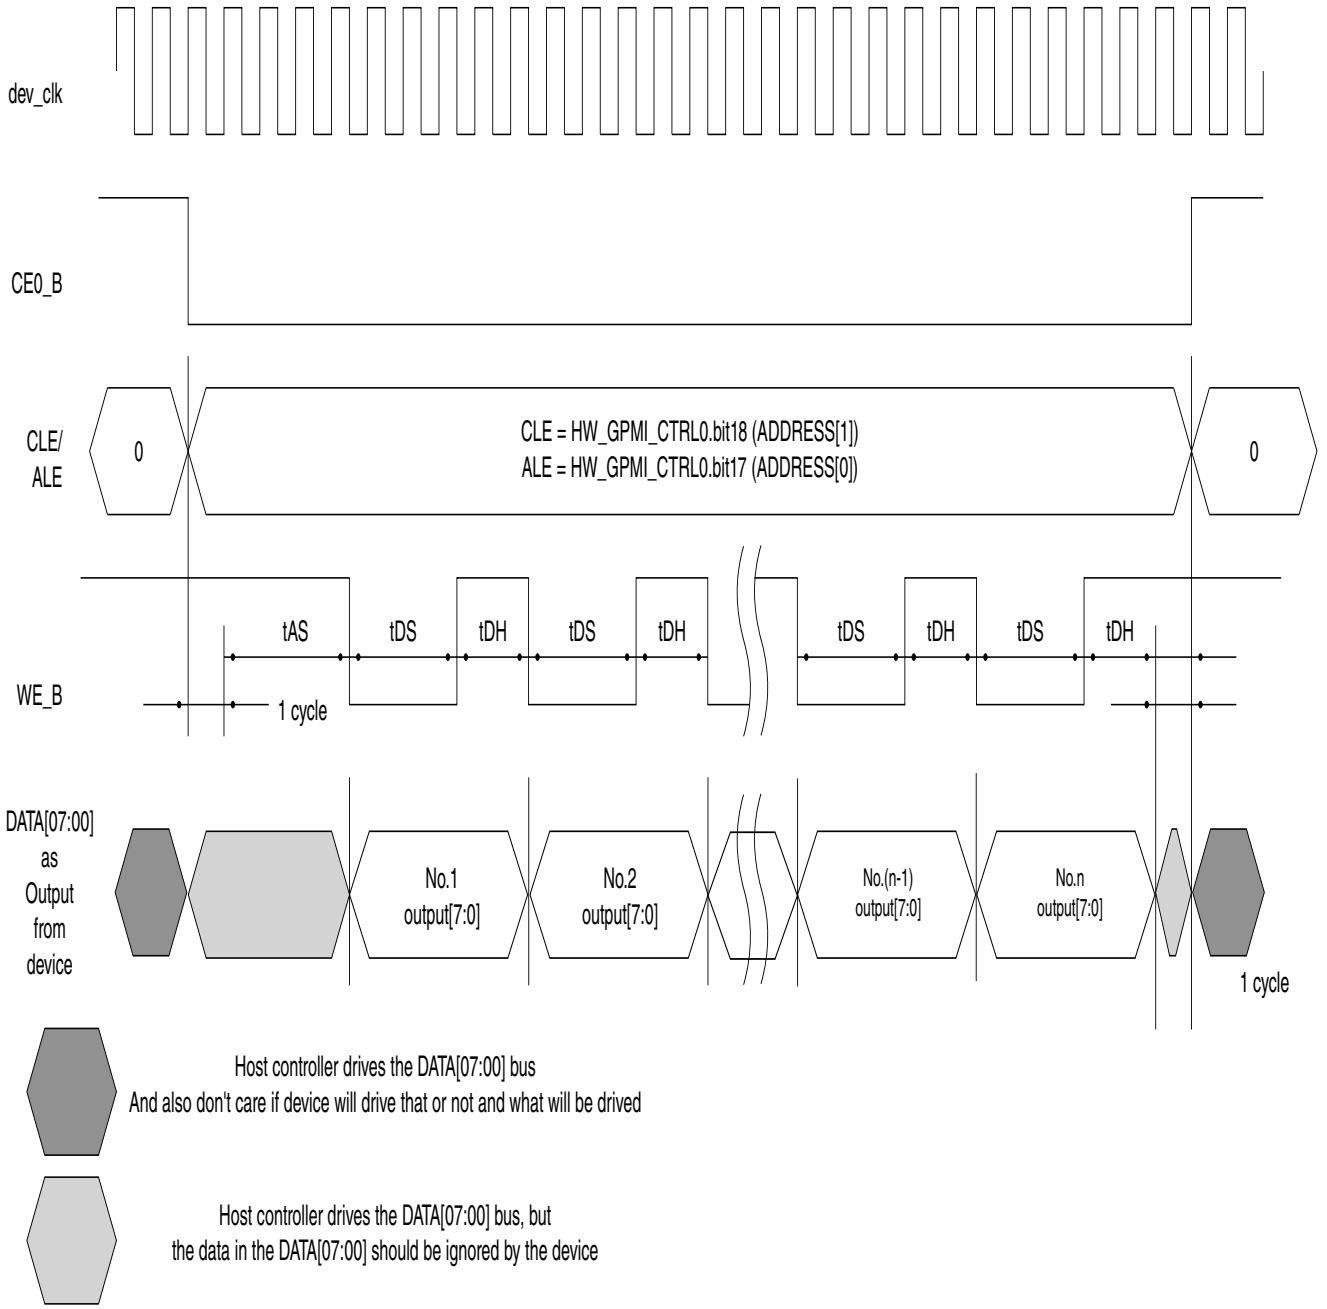
- **Data/Register Read/Write**-The GPMI can be programmed to read or write multiple cycles to the NAND address, command or data registers.
- **Wait for NAND Ready**-The GPMI's Wait-for-Ready mode can monitor the ready/busy signal of a single NAND flash and signal the DMA when the device has become ready. It also has a time-out counter and can indicate to the DMA that a time-out error has occurred. The DMAs can conditionally branch to a different descriptor in the case of an error.
- **Check Status**-The Read-and-Compare mode allows the GPMI to check NAND status against a reference. If an error is found, the GPMI can instruct the DMA to branch to an alternate descriptor, which attempts to fix the problem or asserts a CPU IRQ.

9.7.2.1.1 Multiple NAND Support

The GPMI supports up to four NAND chip selects, with ganged ready/busy pins. Since they share a data bus and control lines, the GPMI can only actively communicate with a single NAND at a time. However, all NANDs can concurrently perform internal read, write, or erase operations. With fast NAND flash and software support for concurrent NAND operations, this architecture allows the total throughput to approach the data bus speed, which can be as high as 50 MB/s (8-bit bus running at 50 MHz single clock edge) in asynchronous mode and 200MB/s (8-bit bus running at 100MHz both clock edges) in Source Synchronous mode.

There are two options for controlling the four NAND chip selects via the DMA interface. The first option is the one to one mapping, where the each DMA channel is tied to its own NAND chip select. For example DMA channel 'n' accesses only NAND attached to chip select 'n'. The second option is the decoupled mode where a DMA channel can access any or all NAND chip selects connected to the GPMI. A DMA channel will signify the NAND chip select it wants to access by writing its chip select value in the GPMI_CTRL0[CS] field and setting the GPMI_CTRL1[DECOUPLE_CS] to 1. This option is useful if software chooses to use only one DMA channel to access all the attached NAND devices.

9.7.2.1.2 GPMI NAND Timing and Clocking



The dedicated clock, GPMICLK, is used as a timing reference for NAND flash I/O. Since various NANDs have different timing requirements, GPMICLK may need to be adjusted for each application.

While the actual pin timings are limited by the NAND chips used and the I/O pad configuration, the GPMI can support data bus speeds of up to 200 MHz x 8 bits. The actual read/write strobe timing parameters are adjusted as indicated in the register descriptions in Memory Map.

9.7.2.1.3 Basic NAND Timing

9.7.2.1.3.1 NAND Asynchronous Timing

The following figures illustrate the operation of the output (from host to device) timing parameters in NAND ONFI asynchronous mode.

- tAS is configurable by programming HW_GPMI_TIMING0 Address_Setup: in this example, Address_Setup = 4, tAS is equal to 4 dev_clk cycles.
- tDS is configurable by programming HW_GPMI_TIMING0 Data_Setup; in this example, Data_Setup = 3, tDS is equal to 3 dev_clk cycles
- tDH is configuarble by programming HW_GPMI_TIMING0 Data_Hold: in this example, Data_Hold = 2, tDH is equal to 2 dev_clk cycles
- tAS/tDS/tDH will extend, if the output data is not ready in device fifo.

Figure 9-20. Asynchronous Mode Basic Write Timing Diagram (command write, address write, or data write)

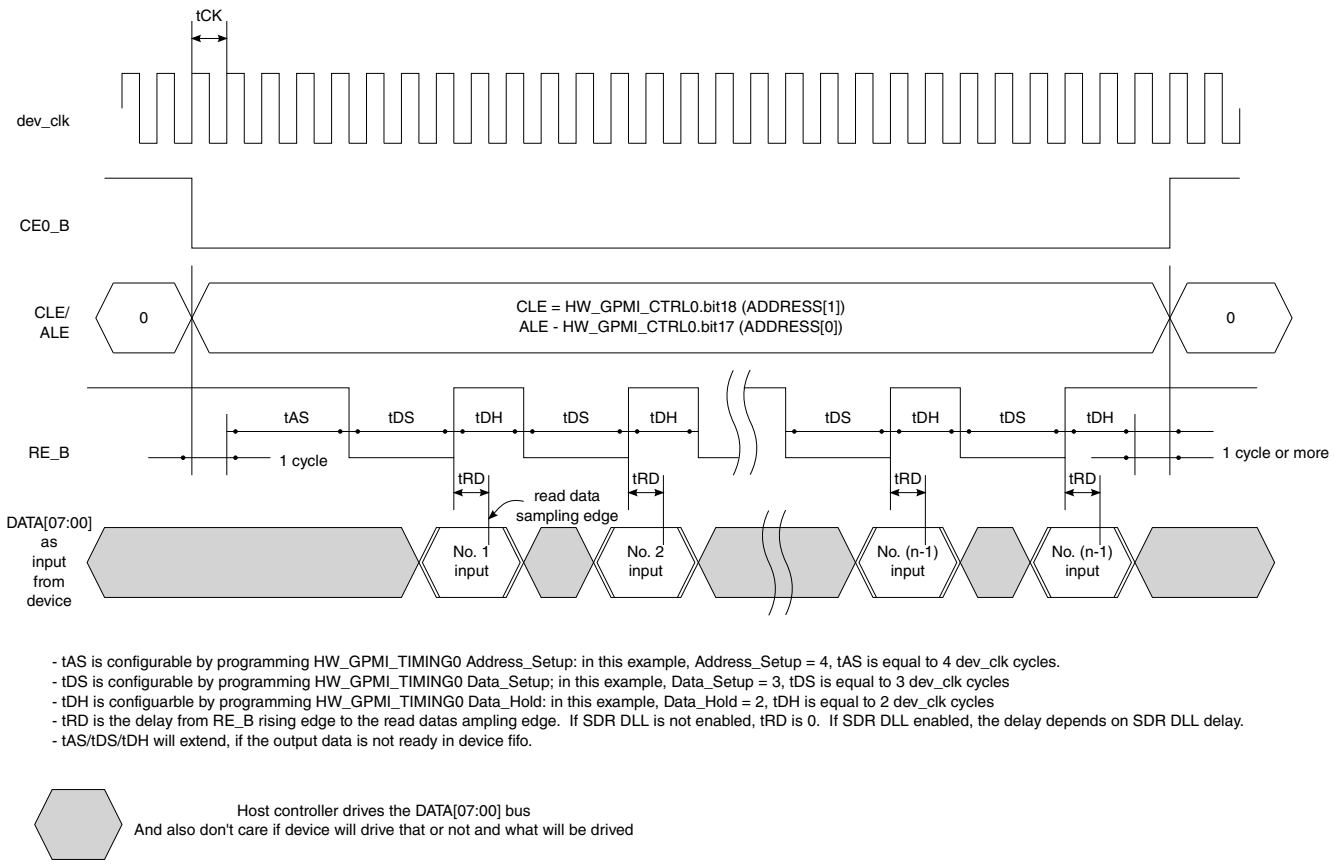


Figure 9-21. ONFI Asynchronous Mode Basic Read Timing Diagram (data read)

9.7.2.1.3.2 NAND Asynchronous EDO Mode Timing

In high-speed NANDs, the read data may not be valid until after the read strobe (NAND_RE_B) deasserts. This is the case when the minimum tDS is programmed to achieve higher bandwidth.

The GPMI implements a feedback read strobe to sample the read data. The feedback read strobe can be delayed to support fast nand EDO (Extended Data Out) timing where the read strobe may deassert before the read data is valid, and read data is valid for some time after read strobe. Nand EDO timings is applied typically for read cycle frequency above 33 MHz. See Figure 9-22.

The GPMI provides control over the amount of delay applied to the feedback read strobe. This delay depends on the maximum read access time (tREA) of the nand and the read pulse width (tRP) used to access the nand. tRP is specified by GPMI_TIMING0[DATA_SETUP] register. When (tREA + 4ns) is less than tRP, no

delay is required to sample to nand read data. (The 4ns provides adequate data setup time for the GPMI.) In this case set GPMI_CTRL1[HALF_PERIOD] = 0; GPMI_CTRL1[RDN_DELAY] = 0; GPMI_CTRL1[DLL_ENABLE] = 0.

When (tREA + 4ns) is greater than or equal to tRP, a delay of the feedback read strobe is required to sample to nand read data. This delay is equal to the difference between these two timings:

DELAY = tREA + 4ns - tRP.

Since the GPMI delay chain is limited to 6ns maximum, if DELAY > 6ns then increase tRP by increasing the value of GPMI_TIMING0[DATA_SETUP] until DELAY is less than or equal to 6ns.

The GPMI programming for this DELAY depends on the GPMICLK period. The GPMI DLL will not function properly if the GPMICLK period is greater than 12ns: disable the DLL if this is the case. If the GPMICLK period is greater than 6ns (and not greater than 12ns), set the GPMI_CTRL1[HALF_PERIOD]=1; This will cause the DLL reference period (RP) to be one-half of the GPMICLK period. If the GPMICLK period is 6ns or less then set the GPMI_CTRL1[HALF_PERIOD]=0; This will cause the DLL reference period (RP) to be equal to the GPMICLK period. DELAY is a multiple (0 to 1.875) of RP.

The GPMI_CTRL1[RDN_DELAY] is encoded as a 1-bit integer and 3-bit fraction delay factor. DELAY is a multiple of the delay factor and the reference period. See table below for details.

Table 9-14. RDN DELAY

HW_GPMI_CTRL1[RDN_DELAY]	Delay Factor
0	0.000
1	0.125
2	0.250
3	0.375
4	0.500
5	0.625
6	0.750
7	0.875
8	1.000
9	1.125
10	1.250
11	1.375
12	1.500
13	1.625

Table continues on the next page...

Table 9-14. RDN DELAY (continued)

HW_GPMI_CTRL1[RDN_DELAY]	Delay Factor
14	1.750
15	1.875

DELAY = DelayFactor x RP or DELAY = GPMI_CTRL1[RDN_DELAY] x 0.125 x RP.

Use this equation to calculate the value for GPMI_CTRL1[RDN_DELAY]. Then set GPMI_CTRL1[DLL_ENABLE]=1.

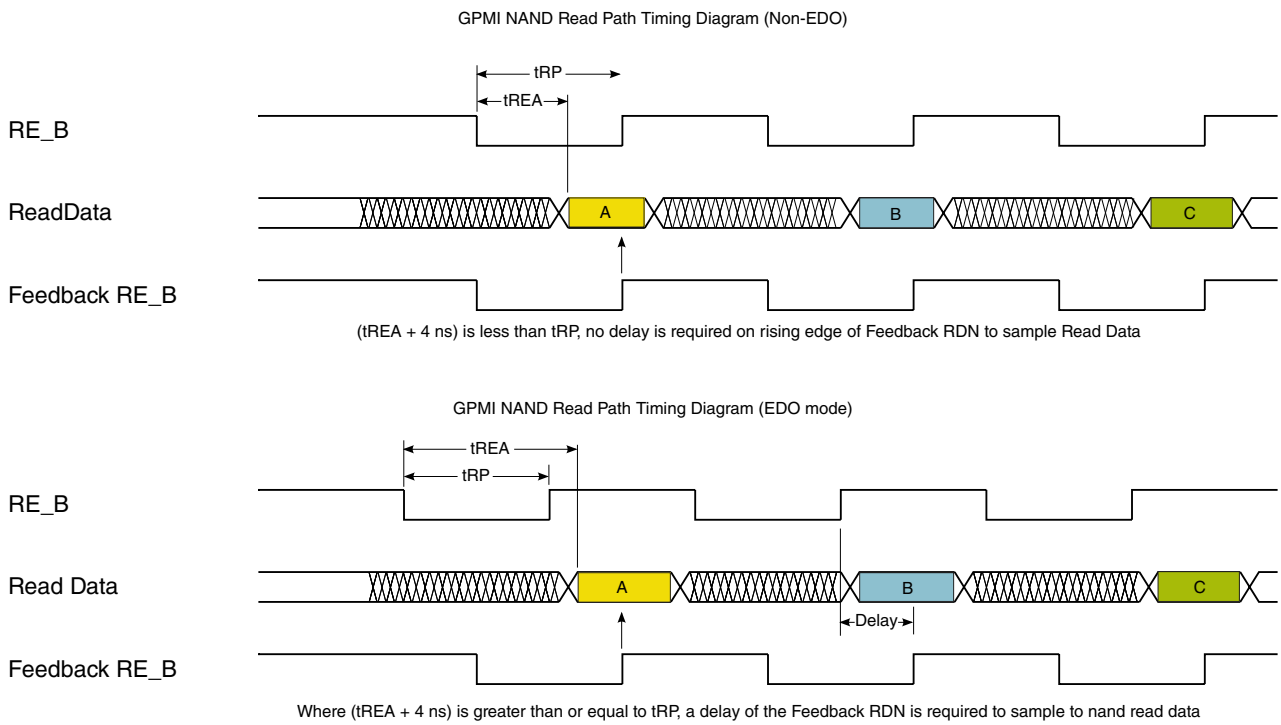

Figure 9-22. NAND Read Path Timing

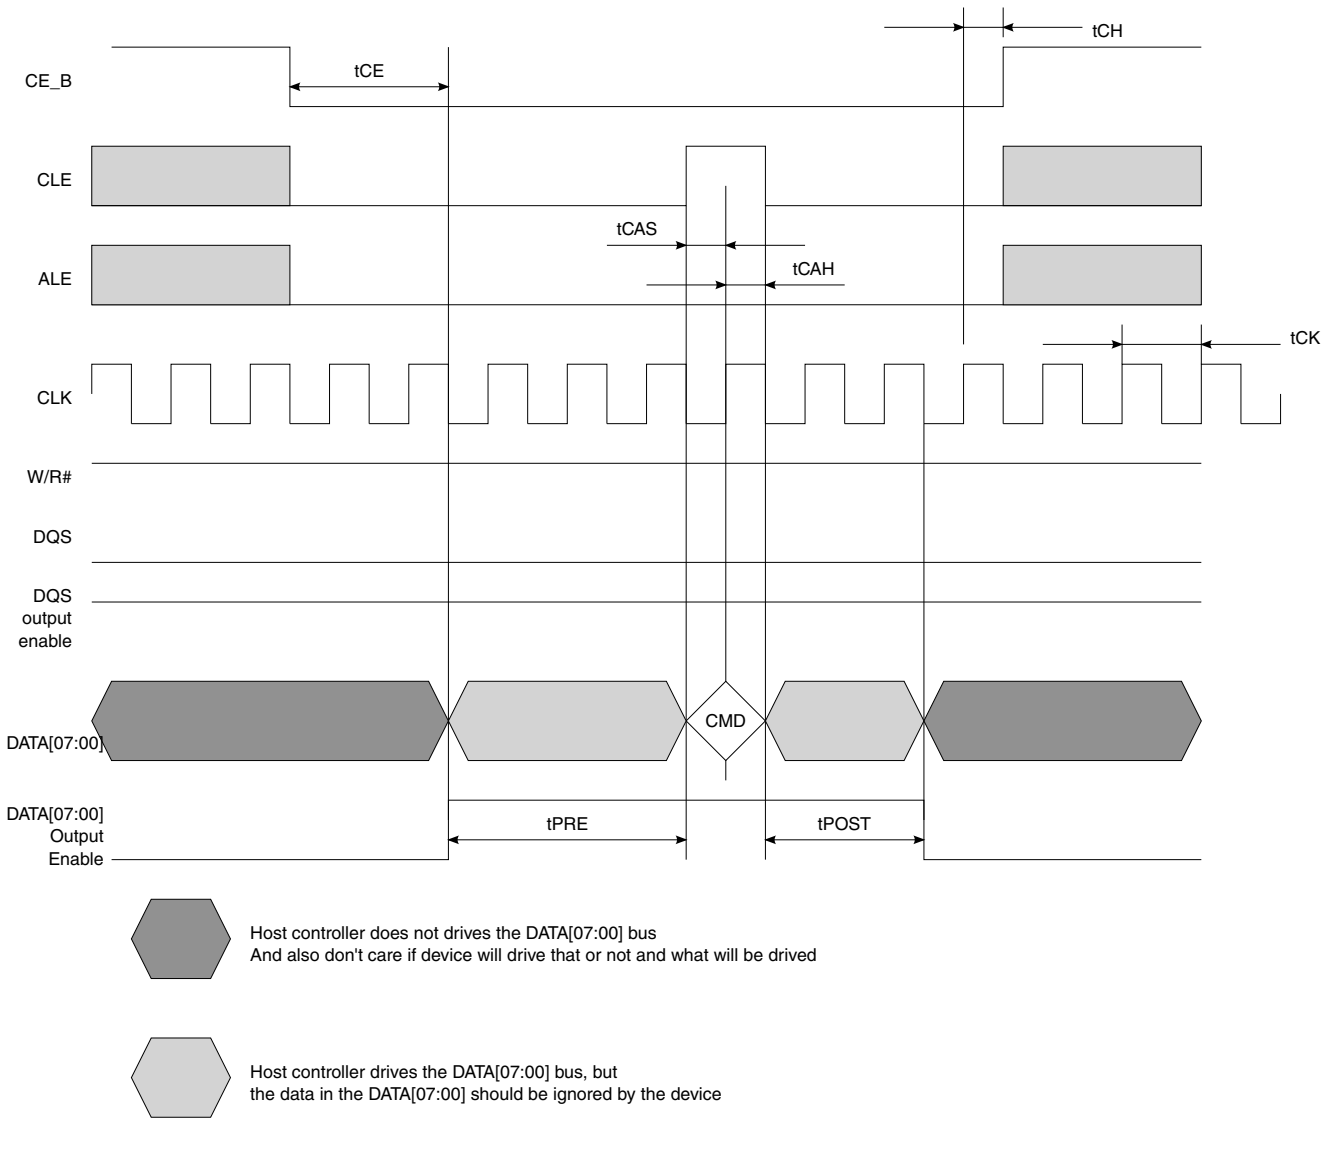
For example, a NAND with tREAmax = 20 ns, tRPmin = 12 ns, and tRCmin = 25 ns (read cycle time) may be programmed as follows:

- GPMICLK clock frequency: Consider 480/6 = 80 MHz which is 12.5 ns clock period. This is too close to the minimum NAND spec if we program the data setup and hold to 1 GPMICLK cycle. Consider 480/7=68.57 MHz which is 14.58 ns clock period. With data setup and hold set to 1, we have a tRP of 14.58ns and a tRC of 29.16 ns (good margins).
- Since (tREA +4ns) is greater than tRP, required DELAY = tREA + 4ns - tRP = 20 + 4 - 14.58ns = 9.42 ns.

- GPMI_CTRL1[HALF_PERIOD] =0, since GPMICLK period is less than 16ns. So RP=GPMICLK period = 14.58ns.
- DELAY = GPMI_CTRL1[RDN_DELAY] x 0.125 x RP. 9.42 ns = GPMI_CTRL1[RDN_DELAY] x 0.125 x 14.58ns. GPMI_CTRL1[RDN_DELAY] = 5 (round of 5.169)



NOTE

It is recommended that the drive strength of NAND_RE_B and NAND_WE_B output pins be set to 8 mA. This will reduce the transition time under heavy loads. Low transition times will be important when NAND interface read and write cycle times are below 30 ns. The other GPMI pins may remain at 4 mA, since their frequency is only up to half that of NAND_RE_B and NAND_WE_B.

9.7.2.1.3.3 NAND ONFI Source Synchronous Mode Timing

9.7.2.2 Hardware BCH Interface

The GPMI provides an interface to the BCH module. This reduces the SOC bus traffic and the software involvement.

The GPMI also provides an interface to the Randomizer module. The Randomizer can generate random data based on BCH ECC encoded / decoded data. It can be employed to reduce the disturbances caused by neighboring cells in the NAND chip, thus reducing bit errors. To enable the Randomizer module, set GPMI_ECCCTRL[RANDOMIZER_ENABLE] to 1, then set GPMI_ECCCOUNT[RANDOMIZER_PAGE] to select randomizer page number needed to be randomized. All these registers can be programmed by the DMA chain. The

randomized data should start from the zero column address and be the size of the whole NAND page. If the randomizer function is enabled, GPMI_ECCCTRL[ENABLE_ECC] should also be enabled. To bypass BCH error correction function, set BCH_FLASHxLAYOUT0[ECC0] and BCH_FLASHxLAYOUT1[ECCN] to 0.

When BCH ECC is enable, parity information is inserted on-the-fly during writes to 8-bit NAND devices. The BCH will supply payload and parity to the GPMI to write to the NAND. During NAND reads, parity is checked and ECC processing is performed after each read block. In this case the GPMI reads the NAND device and redirects the data and parity to the BCH module for ECC processing.

To program the BCH for NAND writes, remove the soft reset and clock gates from BCH_CTRL[SFTRST] and BCH_CTRL[CLKGATE]. The bulk of BCH programming is actually applied to the GPMI via PIO operations embedded in its DMA command structures. This has a subtle implication when writing to the GPMI ECC registers: access to the these registers must be written in progressive register order. Thus, to write to the GPMI_ECCCOUNT register, write first (in order) to registers GPMI_CTRL0, GPMI_COMPARE, and GPMI_ECCCTRL before writing to GPMI_ECCCOUNT. These additional register writes need to be accounted for in the CMDWORDS field of the respective DMA channel command register.

NOTE

Note that the GPMI_PAYLOAD and GPMI_AUXILIARY pointers need to be word-aligned for proper ECC operation. If those pointers are non-word-aligned, then the BCH engine will not operate properly and could possibly corrupt system memory in the adjoining memory regions.

9.7.2.3 Clocks

The table found here describes the clock sources for GPMI. Please see clock control module for clock setting, configuration and gating information.

Table 9-15. GPMI Clocks

Clock name	Description
bch_input_apb_clk	BCH to APBH input clock
gpmi_bch_input_bch_clk	BCH input clock
gpmi_bch_input_gpmi_io_clk	GPMI IO input clock
gpmi_input_apb_clk	GPMI to APBH clock

9.7.2.4 Behavior During Reset

A soft reset (SFTRST) can take multiple clock periods to complete, so do NOT set CLKGATE when setting SFTRST. The reset process gates the clocks automatically.

9.7.3 External Signals

The table found here describes the external signals of GPMI.

Table 9-16. GPMI External Signals

Signal	Description
NAND_ALE	Address latch enable signal
NAND_CEn_B	Chip enable signal
NAND_CLE	Command latch enable signal
NAND_DATAn	Data signal
NAND_DQS	DQS signal
NAND_RE_B	Read enable signal
NAND_READY	Ready signal
NAND_WE_B	Write enable signal
NAND_WP_B	Wait polarity signal
NAND_TESTER_TRIGGER	Tester trigger signal

9.7.4 GPMI register descriptions

The following registers provide control for programmable elements of the GPMI module.

NOTE

All ATA or UDMA features are not supported for the chip.

NOTE

GPMI does not support the Set feature command in Toggle mode. The NANDF_DQS output is only enabled in program operation for Toggle mode, but the Set feature command also needs to use the NANDF_DQS signal to write data to Toggle NAND flash. So the Set feature command in Toggle mode is not supported.

9.7.4.1 GPMI memory map

GPMI base address: 3300_2000h

Offset	Register	Width (In bits)	Access	Reset value
0h	GPMI Control Register 0 Description (CTRL0)	32	RW	C000_0000h

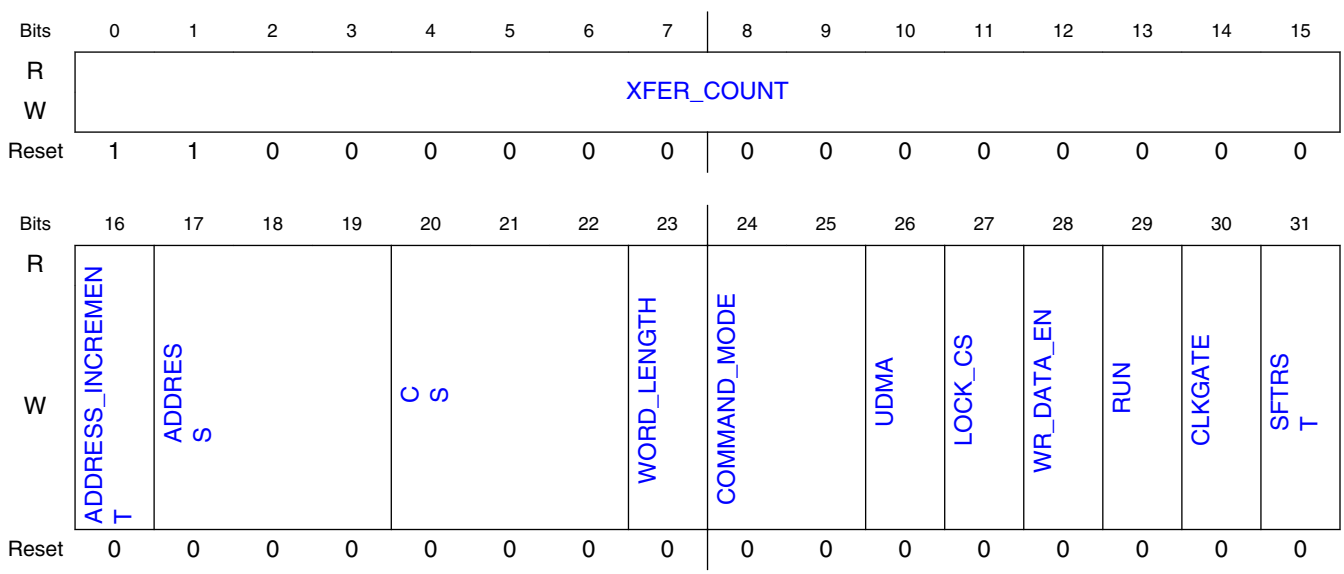
9.7.4.2 GPMI Control Register 0 Description (CTRL0)



9.7.4.2.1 Offset

Register	Offset	Description
CTRL0	0h	GPMI Control Register 0 Description
CTRL0_SET	4h	Writing a 1 to a bit in this register sets the corresponding bit in CTRL0
CTRL0_CLR	8h	Writing a 1 to a bit in this register clears the corresponding bit in CTRL0
CTRL0_TOG	Ch	Writing a 1 to a bit in this register toggles the corresponding bit in CTRL0

9.7.4.2.2 Function

The GPMI control register 0 specifies the GPMI transaction to perform for the current command chain item.

9.7.4.2.3 Diagram

9.7.4.2.4 Fields

Field	Function
0-15	XFER_COUNT

Table continues on the next page...

Field	Function
XFER_COUNT	Number of bytes to transfer for this command. A value of zero will transfer 64K bytes.
16 ADDRESS_INCREMENT	ADDRESS_INCREMENT In ATA mode, the address will increment with each cycle. In NAND mode, the address will increment once, after the first cycle (going from CLE to ALE). DISABLED = 0x0 Address does not increment. ENABLED = 0x1 Increment address.
17-19 ADDRESS	ADDRESS Specifies the three address lines for ATA mode. In NAND mode, use A0 for CLE and A1 for ALE. NAND_DATA = 0x0 In NAND mode, this address is used to read and write data bytes. NAND_CLE = 0x1 In NAND mode, this address is used to write command bytes. NAND_ALE = 0x2 In NAND mode, this address is used to write address bytes.
20-22 CS	CS Selects which chip select is active for this command. For ATA WAIT_FOR_READY command, this must be set to b01.
23 WORD_LENGTH	WORD_LENGTH This bit should only be changed when RUN==0. Reserve = 0x0 Reserved. 8_BIT = 0x1 8-bit Data Bus mode. 0b - Reserved. 1b - 8-bit Data Bus mode.
24-25 COMMAND_MODE	COMMAND_MODE WRITE = 0x0 Write mode. READ = 0x1 Read mode. READ_AND_COMPARE = 0x2 Read and Compare mode (setting sense flop). WAIT_FOR_READY = 0x3 Wait for Ready mode. For ATA WAIT_FOR_READY command set CS=01. 00b - Write mode. 01b - Read Mode. 10b - Read and Compare Mode (setting sense flop). 11b - Wait for Ready.
26 UDMA	UDMA DISABLED = 0x0 Use ATA-PIO mode on the external bus. ENABLED = 0x1 Use ATA-Ultra DMA mode on the external bus. 0b - Use ATA-PIO mode on the external bus. 1b - Use ATA-Ultra DMA mode on the external bus.
27 LOCK_CS	LOCK_CS For ATA/NAND mode: 0= Deassert chip select (CS) after RUN is complete. 1= Continue to assert chip select (CS) after RUN is complete. For Camera Mode: 0= Dont wait for VSYNC rising edge before capturing data. 1= Wait for VSYNC rising edge before capturing data (Camera mode only). DISABLED = 0x0 Deassert chip select (CS) after RUN is complete. ENABLED = 0x1 Continue to assert chip select (CS) after RUN is complete.
28	WR_DATA_EN

Table continues on the next page...

Field	Function
WR_DATA_EN	When operation is writing at toggle/toggle2.0 mode, this bit should be set to 0x1.
29 RUN	RUN The GPMI is busy running a command whenever this bit is set to '1'. The GPMI is idle whenever this bit set to zero. This can be set to one by a CPU write. In addition, the DMA sets this bit each time a DMA command has finished its PIO transfer phase. IDLE = 0x0 The GPMI is idle. BUSY = 0x1 The GPMI is busy running a command.
30 CLKGATE	CLKGATE Set this bit zero for normal operation. Setting this bit to one (default), gates all of the block level clocks off for miniminizing AC energy consumption. RUN = 0x0 Allow GPMI to operate normally. NO_CLKS = 0x1 Do not clock GPMI gates in order to minimize power consumption.
31 SFTRST	SFTRST Set to zero for normal operation. When this bit is set to one (default), then the entire block is held in its reset state. This will not work if the CLKGATE bit is already set to '1'. CLKGATE must be cleared to '0' before issuing a soft reset. Also the GPMICLK must be running for this to work properly. RUN = 0x0 Allow GPMI to operate normally. RESET = 0x1 Hold GPMI in reset.

9.7.4.3 GPMI Compare Register Description (COMPARE)

9.7.4.3.1 Offset

Register	Offset
COMPARE	10h

9.7.4.3.2 Function

The GPMI compare register specifies the expect data and the xor mask for comparing to the status values read from the device. This register is used by the Read and Compare command.

GPMI_COMPARE 0x010

9.7.4.3.3 Diagram

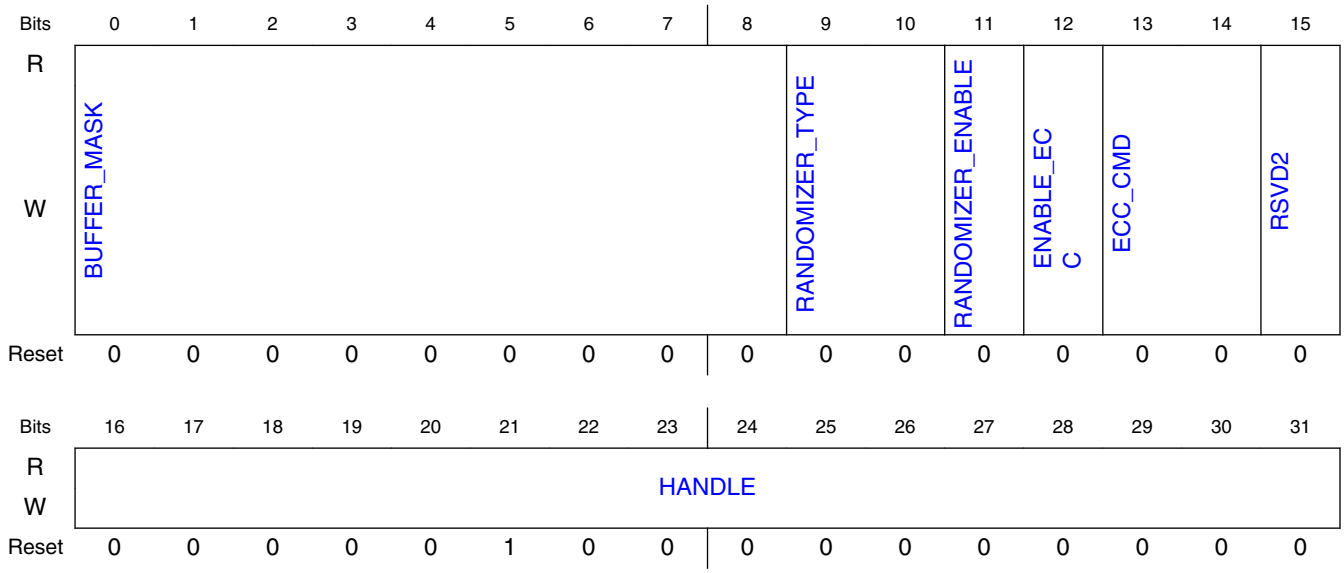
Bits	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	REFERENCE															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	MASK															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

9.7.4.3.4 Fields

Field	Function
0-15 REFERENCE	REFERENCE 16-bit value which is XORed with data read from the NAND device.
16-31 MASK	MASK 16-bit mask which is applied after the read data is XORed with the REFERENCE bit field.

9.7.4.4 GPMI Integrated ECC Control Register Description (ECCCTRL)



9.7.4.4.1 Offset

Register	Offset	Description
ECCCTRL	20h	GPMI Integrated ECC Control Register Description
ECCCTRL_SET	24h	Writing a 1 to a bit in this register sets the corresponding bit in ECCCTRL
ECCCTRL_CLR	28h	Writing a 1 to a bit in this register clears the corresponding bit in ECCCTRL
ECCCTRL_TOG	2Ch	Writing a 1 to a bit in this register toggles the corresponding bit in ECCCTRL

9.7.4.4.2 Function

The GPMI ECC control register handles configuration of the integrated ECC / Randomizer accelerator.

9.7.4.4.3 Diagram

9.7.4.4.4 Fields

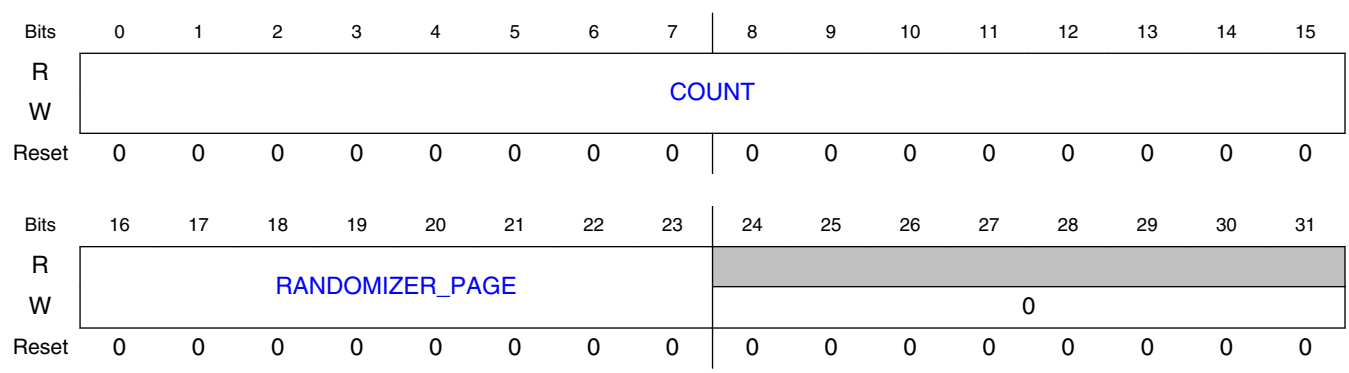
Field	Function
0-8 BUFFER_MASK	BUFFER_MASK ECC buffer information. The BCH error correction only allows two configurations of the buffer mask - software may either read just the first block on the flash page or the entire flash page. Write operations must be for the entire flash page. Invalid buffer mask values will cause the DMA descriptor command to be terminated. BCH_AUXONLY = 0x100 Set to request transfer from only the auxiliary buffer (block 0 on flash). BCH_PAGE = 0x1FF Set to request transfer to/from the entire page.
9-10 RANDOMIZER_TYPE	RANDOMIZER_TYPE Set randomizer type 00b - Type 0 01b - Type 1 10b - Type 2
11 RANDOMIZER_ENABLE	RANDOMIZER_ENABLE Enable randomizer function. If this bit is set to enable, ENABLE_ECC should be also enable. 0b - disable 1b - enable
12 ENABLE_ECC	ENABLE_ECC Enable ECC processing of GPMI transfers. ENABLE = 0x1 Use integrated ECC for read and write transfers. DISABLE = 0x0 Integrated ECC remains in idle.
13-14	ECC_CMD

Table continues on the next page...

Field	Function
ECC_CMD	ECC Command information. DECODE = 0x0 Decode. ENCODE = 0x1 Encode. RESERVE2 = 0x2 Reserved. RESERVE3 = 0x3 Reserved.
15 RSVD2	RSVD2 Always write zeroes to this bit field.
16-31 HANDLE	HANDLE This is a register available to software to attach an identifier to a transaction in progress. This handle will be available from the ECC register space when the completion interrupt occurs.

9.7.4.5 GPMI Integrated ECC Transfer Count Register Description (ECCCOUNT)

9.7.4.5.1 Offset



Register	Offset
ECCCOUNT	30h

9.7.4.5.2 Function

The GPMI ECC Transfer Count Register contains the count of bytes that flow through the ECC / Randomizer subsystem.

GPMI_ECCCOUNT 0x030

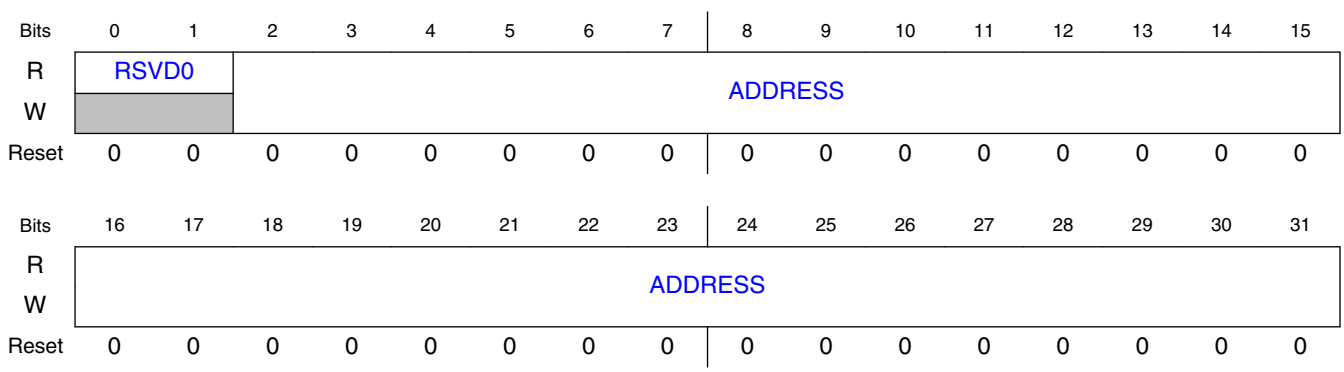
9.7.4.5.3 Diagram

9.7.4.5.4 Fields

Field	Function
0-15 COUNT	COUNT Number of bytes to pass through ECC. This is the GPMI transfer count plus the syndrome count that will be inserted into the stream by the ECC. In DMA2ECC_MODE this count must match the GPMI_CTRL0_XFER_COUNT. A value of zero will transfer 64K words.
16-23 RANDOMIZER_PAGE	RANDOMIZER_PAGE Set NAND page number needed to be randomized. The value is between 0-255
24-31 —	- Always write zeroes to this bit field.

9.7.4.6 GPMI Payload Address Register Description (PAYLOAD)

9.7.4.6.1 Offset



Register	Offset
PAYLOAD	40h

9.7.4.6.2 Function

The GPMI payload address register specifies the location of the data buffers in system memory. This value must be word aligned.

GPMI_PAYLOAD 0x040

9.7.4.6.3 Diagram

9.7.4.6.4 Fields

Field	Function
0-1 RSVD0	RSVD0 Always write zeroes to this bit field.
2-31 ADDRESS	ADDRESS Pointer to an array of one or more 512 byte payload buffers.

9.7.4.7 GPMI Auxiliary Address Register Description (AUXILIARY)

9.7.4.7.1 Offset

Register	Offset
AUXILIARY	50h

9.7.4.7.2 Function

The GPMI auxiliary address register specifies the location of the auxiliary buffers in system memory. This value must be word aligned.

GPMI_AUXILIARY 0x050

9.7.4.7.3 Diagram

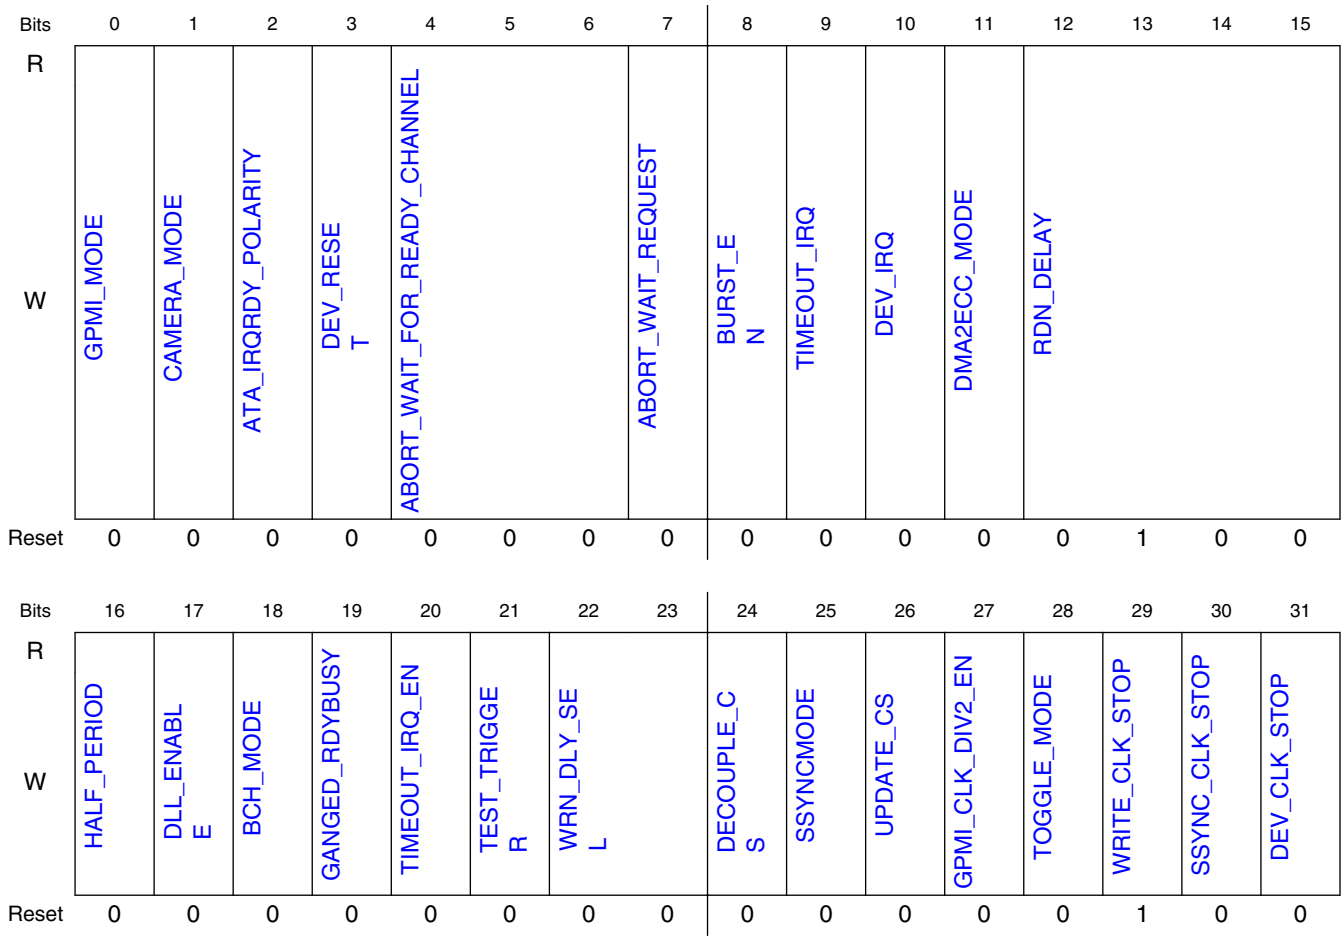
Bits	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	RSVD0		ADDRESS													
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	ADDRESS															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

9.7.4.7.4 Fields

Field	Function
0-1 RSVD0	RSVD0 Always write zeroes to this bit field.
2-31 ADDRESS	ADDRESS Pointer to ECC control structure and meta-data storage.

9.7.4.8 GPMI Control Register 1 Description (CTRL1)



9.7.4.8.1 Offset

Register	Offset	Description
CTRL1	60h	GPMI Control Register 1 Description
CTRL1_SET	64h	Writing a 1 to a bit in this register sets the corresponding bit in CTRL1
CTRL1_CLR	68h	Writing a 1 to a bit in this register clears the corresponding bit in CTRL1
CTRL1_TOG	6Ch	Writing a 1 to a bit in this register toggles the corresponding bit in CTRL1

9.7.4.8.2 Function

The GPMI control register 1 specifies additional control fields that are not used on a per-transaction basis.

9.7.4.8.3 Diagram

9.7.4.8.4 Fields

Field	Function
0 GPMI_MODE	GPMI_MODE ATA mode is only supported on channel zero. If ATA mode is selected, then only channel three is available for NAND use. NAND = 0x0 NAND mode. ATA = 0x1 ATA mode. 0b - NAND mode. 1b - ATA mode.
1 CAMERA_MODE	CAMERA_MODE When set to 1 and ATA UDMA is enabled the UDMA interface becomes a camera interface.
2 ATA_IRQRDY_POLARITY	ATA_IRQRDY_POLARITY For ATA MODE:

Table continues on the next page...

Field	Function
	Note NAND_RDY_BUSY[3:2] are not affected by this bit. ACTIVELOW = 0x0 ATA IORDY and IRQ are active low, or NAND_RDY_BUSY[1:0] are active low ready. ACTIVEHIGH = 0x1 ATA IORDY and IRQ are active high, or NAND_RDY_BUSY[1:0] are active high ready. 0 External ATA IORDY and IRQ are active low. 1 External ATA IORDY and IRQ are active high. For NAND MODE: 0b - External RDY_BUSY[1] and RDY_BUSY[0] pins are ready when low and busy when high. 1b - External RDY_BUSY[1] and RDY_BUSY[0] pins are ready when high and busy when low.
3 DEV_RESET	DEV_RESET ENABLED = 0x0 NANDF_WP_B(WPN) pin is held low (asserted). DISABLED = 0x1 NANDF_WP_B(WPN) pin is held high (de-asserted). 0b - NANDF_WP_B pin is held low (asserted). 1b - NANDF_WP_B pin is held high (de-asserted).
4-6 ABORT_WAIT_FOR_READY_CHANNEL	ABORT_WAIT_FOR_READY_CHANNEL Abort a wait for ready command on selected channel. Set the ABORT_WAIT_REQUEST to kick of operation.
7 ABORT_WAIT_REQUEST	ABORT_WAIT_REQUEST Request to abort "wait for ready" command on channel indicated by ABORT_WAIT_FOR_READY_CHANNEL. Hardware will clear this bit when abort is done.
8 BURST_EN	BURST_EN When set to 1 each DMA request will generate a 4-transfer burst on the APB bus.
9 TIMEOUT_IRQ	TIMEOUT_IRQ This bit is set when a timeout occurs using the Device_Busy_Timeout value. Write 0 to clear.
10 DEV_IRQ	DEV_IRQ This bit is set when an Interrupt is received from the ATA device. Write 0 to clear.
11 DMA2ECC_MODE	DMA2ECC_MODE This is mainly for testing HWECC without involving the Nand device. Setting this bit will cause DMA write data to redirected to HWECC module (instead of Nand Device) for encoding or decoding.
12-15 RDN_DELAY	RDN_DELAY This variable is a factor in the calculated delay to apply to the internal read strobe for correct read data sampling. The applied delay (AD) is between 0 and 1.875 times the reference period (RP). RP is one half of the GPMI clock period if HALF_PERIOD=1 otherwise it is the full GPMI clock period. The equation is: AD = RDN_DELAY x 0.125 x RP. This value must not exceed 16ns. This variable is used to achieve faster NAND access. For example if the Read Strobe is asserted from time 0 to 13ns but the read access time is 20ns, then choose AD=12ns will cause the data to be sampled at time 25ns (13+12) giving a 5ns data setup time. If RP=13ns then RDN_DELAY = 12/(0.125 x 13ns) = 7.38 (0111b). DLL_ENABLE must be zero while changing this field.
16	HALF_PERIOD

Table continues on the next page...

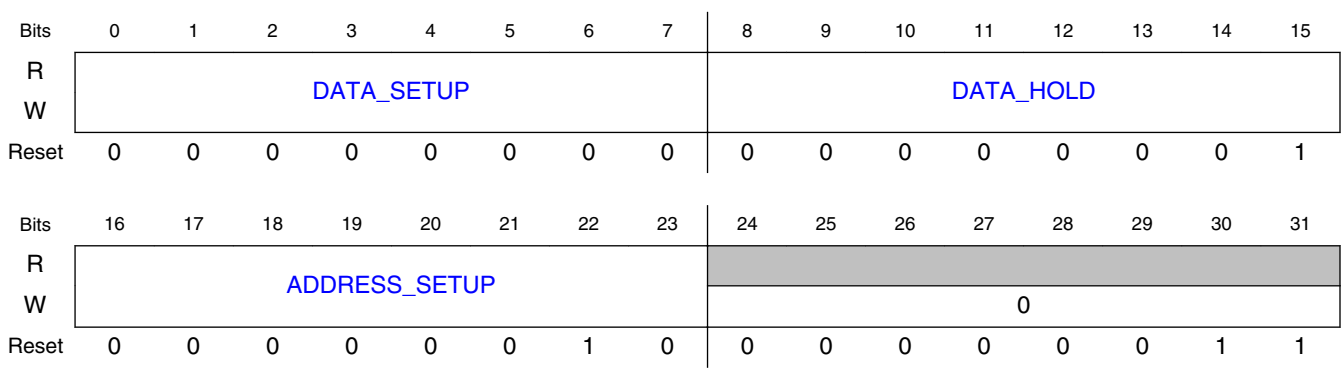
Field	Function
HALF_PERIOD	Set this bit to 1 if the GPMI clock period is greater than 16ns for proper DLL operation. DLL_ENABLE must be zero while changing this field.
17 DLL_ENABLE	DLL_ENABLE Set this bit to 1 to enable the GPMI DLL. This is required for fast NAND reads (above 30 MHz read strobe). After setting this bit, wait 64 GPMI clock cycles for the DLL to lock before performing a NAND read.
18 BCH_MODE	BCH_MODE This bit selects which error correction unit will access GPMI. This bit must always be set to '1', since only the BCH unit is available in this design.
19 GANGED_RDYBUSY	GANGED_RDYBUSY Set this bit to 1 will force all Nand RDY_BUSY inputs to be sourced from (tied to) RDY_BUSY0. This will free up all, except one, RDY_BUSY input pins.
20 TIMEOUT_IRQ_EN	TIMEOUT_IRQ_EN Setting this bit to '1' will enable timeout IRQ for transfers in ATA mode only, and for WAIT_FOR_READY commands in both ATA and Nand mode. The Device_Busy_Timeout value is used for this timeout.
21 TEST_TRIGGER	TEST_TRIGGER Test Trigger Enable 0b - Disable 1b - Enable
22-23 WRN_DLY_SEL	WRN_DLY_SEL Since the GPMI write strobe (WRN) is a fast clock pin, the delay on this signal can be programmed to match the load on this pin. 0 = ~2ns; 1 = ~4ns; 2 = ~6ns; 3 = no delay.
24 DECOUPLE_CS	DECOUPLE_CS Decouple Chip Select from DMA Channel. Setting this bit to 1 will allow a DMA channel to specify any value in the CTRL0_CS register field. Software can use one DMA channel to access all 8 Nand devices.
25 SSYNCMODE	SSYNCMODE source synchronouse mode 1 or asynchrous mode 0. ASYNC = 0x0 Asynchronous mode. SSYNC = 0x1 Source Synchronous mode.
26 UPDATE_CS	UPDATE_CS force the CS value is be updated to external chip select pin, even GPMI is idle.
27 GPMI_CLK_DIV2_EN	GPMI_CLK_DIV2_EN This bit should be reset to 0 in asynchronous mode. The frequence ratio of (device clock : ccm gpmi clock) will be (1 : 1). This bit should be set to 1, in source synchronous mode or toggle mode. The frequence raito of (device clock : ccm gpmi clock) will be (1 : 2). enable the gpmi clk divider. 0b - internal factor-2 clock divider is disabled 1b - internal factor-2 clock divider is enabled.
28 TOGGLE_MODE	TOGGLE_MODE enable samsung toggle mode.

Table continues on the next page...

Field	Function
29 WRITE_CLK_STOP	WRITE_CLK_STOP In onfi source synchronous mode, host may save power during the data write cycles by holding the CLK signal high (i.e. stopping the CLK). The host may only stop the CLK during data write, by setting this bit to 1, if the device supports this feature as indicated in the parameter page.
30 SSYNC_CLK_STOP	SSYNC_CLK_STOP set this bit to 1 will stop the source synchronous mode clk.
31 DEV_CLK_STOP	DEV_CLK_STOP set this bit to 1 will stop gpmi io working clk.

9.7.4.9 GPMI Timing Register 0 Description (TIMING0)

9.7.4.9.1 Offset



Register	Offset
TIMING0	70h

9.7.4.9.2 Function

The GPMI timing register 0 specifies the timing parameters that are used by the cycle state machine to guarantee the various setup, hold and cycle times for the external media type.

GPMI_TIMING0 0x070

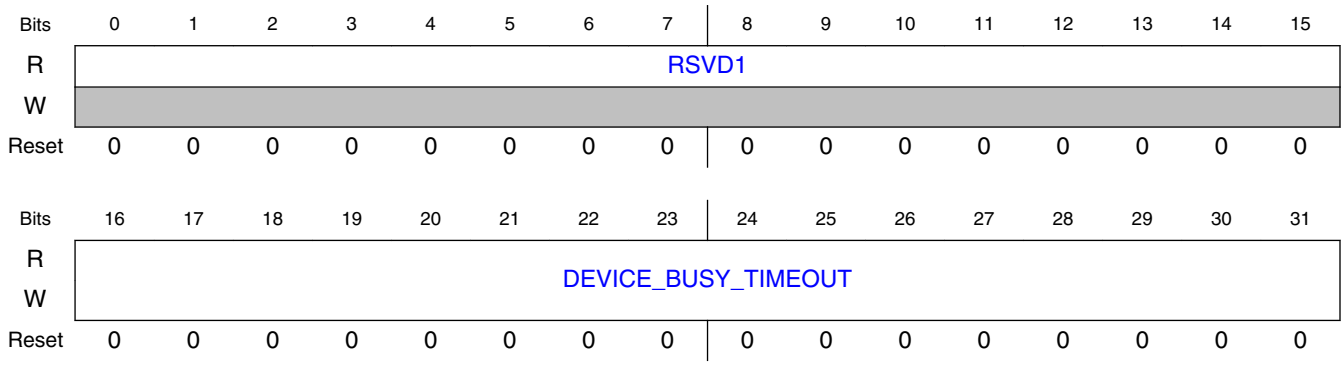
9.7.4.9.3 Diagram

9.7.4.9.4 Fields

Field	Function
0-7 DATA_SETUP	DATA_SETUP Data bus setup time in GPMICLK cycles. Also the time that the data strobe is asserted in a cycle. This value must be greater than 2 for ATA devices that use IORDY to extend transfer cycles. A value of zero is interpreted as 256. For ATA PIO modes this is known in the ATA7 specification as ""DIOR-/DIOW-"
8-15 DATA_HOLD	DATA_HOLD Data bus hold time in GPMICLK cycles. Also the time that the data strobe is de-asserted in a cycle. A value of zero is interpreted as 256. For ATA PIO modes this is known in the ATA7 specification as "DIOR-/DIOW- recovery time"
16-23 ADDRESS_SETUP	ADDRESS_SETUP Number of GPMICLK cycles that the CE/ADDR signals are active before a strobe is asserted. A value of zero is interpreted as 0. For ATA PIO modes this is known in the ATA7 specification as "Address valid to DIOR-/DIOW- setup"
24-31 RSVD1	RSVD1 Always write zeroes to this bit field.

9.7.4.10 GPMI Timing Register 1 Description (TIMING1)

9.7.4.10.1 Offset



Register	Offset
TIMING1	80h

9.7.4.10.2 Function

The GPMI timing register 1 specifies the timeouts used when monitoring the NAND READY pin or the ATA IRQ and IOWAIT signals.

GPMI_TIMING1 0x080

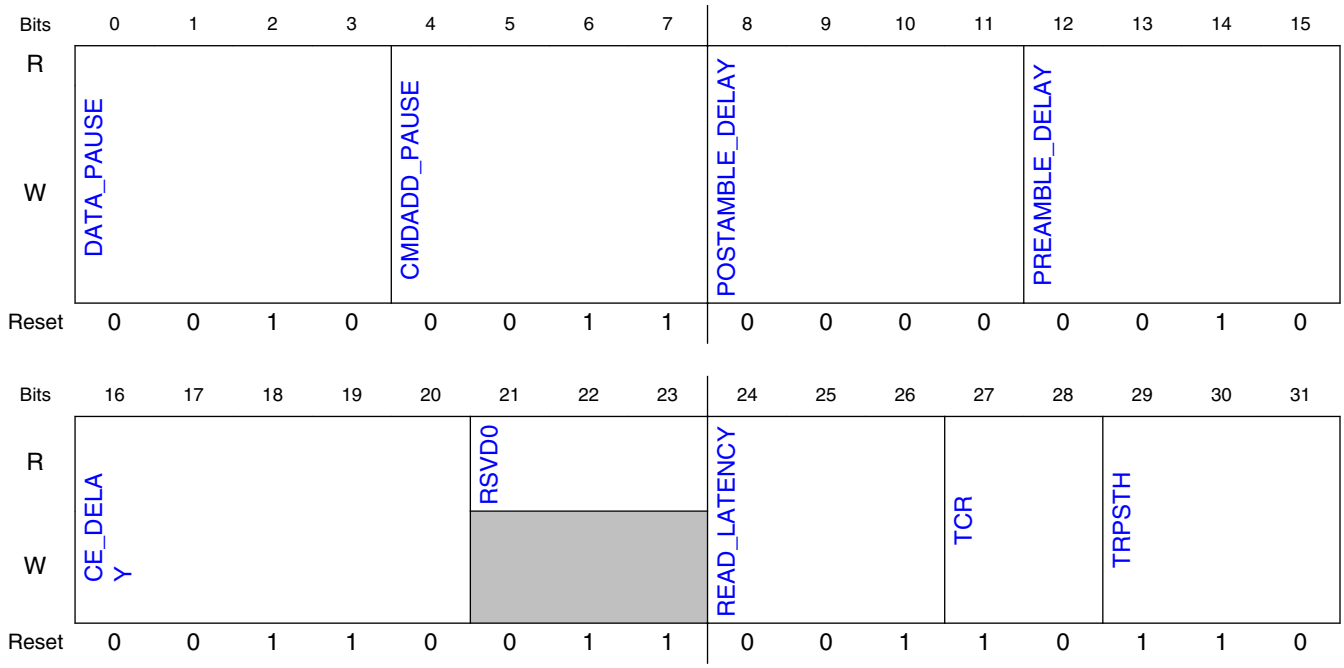
9.7.4.10.3 Diagram

9.7.4.10.4 Fields

Field	Function
0-15 RSVD1	RSVD1 Always write zeroes to this bit field.
16-31 DEVICE_BUSY_TIMEOUT	DEVICE_BUSY_TIMEOUT Timeout waiting for NAND Ready/Busy or ATA IRQ. Used in WAIT_FOR_READY mode. This value is the number of GPMI_CLK cycles multiplied by 4096.

9.7.4.11 GPMI Timing Register 2 Description (TIMING2)

9.7.4.11.1 Offset



Register	Offset
TIMING2	90h

9.7.4.11.2 Function

The GPMI timing register 2 specifies the double data rate timing parameters that are used by the cycle state machine to guarantee the various cs delay, pre-amble delay, post-amble delay, command/address delay, data delay, TCR, TRPSTH, and read latency cycle times for the external media type.

GPMI_TIMING2 0x090

9.7.4.11.3 Diagram

9.7.4.11.4 Fields

Field	Function
0-3 DATA_PAUSE	DATA_PAUSE GPMI delay time from data pause to data resume in GPMICLK cycles. A value of zero is interpreted as 16.
4-7 CMDADD_PAUSE	CMDADD_PAUSE GPMI delay time from command or addres pause to command or address resume in GPMICLK cycles. A value of zero is interpreted as 16.
8-11 POSTAMBLE_DELAY	POSTAMBLE_DELAY GPMI post-amble delay in GPMICLK cycles. A value of zero is interpreted as 16.
12-15 PREAMBLE_DELAY	PREAMBLE_DELAY GPMI pre-amble delay in GPMICLK cycles. A value of zero is interpreted as 16.
16-20 CE_DELAY	CE_DELAY GPMI dealy from CEn assert to W/Rn changing edge. value of zero is interpreted as 32.
21-23 RSVD0	RSVD0 Always write zeroes to this bit field.
24-26 READ_LATENCY	READ_LATENCY This field is for double data rate read latency configuration. others READ LATENCY is 3

Table continues on the next page...

Field	Function
	000b - READ LATENCY is 0 001b - READ LATENCY is 1 010b - READ LATENCY is 2 011b - READ LATENCY is 3 100b - READ LATENCY is 4 101b - READ LATENCY is 5
27-28 TCR	TCR Only for Toggle NAND timing control delay (TCR+1) GPMICLK cycles for CEn_B low to RE_B low, 0 is less than or equal to TCR, which is less than the PREAMBLE_DELAY
29-31 TRPSTH	TRPSTH Only for Toggle NAND timing control delay TRPSTH GPMICLK cycles for CEn_B high to RE_B high, A value of zero is interpreted as 8

9.7.4.12 GPMI DMA Data Transfer Register Description (DATA)

9.7.4.12.1 Offset

Register	Offset
DATA	A0h

9.7.4.12.2 Function

The GPMI DMA data transfer register is used by the DMA to read or write data to or from the ATA/NAND control state machine.

GPMI_DATA 0x0A0

9.7.4.12.3 Diagram

9.7.4.13.4 Fields

Field	Function
0 PRESENT	PRESENT UNAVAILABLE = 0x0 GPMI is not present in this product. AVAILABLE = 0x1 GPMI is present in this product. 0b - GPMI is not present in this product. 1b - GPMI is present is in this product.
1 FIFO_FULL	FIFO_FULL NOT_FULL = 0x0 FIFO is not full. FULL = 0x1 FIFO is full. 0b - FIFO is not full. 1b - FIFO is full.
2 FIFO_EMPTY	FIFO_EMPTY NOT_EMPTY = 0x0 FIFO is not empty. EMPTY = 0x1 FIFO is empty. 0b - FIFO is not empty. 1b - FIFO is empty.
3 INVALID_BUFFER_MASK	INVALID_BUFFER_MASK Buffer Mask Validity bit. 0b - ECC Buffer Mask is not invalid. 1b - ECC Buffer Mask is invalid.
4 ATA_IRQ	ATA_IRQ Status of the ATA_IRQ input pin.
5-7 RSVD1	RSVD1 Always write zeroes to this bit field.
8 DEV0_ERROR	DEV0_ERROR DMA channel 0 (Timeout or compare failure, depending on COMMAND_MODE). 0b - No error condition present on ATA/NAND Device accessed by DMA channel 0. 1b - An Error has occurred on ATA/NAND Device accessed by
9 DEV1_ERROR	DEV1_ERROR DMA channel 1 (Timeout or compare failure, depending on COMMAND_MODE). 0b - No error condition present on ATA/NAND Device accessed by DMA channel 1. 1b - An Error has occurred on ATA/NAND Device accessed by
10 DEV2_ERROR	DEV2_ERROR DMA channel 2 (Timeout or compare failure, depending on COMMAND_MODE). 0b - No error condition present on ATA/NAND Device accessed by DMA channel 2. 1b - An Error has occurred on ATA/NAND Device accessed by
11 DEV3_ERROR	DEV3_ERROR DMA channel 3 (Timeout or compare failure, depending on COMMAND_MODE). 0b - No error condition present on ATA/NAND Device accessed by DMA channel 3. 1b - An Error has occurred on ATA/NAND Device accessed by

Table continues on the next page...

Field	Function
12 DEV4_ERROR	DEV4_ERROR DMA channel 4 (Timeout or compare failure, depending on COMMAND_MODE). 0b - No error condition present on ATA/NAND Device accessed by DMA channel 4. 1b - An Error has occurred on ATA/NAND Device accessed by
13 DEV5_ERROR	DEV5_ERROR DMA channel 5 (Timeout or compare failure, depending on COMMAND_MODE). 0b - No error condition present on ATA/NAND Device accessed by DMA channel 5. 1b - An Error has occurred on ATA/NAND Device accessed by
14 DEV6_ERROR	DEV6_ERROR DMA channel 6 (Timeout or compare failure, depending on COMMAND_MODE). 0b - No error condition present on ATA/NAND Device accessed by DMA channel 6. 1b - An Error has occurred on ATA/NAND Device accessed by
15 DEV7_ERROR	DEV7_ERROR DMA channel 7 (Timeout or compare failure, depending on COMMAND_MODE). 0b - No error condition present on ATA/NAND Device accessed by DMA channel 7. 1b - An Error has occurred on ATA/NAND Device accessed by
16-23 RDY_TIMEOUT	RDY_TIMEOUT State of the RDY/BUSY Timeout Flags. When any bit is set to '1' in this field, it indicates that a time out has occurred while waiting for the ready state of the requested NAND device. Multiple bits may be set simultaneously. When GPMI_CTRL1_DECOUPLE_CS = 0, RDY_TIMEOUT[n] is associated with the NAND device on chip_select[n]. When GPMI_CTRL1_DECOUPLE_CS = 1, these flags become associated to a DMA channel instead of a NAND device. For example if DMA channel 6 sends a WAIT_FOR_READY command for NAND Device 2, and a timeout occured on READY_BUSY2, then READY_TIMEOUT[6] will be set instead of READY_TIMEOUT[2].
24-31 READY_BUSY	READY_BUSY Read-only view of NAND Ready_Busy Input pins.

9.7.4.14 GPMI Debug Information Register Description (DEBUG)

9.7.4.14.1 Offset

Register	Offset
DEBUG	C0h

GPMI DDR Read Delay Loop Lock Control Register. This register provides programmability in DDR mode for data input timing and data formats.

GPMI_READ_DDR_DLL_CTRL 0x100

9.7.4.18.3 Diagram

9.7.4.18.4 Fields

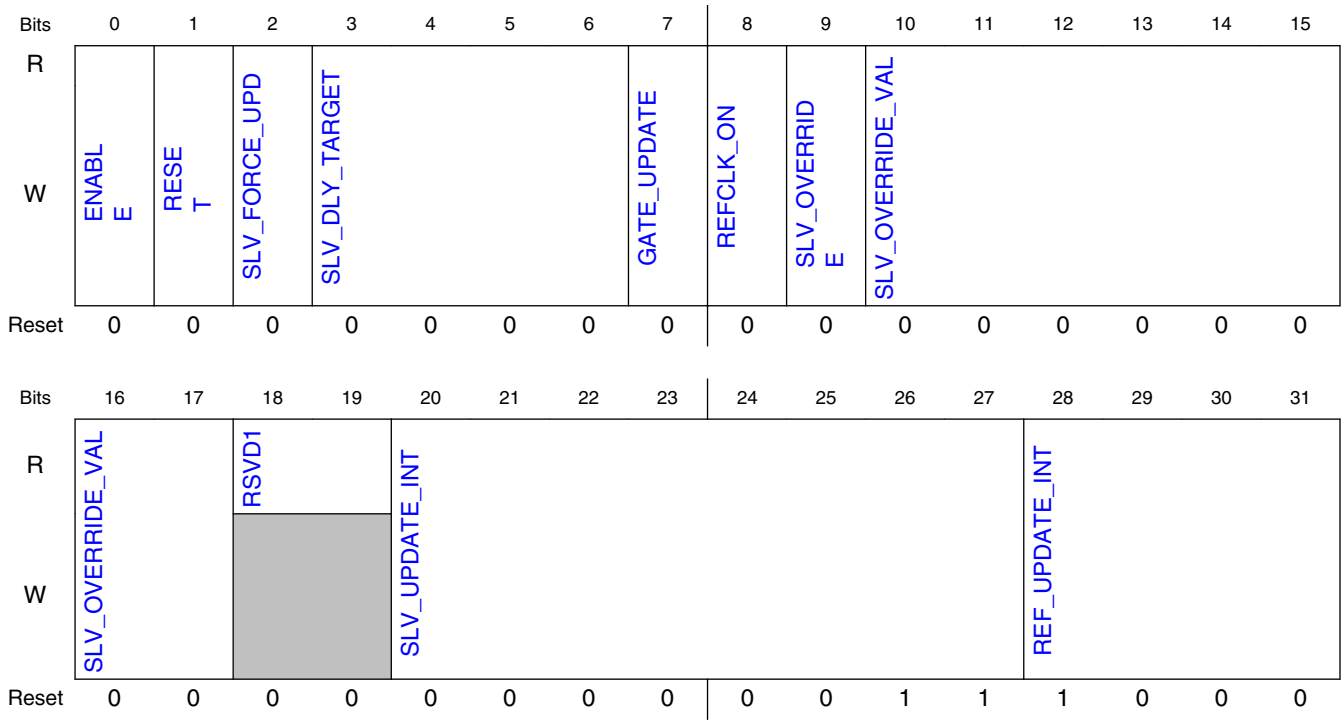
Field	Function
0 ENABLE	ENABLE Set this bit to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.
1 RESET	RESET Setting this bit to 1 force a reset on DLL. This will cause the DLL to lose lock and re-calibrate to detect an GPMICLK half period phase shift. This signal is used by the DLL as edge-sensitive, so in order to create a subsequent reset, RESET must be taken low and then asserted again.
2 SLV_FORCE_UPD	SLV_FORCE_UPD Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line shall update automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered).
3-6 SLV_DLY_TARGET	SLV_DLY_TARGET The delay target for the read clock is can be programmed in 1/16th increments of an GPMICLK half-period. So the input read-clock can be delayed relative input data from (GPMICLK/2)/16 to GPMICLK/2.
7 GATE_UPDATE	GATE_UPDATE Setting this bit to 1, forces the slave delay line not update
8	REFCLK_ON

Table continues on the next page...

Field	Function
REFCLK_ON	set this bit to 1 will turn on the reference clock
9 SLV_OVERRIDE	SLV_OVERRIDE Set this bit to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to tbe enabled using the ENABLE bit. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE=0
10-17 SLV_OVERRIDE_VAL	SLV_OVERRIDE_VAL When SLV_OVERRIDE=1 This field is used to select 1 of 256 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 256.
18-19 RSVD1	RSVD1 Reserved
20-27 SLV_UPDATE_INT	SLV_UPDATE_INT Setting a value greater than 0 in this field, shall over-ride the default slave delay-line update interval of 256 GPMICLK cycles. A value of 0 results in an update interval of 256 GPMICLK cycles (default setting). A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line will also update automatically when the reference DLL transitions to a locked state (from an un-locked state).
28-31 REF_UPDATE_INT	REF_UPDATE_INT This field allows the user to add additional delay cycles to the DLL control loop (reference delay line control). By default, the DLL control loop shall update every two GPMICLK cycles. Programming this field results in a DLL control loop update interval of (2 + REF_UPDATE_INT) * GPMICLK. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature)

9.7.4.19 GPMI Double Rate Write DLL Control Register Description (WRITE_DDR_DLL_CTRL)

9.7.4.19.1 Offset



Register	Offset
WRITE_DDR_DLL_CTRL	110h

25-31 RSVD1	RSVD1 Reserved

Chapter 10
Mass Storage

10.1 Enhanced Configurable SPI (ECSPI)

10.1.1 Overview

The Enhanced Configurable Serial Peripheral Interface (ECSPI) is a full-duplex, synchronous, four-wire serial communication block.

The ECSPI contains a 64 x 32 receive buffer (RXFIFO) and a 64 x 32 transmit buffer (TXFIFO). With data FIFOs, the ECSPI allows rapid data communication with fewer software interrupts.

10.1.1.1 Block Diagram

The figure below shows a block diagram of the ECSPI.

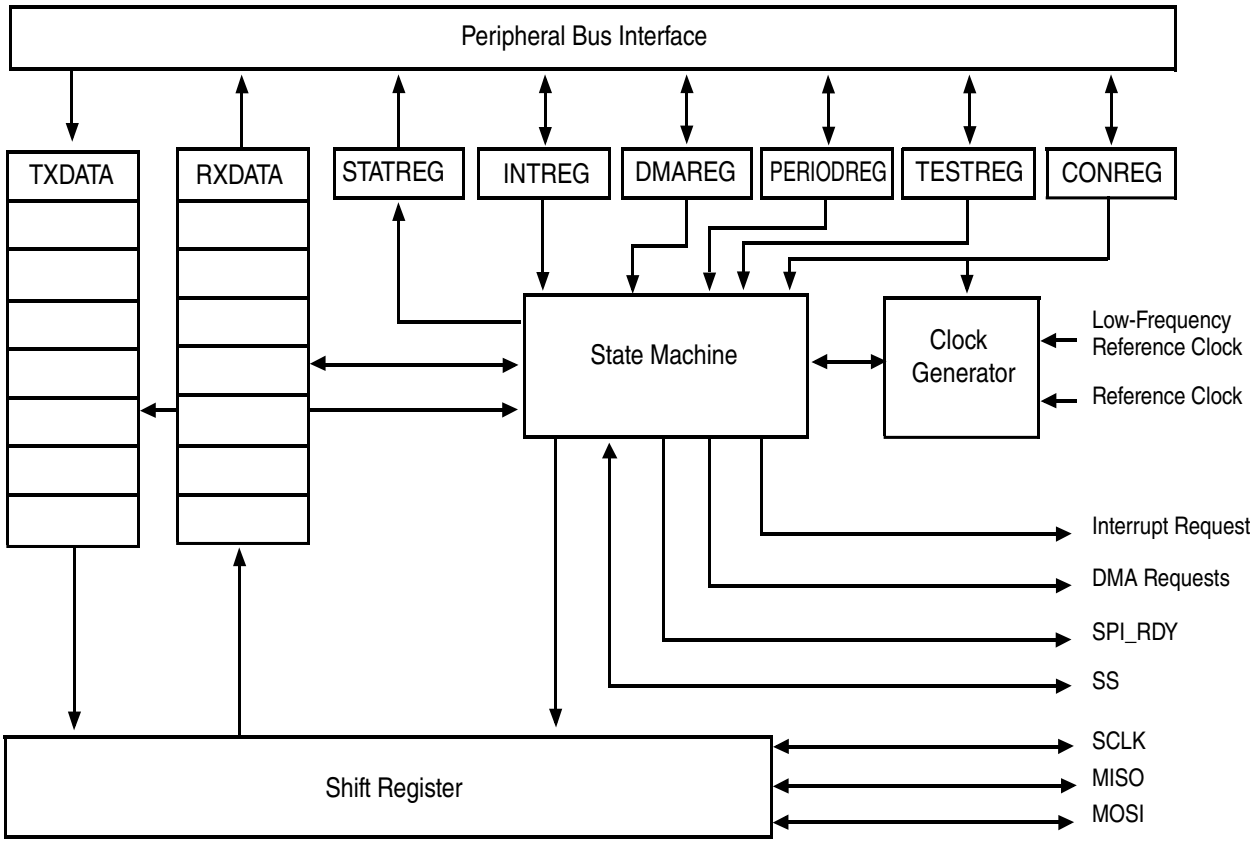

Figure 10-1. ECSPI Block Diagram

10.1.1.2 Features

Key features of the ECSPI include:

- Full-duplex synchronous serial interface
- Master/Slave configurable
- One Chip Select (SS) signal
- Transfer continuation function allows unlimited length data transfers
- 32-bit wide by 64-entry FIFO for both transmit and receive data
- Polarity and phase of the Chip Select (SS) and SPI Clock (SCLK) are configurable
- Direct Memory Access (DMA) support
- Refer to the product data sheet for the maximum operating frequency

10.1.1.3 Modes and Operations

The ECSPI supports the modes described in the indicated sections:

- Master Mode
- Slave Mode
- Low Power Modes

As described in Operations, the ECSPI supports the operations described in the indicated sections:

- Typical Master Mode
  - Master Mode with SPI_RDY
  - Master Mode with Wait States
  - Master Mode with SS_CTL[3:0] Control
  - Master Mode with Phase Control
- Typical Slave Mode

10.1.2 Functional Description

This section provides a complete functional description of the ECSPI. The figure found here shows the relationship of SCLK and data lines while ECSPI has been configured with different POL and PHA settings.

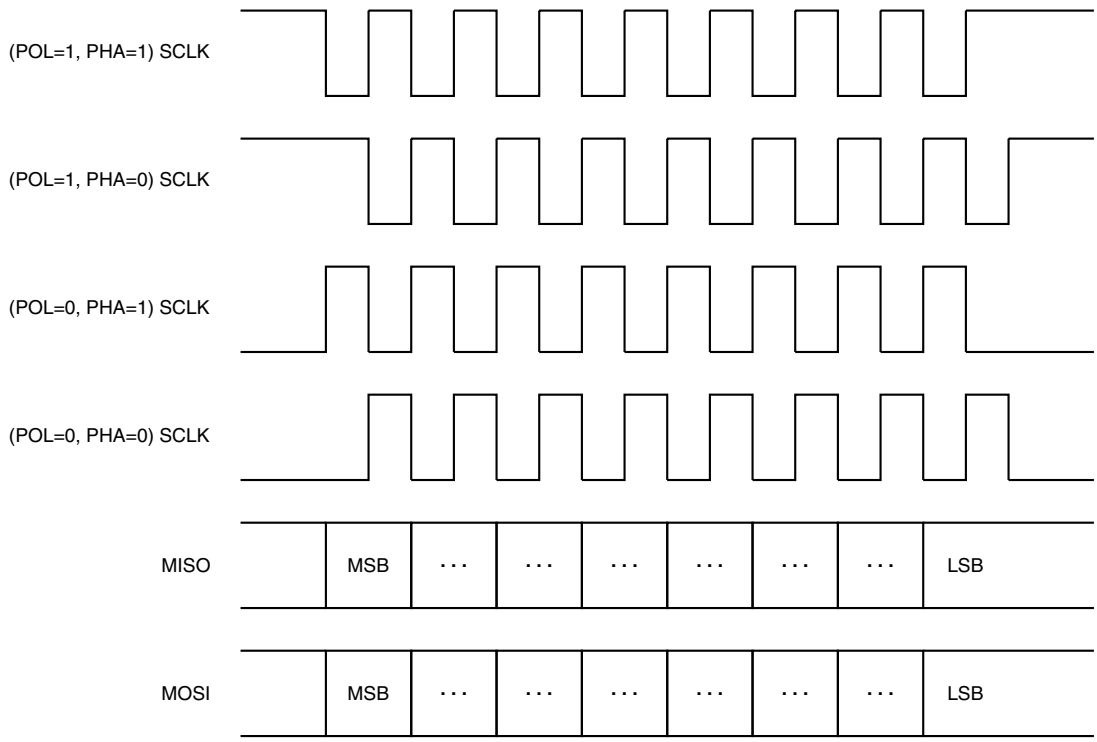

Figure 10-2. ECSPI SCLK, MISO, and MOSI Relationship

10.1.2.1 Master Mode

When the ECSPI is configured as a master, it uses a serial link to transfer data between the ECSPI and an external slave device.

The Chip Select (SS) signal and the clock signal (SCLK) are used to transfer data between two devices. If the external device is a transmit-only device, the ECSPI master's output port can be ignored and used for other purposes. In order to use the internal TXFIFO and RXFIFO, two auxiliary output signals, Chip Select (SS) and SPI_RDY, are used for data transfer rate control. Software can also configure the sample period control register to a fixed data transfer rate.

10.1.2.2 Slave Mode

When the ECSPI is configured as a slave, software can configure the ECSPI Control register to match the external SPI master's timing.

In this configuration, Chip Select (SS) becomes an input signal, and is used to control data transfers through the Shift register, as well as to load/store the data FIFO.

Slave mode only supports the case when ECSPIx_CONFIGREG[SS_CTL] is cleared. The accurate burst length should always be specified using the BURST_LENGTH parameter. ECSPIx_CONFIGREG[SS_CTL] set to 1 is not supported in slave mode.

10.1.2.3 Low Power Modes

The ECSPI does not operate under low power mode.

It holds its operation when its clock is gated off in master mode. In slave mode, the ECSPI does not respond when its clock is gated off.

10.1.2.4 Operations

The information found here describes the ECSPI's operations.

10.1.2.4.1 Typical Master Mode

The ECSPI master uses the Chip Select (SS) signal to enable an external SPI device, and uses the SCLK signal to transfer data in and out of the Shift register.

The SPI_RDY enables fast data communication with fewer software interrupts. By programming the ECSPI_PERIODREG register accordingly, the ECSPI can be used for a fixed data transfer rate.

When the ECSPI is in Master mode the SS, SCLK, and MOSI are output signals, and the MISO signal is an input.

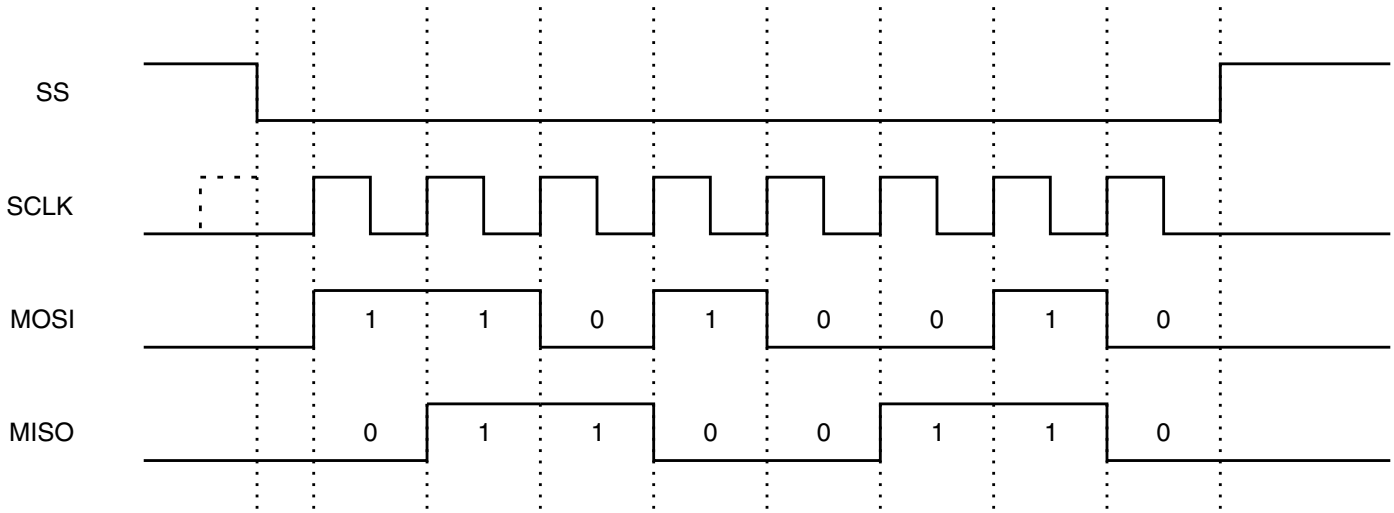

Figure 10-3. Typical SPI Burst (8-bit Transfer)

In the above figure, the Chip Select (SS) signal enables the selected external SPI device, and the SCLK synchronizes the data transfer. The MOSI and MISO signals change on rising edge of SCLK and the MISO signal is latched on the falling edge of the SCLK. The figure above shows a data of 0xD2 is shifted out, and a data of 0x66 is shifted in.

10.1.2.4.1.1 Master Mode with SPI_RDY

By default, the ECSPI does not use the SPI_RDY signal in master mode (MODE =1).

A SPI burst begins when the following events happen:

- The ECSPI is enabled, TXFIFO has data in it, and ECSPI_CONREG[XCH] bit or the ECSPI_CONREG[SMC] bit is set.
- When the SPI Data Ready Control (ECSPI_CONREG[DRCTL]) bits contains either 01 or 10, the SPI_RDY signal controls when a SPI burst starts.

A SPI burst is defined as a bus transaction that starts when the slave select is asserted and ends when the slave select is negated. The Chip Select (SS) signal will remain asserted until all the bits in a SPI burst are shifted out.

If ECSPI_CONREG[DRCTL] is set to 01, the SPI burst can be triggered only if a falling edge of the SPI_RDY signal has been detected.

The following figure shows the relationship between a SPI burst and the falling edge of SPI_RDY signal.

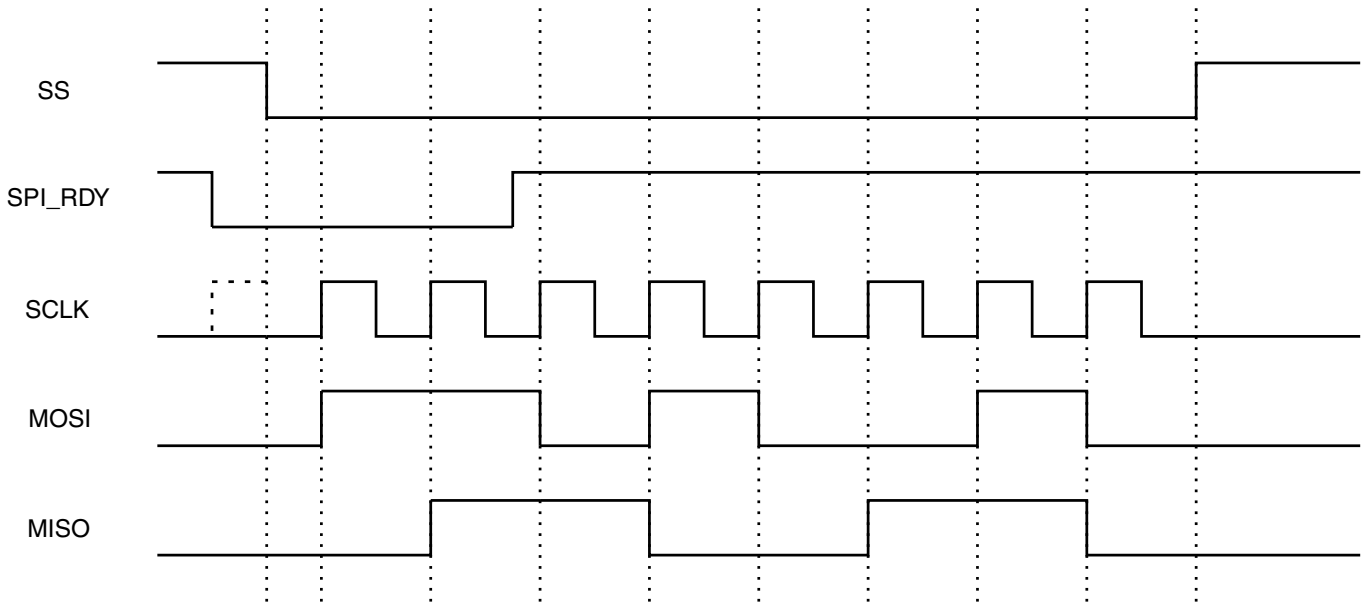

Figure 10-4. Relationship Between a SPI Burst and SPI_RDY: Falling-Edge Triggered

A SPI burst does not start until the falling edge of the SPI_RDY signal is detected. The next SPI burst starts when the next SPI_RDY falling edge is detected, after the last burst has finished.

If SPI Data Ready Control (ECSPI_CONREG[DRCTL]) is set to 10, the SPI burst can be triggered only if the SPI_RDY signal is low.

The following figure shows the relationship between a SPI burst and the SPI_RDY signal. The SPI burst does not begin until the SPI_RDY signal goes low. The ECSPI will keep transmitting SPI burst if the SPI_RDY signal remains low.

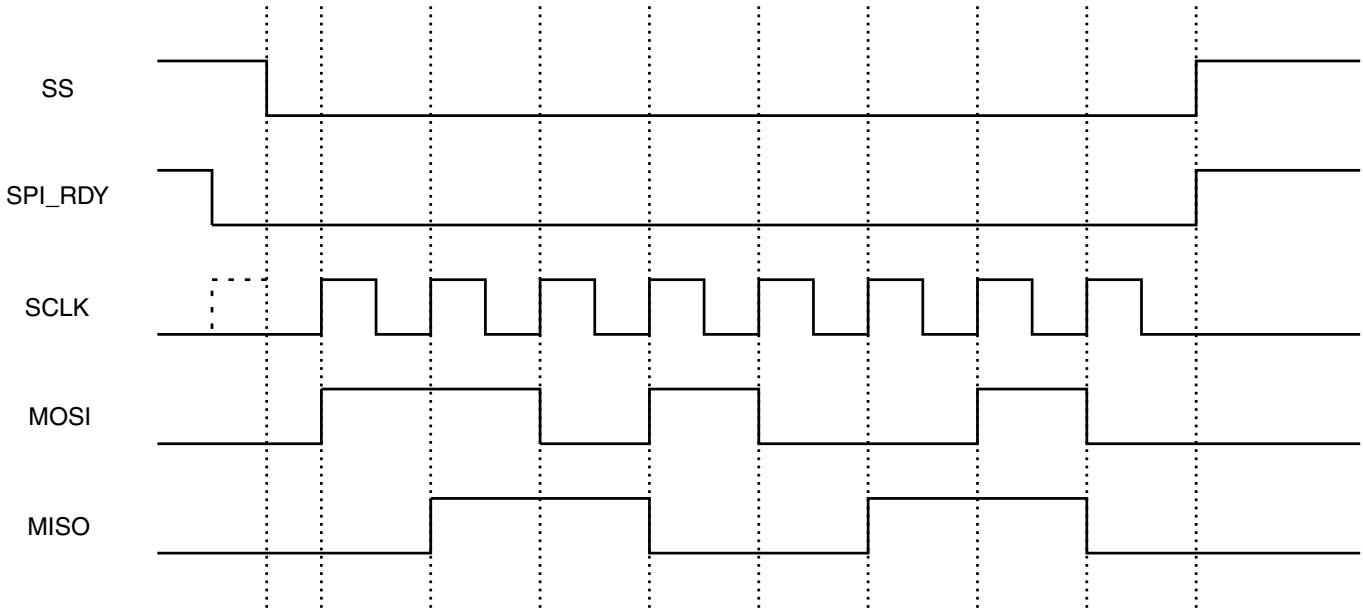

Figure 10-5. Relationship Between a SPI Burst and SPI_RDY: Low-Level Triggered

10.1.2.4.1.2 Master Mode with Wait States

Wait states can be inserted between SPI bursts. This provides a way for software to slow down the SPI burst to meet the timing requirements of a slower SPI device.

The following figure shows wait states inserted between SPI bursts.

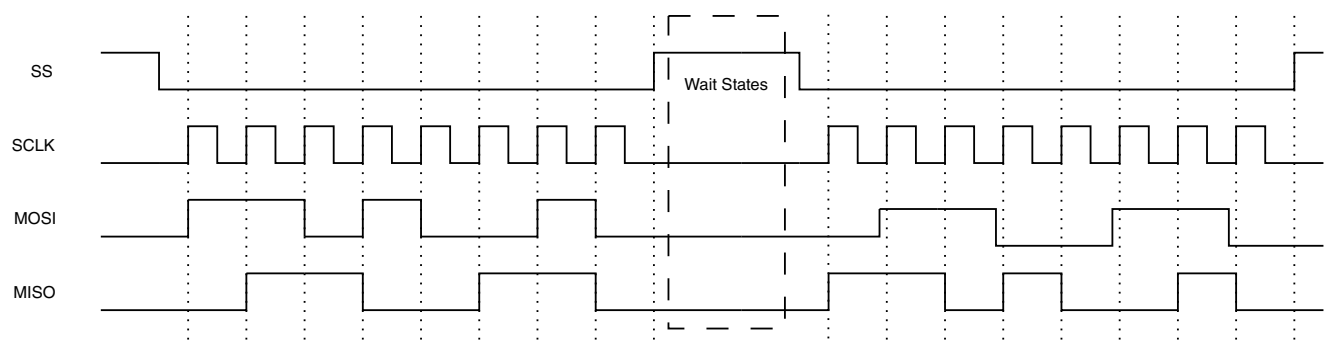

Figure 10-6. SPI Bursts with Wait States

In this case, the number of wait states is controlled by ECSPI_PERIODREG[SAMPLE PERIOD] and the wait states' clock source is selected by ECSPI_PERIODREG[CSRC].

10.1.2.4.1.3 Master Mode with SS_CTL[3:0] Control

The SPI SS Control (SS_CTL[3:0]) controls whether the current operation is single burst or multiple bursts.

When the SPI SS Wave Form Select (SS_CTL[3:0]) is set, the current operation is multiple bursts transfer. When the SPI SS Wave Form Select (SS_CTL[3:0]) bit is cleared, the current operation is single burst transfer. A SPI burst can contains multiple words as defined in the BURST LENGTH field of the ECSPI_CONREG register.

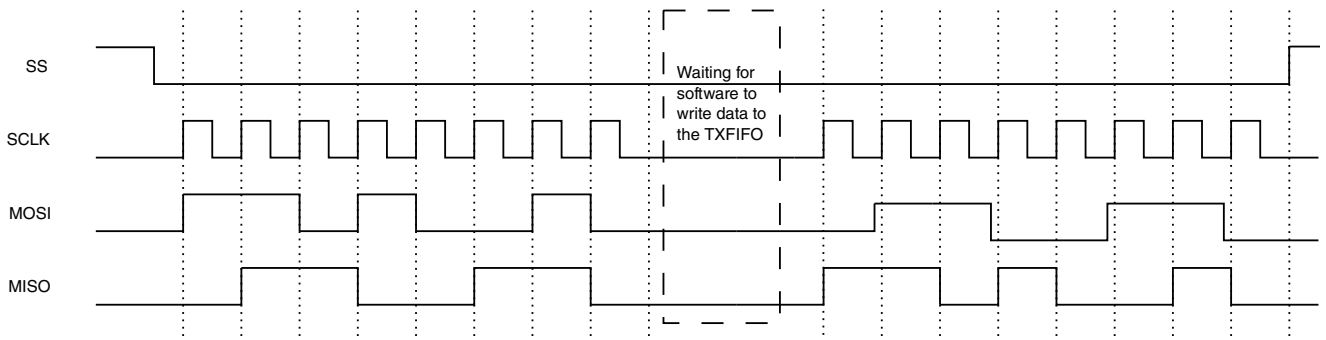

Figure 10-7. SPI Burst While SS_CTL[3:0] is Clear

In Figure 10-7, two 8-bit bursts in the TXFIFO have been combined and transmitted in one SPI burst. The maximum length of a single SPI burst is defined by the BURST LENGTH and limited by the FIFO size. (Figure 10-7 corresponds to a BURST LENGTH of 8.) This provides a way for transferring a longer SPI burst by writing data into TXFIFO while the ECSPI is transmitting.

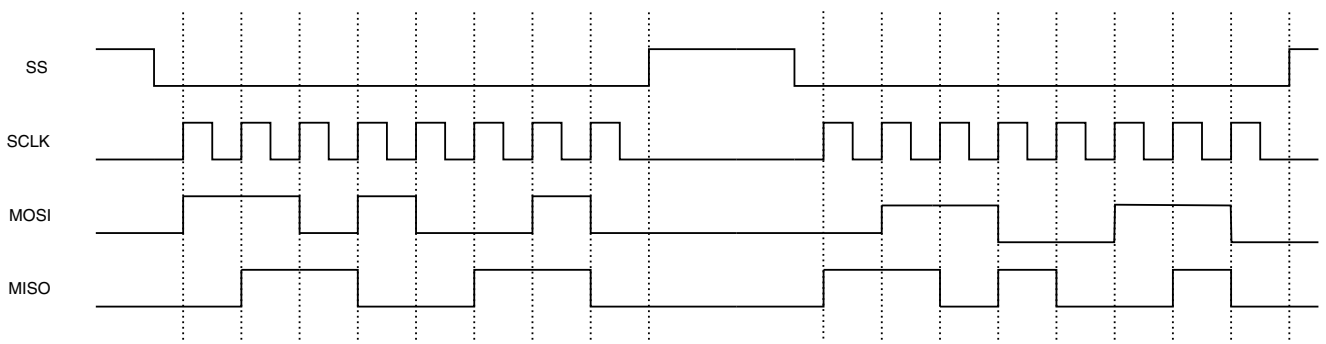

Figure 10-8. SPI Bursts While SS_CTL[3:0] is Set

In Figure 10-8, two FIFO entries are transmitted, one entry with each SPI burst. The ECSPI will continue to transmit SPI bursts until the TXFIFO is empty. When wait states can be inserted between SPI bursts, the SS will negate between SPI bursts until the wait states finish.

10.1.2.4.1.4 Master Mode with Phase Control

The Phase Control (ECSPI_CONREG[PHA]) bit controls how the transmit data shifts out and the receive data shifts in.

When the Phase control (ECSPI_CONREG[PHA]) bit is set, the transmit data will shift out on the rising edge of SCLK, and the receive data is latched on the falling edge of SCLK. The most-significant bit is output on the first rising SCLK edge.

When ECSPI_CONREG[PHA] is cleared, the transmit data is shifted out on the falling edge of SCLK and the receive data is latched on the rising edge of SCLK. The MSB is output when the host processor loads the transmitted data.

Inverting the SCLK polarity does not impact the edge-triggered operations because they are internal to the serial peripheral interface master. Figure 10-9 shows how SPI burst works with different POL and PHA configuration.

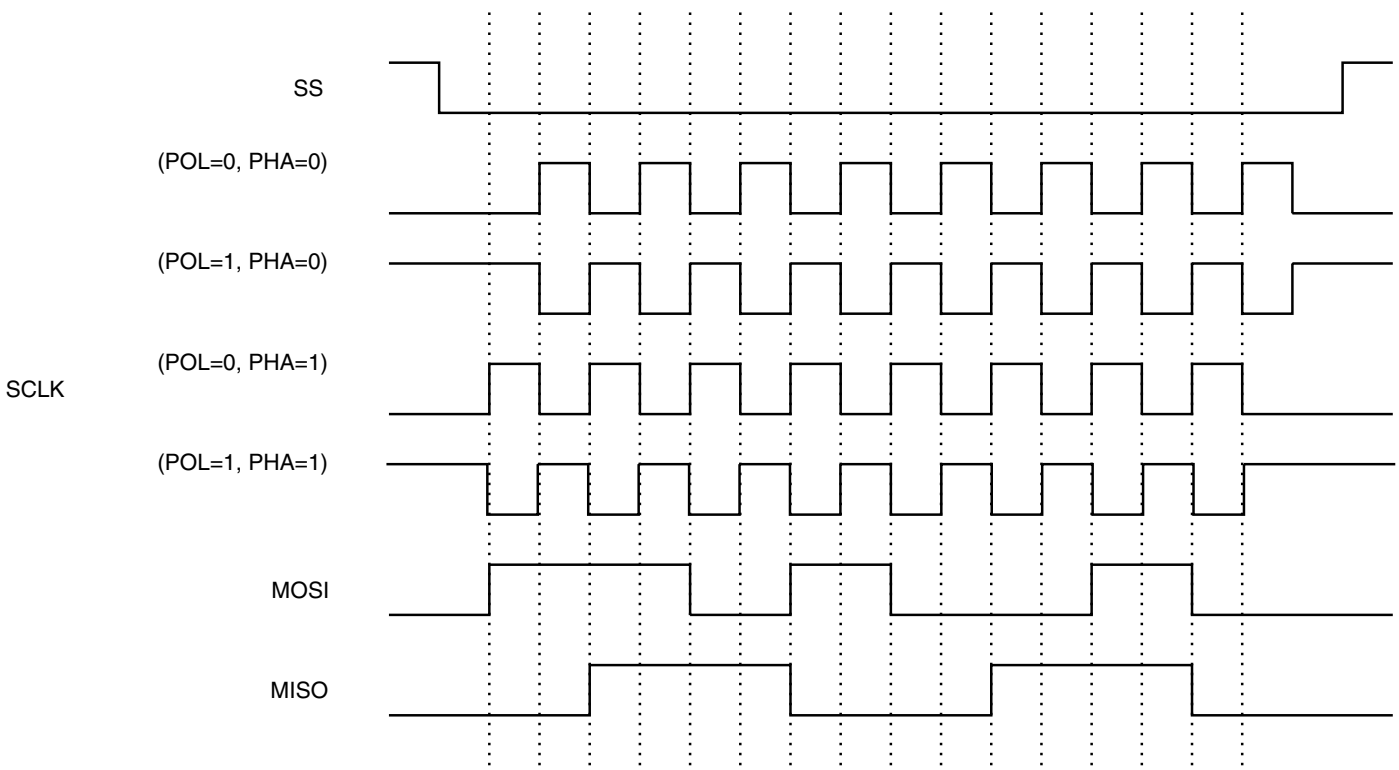

Figure 10-9. SPI Burst with Different POL and PHA Configurations

10.1.2.4.2 Typical Slave Mode

When the ECSPI is configured as a slave (Mode = 0), software can configure the ECSPI Control register to match the external SPI master's timing. The SPI master timing should match the ECSPI timing limitation in the product data sheet. In this configuration, SS becomes an input signal, and is used to latch data in and out of the internal data Shift registers, as well as to advance the data FIFO.

The SS, SCLK, and MOSI are inputs and MISO is output. Most of the timing diagrams are similar to the diagrams shown previously for the SPI in Master mode (Mode = 1), because the inputs come from a SPI master device.

However, the timing is different when SS is used to advance the data FIFO. When the SS_POL=0 is set while the ECSPI is configured in Slave mode, the data FIFO will advance on the rising edge of the SS signal. When the polarity is reversed (SS_POL = 1), the data FIFO will advance on the falling edge of the SS signal.

The figure below shows a SPI burst in which the data FIFO is advanced by the rising edge of the SS signal.

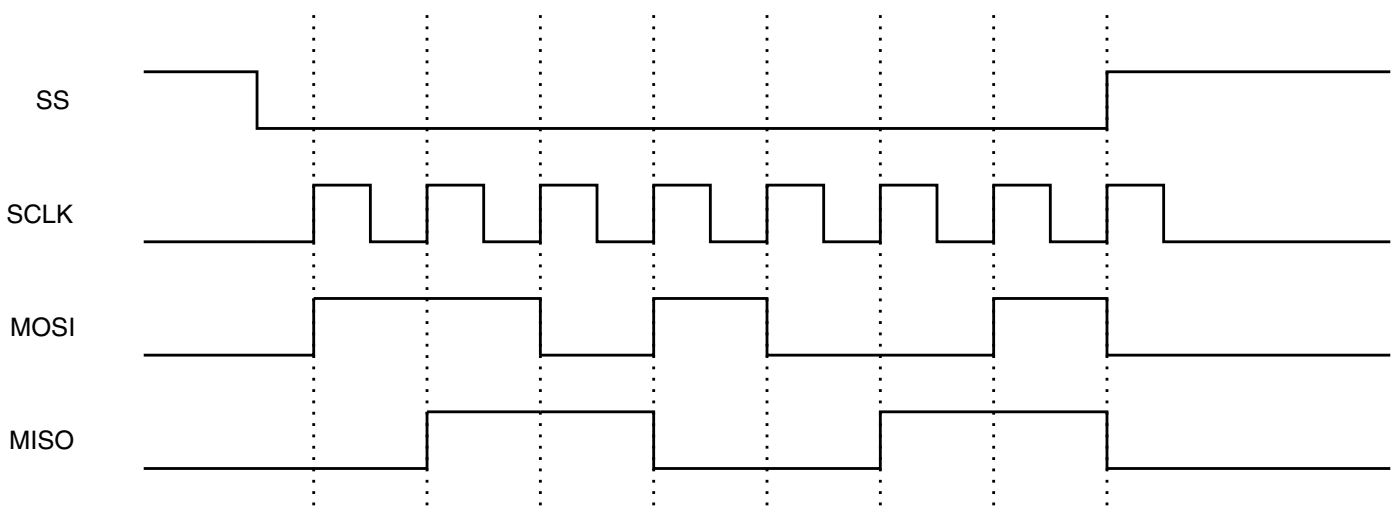

Figure 10-10. Advancing the Data FIFO on the Rising Edge of SS

In the above case, only the most significant 7 bits are loaded to the RXFIFO.

10.1.2.5 Reset

Whenever a device reset occurs, a reset is performed on the ECSPI, resetting all registers to their default values.

Software can reset the block using the CONREG[EN] bit; see ECSPI.

10.1.2.6 Interrupts

Interrupt control provides a way to manage the ECSPI FIFOs:

- For transmitting data, software can enable the TXFIFO empty, TXFIFO data request, and TXFIFO full interrupts to maintain the TXFIFO using an interrupt service routine.
- For receiving data, software can enable the RXFIFO ready, RXFIFO data request, and RXFIFO full interrupts to retrieve data from the RXFIFO using an interrupt service routine.

Other interrupt sources can be used to control or debug the SPI bursts:

- The transfer-completed interrupt means that there is no data left in the TXFIFO and that the data in the Shift register has been shifted out.
- The RXFIFO overflow interrupt means that the RXFIFO received more than 64 words and will not accept any other words.

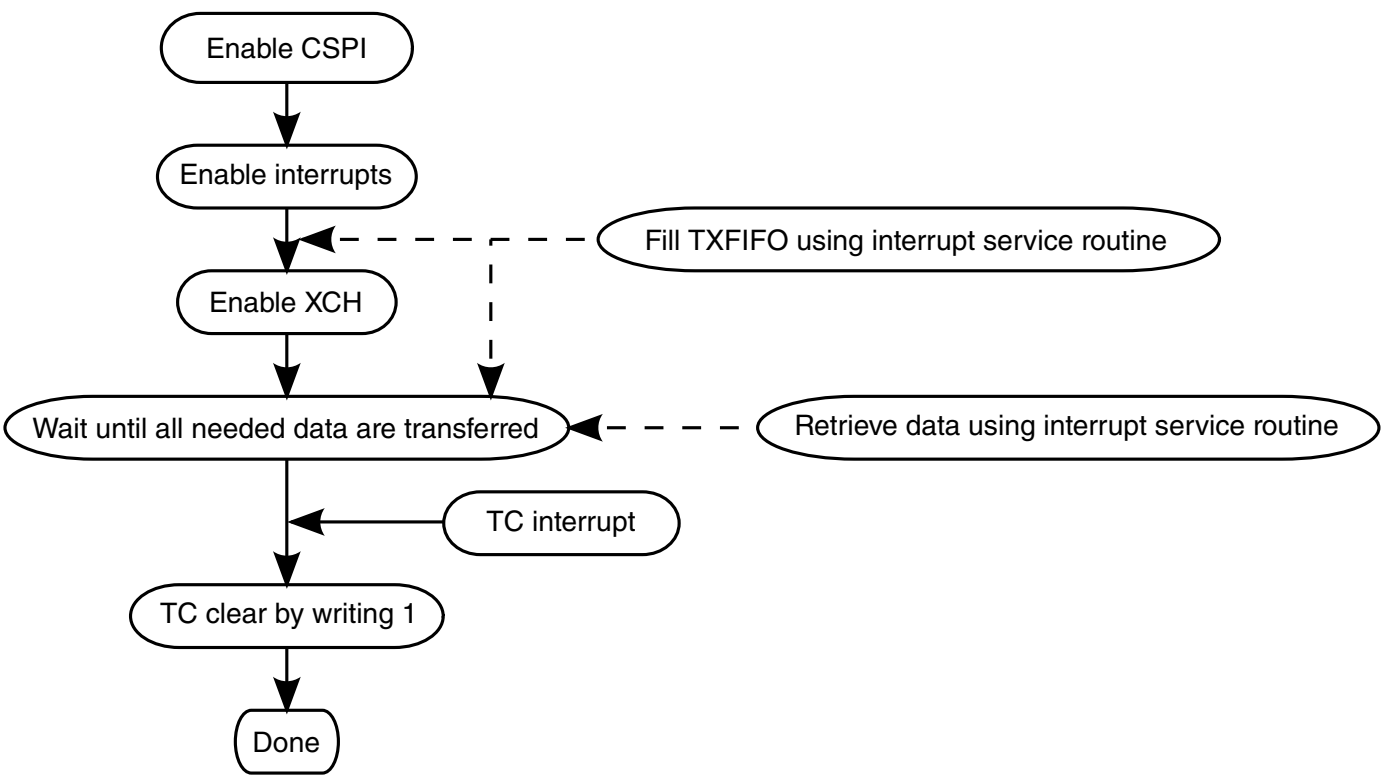

Figure 10-11. Program Sequence of SPI Burst Using Interrupt Control

NOTE

The TC bit does not provide a reliable indication that the transfer is complete. Under some conditions, the TC interrupt can occur before the transfer is completed. If the TC bit is used as an interrupt source, the XCH bit should be polled after the TC interrupt occurs to accurately confirm that the transfer is complete.

10.1.2.7 DMA

DMA control provides another method to utilize the FIFOs in the ECSPI. By using DMA request and acknowledge signals, larger amounts of data can be transferred, and will reduce interrupts and host processor loading. When the appropriate conditions are matched, the block will send out a DMA request.

The DMA can deal with the following conditions:

- TXFIFO empty
- TXFIFO data request
- RXFIFO data request
- RXFIFO full

The figure below shows a program sequence of SPI bursts using DMA control.

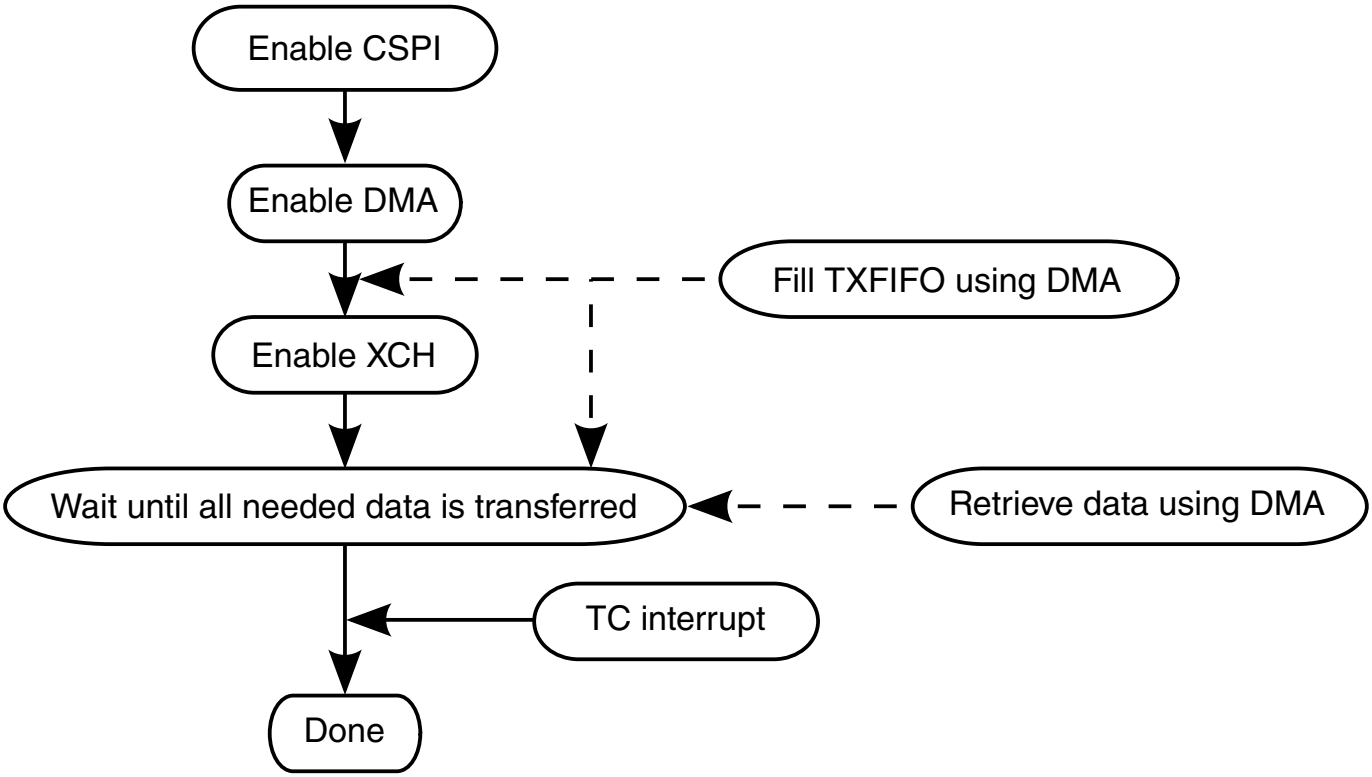

Figure 10-12. Program Sequence of SPI Burst Using DMA

NOTE

The TC bit does not provide a reliable indication that the transfer is complete. Under some conditions, the TC interrupt can occur before the transfer is completed. If the TC bit is used as an interrupt source, the XCH bit should be polled after the TC interrupt occurs to accurately confirm that the transfer is complete.

10.1.2.8 Byte Order

The ECSPI does not support byte re-ordering in hardware.

10.1.3 External Signals

Figure 10-13 shows the ECSPI in master mode connected to an external device in a one-way communication link.

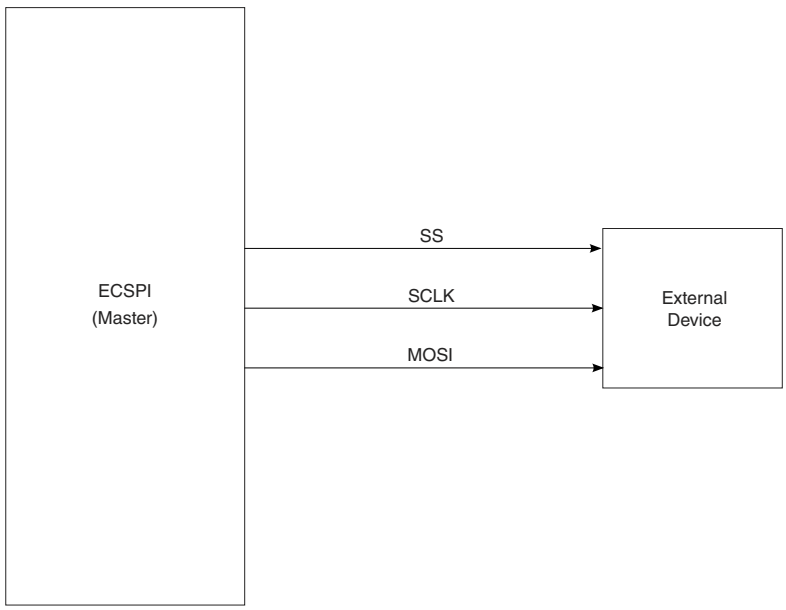

Figure 10-13. Example Connection Diagram

10.1.4 Initialization

This section provides initialization information for ECSPI.

To initialize the block:

1. Clear the EN bit in ECSPI_CONREG to reset the block.
2. Enable the clocks for ECSPI within the CCM.
3. Configure the Control Register and then set the EN bit in the ECSPI_CONREG to put ECSPI out of reset.
4. Configure corresponding IOMUX for ECSPI external signals.
5. Configure registers of ECSPI properly according to the specifications of the external SPI device.

10.1.5 Applications

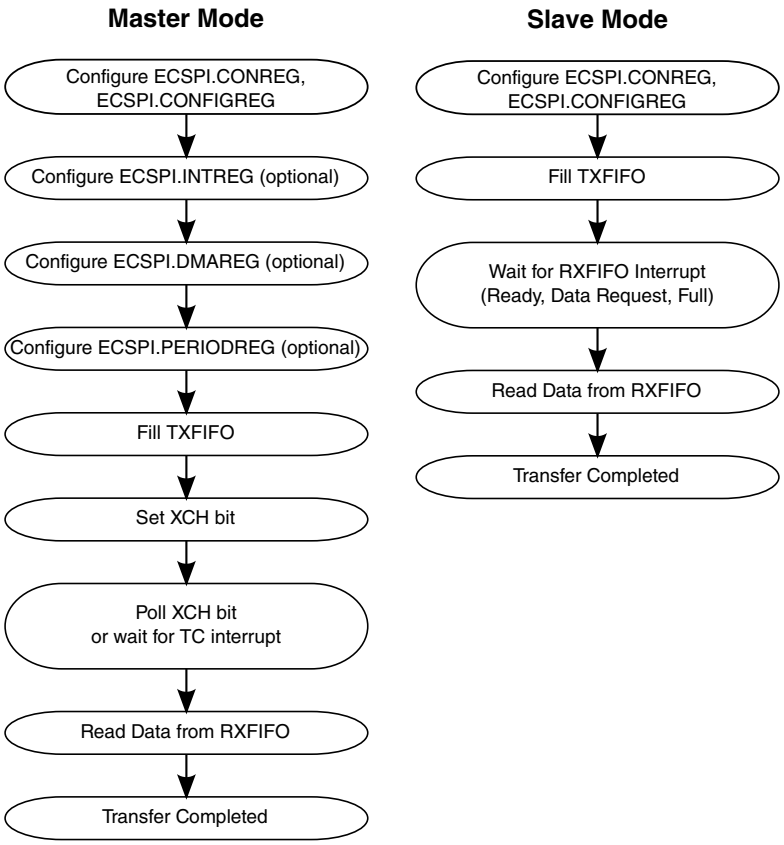

Figure 10-14. Flowchart of the ECSPI Operation

NOTE

The TC bit does not provide a reliable indication that the transfer is complete. Under some conditions, the TC interrupt can occur before the transfer is completed. If the TC bit is used as an interrupt source, the XCH bit should be polled after the TC interrupt occurs to accurately confirm that the transfer is complete.

10.1.6 ECSPI Memory Map/Register Definition

This section includes the block memory map and detailed descriptions of all registers. For the base address of a particular block instantiation, see the system memory map.

ECSPI memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

10.1.6.1 Receive Data Register (ECSPIx_RXDATA)

The Receive Data register (ECSPI_RXDATA) is a read-only register that forms the top word of the 64 x 32 receive FIFO. This register holds the data received from an external SPI device during a data transaction. Only word-sized read operations are allowed.

Address: Base address + 0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ECSPIx_RXDATA field descriptions

Field	Description
ECSPI_RXDATA	Receive Data. This register holds the top word of the receive data FIFO. The FIFO is advanced for each read of this register. The data read is undefined when the Receive Data Ready (RR) bit in the Interrupt Control/Status register is cleared. Zeros are read when ECSPI is disabled.

10.1.6.2 Transmit Data Register (ECSPIx_TXDATA)

The Transmit Data (ECSPI_TXDATA) register is a write-only data register that forms the bottom word of the 64 x 32 TXFIFO. The TXFIFO can be written to as long as it is not full, even when the SPI Exchange bit (XCH) in ECSPI_CONREG is set. This allows software to write to the TXFIFO during a SPI data exchange process. Writes to this register are ignored when the ECSPI is disabled (ECSPI_CONREG[EN] bit is cleared).

Address: Base address + 4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ECSPIx_TXDATA field descriptions

Field	Description
ECSPI_TXDATA	Transmit Data. This register holds the top word of data loaded into the FIFO. Data written to this register must be a word operation. The number of bits actually transmitted is determined by the BURST_LENGTH field of the corresponding SPI Control register. If this field contains more bits than the number specified by BURST_LENGTH, the extra bits are ignored. For example, to transfer 10 bits of data, a 32-bit word must be written to this register. Bits 9-0 are shifted out and bits 31-10 are ignored. When the ECSPI is operating in Slave mode, zeros are shifted out when the FIFO is empty. Zeros are read when ECSPI is disabled.

10.1.6.3 Control Register (ECSPIx_CONREG)

The Control Register (ECSPI_CONREG) allows software to enable the ECSPI , configure its operating modes, specify the divider value, and SPI_RDY control signal, and define the transfer length.

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ECSPIx_CONREG field descriptions

Field	Description
31–20 BURST_ LENGTH	Burst Length. This field defines the length of a SPI burst to be transferred. The Chip Select (SS) will remain asserted until all bits in a SPI burst are shifted out. A maximum of 2^12 bits can be transferred in a single SPI burst. In master mode, it controls the number of bits per SPI burst. Since the shift register always loads 32-bit data from transmit FIFO, only the n least-significant (n = BURST LENGTH + 1) will be shifted out. The remaining bits will be ignored. Number of Valid Bits in a SPI burst. 0x000 A SPI burst contains the 1 LSB in a word. 0x001 A SPI burst contains the 2 LSB in a word. 0x002 A SPI burst contains the 3 LSB in a word. ... 0x01F A SPI burst contains all 32 bits in a word. 0x020 A SPI burst contains the 1 LSB in first word and all 32 bits in second word. 0x021 A SPI burst contains the 2 LSB in first word and all 32 bits in second word. ... 0xFFE A SPI burst contains the 31 LSB in first word and 2^7 -1 words. 0xFFF A SPI burst contains 2^7 words.
19–18 CHANNEL_ SELECT	SPI CHANNEL SELECT bits. Selects the external SPI Master/Slave Device. In master mode, these two bits select the external slave device by asserting the Chip Select (SS) output. 00 Channel 0 is selected. Chip Select (SS) will be asserted. 01 Reserved. 10 Reserved. 11 Reserved.
17–16 DRCTL	SPI Data Ready Control. This field selects the utilization of the SPI_RDY signal in master mode. ECSPI checks this field before it starts an SPI burst. 00 The SPI_RDY signal is a don't care. 01 Burst will be triggered by the falling edge of the SPI_RDY signal (edge-triggered). 10 Burst will be triggered by a low level of the SPI_RDY signal (level-triggered). 11 Reserved.
15–12 PRE_DIVIDER	SPI Pre Divider. ECSPI uses a two-stage divider to generate the SPI clock. This field defines the pre-divider of the reference clock. 0000 Divide by 1. 0001 Divide by 2. 0010 Divide by 3. ... 1101 Divide by 14. 1110 Divide by 15. 1111 Divide by 16.
11–8 POST_DIVIDER	SPI Post Divider. ECSPI uses a two-stage divider to generate the SPI clock. This field defines the post-divider of the reference clock using the equation: 2^n . 0000 Divide by 1. 0001 Divide by 2. 0010 Divide by 4. ...

Table continues on the next page...

ECSPIx_CONREG field descriptions (continued)

Field	Description
	1110 Divide by 2 ^{14} . 1111 Divide by 2 ^{15} .
7–4 CHANNEL_ MODE	SPI CHANNEL MODE selects the mode for each SPI channel. CHANNEL MODE[3] is for SPI channel 3. CHANNEL MODE[2] is for SPI channel 2. CHANNEL MODE[1] is for SPI channel 1. CHANNEL MODE[0] is for SPI channel 0. 0 Slave mode. 1 Master mode.
3 SMC	Start Mode Control. This bit applies only to channels configured in Master mode (CHANNEL MODE = 1). It controls how the ECSPI starts a SPI burst, either through the SPI exchange bit, or immediately when the TXFIFO is written to. 0 SPI Exchange Bit (XCH) controls when a SPI burst can start. Setting the XCH bit will start a SPI burst or multiple bursts. This is controlled by the SPI SS Wave Form Select (SS_CTL). Refer to XCH and SS_CTL descriptions. 1 Immediately starts a SPI burst when data is written in TXFIFO.
2 XCH	SPI Exchange Bit. This bit applies only to channels configured in Master mode (CHANNEL MODE = 1). If the Start Mode Control (SMC) bit is cleared, writing a 1 to this bit starts one SPI burst or multiple SPI bursts according to the SPI SS Wave Form Select (SS_CTL). The XCH bit remains set while either the data exchange is in progress, or when the ECSPI is waiting for an active input if SPIRDY is enabled through DRCTL. This bit is cleared automatically when all data in the TXFIFO and the shift register has been shifted out. 0 Idle. 1 Initiates exchange (write) or busy (read).
1 HT	Hardware Trigger Enable. This bit is used in master mode only. It enables hardware trigger (HT) mode. Note, HT mode is not supported by this product. 0 Disable HT mode. 1 Enable HT mode.
0 EN	SPI Block Enable Control. This bit enables the ECSPI. This bit must be set before writing to other registers or initiating an exchange. Writing zero to this bit disables the block and resets the internal logic with the exception of the ECSPI_CONREG. The block's internal clocks are gated off whenever the block is disabled. 0 Disable the block. 1 Enable the block.

10.1.6.4 Config Register (ECSPIx_CONFIGREG)

The Config Register (ECSPI_CONFIGREG) allows software to configure each SPI channel, configure its operating modes, specify the phase and polarity of the clock, configure the Chip Select (SS), and define the HT transfer length. Note, HT mode is not supported by this product.

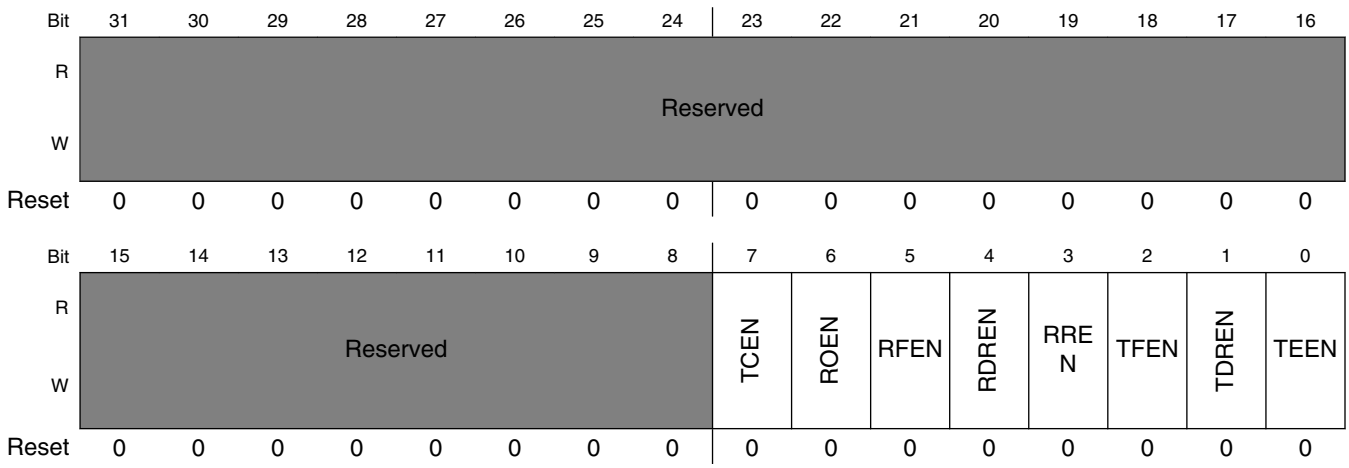
Address: Base address + Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved			HT_LENGTH					SCLK_CTL				DATA_CTL				SS_POL				SS_CTL				SCLK_POL				SCLK_PHA			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ECSPIx_CONFIGREG field descriptions

Field	Description
31–29 -	This field is reserved. Reserved
28–24 HT_LENGTH	HT LENGTH. This field defines the message length in HT Mode. Note, HT mode is not supported by this product. The length in bits of one message is (HT LENGTH + 1).
23–20 SCLK_CTL	SCLK CTL. This field controls the inactive state of SCLK for each SPI channel. SCLK CTL[3] is for SPI channel 3. SCLK CTL[2] is for SPI channel 2. SCLK CTL[1] is for SPI channel 1. SCLK CTL[0] is for SPI channel 0. 0 Stay low. 1 Stay high.
19–16 DATA_CTL	DATA CTL. This field controls inactive state of the data line for each SPI channel. DATA CTL[3] is for SPI channel 3. DATA CTL[2] is for SPI channel 2. DATA CTL[1] is for SPI channel 1. DATA CTL[0] is for SPI channel 0. 0 Stay high. 1 Stay low.
15–12 SS_POL	SPI SS Polarity Select. In both Master and Slave modes, this field selects the polarity of the Chip Select (SS) signal. SS POL[3] is reserved. SS POL[2] is reserved. SS POL[1] is reserved. SS POL[0] is for SPI channel 0.

Table continues on the next page...



ECSPIx_CONFIGREG field descriptions (continued)

Field	Description
	0 Active low. 1 Active high.
11–8 SS_CTL	SPI SS Wave Form Select. In master mode, this field controls the output wave form of the Chip Select (SS) signal when the SMC (Start Mode Control) bit is cleared. The SS_CTL bits are ignored if the SMC bit is set. SS CTL[3] is reserved. SS CTL[2] is reserved. SS CTL[1] is reserved. SS CTL[0] is for SPI channel 0. In slave mode, this bit controls when the SPI burst is completed. An SPI burst is completed by the Chip Select (SS) signal edges. (SSPOL = 0: rising edge; SSPOL = 1: falling edge) The RXFIFO is advanced whenever a Chip Select (SS) signal edge is detected or the shift register contains 32-bits of valid data. 0 In master mode - only one SPI burst will be transmitted. 1 In master mode - Negate Chip Select (SS) signal between SPI bursts. Multiple SPI bursts will be transmitted. The SPI transfer will automatically stop when the TXFIFO is empty. 0 In slave mode - an SPI burst is completed when the number of bits received in the shift register is equal to (BURST LENGTH + 1). Only the n least-significant bits (n = BURST LENGTH[4:0] + 1) of the first received word are valid. All bits subsequent to the first received word in RXFIFO are valid. 1 Reserved
7–4 SCLK_POL	SPI Clock Polarity Control. This field controls the polarity of the SCLK signal. See Figure 10-9 for more information. SCLK_POL[3] is for SPI channel 3. SCLK_POL[2] is for SPI channel 2. SCLK_POL[1] is for SPI channel 1. SCLK_POL[0] is for SPI channel 0. 0 Active high polarity (0 = Idle). 1 Active low polarity (1 = Idle).
SCLK_PHA	SPI Clock/Data Phase Control. This field controls the clock/data phase relationship. See Figure 10-9 for more information. SCLK PHA[3] is for SPI channel 3. SCLK PHA[2] is for SPI channel 2. SCLK PHA[1] is for SPI channel 1. SCLK PHA[0] is for SPI channel 0. 0 Phase 0 operation. 1 Phase 1 operation.

10.1.6.5 Interrupt Control Register (ECSPIx_INTREG)

The Interrupt Control Register (ECSPI_INTREG) enables the generation of interrupts to the host processor. If the ECSPI is disabled, this register reads zero.

Address: Base address + 10h offset

ECSPIx_INTREG field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
7 TCEN	Transfer Completed Interrupt enable. This bit enables the Transfer Completed Interrupt. 0 Disable 1 Enable
6 ROEN	RXFIFO Overflow Interrupt enable. This bit enables the RXFIFO Overflow Interrupt. 0 Disable 1 Enable
5 RFEN	RXFIFO Full Interrupt enable. This bit enables the RXFIFO Full Interrupt. 0 Disable 1 Enable
4 RDREN	RXFIFO Data Request Interrupt enable. This bit enables the RXFIFO Data Request Interrupt when the number of data entries in the RXFIFO is greater than RX_THRESHOLD. 0 Disable 1 Enable
3 RREN	RXFIFO Ready Interrupt enable. This bit enables the RXFIFO Ready Interrupt. 0 Disable 1 Enable

Table continues on the next page...

ECSPIx_INTREG field descriptions (continued)

Field	Description
2 TFEN	TXFIFO Full Interrupt enable. This bit enables the TXFIFO Full Interrupt. 0 Disable 1 Enable
1 TDREN	TXFIFO Data Request Interrupt enable. This bit enables the TXFIFO Data Request Interrupt when the number of data entries in the TXFIFO is less than or equal to TX_THRESHOLD. 0 Disable 1 Enable
0 TEEN	TXFIFO Empty Interrupt enable. This bit enables the TXFIFO Empty Interrupt. 0 Disable 1 Enable

10.1.6.6 DMA Control Register (ECSPIx_DMAREG)

The Direct Memory Access Control Register (ECSPI_DMAREG) provides software a way to use an on-chip DMA controller for ECSPI data. Internal DMA request signals enable direct data transfers between the ECSPI FIFOs and system memory. The ECSPI sends out DMA requests when the appropriate FIFO conditions are matched.

If the ECSPI is disabled, this register is read as 0.

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ECSPIx_DMAREG field descriptions

Field	Description
31 RXTDEN	RXFIFO TAIL DMA Request/Interrupt Enable. This bit enables an internal counter that is increased at each read of the RXFIFO. This counter is cleared automatically when it reaches RX DMA LENGTH. If the number of words remaining in the RXFIFO is greater than or equal to RX DMA LENGTH, a DMA request/ interrupt is generated even if it is less than or equal to RX_THRESHOLD. 0 Disable 1 Enable
30 -	This field is reserved. Reserved
29–24 RX_DMA_ LENGTH	RX DMA LENGTH. This field defines the burst length of a DMA operation. Applies only when RXTDEN is set.
23 RXDEN	RXFIFO DMA Request Enable. This bit enables/disables the RXFIFO DMA Request. 0 Disable 1 Enable
22 -	This field is reserved. Reserved
21–16 RX_ THRESHOLD	RX THRESHOLD. This field defines the FIFO threshold that triggers a RX DMA/INT request. A RX DMA/INT request is issued when the number of data entries in the RXFIFO is greater than RX_THRESHOLD.
15–8 -	This field is reserved. Reserved
7 TEDEN	TXFIFO Empty DMA Request Enable. This bit enables/disables the TXFIFO Empty DMA Request. 0 Disable 1 Enable
6 -	This field is reserved. Reserved
TX_ THRESHOLD	TX THRESHOLD. This field defines the FIFO threshold that triggers a TX DMA/INT request. A TX DMA/INT request is issued when the number of data entries in the TXFIFO is not greater than TX_THRESHOLD.

10.1.6.7 Status Register (ECSPIx_STATREG)

The ECSPI Status Register (ECSPI_STATREG) reflects the status of the ECSPI's operating condition. If the ECSPI is disabled, this register reads 0x0000_0003.

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

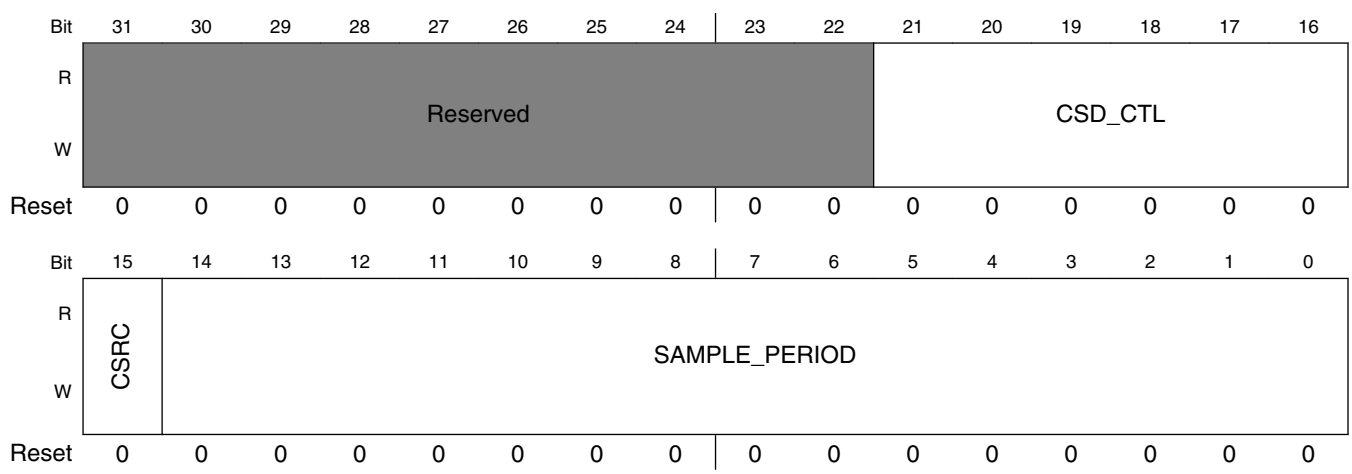
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								TC	RO	RF	RDR	RR	TF	TDR	TE
W									w1c	w1c						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

ECSPIx_STATREG field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
7 TC	Transfer Completed Status bit. Writing 1 to this bit clears it. **NOTE:** The TC bit does not provide a reliable indication that the transfer is complete. Under some conditions, the TC interrupt can occur before the transfer is completed. If the TC bit is used as an interrupt source, the XCH bit should be polled after the TC interrupt occurs to accurately confirm that the transfer is complete. 0 Transfer in progress. 1 Transfer completed.
6 RO	RXFIFO Overflow. When set, this bit indicates that RXFIFO has overflowed. Writing 1 to this bit clears it. 0 RXFIFO has no overflow. 1 RXFIFO has overflowed.
5 RF	RXFIFO Full. This bit is set when the RXFIFO is full. 0 Not Full. 1 Full.
4 RDR	RXFIFO Data Request. 0 When RXTDE is set - Number of data entries in the RXFIFO is not greater than RX_THRESHOLD. 1 When RXTDE is set - Number of data entries in the RXFIFO is greater than RX_THRESHOLD or a DMA TAIL DMA condition exists. 0 When RXTDE is clear - Number of data entries in the RXFIFO is not greater than RX_THRESHOLD. 1 When RXTDE is clear - Number of data entries in the RXFIFO is greater than RX_THRESHOLD.

Table continues on the next page...

ECSPIx_STATREG field descriptions (continued)



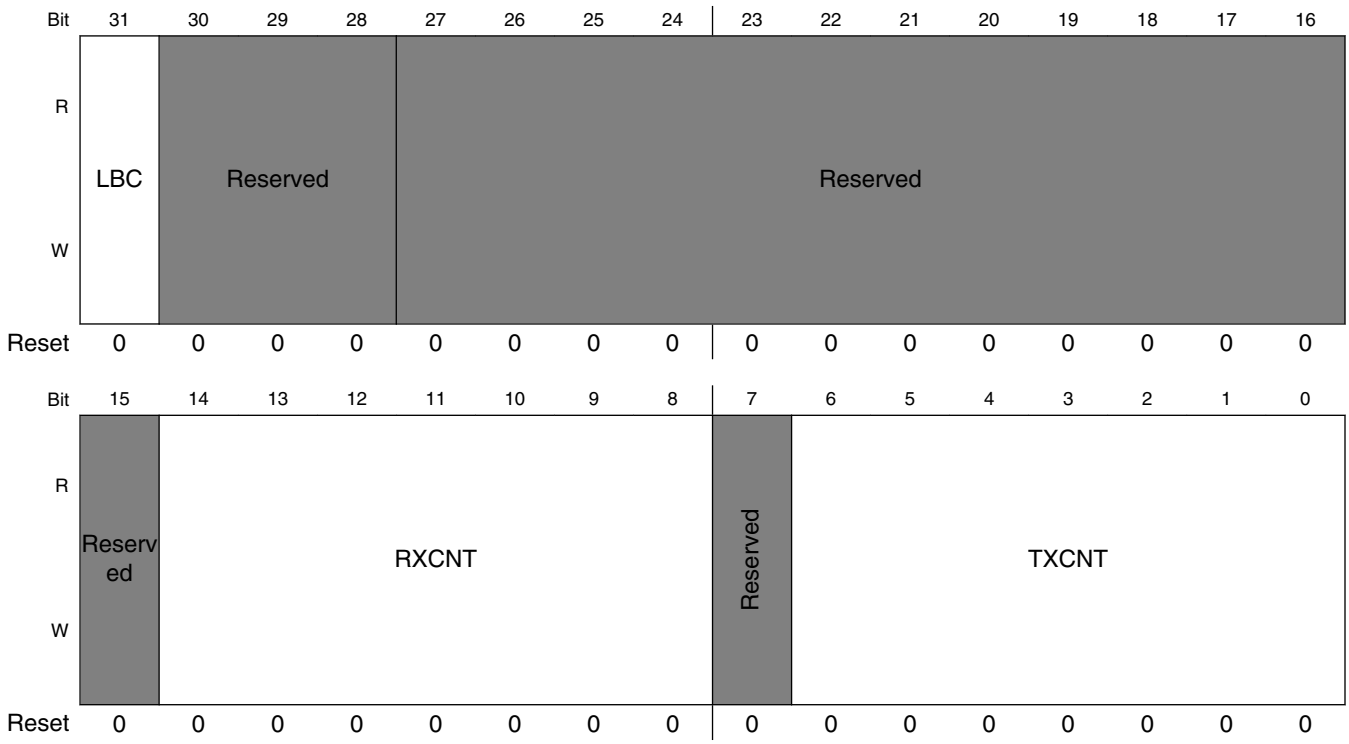
Field	Description
3 RR	RXFIFO Ready. This bit is set when one or more words are stored in the RXFIFO. 0 No valid data in RXFIFO. 1 More than 1 word in RXFIFO.
2 TF	TXFIFO Full. This bit is set when if the TXFIFO is full. 0 TXFIFO is not Full. 1 TXFIFO is Full.
1 TDR	TXFIFO Data Request. 0 Number of valid data slots in TXFIFO is greater than TX_THRESHOLD. 1 Number of valid data slots in TXFIFO is not greater than TX_THRESHOLD.
0 TE	TXFIFO Empty. This bit is set if the TXFIFO is empty. 0 TXFIFO contains one or more words. 1 TXFIFO is empty.

10.1.6.8 Sample Period Control Register (ECSPIx_PERIODREG)

The Sample Period Control Register (ECSPI_PERIODREG) provides software a way to insert delays (wait states) between consecutive SPI transfers. Control bits in this register select the clock source for the sample period counter and the delay count indicating the number of wait states to be inserted between data transfers.

The delay counts apply only when the current channel is operating in Master mode (ECSPI_CONREG[CHANNEL MODE] = 1).ECSPI_PERIODREG also contains the CSD CTRL field used to insert a delay between the Chip Select's active edge and the first SPI Clock edge.

Address: Base address + 1Ch offset



ECSPIx_PERIODREG field descriptions

Field	Description
31–22 -	This field is reserved. Reserved
21–16 CSD_CTL	Chip Select Delay Control bits. This field defines how many SPI clocks will be inserted between the chip select's active edge and the first SPI clock edge. The range is from 0 to 63.
15 CSRC	Clock Source Control. This bit selects the clock source for the sample period counter. 0 SPI Clock (SCLK) 1 Low-Frequency Reference Clock (32.768 KHz)
SAMPLE_ PERIOD	Sample Period Control. These bits control the number of wait states to be inserted in data transfers. During the idle clocks, the state of the SS output will operate according to the SS_CTL control field in the ECSPI_CONREG register. 0x0000 0 wait states inserted 0x0001 1 wait state inserted ... ... 0x7FFE 32766 wait states inserted 0x7FFF 32767 wait states inserted

10.1.6.9 Test Control Register (ECSPIx_TESTREG)

The Test Control Register (ECSPI_TESTREG) provides software a mechanism to internally connect the receive and transmit devices of the ECSPI, and monitor the contents of the receive and transmit FIFOs.

Address: Base address + 20h offset

ECSPIx_TESTREG field descriptions

Field	Description
31 LBC	Loop Back Control. This bit is used in Master mode only. When this bit is set, the ECSPI connects the transmitter and receiver sections internally, and the data shifted out from the most-significant bit of the shift register is looped back into the least-significant bit of the Shift register. In this way, a self-test of the complete transmit/receive path can be made. The output pins continue to operate normally, however the input pins are ignored. 0 Not connected. 1 Transmitter and receiver sections internally connected for Loopback.
30–28 -	This field is reserved. Reserved, all bits should be ignored.
27–15 -	This field is reserved. Reserved
14–8 RXCNT	RXFIFO Counter. This field indicates the number of words in the RXFIFO.

Table continues on the next page...

ECSPIx_TESTREG field descriptions (continued)

Field	Description
7 -	This field is reserved. Reserved
TXCNT	TXFIFO Counter. This field indicates the number of words in the TXFIFO.

10.1.6.10 Message Data Register (ECSPIx_MSGDATA)

The Message Data Register (ECSPI_MSGDATA) forms the top word of the 16 x 32 MSG Data FIFO. Only word-size accesses are allowed for this register. Reading from this register returns zero, and writing to this register stores data in the MSG Data FIFO.

Address: Base address + 40h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																																
W	ECSPI_MSGDATA																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ECSPIx_MSGDATA field descriptions

Field	Description
ECSPI_ MSGDATA	ECSPI_MSGDATA holds the top word of MSG Data FIFO. The MSG Data FIFO is advanced for each write of this register. The data read is zero. The data written to this register is stored in the MSG Data FIFO.

10.2 FlexSPI Controller (FlexSPI)

10.2.1 Overview

The Flexible Serial Peripheral Interface (FlexSPI) host controller supports two SPI channels and up to 4 external devices. Each channel supports Single/Dual/Quad/Octal mode data transfer (1/2/4/8 bidirectional data lines).

NOTE

FlexSPI configuration is dependent on the chip configuration. Please refer to the system-level sections for boot and pinmux for chip specific information regarding the modes and number of devices supported.

10.2.1.1 Block diagram

The block diagram of FlexSPI is indicated in following figure:

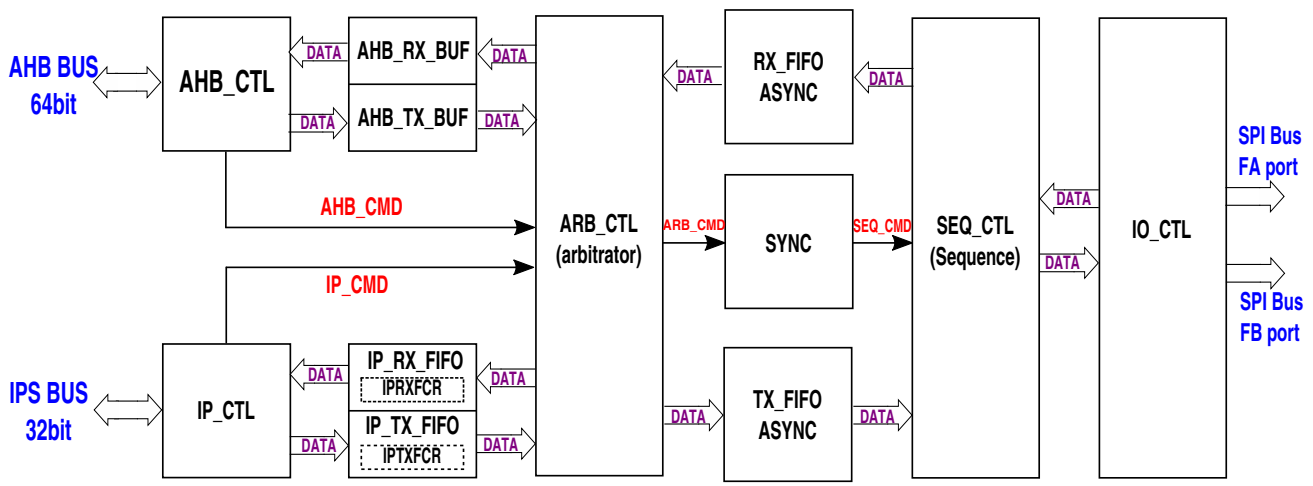


Figure 10-15. FlexSPI block diagram

10.2.1.2 Features

FlexSPI block supports following features:

- Flexible sequence engine (LUT table) to support various vendor devices
  - Serial NOR Flash or other device with similar SPI protocol as Serial NOR Flash
  - Serial NAND Flash
  - HyperBus device (HyperFlash/HyperRAM)
  - FPGA device
- Flash access mode
  - Single/Dual/Quad/Octal mode
  - SDR/DDR mode
  - Individual/Parallel mode
- Support sampling clock mode:
  - Internal dummy read strobe loopbacked internally
  - Internal dummy read strobe loopbacked from pad
  - Flash provided read strobe
- Automatic Data Learning to select correct sample clock phase
- Memory mapped read/write access by AHB Bus
  - AHB RX Buffer implemented to reduce read latency. Total AHB RX Buffer size: 2048 KBytes
  - 16 AHB masters supported with priority for read access

    - 8 flexible and configurable buffers in AHB RX Buffer
    - AHB TX Buffer implemented to buffer all write data from one AHB burst. AHB TX Buffer size: 64 Bytes
    - All AHB masters share this AHB TX Buffer. No AHB master number limitation for Write Access.
- Software triggered Flash read/write access by IP Bus
    - IP RX FIFO implemented to buffer all read data from External device. FIFO size: 512 Bytes
    - IP TX FIFO implemented to buffer all Write data to External device. FIFO size: 1024 Bytes
    - DMA support to fill IP TX FIFO
    - DMA support to read IP RX FIFO
    - SCLK stopped when reading flash data and IP RX FIFO is full
    - SCLK stopped when writing flash data and IP TX FIFO is empty

10.2.2 Functional description

The following sections describe functional details of the FlexSPI module.

10.2.2.1 Flash Connection

There are two FlexSPI interface ports (A port and B port). Each port supports 2 flash devices by providing 2 chip select outputs.

NOTE

FlexSPI configuration is dependent on the chip configuration. See the chip-specific FlexSPI information regarding the number of devices supported.

The connection diagram with 4 devices is as following:

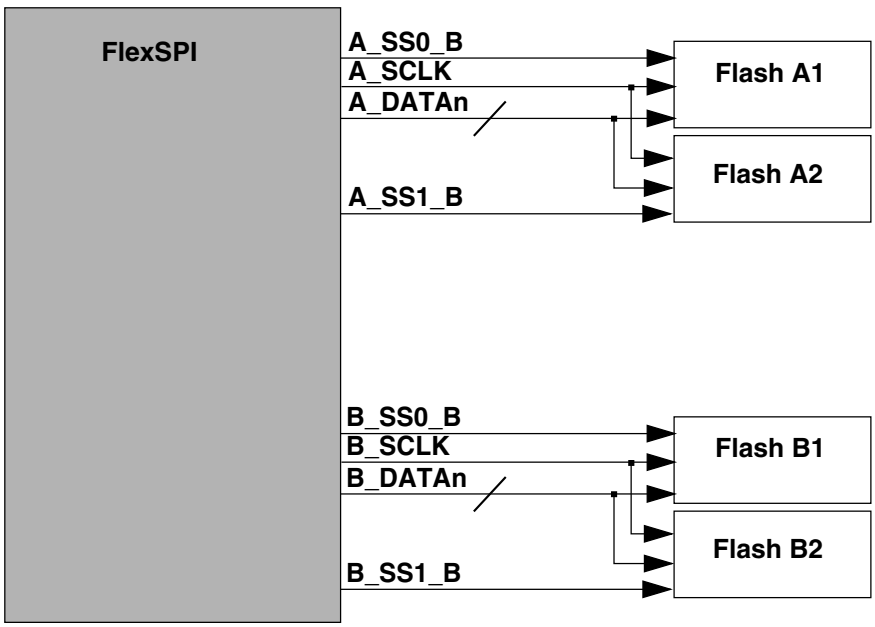

Figure 10-16. Flash connection diagram with four devices

NOTE

- Flash A1 and A2 could be two flash chip package or two flash die on the same package. There is no difference to FlexSPI. Same for Flash B1 and B2.
- Flash A1 and B1 could be accessed in parallel, using parallel mode. FlexSPI will merge/split the flash read/program data automatically. Same for A2 and B2.
- In parallel mode, A1 and A2 could not be accessed at the same time. Same for B1 and B2.
- In individual mode, A1, A2, B1 and B2 could not be accessed at the same time. But these four device could be accessed separately.

There is a combination mode to provide octal flash support by combining A port (A_DATA[3:0]) and B port (B_DATA[3:0]) together. Octal mode can also be supported by normal mode but the I/O width of A port and B port should be 8. The connection diagram for the combination mode is as following:

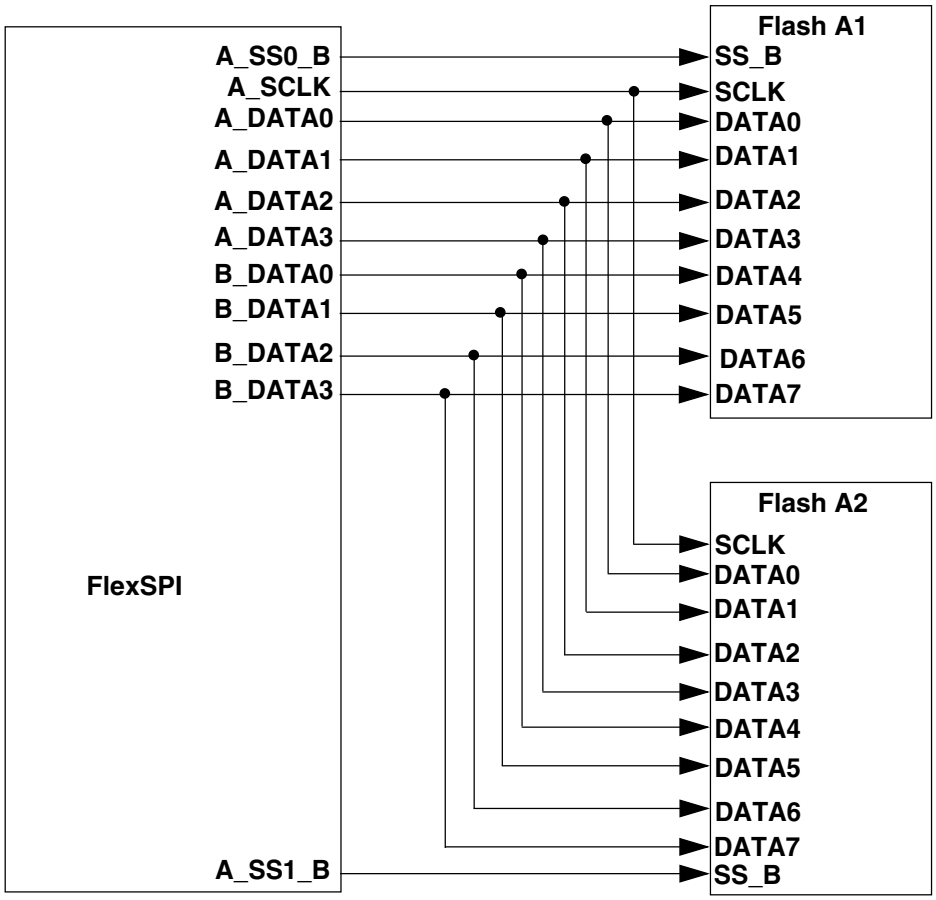

Figure 10-17. Flash connection diagram with combination mode

10.2.2.2 Flash Access mode

This section describes flash access mode.

10.2.2.2.1 SPI clock mode

FlexSPI supports only SPI clock mode 0: Clock polarity (CPOL)=0 and Clock Phase (CPHA)=0. SCLK will stay at logic low state when SPI bus is idle.

10.2.2.2.2 Flash Individual mode and Parallel mode

In individual mode, Flash read/write data is received/transmitted on port A or port B.

In parallel mode, Flash read/write data is received/transmitted on port A and B port in parallel. FlexSPI will merge/split the flash read/program data automatically. Please note that only read/program data is merged/split (READ/WRITE instruction). For other

instructions (such as Command/Address/Mode/Data size), same command code/address/mode bits/data size information will be transmitted to port A and port B devices. For more details, please refer to Instruction execution on SPI interface.

Individual and Parallel mode is determined statically by the register field IPCR1[IPAREN] (for IP command) or AHBCR[APAREN] (for AHB command).

10.2.2.2.3 SDR mode and DDR mode

In SDR (Single Data transfer Rate) mode, Flash receives data on SCLK rise edge and transmit data on SCLK fall edge.

In DDR (Dual Data transfer Rate) mode, Flash receives data on both SCLK rise and fall edges and transmit data on both SCLK rise and fall edges.

SDR and DDR mode is determined by instruction (opcode) in LUT sequence dynamically. There is no static configuration register field setting for SDR and DDR mode. For more details about input and output timing, please refer to FlexSPI Input Timing and FlexSPI Output Timing.

10.2.2.2.4 Single, Dual, Quad, and Octal mode

In Single mode, flash transmit/receive data on 1 Data pin (DATA0 for transmitting, DATA1 for receiving).

In Dual mode, flash transmit/receive data on 2 Data pins (DATA0~DATA1 for both transmitting and receiving).

In Quad mode, flash transmit/receive data on 4 Data pins (DATA0~DATA3 for both transmitting and receiving).

In Octal mode, flash transmit/receive data on 8 Data pins (DATA0~DATA7 for both transmitting and receiving).

Single, Dual, Quad and Octal mode is determined by instruction (num_pads) in LUT sequence dynamically. There is no static configuration register field setting for Single, Dual, Quad and Octal mode.

10.2.2.3 Operation Modes

This section provides information about the modes FlexSPI could be used.

- Module Disable mode

This mode is low power mode in FlexSPI module.

In module disable mode, AHB clock and serial clock domain will be gated off internally, but IPS Bus clock is not gated off. Control and status register read/write access is available except LUT/IP RX FIFO/IP TX FIFO read/write access. Serial Flash Memory access is also not available.

This mode is entered by setting MCR0[MDIS], and exited by clearing MCR0[MDIS].

- Doze mode

  This mode is low power mode in SOC system.

  When the system requires FlexSPI to enter doze mode and MCR0[DOZEEN] is set, the FlexSPI will wait for all transactions to complete (STS0[ARBIDLE]=0x1) and enter doze mode. In doze mode, the AHB clock and serial clock domain will be gated off internally, but IPS Bus clock is not gated off. Control and status register read/write access is available except LUT/IP RX FIFO/IP TX FIFO read/write access. Serial Flash Memory access is also not available.

  This mode is entered by system request, and exited by deasserting this system request.

- Stop mode

  This mode is low power mode in SOC system.

  When the system requires FlexSPI to enter stop mode, FlexSPI will wait for all transactions to complete (STS0[ARBIDLE]=0x1) and return ACK handshake to system. After ACK handshake returned, IP will gate off the AHB clock and serial clock domain internally, the system can gate the AHB Bus clock, IPS Bus clock and serial clock in system level.

  This mode is entered by system stop mode request. When all command sequences finish, FlexSPI enters stop mode and returns ACK handshake. This mode is exited by deasserting system stop mode request, the ACK handshake is also deasserted immediately.

- Normal mode

  In normal mode, all clocks are not gated internally. Normal register access and serial flash memory access is available.

10.2.2.4 Flash memory map

Flash memory map in individual and parallel mode is as following:

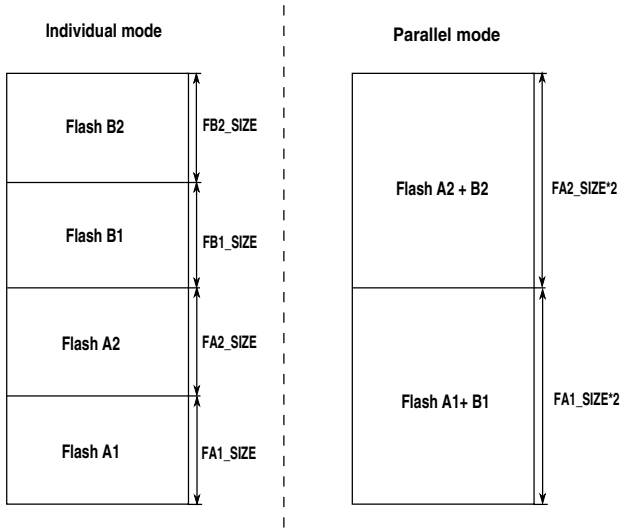

Figure 10-18. Flash memory map in individual and parallel mode

Flash memory map in individual mode:

- Flash A1 address range: 0x00000000 ~ FA1_SIZE
- Flash A2 address range: FA1_SIZE ~ (FA1_SIZE + FA2_SIZE)
- Flash B1 address range: (FA1_SIZE + FA2_SIZE) ~ (FA1_SIZE + FA2_SIZE + FB1_SIZE)
- Flash B2 address range: FA1_SIZE + FA2_SIZE + FB1_SIZE) ~ (FA1_SIZE + FA2_SIZE + FB1_SIZE + FB2_SIZE)

Flash memory map in parallel mode:

- Flash A1+B1 address range: 0x00000000 ~ FA1_SIZE*2
- Flash A2+B2 address range: FA1_SIZE*2 ~ (FA1_SIZE*2 + FA2_SIZE*2)

NOTE

- When MCR2[SAMEDEVICEEN] is set to 0x1, FA1_SIZE/FA2_SIZE/FB1_SIZE/FB2_SIZE = FLSHA1CR0[FLSHSZ] * 1KByte
- When MCR2[SAMEDEVICEEN] is set to 0x0, FA1_SIZE = FLSHA1CR0[FLSHSZ] * 1KByte; FA2_SIZE = FLSHA2CR0[FLSHSZ] * 1KByte; FB1_SIZE = FLSHB1CR0[FLSHSZ] * 1KByte; FB2_SIZE = FLSHB2CR0[FLSHSZ] * 1KByte
- Flash B1/B2 size setting are ignored in parallel mode (FLSHB1CR0[FLSHSZ], FLSHB2CR0[FLSHSZ]). To

support parallel mode application, Flash B1 should be same device as A1 and Flash B2 should be same device as A2.

10.2.2.5 Flash address sent to Device

Flash access start address is determined by AHB address (AHB command) or IPCR0[SFAR] register (IP command). Refer Flash access by AHB Command and Flash access by IP Command for more details.

For AHB command, the FlexSPI controller will remove flash base address automatically when sending flash address to devices. For IP command, the address in IPCR0[SFAR] should be the flash device's address without base address. Flash address is sent to devices in two parts: Row Address and Column Address. For flash devices not supportting Column address, set the register field FLSHxCR1[CAS] to 0. Then all flash address bits will be sent to Flash device as Row address. For flash device supporting word-addressable feature, the last bit of flash address is not needed because flash is read/programmed in terms of 2 bytes. For parallel mode, Flash A1/B1 (or A2/B2) is accessed parallelly, so the flash address sent to flash device should be divided by 2. Following table indicates the relationship of Row/Column Address and flash address (FA)

Table 10-1. Flash Row/Column Address

Parallel mode	Word-addressable	Row Address	Column Address	Comment
0	0	FA[31:CAS]	FA[CAS-1:0]	There is no limitation on FA and data size alignment.
0	1	FA[31:CAS+1]	FA[CAS:1]	FA and data size should be 2 byte aligned.
1	0	FA[31:CAS+1]	FA[CAS:1]	FA and data size should be 2 byte aligned.
1	1	FA[31:CAS+2]	FA[CAS+1:2]	FA and data size should be 4 byte aligned.

NOTE

- FA is the flash address with flash base address removed.
- If the Row/Column Flash Address bit number to be sent to Flash device defined in Instructions is more than valid Row/Column Flash Address bit number, then high position bits will be supplimented with zero. Refer Programmable Sequence Engine for more details about Row/Column Address instruction.

When the parallel mode is enabled or the word-addressable flash is used, then there are limitations on the flash start address and data size. This requirement could be met by aligning AHB bus access address (For AHB command) or IP command address IPCR0[SFAR] (For IP command) in software. There are two ways to avoid these limitations in specified case.

1. For **AHB Read Command** only:

   When AHBCR[READADDROPT] and AHBCR[PREFETCHEN] are both set to 1, FlexSPI guarantees flash access start address and data size of 64 bit aligned by hardware.

   When AHBCR[READADDROPT] is set to 1, FlexSPI will fetch redundant data to guarantee flash start address aligned with 8 bytes. When prefetch enabled (AHBCR[PREFETCHEN] is set to 1), flash read data size is determined by AHB RX Buffer size which is 64 bit aligned.

2. For **AHB Write Command and Individual mode** only:

   By default, FlexSPI will guarantee flash write access start address and data size of 16 bit aligned by using DQS as write mask.

   This feature is not applied in parallel mode and should only be used if external devices supports write mask feature.

10.2.2.6 Look Up Table

The LUT (Look Up Table) is an internal memory to preserve a number of pre-programmed sequences. Each sequence consists of up to 8 instructions which are executed sequentially. When a flash access is triggered by an IP command or an AHB command, FlexSPI controller will fetch the sequence from LUT according to sequence index/number and execute it to generate a valid flash transaction on SPI interface.

Following figure indicates the structure of LUT, sequence and instruction.

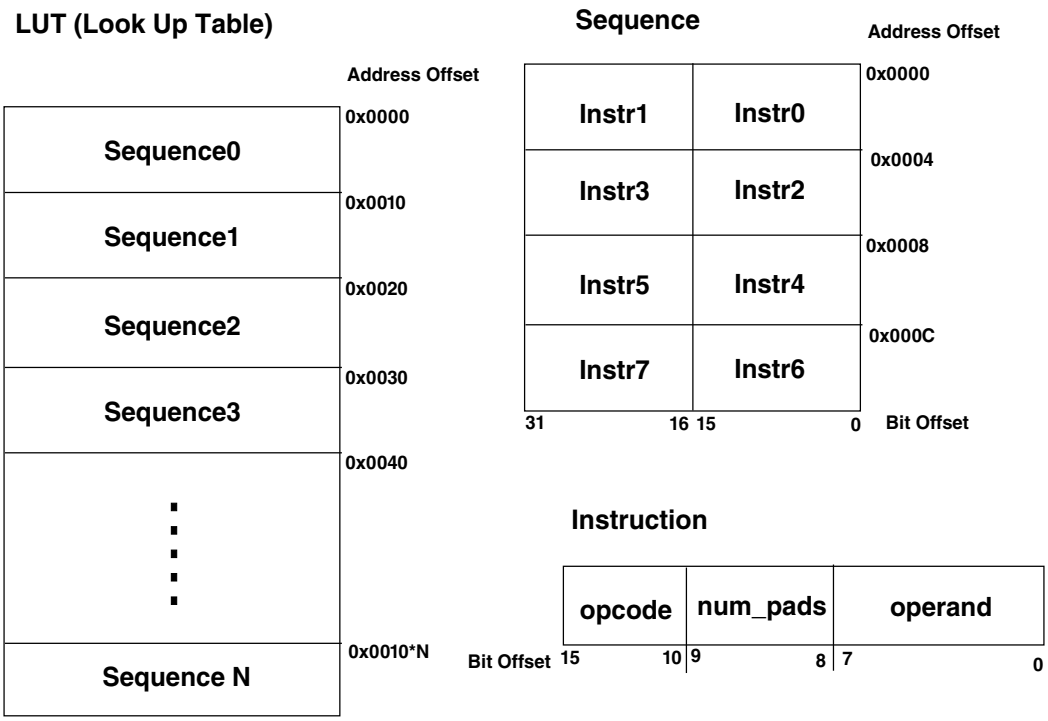

Figure 10-19. LUT and sequence structure

NOTE

If the instruction number needed is less than 8 for a flash transaction, STOP instruction should be programmed for the unneeded instructions (instruction code 8'h00).

For IP command and AHB write command, FlexSPI controller always executes from instruction pointer 0. For AHB read command, FlexSPI controller executes from a saved instruction start pointer. FlexSPI controller saves the instruction start pointers separately for each flash device. All these saved instruction pointers are zero before JMP_ON_CS instruction is executed,. When JMP_ON_CS instruction is executed, the operand in JMP_ON_CS instruction will be saved as instruction start pointer. Refer XIP Enhanced Mode for more details.

The reset value of LUT is unknown because it is implemented as internal memory. LUT should be programmed according to the device connected on board. In order to protect its contents during a code runover, the LUT could be locked/unlocked to avoid change by mistake after programmed. The key for locking or unlocking the LUT is **0x5AF05AF0**. The process for locking and unlocking the LUT is as follows:

Locking the LUT

1. Write the key **(0x5AF05AF0)** in to the LUT Key Register LUT Key Register (LUTKEY).

2. Write 1b1 to LUTCR[LOCK] and 1b0 to LUTCR[UNLOCK] fields of the LUT Control Register, immediately after the above KEY register writing. LUT is not successfully locked if there is any other register write access to FlexSPI between these two write accesses.

Unlocking the LUT

1. Write the key **(0x5AF05AF0)** in to the LUT Key Register LUT Key Register (LUTKEY).
2. Write 1b0 to LUTCR[LOCK] and 1b1 to LUTCR[UNLOCK] fields of the LUT Control Register, immediately after the above KEY register writing. LUT is not successfully unlocked if there is any other register write access to FlexSPI between these two write accesses.

The lock status of the LUT can be read from register field LUTCR[LOCK] and LUTCR[UNLOCK].

10.2.2.7 Programmable Sequence Engine

FlexSPI controller implements a programmable sequence engine that executes the sequence from LUT. FlexSPI controller executes the instructions sequentially and generates flash transaction on the SPI interface accordingly. The following table is a complete list of the supported instructions.

Table 10-2. Instruction set

Name	Opcode	Num_pads	Action on SPI interface	Transmit Data	Bits/Bytes/Cycle Number
CMD_SDR/ CMD_DDR	6'h01/ 6'h21	2'h0 - one pad (Single mode) 2'h1 - two pad (Dual mode) 2'h2 - four pad (Quad mode) 2'h3 - eight pad (Octal mode)	Transmit Command code to Flash	Command code: Operand[7:0]	Bit number: 8
RADDR_SDR/ RADDR_DDR	6'h02/ 6'h22		Transmit Row Address to Flash	Row_Address[31:0]	Bit number: operand[7:0]
CADDR_SDR/ CADDR_DDR	6'h03/ 6'h23		Transmit Column Address to Flash	Column_Address[31:0]	Bit number: operand[7:0]
MODE1_SDR/ MODE1_DDR	6'h04/ 6'h24		Transmit Mode bits to Flash	Mode bits: Operand[0]	Bit number: 1
MODE2_SDR/ MODE2_DDR	6'h05/ 6'25			Mode bits: Operand[1:0]	Bit number: 2
MODE4_SDR/ MODE4_DDR	6'h06/ 6'h26			Mode bits: Operand[3:0]	Bit number: 4
MODE8_SDR/ MODE8_DDR	6'h07/ 6'h27			Mode bits: Operand[7:0]	Bit number: 8

Table continues on the next page...

Table 10-2. Instruction set (continued)

Name	Opcode	Num_pads	Action on SPI interface	Transmit Data	Bits/Bytes/Cycle Number
WRITE_SDR/ WRITE_DDR	6'h08/ 6'h28		Transmit Programming Data to Flash	Programming Data in IP TX FIFO or AHB_TX_BUF	Byte number (data size) is determined by AHB burst size and burst type (AHB Command) or IPCR1[IDATSZ] (IP command). For more detail about flash read/ program data size, refer Flash access by AHB Command and Flash access by IP Command.
READ_SDR/ READ_DDR	6'h09/ 6'h29		Receive Read Data from Flash Read Data is put into AHB_RX_BUF or IP_RX_FIFO.	-	
LEARN_SDR/ LEARN_DDR	6'h0A/ 6'h2A		Receive Read Data or Preamble bit from Flash device FlexSPI Controller will compare the data line bits with DLPR register to determine a correct sampling clock phase.	-	Learning pattern bit number: operand[7:0] Never set operand to zero for LEARN instruction. It indicates length of data learning pattern based on bits number. For example, 8bits pattern 0x5A on each data line needs to set operand to 8.
DATSZ_SDR/ DATSZ_DDR	6'h0B/ 6'h2B		Transmit Read/ Program Data size (byte number) to Flash	Internal Logic Read/Program data size for current command sequence.	Bit number: operand[7:0] Please never set operand to zero or larger than 64 for DATSZ instruction.
DUMMY_SDR/ DUMMY_DDR	6'h0C/ 6'h2C		Leave data lines undriven by FlexSPI controller. Provide turnaround cycles from host driving to device driving. num_pads will determine the number of pads in input mode.	-	Dummy cycle number (in serial root clock): Operand[7:0] **Dummy cycle (N), described in the Flash device data sheet is in number of SCLK cycles and this number may be configurable.** **In SDR mode, SCLK cycle is same as serial root clock. The operand value should be set as N.** **In DDR mode, SCLK cycle is double the serial root clock cycle. The operand value should be set as 2*N, 2*N-1 or 2*N+1 depending on how dummy cycle defined in device data sheet. Please refer to Flash access sequence example and dummy cycle definition on device data sheet.**

Table continues on the next page...

Table 10-2. Instruction set (continued)

Name	Opcode	Num_pads	Action on SPI interface	Transmit Data	Bits/Bytes/Cycle Number
DUMMY_RWDS_SDR/ DUMMY_RWDS_DDR	6'h0D/ 6'h2D		This instruction is similar as DUMMY_SDR/ DUMMY_DDR instruction. But the dummy cycle number is different. DQS pins is called "RWDS" in HyperBus specification. Refer Dummy instruction for more details. **Set operand as "Latency count" for HyperBus devices.**	-	For read command, dummy cycle number (in serial root clock): (operand[7:0]*4-1) if RWDS (DQS pin) is high; (operand[7:0]*2-1) if RWDS (DQS pin) is low; For write command, dummy cycle number (in serial root clock): (operand[7:0]*4-2) if RWDS (DQS pin) is high; (operand[7:0]*2-2) if RWDS (DQS pin) is low;
JMP_ON_CS	6'h1F	Num_pads setting will be ignored. Always set num_pads to 2'h0.	Stop execution, deassert CS and save operand[7:0] as the instruction start pointer for next sequence. Normally this instruction is used to support Execute-In-Place enhance mode. Refer XIP Enhanced Mode for more details. This instruction is only allowed for AHB read command. If this instruction is used in IP command or AHB write command, there will be interrupt status bit set (INTR[IPCMDERR] or INTR[AHBCMDERR]).	-	No transaction on SPI interface.
STOP	6'h00		Stop execution, deassert CS. Next command sequence (to the same flash device)	-	

Table 10-2. Instruction set

Name	Opcode	Num_pads	Action on SPI interface	Transmit Data	Bits/Bytes/Cycle Number
			will started from instruction pointer 0.		

The programmable sequence engine allows the software to configure the FlexSPI LUT according to external serial device connected on board. The flexible structure is easily adaptable to new command/protocol changes from different vendors.

DDR sequence is a flash access sequence that contains DDR instruction which is not DUMMY, it may optionally contain SDR instructions. SDR sequence is a flash access sequence that doesn't contain any DDR instruction. FlexSPI controller determines instruction SDR or DDR mode by decoding bit 5 of instruction opcode. The output/input timing on FlexSPI is different for SDR and DDR sequences. Especially note that SDR instruction in SDR sequence and DDR sequence is executed differently. Refer FlexSPI Input Timing and FlexSPI Output Timing for more details.

10.2.2.7.1 Instruction execution on SPI interface

This section describes the detail of instruction execution on SPI interface. For all instructions transmitting/receiving data bits to/from flash, the bit order in one byte is higher on DATA3 than DATA0, and higher on B port than A port.

1. **Command Instruction**

   Command Instruction (CMD_SDR/CMD_DDR) is normally used to transmit command code to external flash device. Command code is the 8-bit operand in instructions. Command code will be send to both B port and A port in parallel mode. Refer Flash access sequence example for examples.

2. **Address Instruction**

   Address Instructions (RADDR_SDR/RADDR_DDR/CADDR_SDR/CADDR_DDR) are normally used to send Flash access start address (Row/Column Address) to external flash device. Row/Column Address bits are determined by FlexSPI according to AHB access address or IP command address. Refer Flash address sent to Device for more details. The bit number is the operand value in instruction code. Row/Column address bits will be sent to both B port and A port in parallel mode. For memories that read the flash address on 4 SCK edges, the sum of CADDR+RADDR must be 32. Otherwise, the FlexSPI will not generate 4 SCK edges of address phase. Refer Flash access sequence example for examples.

3. **Mode Instruction**

   Mode Instructions (MODEx_SDR/MODEx_DDR) are normally used to send mode bits to external flash devices. Mode bits are the (lower) bits of the instruction operand. The transition bit number is 1 for MODE1_SDR/MODE1_DDR, 2 for MODE2_SDR/MODE2_DDR, 4 for MODE4_SDR/MODE4_DDR and 8 for MODE8_SDR/MODE8_DDR. Note that pad number should be no more than mode bit number. For example, it is not allowed to set num_pads to 2'b11 (Octal mode) for MODE4_* instructions. Mode bits will be sent to both B port and A port in parallel mode. Refer Flash access sequence example for examples.

4. **Data Size Instruction**

   Data Size Instructions (DATSZ_SDR/DATSZ_DDR) are used to send program/read data size (byte number) to external device. This instruction is normally used in FPGA application when the memory space in external device acts similar as a FIFO. The device needs data size information to determine how much data will be popped from or pushed into internal FIFO. The bit number is the operation value in the instruction. Data size bits will be send to both B port and A port in parallel mode. Refer Flash access sequence example for examples.

5. **Write Instruction**

   Write Instructions (WRITE_SDR/WRITE_DDR) are normally used to send program data to external device. Programming data are fetched from IP TX FIFO (IP Command) or AHB TX Buffer (AHB command). For more details about flash program data size, refer Flash access by AHB Command and Flash access by IP Command. The byte order for programming data is always from low to high. Odd bytes are send on A port and Even bytes are send on B port in parallel mode. Refer Flash access sequence example for examples.

6. **Read Instruction**

   Read Instructions (READ_SDR/READ_DDR) are normally used to receive flash data from external device. Received data will be put into IP RX FIFO (IP Command) or AHB RX Buffer (AHB command). For more detail about flash read data size, refer Flash access by AHB Command and Flash access by IP Command. The byte order for reading data is always from low to high. Odd bytes are received from A port and Even bytes are received from B port in parallel mode. Refer Flash access sequence example for examples.

7. **Dummy Instruction**

Dummy Instructions (DUMMY_SDR/DUMMY_DDR/DUMMY_RWDS_SDR/DUMMY_RWDS_DDR) are used to provide turnaround cycles on SPI interface. During dummy instruction, neither FlexSPI controller nor external device drives SPI interface. Refer Programmable Sequence Engine for more details about dummy cycle number.

DUMMY_RWDS_DDR could be used for HyperBus device which use "RWDS" pin to indicate whether extra latency count needed. DUMMY_RWDS_SDR is reserved for future. FlexSPI controller checks DQS pin input level at the 4th cycle after SCLK output toggling is enabled. DQS pins is called "RWDS" in HyperBus specification. Refer Flash access sequence example for examples.

NOTE

The FlexSPI releases the bus after at least one cycle. Therefore, to avoid data contention, number of dummy lines should be programmed more than 1 if data is transferred on more than 1 line.

8. **Learn Instruction**

   Learn Instructions (LEARN_SDR/LEARN_DDR) are used to determine the correct sample clock phase for flash read data sampling. External device drives read data (or data learning pattern) bits on FlexSPI interface. FlexSPI Controller will compare the data line bits with DLPR register to determine a correct sampling clock phase.

   Clock phase selection is automatically updated after learn instruction execution. Refer Data Learning Feature for more details. The byte number is the operand value in instruction. FlexSPI checks the same data pattern on ech data line.

   The byte order is byte 0, byte 1, byte 2, byte 3, byte0, byte 1, ... (byte 0 is DLPR register bit 7-0, byte 1 is DLPR register bit 15-8, byte 2 is DLPR register bit 23-16, byte 3 is DLPR register bit 31-24); The bit order is from high to low in each byte. Refer Flash access sequence example for examples.

10.2.2.7.2 Flash access sequence example

Following is an example for SDR single I/O Read sequence (Cypress Serial Nor Flash S25FS512S) in individual mode.

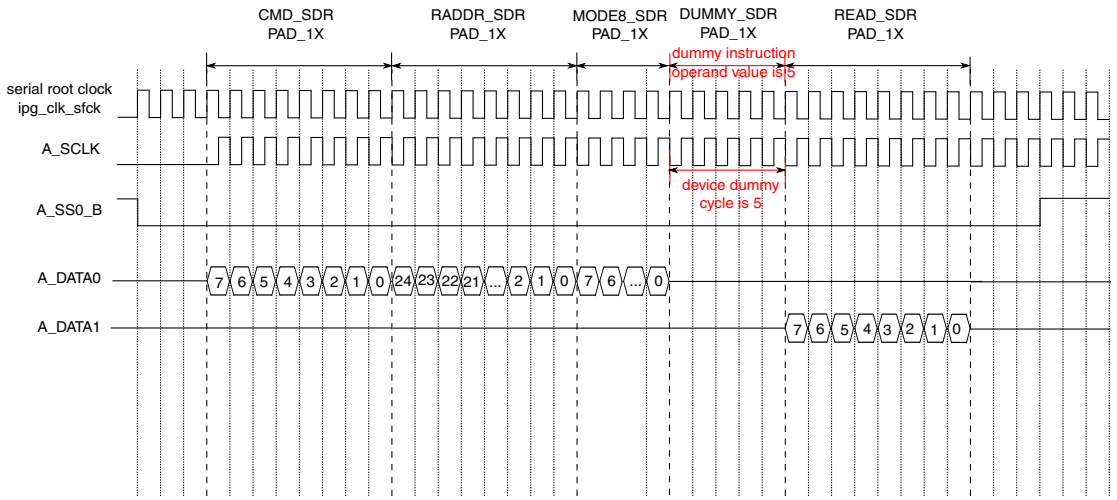

Figure 10-20. Flash access sequence example (SDR Single I/O Read sequence)

NOTE

- FlexSPI dummy instruction starts and ends at serial root clock rise edge.
- Device dummy cycle starts and ends at SCLK fall edge (on Cypress S25FS512S data sheet).

Following is an example for SDR Quad I/O Read sequence (Cypress Serial Nor Flash S25FS512S) in individual mode.

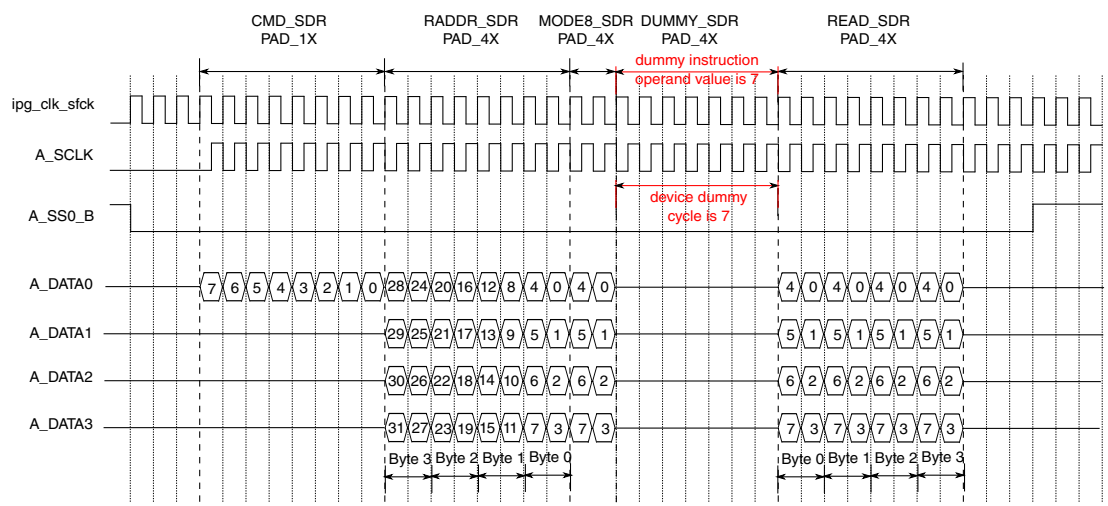

Figure 10-21. Flash access sequence example (SDR Quad I/O Read sequence)

NOTE

- FlexSPI dummy instruction starts and ends at serial root clock rise edge.
- Device dummy cycle starts and ends at SCLK fall edge (on Cypress S25FS512S data sheet).

Following is an example for DDR Quad I/O Read sequence (Cypress Serial Nor Flash S25FS512S) in parallel mode.

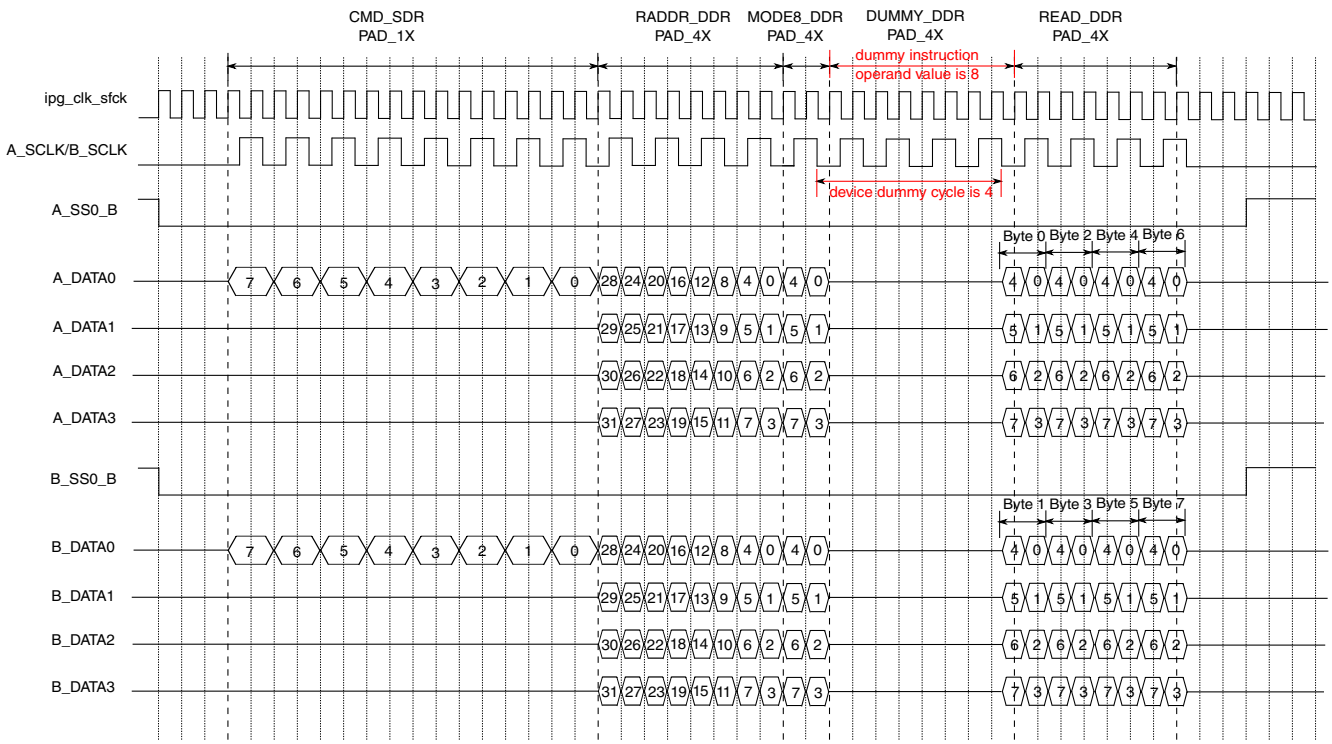

Figure 10-22. Flash access sequence example (DDR Quad I/O Read sequence)

Following is an example indicating Learning instruction (not for a specified flash device) in individual mode.

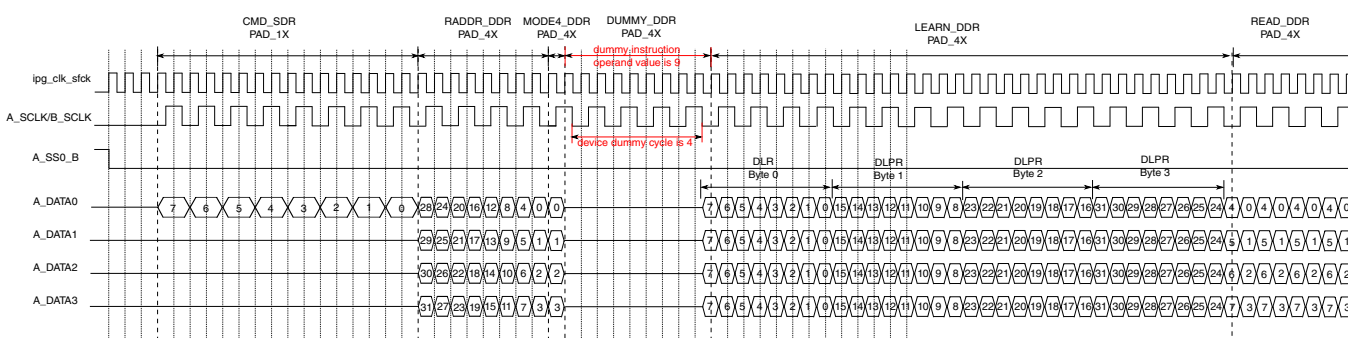

Figure 10-23. Flash access sequence example (Data Learning)

NOTE

- FlexSPI dummy instruction starts and ends at serial root clock rise edge.
- Device dummy cycle starts and ends at SCLK fall edge.
- DUMMY_DDR instruction operand value is odd because the total cycle number before DUMMY_DDR cycle is odd.

Following is an example for HyperBus device read transaction (Single latency count) in individual mode.

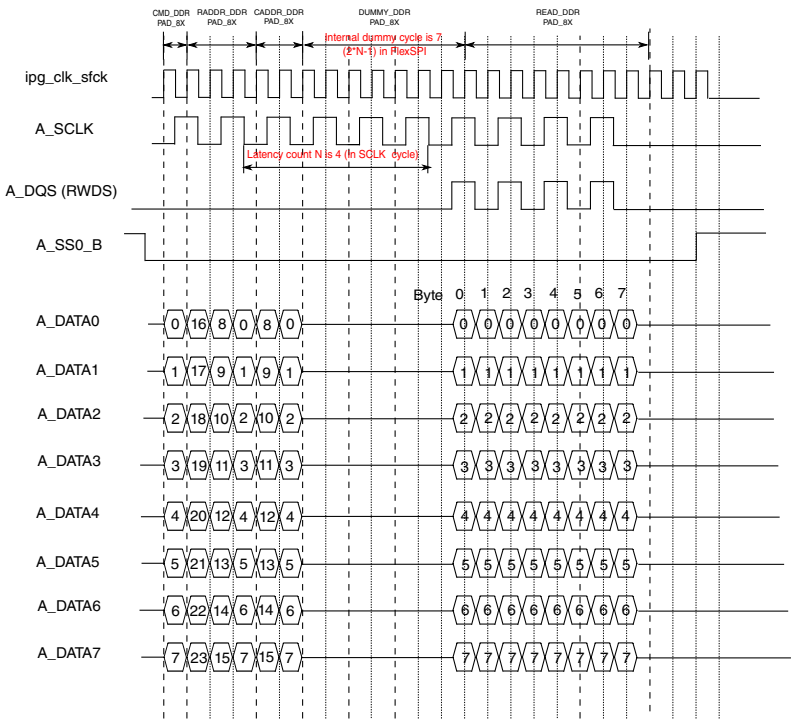

Figure 10-24. HyperBus device read transaction with single latency count

NOTE

The FlexSPI module continues to drive the clock until it has latched in all of the read data it is expecting. On-chip delay for the data to reach the FlexSPI module can increase the number of SCK clock pulses.

Following is an example for HyperBus device read transaction (Additional latency count) in individual mode.

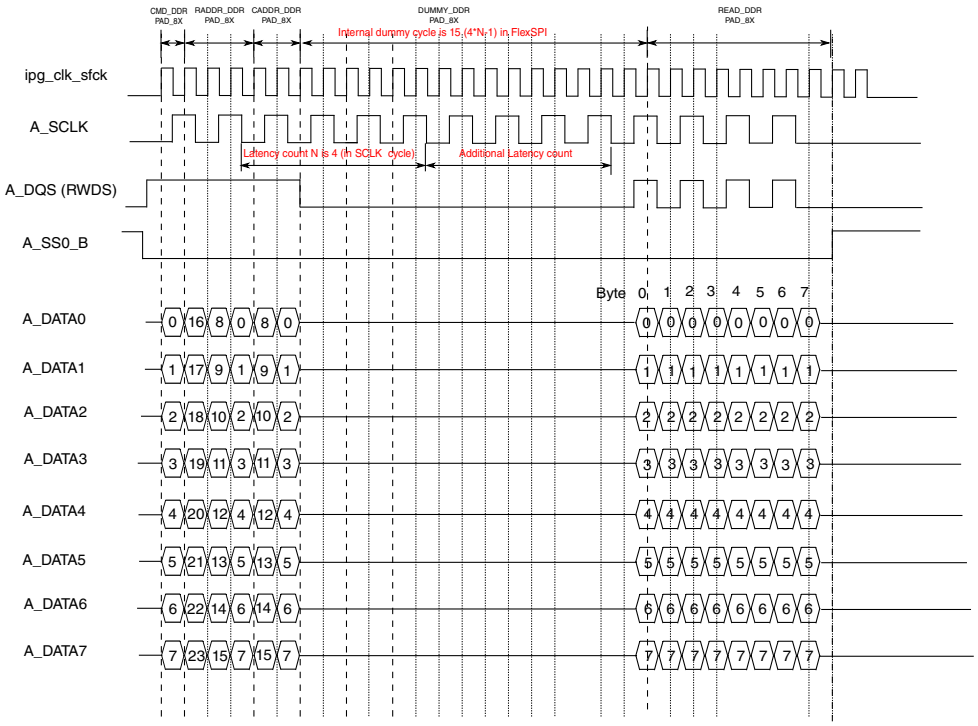

Figure 10-25. HyperBus device read transaction with additional latency count

Following is an example for HyperBus device write transaction (Single latency count) in individual mode.

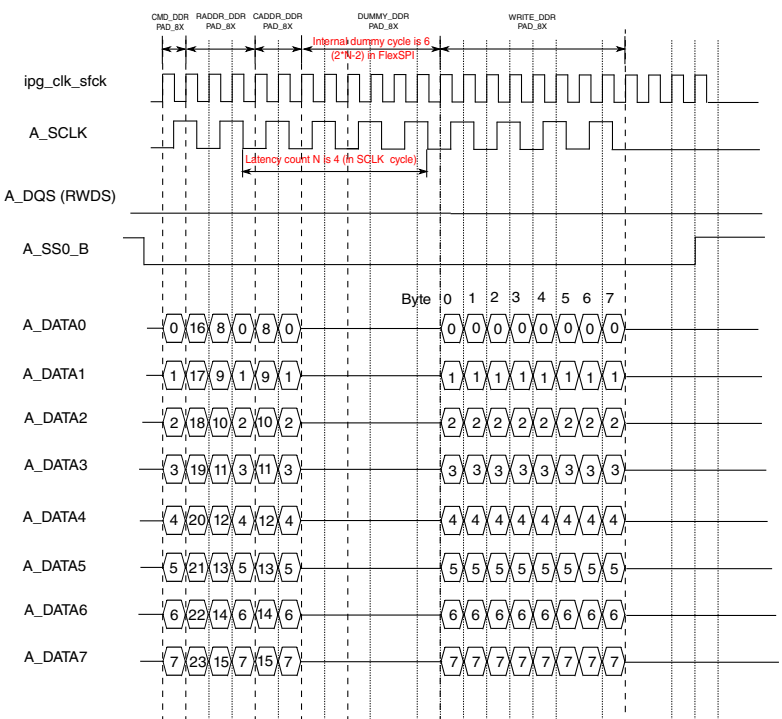

Figure 10-26. HyperBus device write transaction with single latency count

Following is an example for HyperBus device write transaction (Additional latency count) in individual mode.

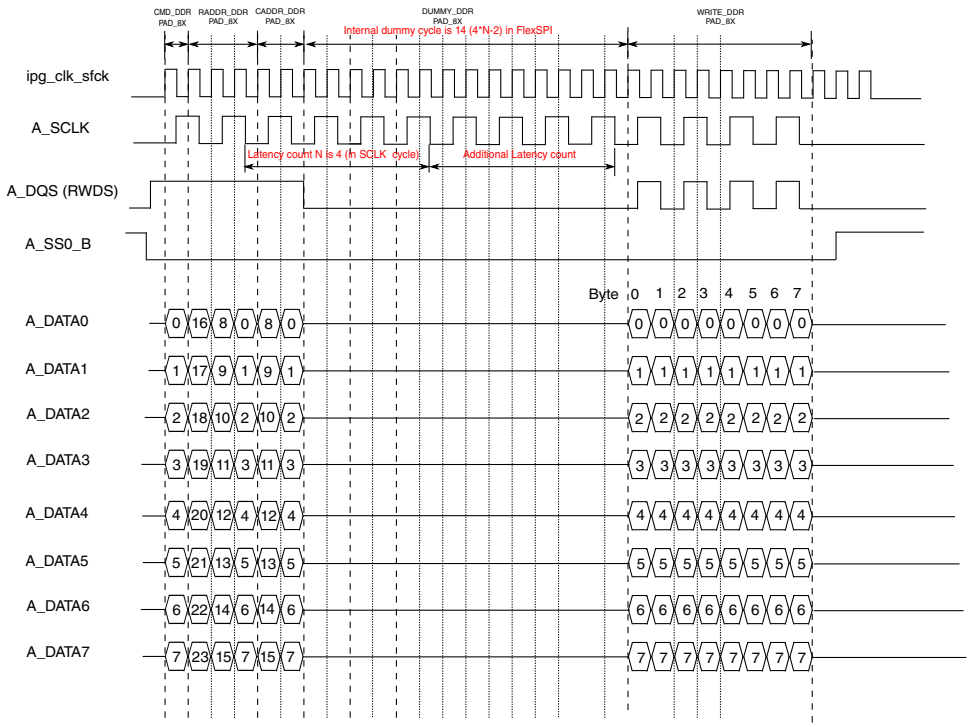

Figure 10-27. HyperBus device write transaction with additional latency count

10.2.2.8 Clocks

This section describes clocks and special clocking requirements of the FlexSPI module.

Table 10-3. Clock Usage

Clock Name	Description	Comment
serial clock root (ipg_clk_sfck)	Root clock for Serial domain	-
ahb clock (hclk)	AHB Bus clock	-
ipg clock (ipg_clk)	IPS Bus clock	-
SCLK	FlexSPI serial clock. Output clock on SCLK pin	Half clock frequency of serial clock root in DDR mode, and same frequency as serial clock root in SDR mode. Clock output toggles during the whole flash access sequence.
DQS_OUT	Dummy Read Strobe output	Same frequency as SCLK. Clock output toggles during READ/LEARN instructions.
DQS_IN	Sample clock for RX Data	Same frequency as SCLK. Sample clock comes from loopbacked dummy read

Table 10-3. Clock Usage

Clock Name	Description	Comment
		strobe, loopbacked SCLK or Flash provided read strobe.

NOTE

- hclk should be **synchronous** with ipg_clk, but ipg_clk can be integer times of slower than hclk, for example hclk frequency = 4/3/2 X ipg_clk frequency.
- ipg_clk_sfck is **asynchronous** with hclk and ipg_clk.
- ipg_clk_sfck should be **synchronous** with its all divided version of generated clock.
- DQS is **asynchronous** with ipg_clk_sfck or hclk or ipg_clk.
- Please refer flexspi_mix_wrapper/contraints/ flexspi_mix_wrapper.sdc for clock domain information.

10.2.2.9 Interrupts

This section describes all the interrupts that the FlexSPI module generates.

- **IP command done interrupt**

  When IP command is finished, there will be interrupt generated if INTEN[IPCMDDONEEN] is set to 0x1.

- **IP command grant error interrupt**

  When IP command grant timeout (not grant after MCR0[IPGRANTWAIT] * 1024 ahb clock cycles), there will be interrupt generated if INTEN[IPCMDGEEN] is set to 0x1.

- **AHB command grant error interrupt**

  When AHB command grant timeout (not grant after MCR0[AHBGRANTWAIT] * 1024 ahb clock cycles), there will be interrupt generated if INTEN[AHBCMDGEEN] is set to 0x1.

- **IP command error interrupt**

  When there is command check error or command execution error for IP command, there will be interrupt generated if INTEN[IPCMDERREN] is set to 0x1. Refer Overview of Error Flags for more details.

- **AHB command error interrupt**

  When there is command check error or command execution error for AHB command, there will be interrupt generated if INTEN[AHBCMDERREN] is set to 0x1. Refer Overview of Error Flags for more details.

- **IP RX FIFO watermark available interrupt**

  When the fill level of IP RX FIFO is no less than watermark level (IPRXFCR[RXWMRK]), there will be interrupt generated if INTEN[IPRXWAEN] is set to 0x1.

- **IP TX FIFO watermark exceed interrupt**

  When the empty level of IP TX FIFO is no less than watermark level (IPTXFCR[TXWMRK]), there will be interrupt generated if INTEN[IPRXWAEN] is set to 0x1.

- **Data learning failed interrupt**

  When there is no valid sample clock phase found after LEARN instruction executed, there will be interrupt generated if INTEN[DATALEARNFAILEN] is set to 0x1.

- **Sequence execution timeout interrupt**

  When a sequence execution time exceeds the timeout wait time (MCR1[SEQWAIT]), an interrupt will be generated if INTEN[SEQTIMEOUTEN] is set to 0x1. For example, the following flash read command sequence will lasts about 8000000 cycle (ipg_clk_sfck). If SEQWAIT is set 0xFFFF, there will be sequence timeout interrupt generated.

  - Triggered by IP command
  - Flash read data size is 0x1000000 bytes
  - Flash accessed in Single mode and SDR mode,

- **AHB Bus timeout interrupt**

  When AHB bus response timeout, there will be interrupt generated if INTEN[AHBBUSTIMEOUTEN] is set to 0x1. A typical case is AHB read sequence is not configured properly in LUT (such as without READ instruction). There will never be data read from external device, then FlexSPI will never hit the read data in AHB RX Buffers for AHB Read command.

- **SCLK stopped by write command interrupt**

When IP TX FIFO is empty during write command sequence execution, FlexSPI will stop SCLK output clock toggling and wait for write data filling. At this time, this interrupt is generated if enabled by INTEN register.

- **SCLK stopped by read command interrupt**

  When IP RX FIFO is full during read command sequence execution, FlexSPI will stop SCLK output clock toggling and wait for read data read out from IP RX FIFO. At this time, this interrupt is generated if enabled by INTEN register.

10.2.2.10 Flash access by IP Command

Flash access could be triggered by IP command in following steps.

- Fill IP TX FIFO with programming data if this is a programing command (programming flash data, flash status registers, etc.)
- Set flash access start address (IPCR0[SFAR]), read/program data size, sequence index in LUT and sequence number (IPCR1[ISEQNUM]).
- Trigger flash access command by writing 1 to register bit IPCMD[TRG]
- Polling register bit INTR[IPCMDDONE] to wait for this IP command to finish on FlexSPI interface.

NOTE

- IP TX FIFO could be filled before or after writing IPCR0/IPCR1/IPCMD register. If SFM command is started with IP TX FIFO empty, FlexSPI will stop SCLK toggling to wait for TX data ready automatically.
- IPCMD register must be written after writing IPCR0/IPCR1 register.
- Multiple Command sequences (8 at most) could be issued by one IP command.
- It is not allowed to issue another IP command before the previous IP command is finished. The behaviour is unknown in this case.

If this is a Read command to Serial Flash Memory, all read data from Flash will be put into IP RX FIFO. Software will need to read out data from IP RX FIFO by AHB bus or IP Bus. When IP RX FIFO is full and there is more data to be read from Flash device, FlexSPI will stop SCLK output clock toggling until there is free space in IP RX FIFO. See SCLK stop feature for more details.

The detail of triggered Serial Flash Command is as following:

- Flash access start address:

  Determined by register field IPCR0[SFAR]

- Flash Chip Select:

  Determined by flash access address and Flash size setting (FLSHxCR0[FLSHSZ]).

- Flash command Sequence Index and Sequence Number:

  The sequences indexed from IPCR1[ISEQID] to (IPCR1[ISEQID] + IPCR1[ISEQNUM]) in LUT will be executed by FlexSPI sequentially.

- Flash Individual/Parallel access mode

  Determined by IPCR1[IPAREN].

- Flash Read/Program Data Size:
  - If IPCR1[IDATSZ] value is non-zero, flash read/program data size (in byte) is IPCR1[IDATSZ].
  - If IPCR1[IDATSZ] value is zero, flash read/program data size (in byte) will the operand value in the READ/WRITE instruction.

NOTE

- Software should make sure the last sequence index never exceeds the LUT sequence number (IPCR1[ISEQID] + IPCR1[ISEQNUM] < 32).
- Data size is applied to every command sequence if sequence number is more than one.
- Data size is ignored if there is no WRITE/READ instruction in the command sequence .

IP command request is sent to arbitrator after triggered by software. It is not executed on FlexSPI Interface until granted by arbitrator. Please refer to Command Arbitration for more details.

10.2.2.10.1 Reading Data from IP RX FIFO

FlexSPI put the read data from external device into IP RX FIFO for IP command.

These data could be read out by following two memory space access.

- 0x100 - 0x180 (by IPS Bus)
- 0x34000000 - 0x34000200 (by AHB Bus)

If MCR0[ARDFEN] is set to 0x1, read data in IP RX FIFO could only be read out by AHB Bus, IP Bus read access to IP RX FIFO will always return with data zero and no bus error occur.

If MCR0[ARDFEN] is set to 0x0, read data in IP RX FIFO could only be read out by IPS Bus, AHB Bus read access to IP RX FIFO will trigger bus error.

FlexSPI push read data into IP RX FIFO in terms of 64 bits every time it receives 64 bits data from external device. When read data bits number is not 64 bits aligned, FlexSPI will push additional zero bits into IP RX FIFO for the last push.

IP RX FIFO could be read by processor or DMA. Following is the detail flow for processor and DMA reading:

1. **Reading by processor**

   To read by processor, following register settings are needed:

   - Set register field IPRXFCR[RXDMAEN] to 0.
   - Set watermark level by IPRXFCR[RXWMRK], watermark level is (IPRXFCR[RXWMRK]+1)*8 bytes.
   - Set register field INTEN[IPRXWAEN] to enable IP RX FIFO watermark available interrupt (optional).

   Processor needs to poll register INTR[IPRXWA] or wait for IP RX FIFO Watermark Available interrupt before reading IP RX FIFO. This is to make sure there is a watermark level Data filled in IP RX FIFO before reading.

   After reading a watermark level data from IP RX FIFO, software need to set register bit INTR[IPRXWA]. This set action will pop out a watermark level data from IP RX FIFO.

   Following diagram indicates the reading flow from IP RX FIFO by processor.

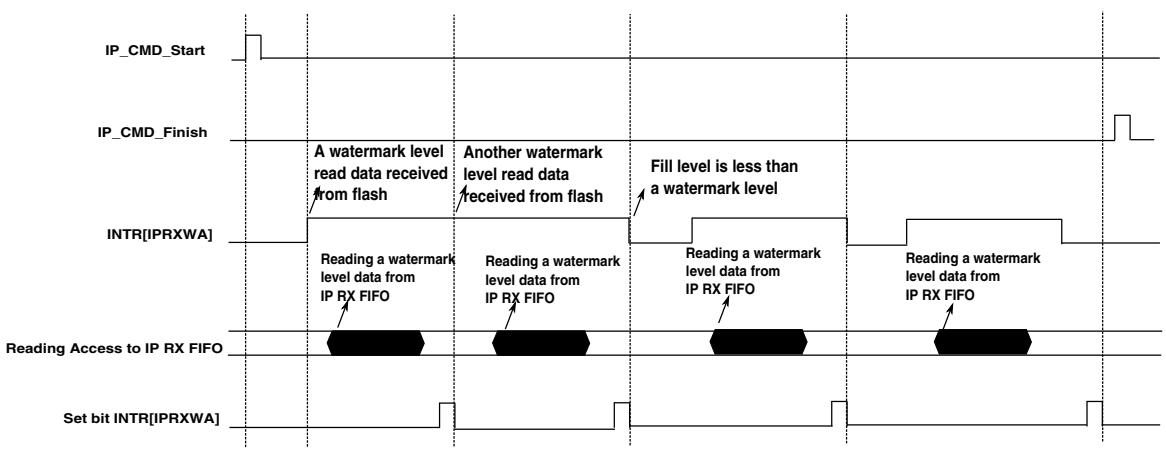

Figure 10-28. Reading IP RX FIFO by processor

NOTE

- Processor need to read out a watermark level data from IP RX FIFO each time before set register bit INTR[IPRXWA].
- It's supported that the total flash read/program data size is not multiple of watermark level. In this case, the reading data size from IP RX FIFO will be less than a watermark level for the last time, software should poll IPRXSTS[FILL] field instead of polling INTR[IPRXWA]. After copying all the data from IP RX FIFO and all command sequences to Flash are finished (INTR[IPCMDDONE]=1), software should clear IP RX FIFO by setting IPRXFCR[CLRIPRXF]. Otherwise, the reading data will be wrong for the next reading command to Flash.
- IP RX FIFO data is not popped out by each reading access to IP RX FIFO, but popped by writing 0x1 to register INTR[IPRXWA] bit.

2. **Reading by DMA**

To read IP RX FIFO by DMA, following setting is needed:

- Set register field IPRXFCR[RXDMAEN] to 1.
- Set watermark level by IPRXFCR[RXWMRK], watermark level is (IPRXFCR[RXWMRK]+1)*8 bytes.
- Set DMA transfer Minor loop size to same watermark level.

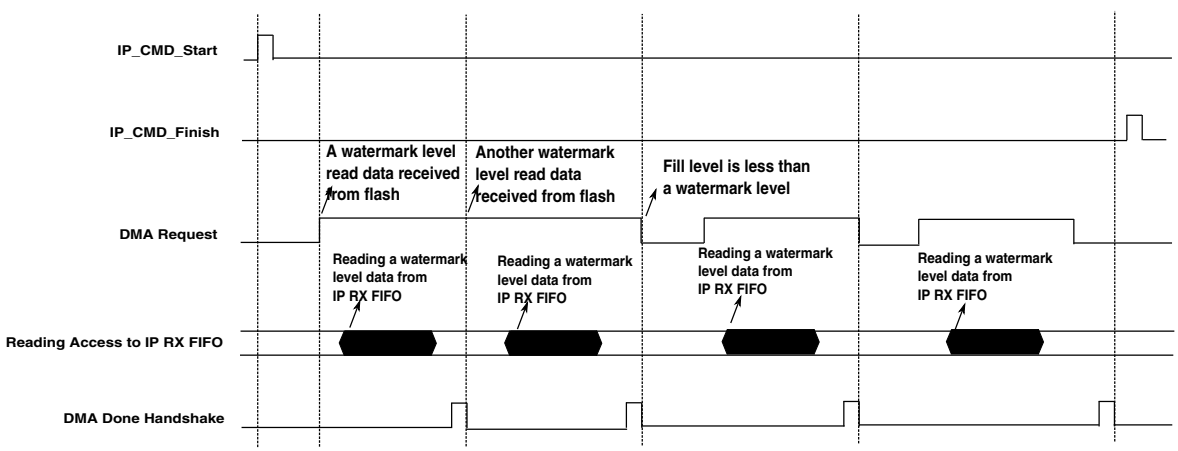

Figure 10-29. Reading from IP RX FIFO by DMA

NOTE

- DMA request is generated when the fill level of IP RX FIFO is higher than (or equal) watermark level. This request is not pulse valid but level valid.
- DMA should read out watermark level data from IP RX FIFO each time (set minor loop size with the same value as watermark level.
- DMA need to return a Done handshake (pulse valid) to FlexSPI each time it finished reading a watermark level data.
- IP RX FIFO data is not popped out by each reading access, but popped by DMA done handshake.
- It is not supported that the total read/write data size (Major loop size) is not multiple of watermark level. Because the DMA does not know when the data is ready for the last reading. It makes the DMA driver too complex to poll IPRXFSTS [FILL] field.

10.2.2.10.2 Filling Data to IP TX FIFO

The programming should be put into IP TX FIFO and then transmit to Flash by FlexSPI. It could be filled by two memory space

- 0x180 - 0x200 (by IP Bus)
- 0x33008000 - 0x33008400 (by AHB Bus)

To fill by AHB Bus, need to set MCR0[ATDFEN] to 1, IP Bus write access to IP TX FIFO will be ignored, but no bus error.

To fill by IP Bus, need to set MCR0[ATDFEN] to 0, AHB Bus write access to IP TX FIFO will return Bus Error.

IP TX FIFO is popped with 64 bits data every time FlexSPI fetch data for transmitting. If the programming data size is not multiple of 64 bits, last popped valid bits will be less than 64 bits. But there is no problem because these invalid bits are not transmitted to Flash at all.

IP TX FIFO could be filled by processor or DMA.

To fill by processor, need following setting:

- Set register field IPTXFCR[TXDMAEN] to 0.

- Set watermark level by IPTXFCR[TXWMRK], watermark level is (IPTXFCR[TXWMRK]+1)*8 bytes.
- Set register field INTEN[IPTXWEEN] to enable IP TX FIFO watermark empty interrupt (optional).

Processor needs to poll register INTR[IPTXWE] or wait for IP TX FIFO Watermark empty interrupt before filling IP TX FIFO. This is to make sure there is enough space for a watermark level Data filling before filling.

After filling a watermark level data to IP TX FIFO, need to set register bit INTR[IPTXWE]. This will push a watermark level data into IP TX FIFO (write pointer is incremented).

NOTE

IP TX FIFO data is not pushed by each write access, only pushed by set INTR[IPTXWE] bit.

Following digram indicates the filling flow to IP TX FIFO by processor.

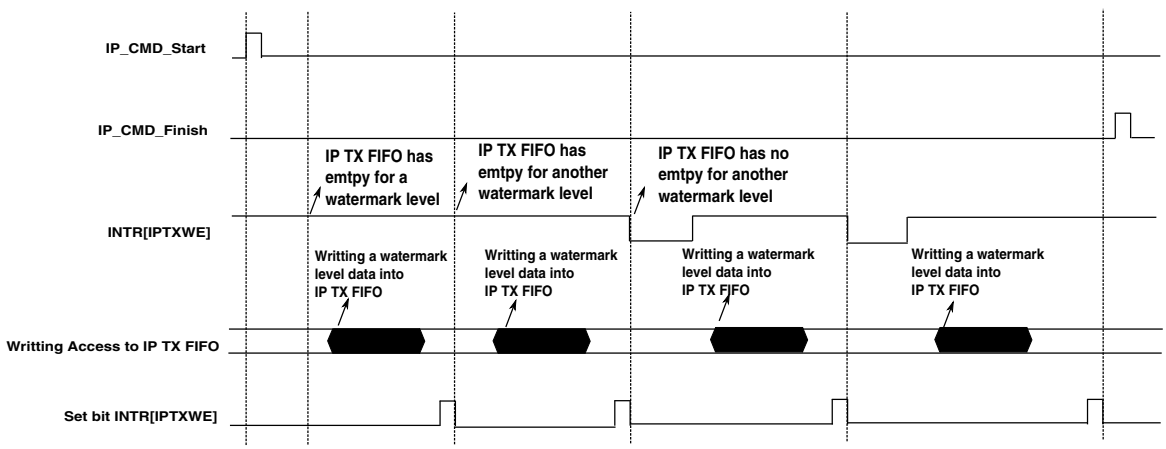

Figure 10-30. Filling IP TX FIFO by processor

NOTE

- Processor will need to fill a watermark level data to IP TX FIFO each time.
- It's allowed that total write data size is not multiple of watermark level. In this case, the writing size will be less than a watermark level for the last time. After filling all data into IP TX FIFO and all Command Sequences to Flash are finished (INTR[IPCMDDONE]=1), processor should clear IP TX FIFO by setting IPTXFCR[CLRIPTXF]. Otherwise, the programming data will be wrong for the next programming Command to Flash.

To fill IP TX FIFO by DMA, need following setting:

- Set register field IPTXFCR[TXDMAEN] to 1.
- Set watermark level by IPTXFCR[TXWMRK], watermark level is (IPTXFCR[TXWMRK]+1)*8 bytes.
- Set DMA transfer Minor loop size to same watermark level.

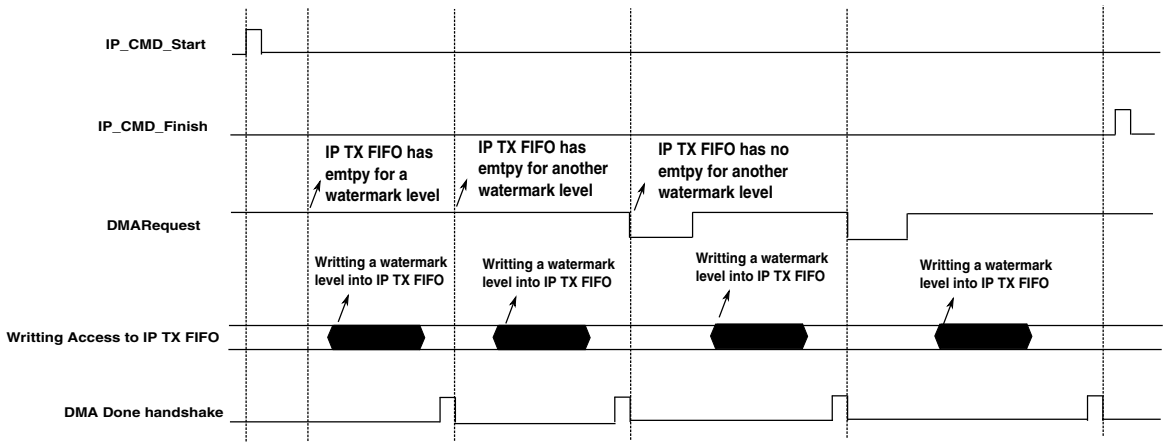

Figure 10-31. Filling from IP TX FIFO by DMA

NOTE

- DMA request is generated when there is empty space more than watermark level in IP TX FIFO. This request is not pulse valid but level valid.
- DMA should fill watermark level data into IP TX FIFO each time (set minor loop size with the same value as watermark level.
- DMA need to return a Done handshake (pulse valid) to FlexSPI each time it finished filling a watermark level data.
- IP TX FIFO data is not pushed in by each reading access, but pushed by DMA done handshake.
- It's allowed that total program data size (Major loop size) is not multiple of watermark level. After filling all data into IP TXFIFO and all command sequences to Flash are finished (INTR[IPCMDDONE]=1), need to clear IP TX FIFO by setting IPTXFCR[CLRIPTXF]. Otherwise, the programming data will be wrong for the next programming Command to Flash.

10.2.2.11 Flash access by AHB Command

Flash can be accessed by AHB bus directly on AHB address space:0~0x10000000. This address space is mapped to Serial Flash Memory in FlexSPI. AHB bus accesses to this address space triggers Flash access command sequences as needed.

For AHB read access to Serial Flash Memory, FlexSPI will fetch data from flash into AHB RX Buffers and then return the data on AHB Bus. For AHB write access to Serial Flash Memory, FlexSPI will buffer AHB Bus write data into AHB TX Buffer and then transmit to Serial Flash memory.

There is no software configuration or polling need for AHB command except FlexSPI initialization. AHB master access external flash device transparently similar as normal AHB slave.

AHB command is normally used to access serial Flash memory space. IP command should be used to access the control and status registers or other spaces such as OTP in external flash device.

The following section describes the AHB commands for read and write in more detail.

NOTE

When FlexSPI controller return AHB bus error for SFM access, AHB master should stop following access beats in current burst.

10.2.2.11.1 AHB write access to Flash

For AHB write access to Flash, FlexSPI will buffer the write data from AHB bus into internal AHB TX Buffer and then transmit them to Flash. FlexSPI only buffers write data for one AHB burst. Following diagram indicates the hardware operation in response to AHB write access to Flash.

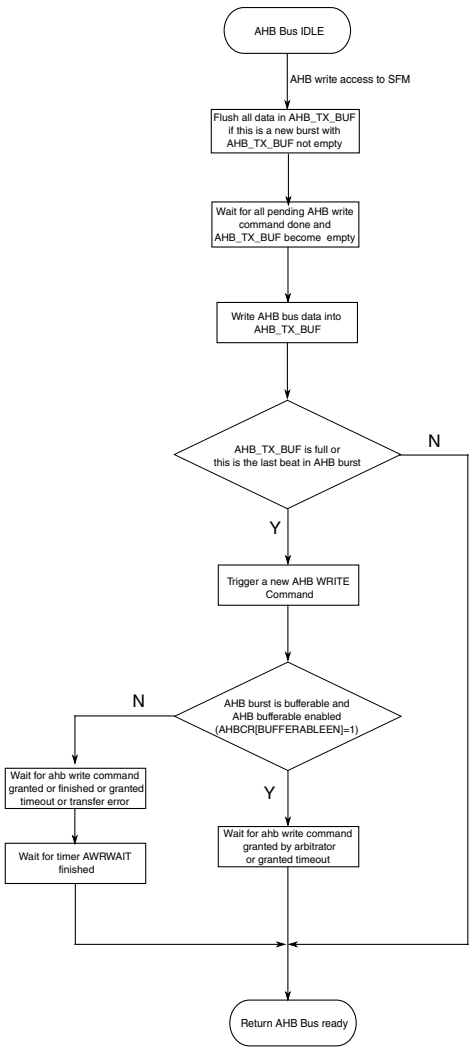

Figure 10-32. Hardware operation in response to AHB write access to Flash

FlexSPI triggers new AHB write command in following cases:

- This beat is the last one in current AHB burst (any burst type except INCR).
- AHB TX Buffer is full after buffering current beat data.
- AHB bus becomes IDLE or a new burst comes with AHB TX Buffer not emtpy.

The detail information about the triggered AHB write command:

- Flash Access Start Address:

  Determined by AHB burst address. FlexSPI will record the start address for the data in AHB TX Buffer and this address will be used as flash access start address

- Flash Chip Select:

FlexSPI determined the chip selection by flash access start address and flash size setting.

- Flash Command Sequence Index:

  Determined by FLSHxCR2[AWRSEQID].

- Flash Command Sequence Number:

  Determined by FLSHxCR2[AWRSEQNUM]. If AWRSEQNUM is not zero, multiple flash access command sequences will be triggered every time for AHB write command. The sequences indexed from AWRSEQID to (AWRSEQID + AWRSEQNUM) in LUT will be executed sequentially.

- Flash access mode (Individual/Parallel)

  Determined by AHBCR[APAREN].

- Flash Data Size:

  Determined by byte number of buffered data in AHB TX Buffer.

Following examples indicates internal logic for AHB write access to Flash. In these examples, AHB_TX_BUF is 64 Bytes (8*64bits) .

- AHB INCR/64bit/Bufferable burst with address sequence 0x8, 0x10, 0x18, 0x20, ..., 0x50 (10 beat total):

  Two AHB write command will be triggered: the first command with flash start address 0x8 and data size 0x40; the second command with flash start address 0x48 and data size 0x10. See Figure 10-33.

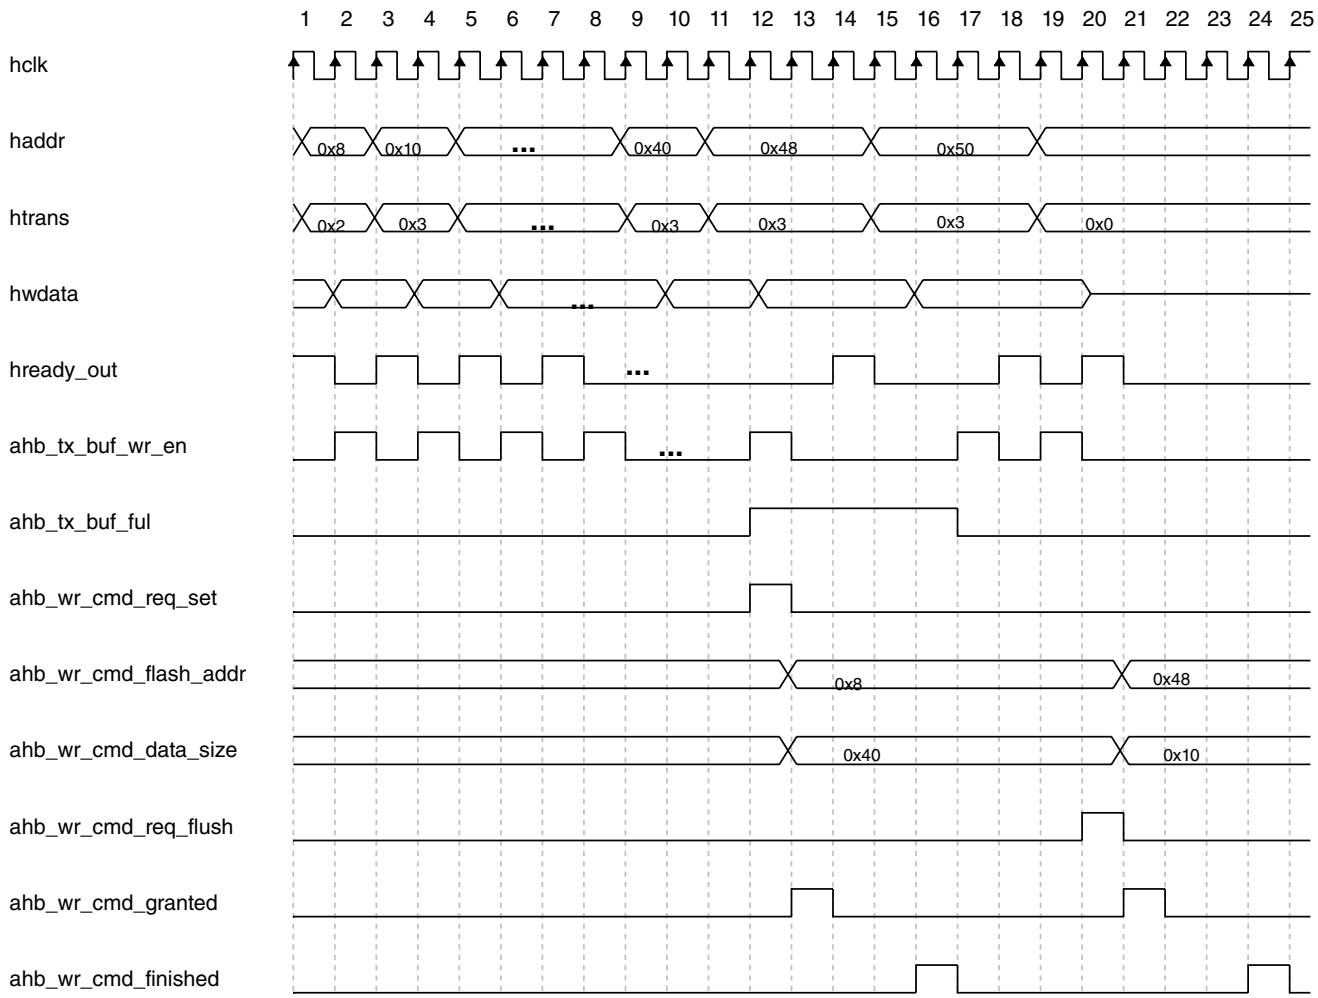

Figure 10-33. AHB write access (INCR/64bit/Bufferable)

- AHB WRAP8/64bit/Bufferable burst with address sequence 0x28, 0x30, 0x38, 0x0, 0x8, 0x10, 0x18, 0x20:

  One AHB write command will be triggered with flash start address 0x0 and data size 0x40. See Figure 10-34.

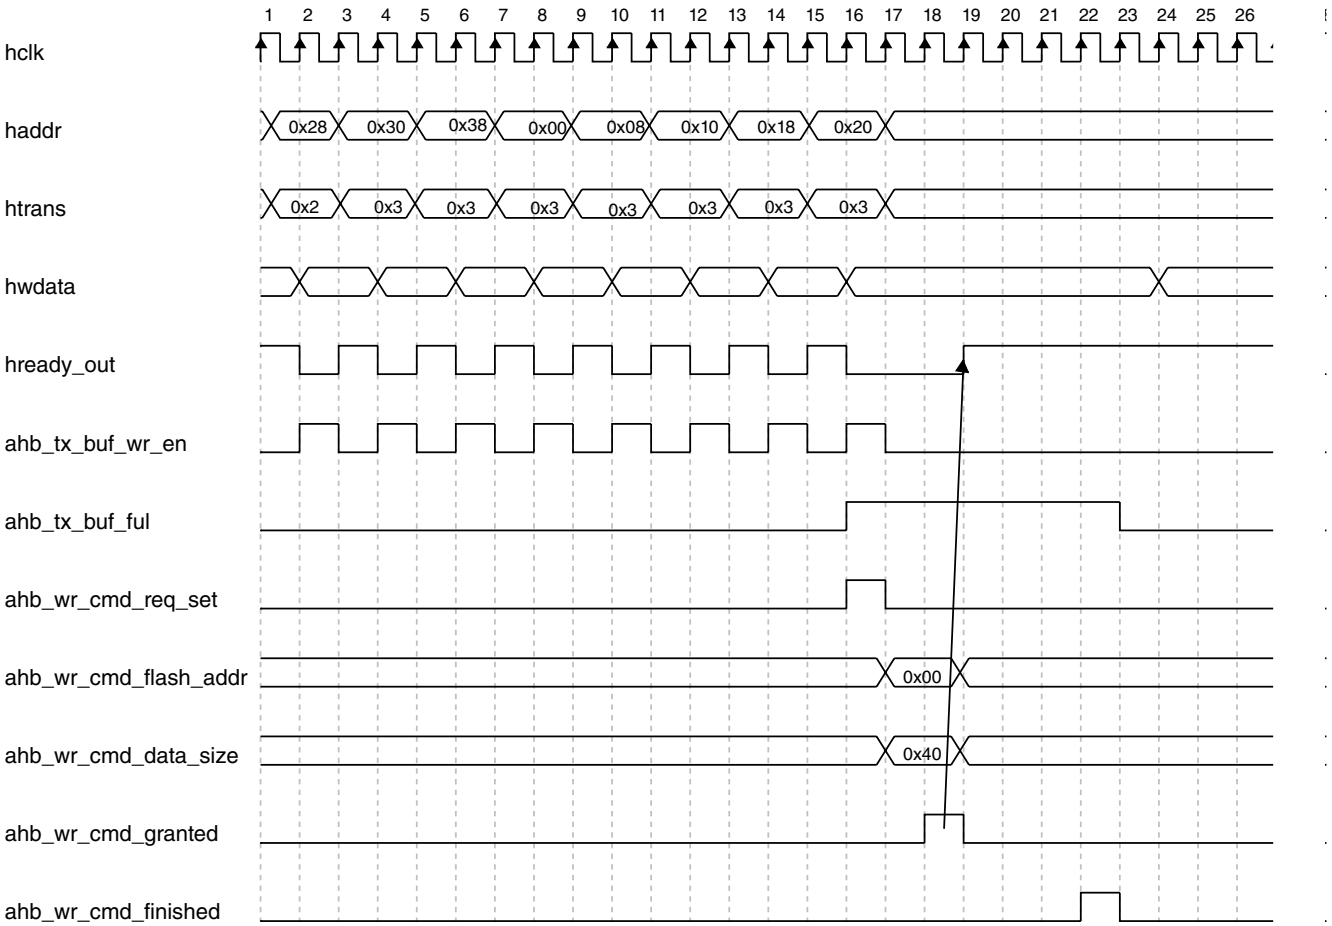

Figure 10-34. AHB write access (WRAP8/64bit/Bufferable)

- AHB WRAP8/64bit/Non-bufferable burst with address sequence 0x28, 0x30, 0x38, 0x0, 0x8, 0x10, 0x18, 0x20:

  One AHB write command will be triggered with flash start address 0x0 and data size 0x40;

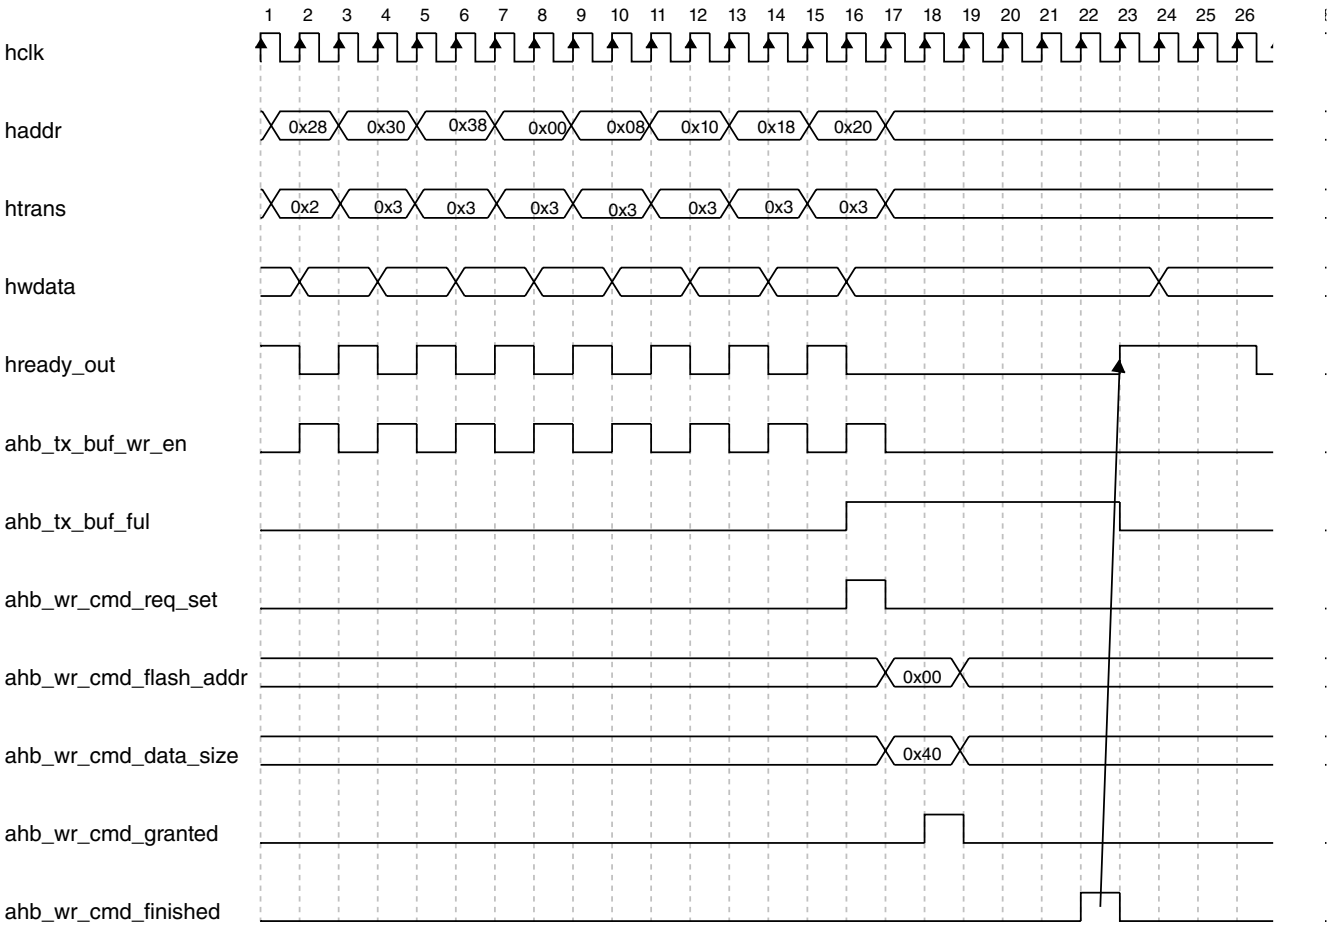

Figure 10-35. AHB write access (WRAP8/64bit/Non-Bufferable)

NOTE

The wrapper burst is not supported if burst data size (in byte) is larger than AHB TX Buffer size (in byte). For example, if AHB_TX_BUF is 64 Bytes (8*64bits), AHB WRAP16 * 64bit writet burst access is not supported.

10.2.2.11.2 AHB read access to Flash

For AHB read access to Flash, FlexSPI will check whether hit AHB TX Buffer/AHB RX Buffer/pending AHB read command according to the burst access type and register setting. If all these miss, FlexSPI trigger a new AHB read command to fetch data from Flash. Following diagram indicates the hardware operation in response to AHB read access to Flash.

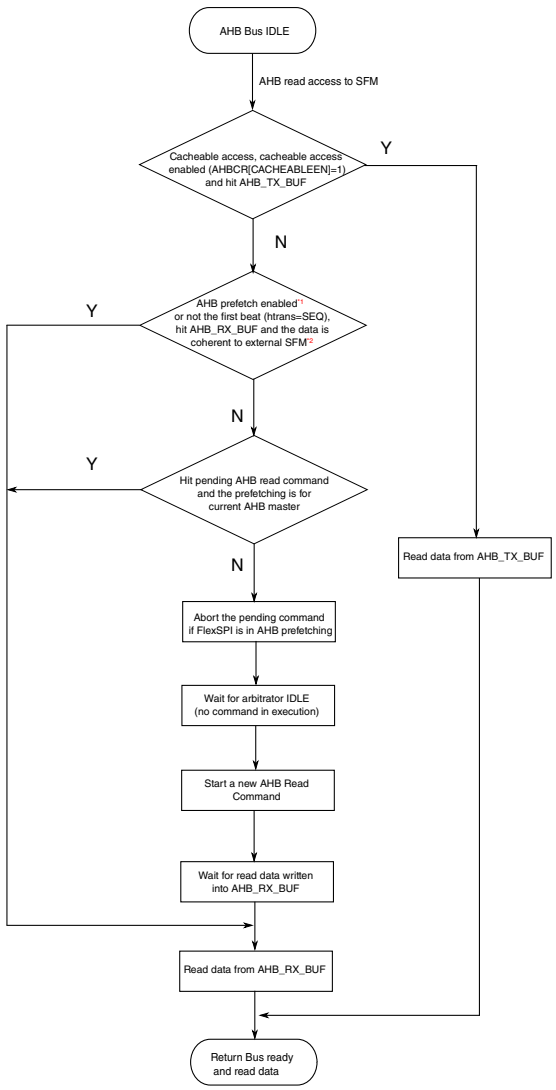

Figure 10-36. Hardware operation in response to AHB read access to Flash

NOTE

1. AHB prefetch is enabled when both AHBCR[PREFETCHEN]=0x1 and AHBRXBUFxCR0[PREFETCHEN]=0x1 (x is the ahb rx buffer ID for current AHB master).
2. AHB RX Buffer holds the data read from Flash. This data may become incoherent if the AHB writes to the same flash address.

The detail information about the triggered AHB read command:

- Flash Access Start Address and Data Size:

Determined by AHB address, burst type and burst size. FlexSPI will fetch read data from the start address for current burst or beat.

Table 10-4. AHB read command flash start address and data size

Prefetch Enable	Cross flash boundary	Burst Type	Flash start address [27:0]	Data Size
0	Never cross flash boundary because AHB burst never cross 1K Byte boundary.	SINGLE/INCR4/ INCR8/INCR16	hbeat_start_address	(hburst_end_address- hbeat_start_address)
		INCR	hbeat_start_address	byte size of current beat For INCR burst with prefetch disabled, each beat is handled same as SINGLE burst.
		WRAP4/ WRAP8/ WRAP16	hburst_start_address	(hburst_end_address- hburst_start_address)
1	No	INCR/SINGLE/ INCR4/INCR8/ INCR16	hbeat_start_address	ahb_rx_buf_sz
	No	WRAP4/ WRAP8/ WRAP16	hburst_start_address	ahb_rx_buf_sz
	Yes	INCR/SINGLE/ INCR4/INCR8/ INCR16	hbeat_start_address	(flash_top_address- hbeat_start_address)
	Yes	WRAP4/ WRAP8/ WRAP16	hburst_start_address	(flash_top_address- hburst_start_address)

NOTE

- hbeat_start_address is HADDR input from AHB master for current beat.
- hburst_start_address (for e.g.0x00) is the lowest address for current burst; hburst_end_address (for e.g. 0x10) is the highest address in current burst plus 1. For example, WRAP4 burst with HADDR 0x8,0xC, 0x0, 0x4.

- ahb_rx_buf_sz is the buffer size in byte of AHB RX Buffer which is used by current master.
- flash_top_address is the top address of currently accessed flash.

- Flash Chip Select:

  FlexSPI determined the chip selection by flash access start address and flash size setting.

- Flash Command Sequence Index:

  Determined by FLSHxCR2[ARDSEQID].

- Flash Command Sequence Number:

  Determined by FLSHxCR2[ARDSEQNUM]. If ARDSEQNUM is not zero, multiple flash access command sequences will be triggered every time for AHB read command. The sequences indexed from ARDSEQID to (ARDSEQID + ARDSEQNUM) in LUT will be executed sequentially.

- Flash access mode (Individual/Parallel):

  Determined by AHBCR[APAREN].

NOTE

- FlexSPI determines which ARDSEQNUM/ARDSEQID fields will be used as sequence ID by flash device chip selection automatically. See MCR2[SAMEDEVICEEN] for more details.
- FlexSPI determines which AHB RX Buffer used for current AHB read access by master ID. For more details about the AHB RX buffer ID and AHB master ID mapping, see AHB RX Buffer Management.
- It is not allowed to allocate AHB RX Buffer less than AHB Burst size. The behaviour is unknown for this case.

10.2.2.11.3 AHB RX Buffer Management

There are 8 buffers (Buffer 0 - Buffer 7) in AHB RX Buffer, which are transparent to AHB masters. FlexSPI fetch flash data and return on AHB Bus automatically. There is no status register polling needed for AHB read access to Serial Flash Memory.

AHB Rx Buffers total size is 2 KBytes . The buffer size is flexibly configurable for each buffer in AHB RX Buffers by register fields AHBRXBUF0CR0[BUFSZ]~AHBRXBUF6CR0[BUFSZ]. The buffer size for Buffer 0 to Buffer 7 could be set 0. If the buffer size is set to 0x0, the related MSTRID field setting (in same AHBRXBUFxCR0 register) is ignored by FlexSPI. Buffer 7 is used for all AHB masters which is not assigned to Buffer 0 - Buffer 6. Buffer 7 size setting field (AHBRXBUF7CR0[BUFSZ]) is ignored by FlexSPI, its buffer size is: AHB RX Buffer total size - sum of (Buffer 0 - Buffer 6 size).

When there is AHB read access to Serial Flash Memory, FlexSPI determines which AHB RX Buffer to use as following:

1. If master ID equal AHBRXBUF0CR0[MSTRID] and AHBRXBUF0CR0[BUFSZ] is not zero, Buffer 0 will be used.
2. If master ID equal AHBRXBUF1CR0[MSTRID] and AHBRXBUF1CR0[BUFSZ] is not zero, Buffer 1 will be used.
3. If master ID equal AHBRXBUF2CR0[MSTRID] and AHBRXBUF2CR0[BUFSZ] is not zero, Buffer 2 will be used.
4. If master ID equal AHBRXBUF3CR0[MSTRID] and AHBRXBUF3CR0[BUFSZ] is not zero, Buffer 3 will be used.
5. If master ID equal AHBRXBUF4CR0[MSTRID] and AHBRXBUF4CR0[BUFSZ] is not zero, Buffer 4 will be used.
6. If master ID equal AHBRXBUF5CR0[MSTRID] and AHBRXBUF5CR0[BUFSZ] is not zero, Buffer 5 will be used.
7. If master ID equal AHBRXBUF6CR0[MSTRID] and AHBRXBUF6CR0[BUFSZ] is not zero, Buffer 6 will be used.
8. If all above case not meet, Buffer 7 will be used.

NOTE

- Software should make sure the buffer size of each buffer is no less than the max burst size of AHB Read access from the master using this buffer. Otherwise the behaviour is undefined. The minimal buffer size request depends on the SoC implementation, for example, if the SoC's capability to send out a maximal burst is 64 Bytes, then minimal AHB RX buffer is 64 Bytes.
- It is not supported to assign multiple buffers for single AHB master.
- When AHB read prefetch is enabled (AHBCR[PREFETCHEN] is set), the prefetch data size will be determined by buffer size. FlexSPI will fetch data

from external Flash with buffer size if no flash boundary across.
- AHB master priority setting (register field AHBRXBUFxCR0[PRIORITY] is used only for the suspending control of AHB prefetching. See Command Abort and Suspend.

10.2.2.12 Command Arbitration

There are four Flash access command sources:

1. AHB Command (triggered by AHB Write access to SFM space)
2. AHB Command (triggered by AHB Read access to SFM space)
3. IP command (triggered by writing IPCMD[TRG])
4. Suspended command (AHB Read prefetch sequence which is suspended)

NOTE

- An AHB bus access never triggers a write command and a read command at the same time.
- AHB prefetch sequence is an AHB Command sequence triggered by AHB Read access when AHB prefetch is enabled. After all read data fetched for current AHB read burst, FlexSPI will prefetch more data to reduce the read latency for next AHB read access. AHB command for read is never aborted while fetching read data for current AHB read burst. But AHB read command could be aborted by any new IP command or AHB command request when it's prefetching data (not for current read burst).

The granted priority of these 4 command source is as following when Arbitrator is idle (STS0[ARBIDLE]=1):

1. AHB command (Read/Write)
2. IP Command
3. Suspended Command

NOTE

Suspended command is not granted immediately when arbitrator is idle and no AHB/IP command request. Arbitrator will wait for n AHB clock cycle idle state before resuming the suspended command (n is the register field value in MCR2[RESUMEWAIT]). This intend to avoid AHB prefetch sequence being resumed and suspended frequently.

All command request are not granted if Arbitrator is busy in executing AHB/IP command (not suspended command), and there will AHB/IP Command granted error if the grant is timeout.

If new AHB/IP command request comes while Arbitrator is executing AHB read prefetch sequence, AHB read prefetch sequence will be aborted (but not immediately). Arbitrator will grant AHB/IP command request after AHB read prefetch sequence is aborted on FlexSPI interface and saved all internal data pointers.

10.2.2.12.1 Command Abort and Suspend

This section describes command abort and suspend mechanism.

1. **Command Abort**

   As mentioned above, AHB read prefetch sequence could be aborted if new AHB/IP command request comes.

2. **Command Suspend**

   When AHB read prefetch sequence is aborted on FlexSPI interface, FlexSPI will save this suspended sequence in following cases and resume this sequence if arbitrator is idle for enough time:

   - There is no valid suspended command (Register field AHBSPNDSTS[ACTIVE] is 0x0). This is possible if there is no suspended command yet or suspended command is resumed.
   - Aborted AHB read prefetch sequence is higher priority than current active suspend sequence.

   NOTE

   Original suspended sequence will be ignored and never resumed by FlexSPI.

3. **Suspended Command**

   The suspended command (internal status) turns active when there is any AHB prefetch command aborted and suspended. It turns inactive in following cases:

   - Suspended command is resumed by Arbitrator.
   - There is a new AHB read command request and it's triggered by AHB master using the same AHB RX Buffer (Buffer ID).

   NOTE

   - MCR0[SWRESET] can be used to clear any suspended command. It means saved suspended command will be dropped and no more resume will happen. Clearing

suspended command is needed after flash page program/erase or any other command may lead period of time that flash can not support read command.

Following is an example indicating command abort/suspend/resume flow:

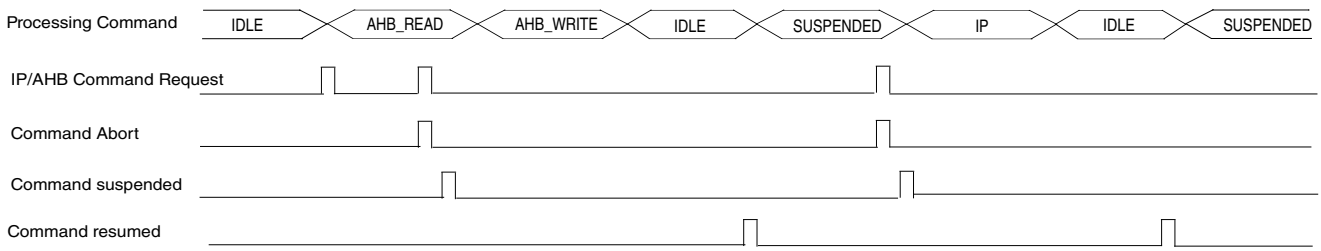

Figure 10-37. Command Instructions Execution on FlexSPI interface

10.2.2.13 SCLK stop feature

FlexSPI will stop SCLK output toggling when programming data is not ready for programming command sequence or there is no space (in internal FIFO) to receive data for reading command sequence.

There may be certain devices that do not support SCLK stopped during command sequence (chip select is valid). SCLK stopping could be avoid as following:

- For flash reading triggered by IP command
  - Never trigger a read command with data size larger than IP RX FIFO size.
  - Internal async FIFO for flash reading should never be full.

    FlexSPI pop data from this async FIFO in 64 bits per AHB clock cycle, and receiving data from FlexSPI interface in serial root clock. The receiving speed is determined by Flash access mode (Single/Dual/Quad/Octal mode and Individual/Parallel mode). For example, in Octal mode and Parallel mode, FlexSPI receives 16 bits per serial root clock cycle. This async FIFO is never full if AHB clock frequency is higher than 1/4 of serial root clock.

- For flash programming triggered by IP command
  - Never trigger a program command with data size larger than IP TX FIFO size.
  - Fill all programming data into IP TX FIFO before trigger the IP command.
  - Internal async FIFO for flash programming should never be empty

    FlexSPI fetch programming data into this async FIFO in 64 bits per AHB clock cycle, and transmitting data to FlexSPI interface in serial root clock. The transmitting speed is determined by Flash access mode (Single/Dual/Quad/Octal

mode and Individual/Parallel mode). For example, in Octal mode and Parallel mode, FlexSPI transmits 16 bits per serial root clock cycle. This async FIFO is never empty if AHB clock frequency is higher than 1/4 of serial root clock.

- For flash reading/programming triggered by AHB command
  - Internal async FIFO for flash reading/programming should never be full/empty. The frequency ratio limitation is same as flash reading/programming triggered by IP command.

NOTE

- FlexSPI never trigger a AHB read command with data size larger than internal AHB RX buffer size.
- FlexSPI never trigger a AHB program command with data size larger than internal AHB TX buffer size.
- All programming data is buffered into AHB TX Buffer before triggering AHB program command in FlexSPI.

10.2.2.14 FlexSPI Output Timing

This section describes the output timing in FlexSPI.

10.2.2.14.1 Output timing between Data and SCLK

This section describes the output timing relationship of data (on A_DATA/B_DATA) and SCLK. There are three cases for the data output timing:

- **SDR instruction in SDR sequence**
  SDR sequence is the sequence which contains only SDR instructions. In this case, all data bits last one serial root clock cycle on FlexSPI interface. Following diagram indicates the relationship of serial root clock, data and SCLK:

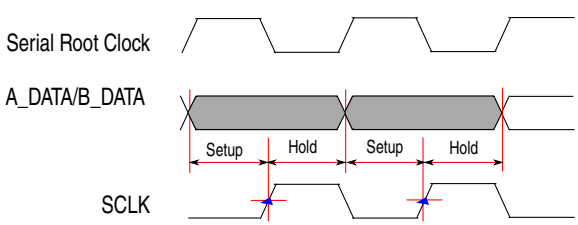

Figure 10-38. SDR instruction in SDR sequence

- **SDR instruction in DDR sequence**

DDR sequence is a flash access command sequence that contain DDR instruction which is not DUMMY, it may contain SDR instructions optionally. In the case of SDR instruction in DDR sequence, all data bits last two serial root clock cycles on FlexSPI interface. Following diagram indicates the relationship of serial root clock, data and SCLK:

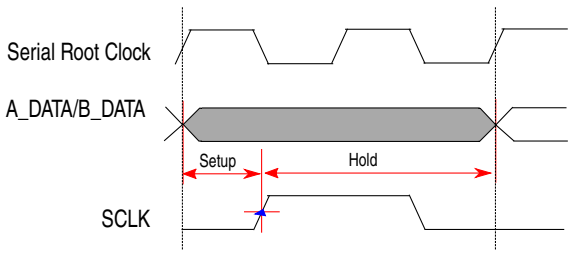

Figure 10-39. SDR instruction in DDR sequence

- **DDR instruction in DDR sequence**

  In the case of DDR instruction in DDR sequence, all data bits last one serial root clock cycle on FlexSPI interface. Following diagram indicates the relationship of serial root clock, data and SCLK:

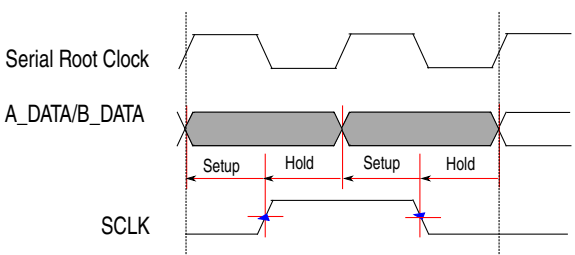

Figure 10-40. DDR instruction in DDR sequence

10.2.2.14.2 Output timing between Chip selection and SCLK

This section describes the output timing relationship of Chip select (on A_SS0_B/ A_SS1_B/B_SS0_B/B_SS1_B) and SCLK. The timing relationship is a little different for SDR sequence and DDR sequence.

- **Chip Select timing in SDR sequence**

  For SDR sequence, the delay from chip select assertion and the SCLK rising edge is **(FLSHxCR1[TCSS]+0.5)** cycles of serial root clock; The delay from SCLK falling edge and chip select deassertion is **FLSHxCR1[TCSH]** cycles of serial root clock. Following diagram indicates the timing relationship between chip selection and SCLK:

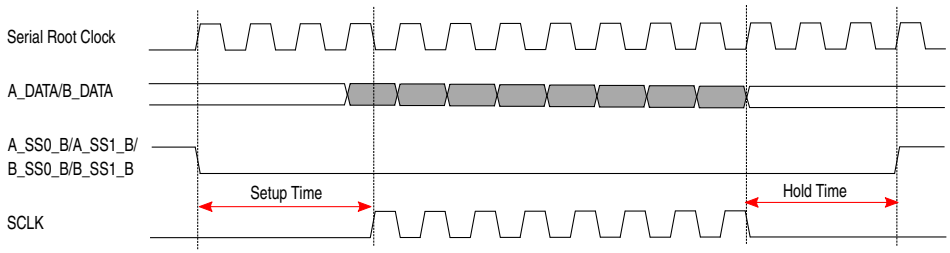

Figure 10-41. Chip selection output timing for SDR sequence

- **Chip Selection timing in DDR sequence**
  For DDR sequence, the delay from chip selection assertion and SCLK rise edge is **(TCSS+0.5)** cycles of serial root clock; The delay from SCLK fall edge and chip selection deassertion is **(TCSH+0.5)** cycles of serial root clock.

NOTE

When AHB RX prefetch is enabled, and prefetch can be aborted, set TCSH to be least 1 to guarantee positive chip select hold time after SCK falling edge.

Following diagram indicates the timing relationship between chip selection and SCLK:

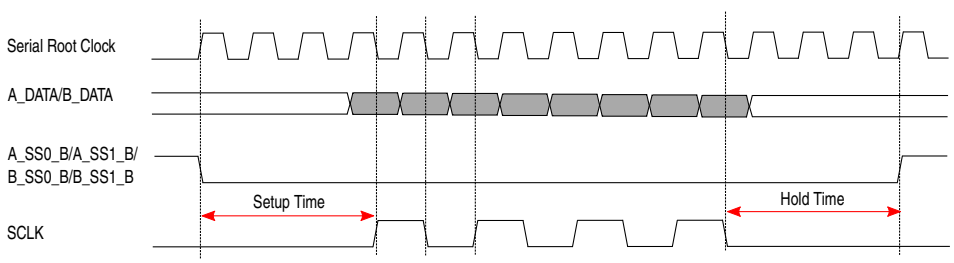

Figure 10-42. Chip selection output timing for DDR sequence

For certain device (such as FPGA device), there is limitation on the interval between Chip Selection valid. FlexSPI will ensure a delay time between chip selection valid if register field FLSHxCR1[CSINTERVAL] is set to non-zero value. The delay time is: CSINTERVAL*256 cycle of serial root clock no matter SDR or DDR sequence. Please set this register field value to zero if there is no this limitation for external device. Following diagram indicates the timing of chip selection interval.

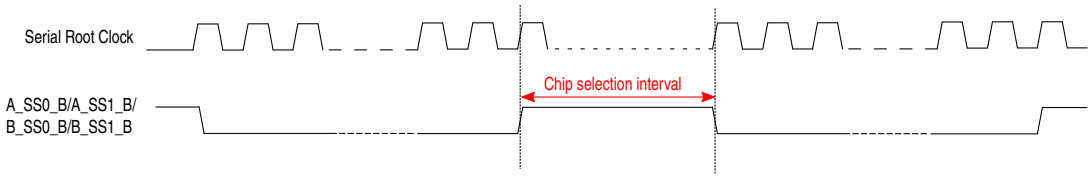

Figure 10-43. Chip Selection Valid interval

10.2.2.15 FlexSPI Input Timing

This section describes the input timing of FlexSPI.

10.2.2.15.1 Receiving Block diagram

This section describes the receiving block in FlexSPI.

FlexSPI determines SDR mode or DDR mode by decoding instruction code and determines whether both edge used or not for flash data sampling. FlexSPI samples the data line for Learn instruction and Read instruction.

There are four clock source for the sampling clock and the source selection is configured by register field MCR0[RXCLKSRC]. For more details about DLL configuration, please refer to DLL configuration for sampling

- Internal dummy read strobe and loopbacked internally
- Internal dummy read strobe and loopbacked from DQS pad
- SCK output and loopbacked from SCK pad
- Flash provided read strobe

Following diagram indicates the sampling block in FlexSPI:

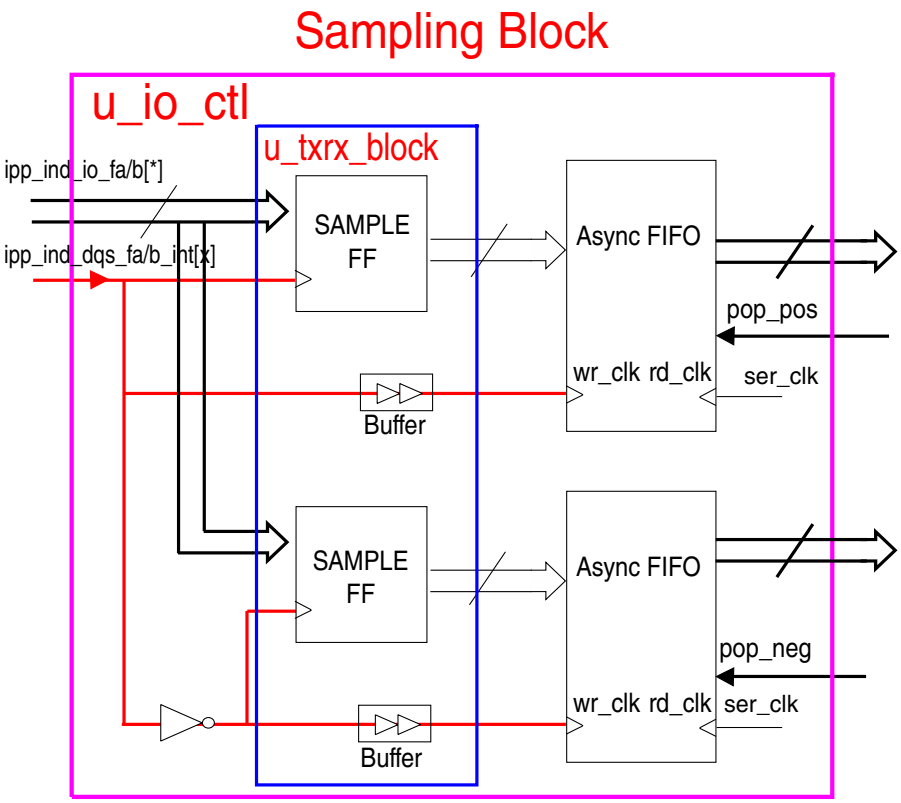

Figure 10-44. Sampling Block in FlexSPI

Following is the RX block diagram for data learning feature.

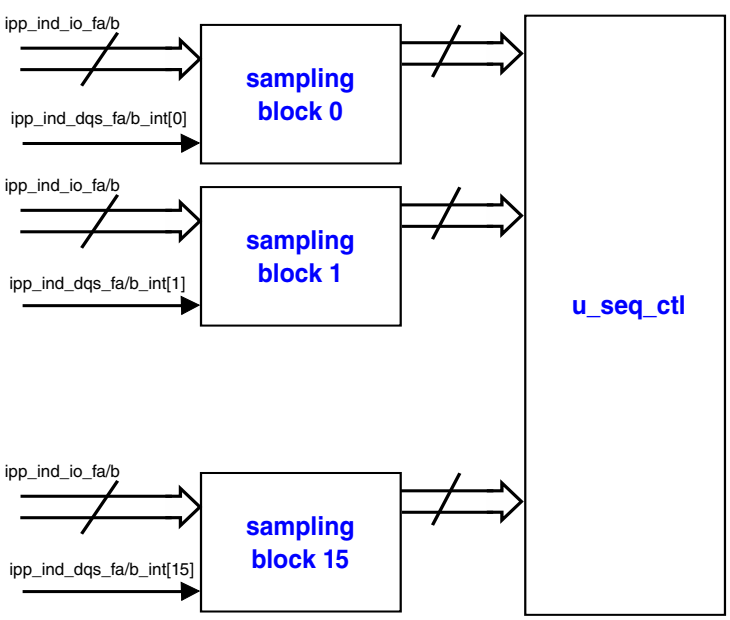

Figure 10-45. Sampling Blocks for Data Learning feature

NOTE

- FlexSPI don't support read with 0 turn around cycle for direction switching on IO pins. This kind of read often happens on QPI configuration register read. For example, in below wavefrom, "QuadSPI configuration register read", IO[3:0] is output for FlexSPI in CMD phase, but is input for FlexSPI in DATA phase. And there is no time left for FlexSPI to switch the direction. This kind of read is not supported. Moreover, FlexSPI and Flash will drive the IO pins at same time, this will cause problem. So, SPI mode or Read with dummy cycles is required to avoid described behavior on IO pins.
- Please notice in below example, cycle number is not accurate, for accurate cycle number, please refer to device's spec.

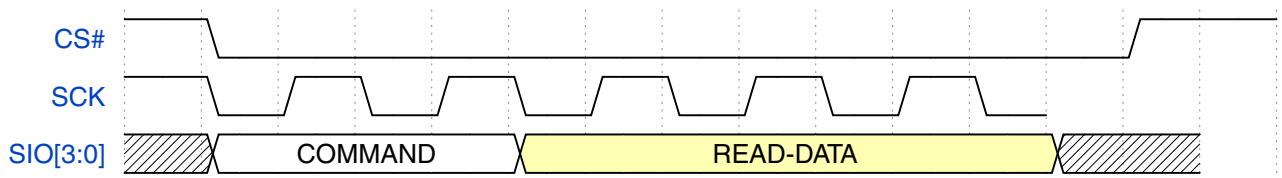

Figure 10-46. Unsupported Read Behavior

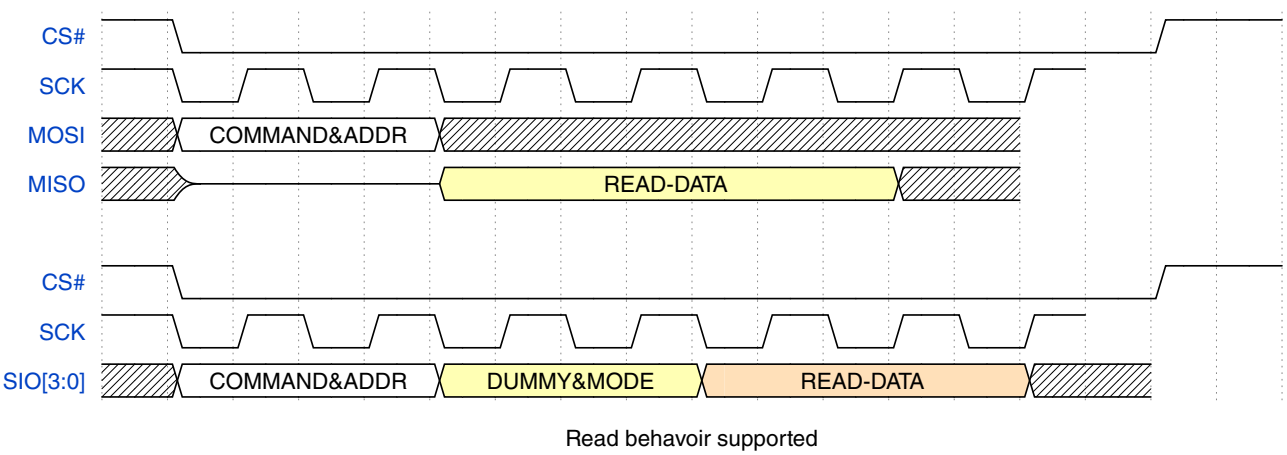

Figure 10-47. Supported Read Behavior

10.2.2.15.2 RX Clock Source Features

This section describes the features of each RX clock source.

- **Internal dummy read strobe and internal loopback (MCR0[RXCLKSRC]==0)**

  Supporting legacy device with zero device output hold time.

Saving one pad(DQS pad).

Supporting low frequency clock for boot up usage.

- **Internal dummy read strobe and loopback from DQS pad (MCR0[RXCLKSRC]==1)**

  Supporting higher frequency than mode "MCR0[RXCLKSRC]==0".

  Supporting device doesn't provide read strobe.

- **Flash provided read strobe (MCR0[RXCLKSRC]==3)**

  Supporting the highest frequency.

  Supporting device provides read strobe.

10.2.2.15.3 Input timing for sampling with dummy read strobe

This section describes the input timing when sampling with internal dummy read strobe (MCR0[RXCLKSRC] is set to 0x0 or 0x1). The timing is very similar for sampling with dummy read strobe loopback internally and loopback from pad. But it could achieve higher read frequency by sampling with dummy read strobe loopback from DQS pad because it will compensate the delay of SCLK output path and Data pin input path. The input timing is different for SDR mode and DDR mode.

- **Input timing for sampling with dummy read strobe in SDR mode**

  For SDR Read/Learn instruction, FlexSPI samples input data pins with the falling edge of dummy read strobe. Following diagram indicates the input timing for sampling with dummy read strobe in SDR mode:

Tdqv - setup time for the SCLK to the next valid data.
Tdqx - hold time for the SCLK to the current valid data.

Figure 10-48. Input Timing for sampling with dummy read strobe in SDR mode

- **Input timing for sampling with dummy read strobe in DDR mode**

  For DDR Read/Learn instruction, FlexSPI sample input data pins with both rise and fall edge of dummy read strobe. Following diagram indicates the input timing for sampling with dummy read strobe in DDR mode

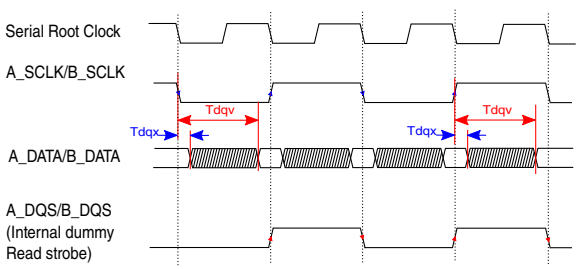

Figure 10-49. Input Timing for sampling with dummy read strobe in DDR mode

10.2.2.15.4 Input timing for sampling with SCK output loopbacked from SCK pad

This section describes the input timing when sampling with SCK output loopbacked from SCK pad (MCR0[RXCLKSRC] is set to 0x2). The input timing is similar as sampling with dummy read strobe. SCK output is toggling for all type instructions, but internal dummy strobe just toggles for Read and Learn instruction. So FlexSPI will got more data bits if sampling with SCK output. FlexSPI will ignore the redundant data bits sampled automatically.

10.2.2.15.5 Input timing for sampling with flash provided read strobe

This section describes the input timing when sampling with flash provided read strobe (MCR0[RXCLKSRC] is set to 0x3). The input timing is different for SDR mode and DDR mode.

NOTE

There are no known devices that provide read strobe and support SDR mode operation.

- **Flash provide read strobe with SCLK**

  For certain flash devices, it provides both read data and read strobes with SCLK. Then the read strobe edge is aligned with read data change. FlexSPI controller should delay read strobe by half cycle in serial root clock (with DLL) and then sample read data with delayed strobe. Refer DLL configuration for sampling for more details. Following diagrams indicates the input timing for sampling with flash read strobe in SDR mode and DDR mode:

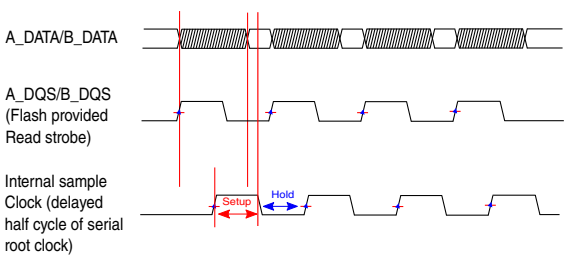

Figure 10-50. Input Timing 2 for Flash provided read strobe in SDR mode

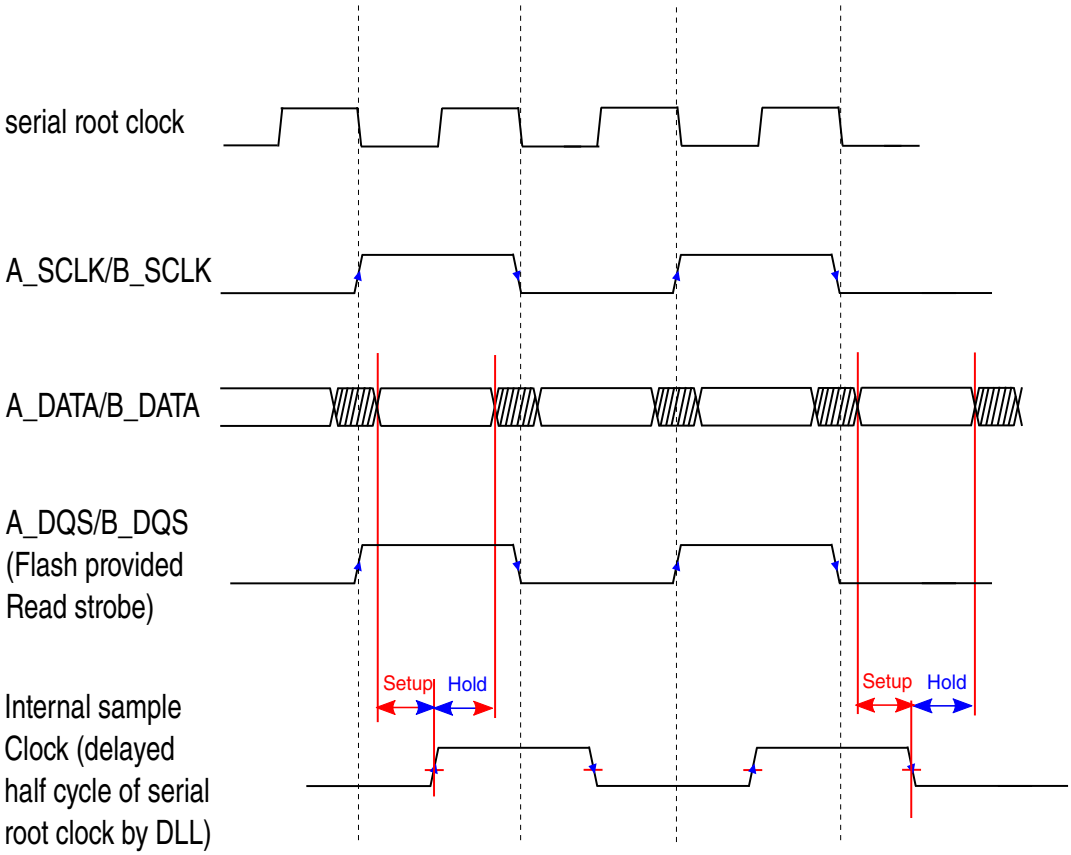

Figure 10-51. Input Timing 2 for Flash provided read strobe in DDR mode

10.2.2.15.6 DLL configuration for sampling

The input timing is different for those four sampling clock source. This is handled by setting register DLLxCR differently according to the sampling clock source mode. DLL is a delay line chain, which could be set to a fixed number of delay cells or auto-adjusted to lock on a certain phase delay to the reference clock.

- In following cases, DLLxCR should be set 0x00000100 (1 fixed delay cells in DLL delay chain) :
  - Sampling data with Dummy read strobe loopbacked internally(MCR0[RXCLKSRC]=0x0)
  - Sampling data with Dummy read strobe loopbacked from DQS pad(MCR0[RXCLKSRC]=0x1)
- When data is sampled with Flash provided read strobe (MCR0[RXCLKSRC]=0x3) and flash provides read strobe with SCLK, DLL should be set as following to lock on half cycle of the reference clock (serial root clock)
  - SLVDLYTARGET=0xF
  - DLLEN=0x1

- OVRDEN=0x0
- Other fields in DLLxCR should be kept as reset value (all zero)

NOTE

If serial root clock is lower than 100 MHz, DLL is unable to lock on half cycle of serial root clock because the delay cell number is limited in delay chain. Then DLL should be configured as following instead:

- OVRDEN=0x1
- OVRDVAL=N; Each delay cell in DLL is about 75 ps~225 ps. The delay of DLL delay chain is (N * Delay_cell_delay), N should be set based on max. DDR frequency that current project supported, N = 18, please notice this is a recommended value. May need to adjust in real application if facing failure.
- Other fields in DLLxCR should be kept as reset value (all zero).

10.2.2.16 Data Learning Feature

FlexSPI controller generates 16 clock phases (Phase 0 ~ Phase 15) by delay cell line with the selected sample clock. Clock Phase 0 is actually the selected sample clock (DQS_IN) without any delay cell. There are 16 sampling blocks implemented for both Port A and 16 sampling blocks for Port B.

During Learn instruction, FlexSPI will compare the sampled data bits with internal data learn pattern (DLPR register) and determine the correct sampling clock phase. The phase selection is automatically updated after Learn instructions and applied to following Read instructions or sequences.

When the data learning feature is disabled (MCR0[LEARNEN]=0x0), FlexSPI always use clock phase 0 to sample FlexSPI data lines. If the data learning feature is disabled, then attempt to execute a LEARN instruction will result in an error flag (INTR[IPCMDERR] or INTR[AHBCMDERR]).

Data learning feature is supported in both SDR mode and DDR mode in FlexSPI. Data learning feature is not supported if sampling clock source is flash provided read strobe (MCR0[RXCLKSRC]=0x3).

Data learning feature would achieve high read frequency, but the highest frequency would be still limited by Flash input timing (Flash need to receive Command code and Flash address bits).

If data learning feature is enabled, FlexSPI will use Clock phase 0 after reset and before Learn instruction execution. The clock phase selection will be updated after Learn instruction executed by FlexSPI. The sample clock phase selected could be polled by register field STS0[DATALEARNPHASEA] and STS0[DATALEARNPHASEB]. If data learning failed, there will be interrupt bit set (INTR[DATALEARNFAIL]) and previous clock phase selection will be kept. Internal clock phase selection could be reset to Clock Phase 0 by write 0x1 to MCR2[CLRLEARNPHASE].

10.2.2.16.1 Data Learning with Flash providing preamble bit

Certain flash devices support driving with preamble bits (which may be also called DLP - Data learning pattern) before driving read data in each read command sequence. This data learning pattern is programmable by configuration register in flash device.

For specified Read Command sequence, flash will return preamble bit after dummy cycles and before returning read data.

For these flash devices, the operation flow with data learning is as following:

1. Set data learning pattern in DLPR register
2. Set same data learning pattern to flash device by triggering IP command.
3. Enable data learning feature in flash device by triggering IP command
4. Configure LUT sequence with valid Read command sequence which contains Learn instruction.
5. Trigger Flash read command by AHB/IP command as normal.

NOTE

The first 4 steps is not needed for every flash read command, only need to executed once.

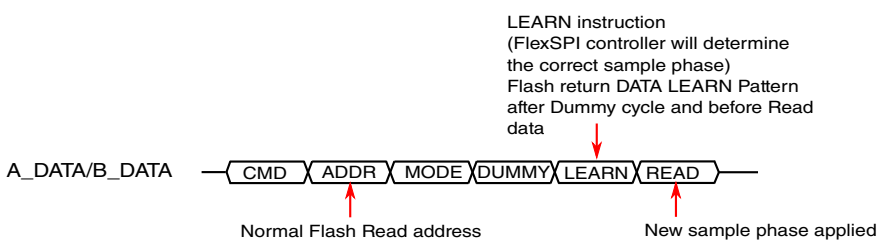

Figure 10-52. Data Learning flow with flash providing preamble bit

10.2.2.16.2 Data Learning with Flash not providing preamble bit

For flash devices not providing preamble bit, there is no way to return data learning pattern automatically by flash device for each read command sequence. Following sequence is data learning with flash not providing preamble bit:

1. Set data learning pattern in DLPR register
2. Reserve a certain Flash Memory area and program data (according to data learning pattern and flash access mode) to this area by IP command.
3. Configure LUT sequence with Read sequence (which using LEARN instruction instead of READ instruction). And trigger Read sequence to reserved flash area by IP command.
4. Trigger Flash read command by AHB/IP command as normal. No Learn instruction needed in this Read sequence.

NOTE

- The first 3 steps is not needed for every flash read command, only need to executed by once.
- Step 4 should be executed with a certain interval to make sure internal sampling clock phase is adjusted in time.

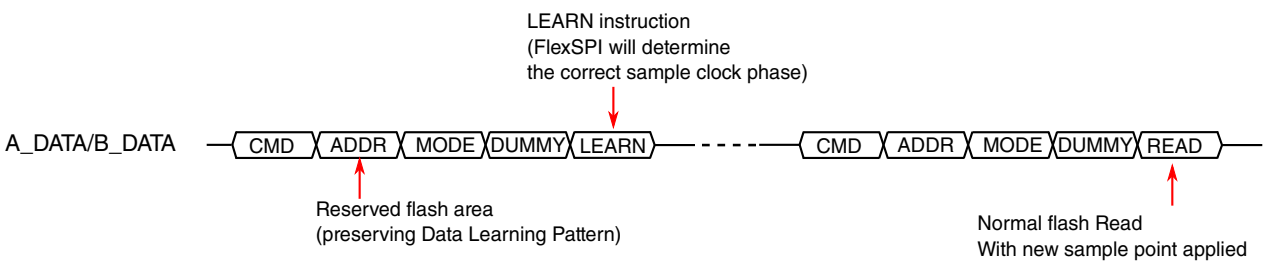

Figure 10-53. Data Learning flow with Flash not providing preamble bit

NOTE

- For Flash not providing preamble bit, there is software overhead because need to read the reserved flash area at interval.

The preprogramming data is determined by following items:

- Data Learning Pattern (DLPR register setting)
- Data Learning Pattern bit length
- Individual/Parallel mode for read command
- Octal/Quad/Dual/Single mode for read command

Following is an example for pre-programming data in case of DLP value is 0x43, 8 bits and flash is read in Quad mode and Parallel mode.

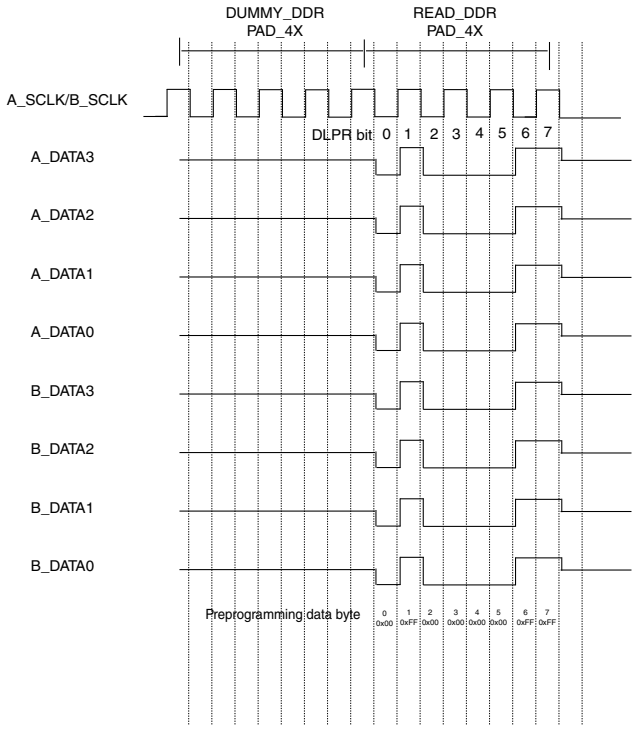

Figure 10-54. Preprogramming data for Data Learning

10.2.2.17 XIP Enhanced Mode

FlexSPI always supports Execute-In-Place (XIP), no matter external device provided XIP enhanced mode or not. Execute-In-Place is supported by putting program code on External device, then read/execute on external device directly by AHB read access to SFM space. There is no configuration or status polling needed during AHB read access to External device memory and AHB RX buffer is fully transparent to software.

Certain devices provide XIP enhanced mode to improve code execution. In this mode, there is no need to provide Command code for Read Sequence. It saves many cycles for Command Instructions and greatly improves code execution. This XIP enhanced mode is entered/exit by a special sequence which is device specified. Please refer to external device data sheet for more detail.

Normally, the XIP enhanced mode is entered by following sequence:

1. Enable XIP enhanced mode in External Flash by IP command
2. Send the first Read Sequence to External Flash device with correct Mode bits. Command code is needed in this Read sequence.
3. Send following Read sequences to External Flash device with correct Mode bits. Command code is not needed in these Read Sequences. But Mode bits should be sent

according to Flash specified. Otherwise Flash will exit Execute-In-Place Enhanced mode.

The instruction JMP_ON_CS in FlexSPI should be used to support external device XIP enhanced mode. This instruction is only allowed in AHB Read command, otherwise there will be IPCMDERR or AHBCDMERR error interrupt generated if this interrupt is enabled. JMP_ON_CS should never be used if device doesn't support XIP enhanced mode. To support XIP enhanced mode, the first instruction in the Read Sequence should be Command instruction and the last valid instruction should be JMP_ON_CS (with operand 0x1).

For the first AHB read Command triggered, FlexSPI will execute the instructions from the instruction pointer 0 in the sequence (which is Command instruction). After this sequence executed FlexSPI will save operand in JMP_ON_CS instruction as start pointer for next Command to current device internally. For the following AHB read Command triggered, FlexSPI will execute from instruction pointer 0x1 and Command instruction is bypassed.

Once XIP enhanced mode has been started it is not possible to access flash by other commands like any program commands. Following diagram indicates XIP operation with Flash XIP Enhanced mode:

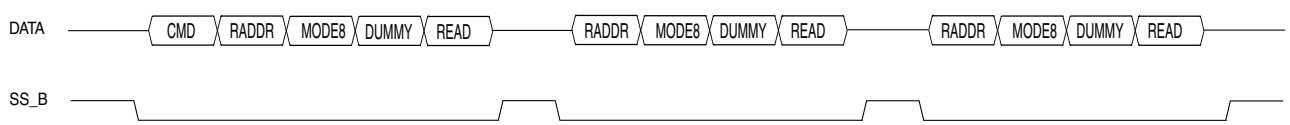

Figure 10-55. XIP Enhanced Mode operation

10.2.3 External Signals

This section provides the external signal information of the FlexSPI module.

Table 10-5. External Signal List

Signal Name	Function	Direction	Description	Port Name
A_SS0_B	Peripheral Chip Select Flash A1	O	This signal is the chip select for the serial flash device A1.	PCSA1
A_SS1_B	Peripheral Chip Select Flash A2	O	This signal is the chip select for the serial flash device A2.	PCSA2
B_SS0_B	Peripheral Chip Select Flash B1	O	This signal is the chip select for the serial flash device B1.	PCSB1
B_SS1_B	Peripheral Chip Select Flash B2	O	This signal is the chip select for the serial flash device B2.	PCSB2

Table continues on the next page...

Table 10-5. External Signal List (continued)

Signal Name	Function	Direction	Description	Port Name
A_SCLK	Serial Clock Flash A	O	This signal is the serial clock output to the serial flash device A. Half clock frequency of serial clock root in DDR mode, and same frequency as serial clock root in SDR mode. Clock output toggles during the whole flash access sequence.	SCKA
B_SCLK	Serial Clock Flash B	O	This signal is the serial clock output to the serial flash device B. Half clock frequency of serial clock root in DDR mode, and same frequency as serial clock root in SDR mode. Clock output toggles during the whole flash access sequence. **NOTE:** • B_SCLK may be optionally used as A_SCLK's differential clock output by setting Register Field MCR2[SCKBDIFFOPT]=1'b1	SCKB
B_SCLK2	Serial Clock 2 Flash B	O	Similar to A_SCLK2.	SCK2B
A_DATAn	Serial I/O Flash A	I/O	These signals are the data I/O lines to/from the serial flash device A.	SIOAn
B_DATAn	Serial I/O Flash B	I/O	These signals are the data I/O lines to/from the serial flash device B.	SIOBn
A_DQS	Data Strobe signal Flash A	I/O	Data strobe signal for port A. There are three functions for this signal: • Driven with Read Strobe by external device: Some flash devices provide the Read Strobe signal together with Read data. In this case, this pad may need a **pull down** resistor if external device drives this pad only when reading flash data. • Driven with Latency Information by external device: Certain devices use this pin to indicate the dummy cycles needed (before Program/Read data transfer) such as HyperRAM/HyperFlash. • Loopback dummy read strobe: FlexSPI controller provides internal dummy read strobe for flash read data. Higher read frequency can be achieved by looping back this dummy read strobe from pad. This pin can be	DQSA

Table continues on the next page...

Table 10-5. External Signal List (continued)

Signal Name	Function	Direction	Description	Port Name
			floated or put some cap loads on board level to compensate DATA/ SCLK pins load.	
B_DQS	Data Strobe signal Flash B	I/O	Similar to A_DQS.	DQSB

10.2.4 Initialization

FlexSPI controller initialization sequence is as following:

- Enable controller clocks (AHB clock/IP Bus clock/Serial root clock) in System level.
- Set MCR0[MDIS] to 0x1 (Make sure controller is configured in module stop mode)
- Configure module control registers: MCR0, MCR1, MCR2. (Don't change MCR0[MDIS])
- Configure AHB bus control register (AHBCR) and AHB RX Buffer control register (AHBRXBUFxCR0) optionally, if AHB command will be used
- Configure Flash control registers (FLSHxCR0,FLSHxCR1,FLSHxCR2) according to external device type
- Configure DLL control register (DLLxCR) according to sample clock source selection
- set MCR0[MDIS] to 0x0 (Exit module stop mode)
- Configure LUT as needed (For AHB command or IP command)
- Reset controller optionally (by set MCR0[SWRESET] to 0x1)

External device needs configuration by IP command normally after controller initialization. For example, the device configuration is done by WRITE STATUS command for most serial NOR Flash.

10.2.5 Application information

This section describes applications supported by the FlexSPI module.

10.2.5.1 Overview of Error Flags

The following table gives an overview of error category, flags and triggered source.

Table 10-6. Error category and flags in FlexSPI

Error Category	Triggered Source	Description	Error Flags
Command grant error	AHB write command	Command grant timeout	INTR[AHBCMDGE] will be set AHB bus error response
	AHB read command		INTR[AHBCMDGE] will be set AHB bus error response
	IP command		INTR[IPCMDGE] will be set
Command check error	AHB write command	• AHB write command with JMP_ON_CS instruction used in the sequence • There is unknown instruction opcode in the sequence. • Instruction DUMMY_SDR/ DUMMY_RWDS_SDR used in DDR sequence. • Instruction DUMMY_DDR/ DUMMY_RWDS_DDR used in SDR sequence.	INTR[AHBCMDERR] will be set Command is not executed when error detected in command check
	AHB read command	• There is unknown instruction opcode in the sequence. • Instruction DUMMY_SDR/ DUMMY_RWDS_SDR used in DDR sequence. • Instruction DUMMY_DDR/ DUMMY_RWDS_DDR used in SDR sequence.	INTR[AHBCMDERR] will be set Command is not executed when error detected in command check
	IP command	• IP command with JMP_ON_CS instruction used in the sequence • There is unknown instruction opcode in the sequence. • Instruction DUMMY_SDR/ DUMMY_RWDS_SDR used in DDR sequence. • Instruction DUMMY_DDR/ DUMMY_RWDS_DDR used in SDR sequence. • Flash boundary across.	INTR[IPCMDERR] will be set Command is not executed when error detected in command check
Command execution error	AHB write command	Command timeout during execution	INTR[AHBCMDERR] will be set INTR[SEQTIMEOUT] will be set There will be AHB bus error response except following case: • AHB write command is triggered by flush (INCR burst

Table continues on the next page...

Table 10-6. Error category and flags in FlexSPI (continued)

Error Category	Triggered Source	Description	Error Flags
			ended with AHB_TX_BUF not empty) • AHB bufferable write access and bufferable enabled (AHBCR[BUFFERABLEEN]=0x1)
	AHB read command		INTR[AHBCMDERR] will be set INTR[SEQTIMEOUT] will be set There will be AHB bus error response
	IP command		INTR[IPCMDERR] will be set INTR[SEQTIMEOUT] will be set
AHB Bus timeout	AHB write command	AHB bus timeout (no bus ready return)	INTR[AHBBUSTIMEOUT] will be set There will be AHB bus error response
	AHB read command		
Data Learning Failed	Any command	There is no valid sample clock phase found after LEARN instruction executed	INTR[DATALEARNFAIL] will be set

NOTE

- flash_top_address is the top address of currently accessed flash

10.2.5.2 Application on Serial NOR Flash device

This section provides the example sequences for serial NOR flash device (Cypress Flash S25FS128S).

10.2.5.2.1 Write Enable command

The following table shows WRITE ENABLE command sequence.

Table 10-7. WRITE ENABLE command

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x0	0x06	command name:WREN
1~7	STOP (0x00)	0x0	0x00	

10.2.5.2.2 Write Registers command

The following table shows Write Registers command sequence.

Table 10-8. Write Registers command

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x0 (Single)	0x01	command name:WRR
1	WRITE_SDR	0x0 (Single)	0x1 or 0x2	Data size is 1 or 2byte. Byte 0 write data for Status Register 1; Byte 1 write data for Configuration Register 1 This value could be overridden by IPCR1[IDATSZ].
2~7	STOP (0x00)	0x0	0x00	

10.2.5.2.3 Page Program command

The following table shows Page Program command sequence.

Table 10-9. PAGE PROGRAM command (Cypress serial NOR flash)

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x0 (Single)	0x02 or 0x12	command name: PP or 4PP PP is 3-Byte address mode. 4PP is 4-Byte address mode
1	ADDR_SDR	0x0 (Single)	0x18 or 0x20	Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.
2	WRITE_SDR	0x0 (Single)	Any non-zero value	This operand value could be used as default programming data size if IPCR1[IDATSZ] is zero. This value is ignored for AHB command.
3~7	STOP (0x00)	0x0	0x00	

The following table shows Page Program command sequence (QPI mode).

Table 10-10. PAGE PROGRAM (QPI mode) command (Cypress serial NOR flash)

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x2 (Quad)	0x02 or 0x12	command name: PP or 4PP PP is 3-Byte address mode. 4PP is 4-Byte address mode
1	ADDR_SDR	0x2 (Quad)	0x18 or 0x20	Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.
2	WRITE_SDR	0x2 (Quad)	Any non-zero value	This operand value could be used as default programming data size if IPCR1[IDATSZ] is zero. This value is ignored for AHB command.
3~7	STOP (0x00)	0x0	0x00	

10.2.5.2.4 Read Status 1 command

The following table shows READ STATUS 1 command sequence.

Table 10-11. READ STATUS 1 command

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x0 (Single)	0x05	command name:RDSR1
1	READ_SDR	0x0 (Single)	0x1	1 Byte for Status register 1
2~7	STOP (0x00)	0x0	0x00	

10.2.5.2.5 Read command

The following table shows READ command sequence.

Table 10-12. READ command

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x0 (Single)	0x03 or 0x13	command name:READ or 4READ READ is 3-Byte address mode. 4READ is 4-Byte address mode
1	ADDR_SDR	0x0 (Single)	0x18 or 0x20	Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.
2	READ_SDR	0x0 (Single)	Any non-zero value	This operand value could be used as default reading data size if IPCR1[IDATSZ] is zero. This value is ignored for AHB command.

Table continues on the next page...

Table 10-12. READ command (continued)

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
3~7	STOP (0x00)	0x0	0x00	

10.2.5.2.6 Fast Read command

The following table shows Fast Read command sequence (In the case of Cypress SPI Configuration Register bits CR2V[7]=0, CR2V[3:0]=0x8).

Table 10-13. FAST_READ command

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x0 (Single)	0x0B or 0x0C	command name:FAST_READ or 4FAST_READ FAST_READ is 3-Byte address mode. 4FAST_READ is 4-Byte address mode
1	ADDR_SDR	0x0 (Single)	0x18 or 0x20	Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.
2	DUMMY_SDR	0x0 (Single)	0x08	Dummy cycle is 8 (in serial root clock) as CR2V[3:0]=0x8.
3	READ_SDR	0x0 (Single)	Any non-zero value	This operand value could be used as default reading data size if IPCR1[IDATSZ] is zero. This value is ignored for AHB command.
4~7	STOP (0x00)	0x0	0x00	

10.2.5.2.7 Dual IO Fast Read command

The following table shows Dual IO FAST_READ command sequence (In the case of Cypress SPI Configuration Register bits CR2V[7]=0, CR2V[3:0]=0x8, Continuous Read mode).

Table 10-14. Dual IO FAST_READ command (Continuous Read mode)

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x0 (Single)	0xBB or 0xBC	command name:DIOR or 4DIOR DIOR is 3-Byte address mode. 4DIOR is 4-Byte address mode

Table continues on the next page...

Table 10-14. Dual IO FAST_READ command (Continuous Read mode) (continued)

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
1	ADDR_SDR	0x1 (Dual)	0x18 or 0x20	Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.
2	MODE8_SDR	0x1 (Dual)	0xAx	Enter continuous read mode or keep in continuous read mode.
3	DUMMY_SDR	0x1 (Dual)	0x08	Dummy cycle is 8 (in serial root clock) as CR2V[3:0]=0x8.
4	READ_SDR	0x1 (Dual)	Any non-zero value	This operand value could be used as default reading data size if IPCR1[IDATSZ] is zero. This value is ignored for AHB command.
5	JMP_ON_CS	0x0 (or Don't care)	0x01	The CMD instruction will be bypassed after the first read access.
6~7	STOP (0x00)	0x0	0x00	

The following table shows Dual IO FAST_READ command sequence (In the case of Cypress SPI Configuration Register bits CR2V[7]=0, CR2V[3:0]=0x8, Non-continuous Read mode).

Table 10-15. Dual IO FAST_READ command (Non-continuous Read mode)

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x0 (Single)	0xBB or 0xBC	command name:DIOR or 4DIOR DIOR is 3-Byte address mode. 4DIOR is 4-Byte address mode
1	ADDR_SDR	0x1 (Dual)	0x18 or 0x20	Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.
2	MODE8_SDR	0x1 (Dual)	Any value other than 0xAx	Exit continuous read mode or keep in non-continuous read mode.
3	DUMMY_SDR	0x1 (Dual)	0x08	Dummy cycle is 8 (in serial root clock) as CR2V[3:0]=0x8.
4	READ_SDR	0x1 (Dual)	Any non-zero value	This operand value could be used as default reading data size if IPCR1[IDATSZ] is zero. This value is ignored for AHB command.
5~7	STOP (0x00)	0x0	0x00	

10.2.5.2.8 Quad IO Fast Read command

The following table shows Quad IO FAST_READ command sequence (In the case of Cypress SPI Configuration Register bits CR2V[7]=0, CR2V[6]=0, CR2V[3:0]=0x8, Non-QPI mode, Non-continuous read mode).

Table 10-16. Quad IO FAST_READ command (Non-QPI mode, Non-continuous read mode)

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x0 (Single)	0xEB or 0xEC	command name:QIOR or 4QIOR QIOR is 3-Byte address mode. 4QIOR is 4-Byte address mode
1	ADDR_SDR	0x2 (Quad)	0x18 or 0x20	Address bit number (operand value) should be 24 in 3-Byte address mode and 32 in 4-Byte address mode.
2	MODE8_SDR	0x2 (Quad)	Any value other than 0xAx	Exit continuous read mode or keep in non-continuous read mode.
3	DUMMY_SDR	0x2 (Quad)	0x08	Dummy cycle is 8 (in serial root clock) as CR2V[3:0]=0x8.
4	READ_SDR	0x2 (Quad)	Any non-zero value	This operand value could be used as default reading data size if IPCR1[IDATSZ] is zero. This value is ignored for AHB command.
5~7	STOP (0x00)	0x0	0x00

2	CADDR_DDR	0x3 (Octal)	0x10	Column Address: (13 zero bits + 3 valid bits)
3	DUMMY_RWDS_DDR	0x3 (Octal)	0x0B	In case of latency count=11
4	WRITE_DDR	0x3 (Octal)	Any non-zero value	This operand value could be used as default write data size if IPCR1[IDATSZ] is zero. This value is ignored for AHB command.
5~7	STOP (0x00)	0x0	0x00	

10.2.5.4 Application on Serial NAND Flash device

This section provides the example sequences for serial NAND flash device (Micron Flash MT29 series). The operation to serial NAND flash is quite similar to serial NOR flash.

READ operation sequence is as following:

- Page Read (Transfer the data from the NAND Flash array to the cache register)
- Get Feature to read the status
- Random Data Read

The following table shows Page Read command sequence.

Table 10-27. Page Read command

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x1 (Single)	0x13	Command code: 0x13
1	RADDR_SDR	0x1 (Single)	0x18	Row Address: 24 bit
2-7	STOP (0x0)	0x0	0x00	

The following table shows Get Feature command sequence.

Table 10-28. Get Feature command

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x1 (Single)	0x0F	Command code: 0x0F
1	CMD_SDR	0x1 (Single)	0xC0	Status register address (0xC0)
2	READ_SDR	0x1 (Single)	0x02	2 Byte read data
3-7	STOP (0x0)	0x0	0x00	

The following table shows Random Data Read command sequence.

Table 10-29. Read From Cache x4 command

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x1 (Single)	0x6B	Command code: 0x6B
1	MODE4_SDR	0x1 (Single)	0x0 or 0x1	Software should decode the flash address and set mode bits as 0x1 if plane selection is one, or 0x0 if plane selection is zero.

Table continues on the next page...

Table 10-29. Read From Cache x4 command (continued)

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
				Plane selection bit is the 18th bit of flash address. If NAND flash size is less than 4Gbit, plane selection will always be zero.
2	CADDR_SDR	0x1 (Single)	0x0C	Column address: 12 bit
3	DUMMY_SDR	0x2 (Quad)	0x08	Dummy cycle number: 8 (serial root clock)
4	READ_SDR	0x2 (Quad)	Any non-zero value	This operand value could be used as default reading data size if IPCR1[IDATSZ] is zero.
5-7	STOP (0x0)	0x0	0x00	

Program operation sequence is as following:

- Write Enable
- Program Load (Transfer the write data to the cache register)
- Program Execute
- Get Feature to read the status

The following table shows Program Load command sequence.

Table 10-30. Program Load command

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x1 (Single)	0x02	Command code: 0x02
1	MODE4_SDR	0x1 (Single)	0x0 or 0x1	Software should decode the flash address and set mode bits as 0x1 if plane selection is one, or 0x0 if plane selection is zero. Plane selection bit is the 18th bit of flash address. If NAND flash size is less than 4Gbit, plane selection will always be zero.
2	CADDR_SDR	0x1 (Single)	0x0C	Column address: 12 bit
3	WRITE_SDR	0x1 (Single)	Any non-zero value	This operand value could be used as default write data size if IPCR1[IDATSZ] is zero.
4-7	STOP (0x0)	0x0	0x00	

The following table shows Program Execute command sequence.

Table 10-31. Program Execute command

Instruction No.	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0x1 (Single)	0x10	Command code: 0x10
1	RADDR_SDR	0x1 (Single)	0x18	Row Address: 24 bit
2-7	STOP (0x0)	0x0	0x00	

10.2.5.5 Application on FPGA device

FPGA device should be accessed by AHB command. All AHB accesses to FPGA will be transparent to SW driver (no SW intervention).There may be some special requirements from FPGA device.

1. **Device type may be different on A1/A2/B1/B2**

   For this case, clear the MCR2[SAMEDEVICEEN] bit and configure FLSHxCR0 and FLSHxCR1 register separately for up to four external devices.

2. **Device needs different wait cycle for Programming.**

   The AHB write wait cycle number could be set separately for these four external devices (by register field FLSHxCR2[AWRWAIT]). Software could configure the sequences in LUT with different DUMMY instructions (operand will determine dummy cycle). Note that FlexSPI will hold AHB bus ready for this wait time, so AHB Bus performance may become very low when this wait time is very long.

3. **Device needs different wait cycle for Reading.**

   The AHB Read Sequence index and Sequence Number could be set separately for these four external devices (by register field FLSHxCR2[ARDSEQID] and FLSHxCR2[ARDSEQNUM]). Software could configure the sequences in LUT with different DUMMY instruction (operand will determine dummy cycle).

4. **Device may be sensitive to read instruction clock cycle number**

   Device will be sensitive to read instruction clock cycle number if its internal memory is implemented similar as FIFO. For this case, software could send the data size information to external device by DATSZ instruction. FPGA device should decode the data size information and determine how much data bytes should be popped.

5. **Device may need interval time between Chip selection valid**

   This could be handled by register field FLSHxCR1[CSINTERVAL] setting.

6. **Device may use SCLK as reference clock for its internal PLL**

In this case, SCLK should be free-running and clock frequency should be stable. This could be achieved by setting MCR0[SCKFREERUNEN] and use SDR sequence only.

10.2.6 Memory Map and register definition

This section includes the FlexSPI module memory map and detailed descriptions of all registers.

10.2.6.1 Register Access

All registers can be accessed with 8-bit, 16-bit, and 32-bit width operations. Never change the setting value of reserved fields in control registers. Changing the value of reserved fields may impact the normal functioning of the controller.

NOTE

For usage that FlexSPI is capable of accessing sensitive memory contents, protection should be done to FlexSPI controller using resource isolation (e.g. RDC) to make sure only trusted software be allowed to access the FlexSPI controller register interface.

10.2.6.2 FlexSPI register descriptions

10.2.6.2.1 FlexSPI memory map

FlexSPI base address: 30BB_0000h

Register	Offset
MCR0	0h

10.2.6.2.2.2 Diagram

10.2.6.2.2.3 Fields

Field	Description
31-24 AHBGRANTWAIT	Timeout wait cycle for AHB command grant. If AHB Triggered Command is not granted by arbitrator, it will timeout after AHBGRANTTIMEOUT * 1024 AHB Clock cycles. This grant timeout may occur when the pending command sequence is IP triggered and the read/write data size is too large. When an AHB command grant timeout occurs, there will be an interrupt generated (INTR[AHBCMDGE]) if this interrupt is enabled (INTEN[AHBCMDGEEN] is set) and AHB command is ignored by arbitrator.

Table continues on the next page...

Field	Description
	NOTE: This field is for debug only, please keep default value! It is not allowed to set this field to value 0x0.
23-16 IPGRANTWAIT	Timeout wait cycle for IP command grant. If IP Triggered Command is not granted by arbitrator, it will timeout after IPGRANTTIMEOUT * 1024 AHB Clock cycles. This grant timeout maybe occur when pending command sequence is AHB triggered and read/write data size is too large. When IP command grant timeout occurs, there will be an interrupt generated (INTR[IPCMDGE]) if this interrupt is enabled (INTEN[IPCMDGEEN] is set 0x1) and IP command is ignored by arbitrator. **NOTE:** This field is for debug only, please keep default value! It is not allowed to set this field to value 0x0.
15 LEARNEN	This bit is used to enable/disable data learning feature. When data learning is disabled, the sampling clock phase 0 is always used for RX data sampling even if LEARN instruction is correctly executed. 0 - Disable. 1 - Enable.
14 SCKFREERUNEN	This bit is used to force SCLK output free-running. For FPGA applications, external device may use SCLK as reference clock to its internal PLL. If SCLK free-running is enabled, data sampling with loopback clock from SCLK pad is not supported (MCR0[RXCLKSRC]=2). 0 - Disable. 1 - Enable.
13 COMBINATIONEN	This bit is to support Flash Octal mode access by combining Port A and B Data pins (A_DATA[3:0] and B_DATA[3:0]), when Port A and Port B are of 4 bit data width. **NOTE:** Combination mode is not supported if Port A and Port B are 8 bit data width. This bit should be set to zero in this case. 0 - Disable. 1 - Enable.
12 DOZEEN	Doze mode enable bit 0 - Doze mode support disabled. AHB clock and serial clock will not be gated off when there is doze mode request from system. 1 - Doze mode support enabled. AHB clock and serial clock will be gated off when there is doze mode request from system.
11 HSEN	Half Speed Serial Flash access Enable. This bit enables the divide by 2 of the clock to external serial flash devices (A_SCLK/B_SCLK) for all commands (for both SDR and DDR mode). FlexSPI need to be set into MDIS mode before changing value of HSEN. Otherwise, it is possible to cause issue on internal logic/state machine. 0 - Disable divide by 2 of serial flash clock for half speed commands. 1 - Enable divide by 2 of serial flash clock for half speed commands.
10-8 SERCLKDIV	Serial root clock The serial root clock could be divided inside FlexSPI . Refer Clocks chapter for more details on clocking. **NOTE:** Don't change this field during IP's normal operation mode. Alter the value after putting IP into stop mode. 000 - Divided by 1 001 - Divided by 2 010 - Divided by 3 011 - Divided by 4

Table continues on the next page...

Field	Description
	100 - Divided by 5 101 - Divided by 6 110 - Divided by 7 111 - Divided by 8
7 ATDFEN	Enable AHB bus Write Access to IP TX FIFO. 0 - IP TX FIFO should be written by IP Bus. AHB Bus write access to IP TX FIFO memory space will get bus error response. 1 - IP TX FIFO should be written by AHB Bus. IP Bus write access to IP TX FIFO memory space will be ignored but no bus error response.
6 ARDFEN	Enable AHB bus Read Access to IP RX FIFO. 0 - IP RX FIFO should be read by IP Bus. AHB Bus read access to IP RX FIFO memory space will get bus error response. 1 - IP RX FIFO should be read by AHB Bus. IP Bus read access to IP RX FIFO memory space will always return data zero but no bus error response.
5-4 RXCLKSRC	Sample Clock source selection for Flash Reading Refer RX Clock Source Features for more details 00 - Dummy Read strobe generated by FlexSPI Controller and loopback internally. 01 - Dummy Read strobe generated by FlexSPI Controller and loopback from DQS pad. 10 - Reserved 11 - Flash provided Read strobe and input from DQS pad
3-2 —	Reserved
1 MDIS	Module Disable When module disabled, AHB/serial clock will be gated off internally to save power. Only register access (except LUT/IP RX FIFO/IP TX FIFO) is allowed.
0 SWRESET	Software Reset This bit is auto-cleared by hardware after software reset done. Configuration registers will not be reset.

Register	Offset
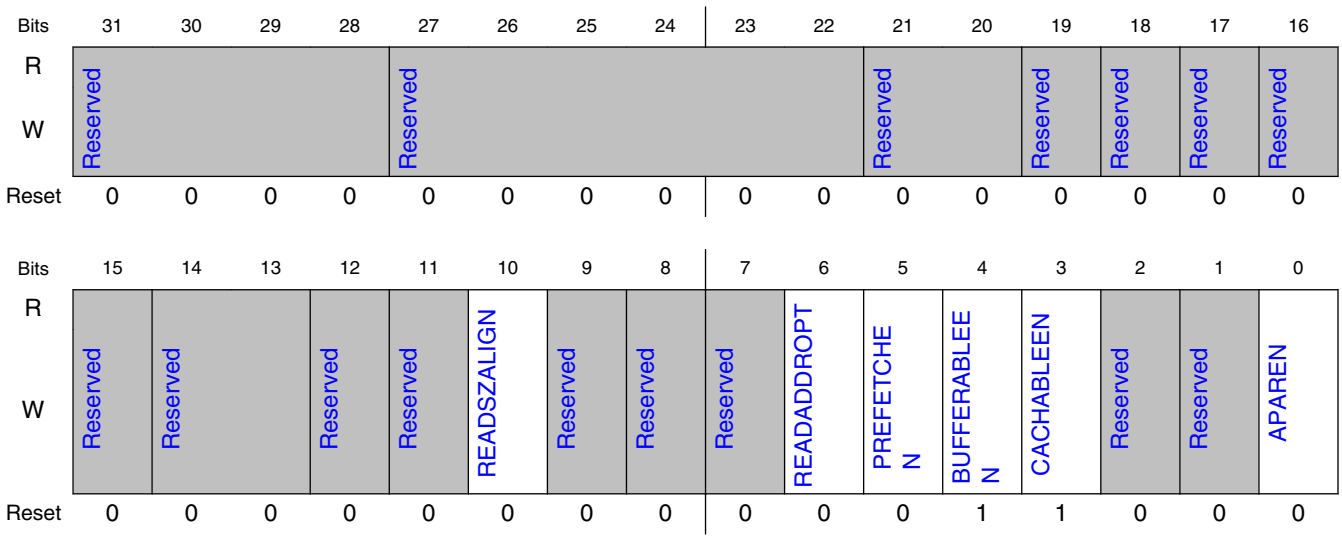
MCR2	8h

10.2.6.2.4.2 Diagram

10.2.6.2.4.3 Fields

Field	Description
31-24 RESUMEWAIT	Wait cycle (in AHB clock cycle) for idle state before suspended command sequence resumed.
23 RX_CLK_SRC_DIFF	Sample Clock source or source_b selection for Flash Reading
22-21 RXCLKSRC_B	Sample Clock source selection for Flash Reading 00 - Dummy Read strobe generated by FlexSPI Controller and loopback internally. 01 - Dummy Read strobe generated by FlexSPI Controller and loopback from DQS pad. 10 - SCLK output clock and loopback from SCLK padReserved 11 - Flash provided Read strobe and input from DQS pad
20 —	Reserved
19 SCKBDIFFOPT	B_SCLK pad can be used as A_SCLK differential clock output (inverted clock to A_SCLK). In this case, port B flash access is not available. After changing the value of this field, MCR0[SWRESET] should be set. 0 - B_SCLK pad is used as port B SCLK clock output. Port B flash access is available. 1 - B_SCLK pad is used as port A SCLK inverted clock output (Differential clock to A_SCLK). Port B flash access is not available.
18-17 —	Reserved

Table continues on the next page...



Field	Description
16 —	Reserved
15 SAMEDEVICEEN	All external devices are same devices (both in types and size) for A1/A2/B1/B2. 0 - In Individual mode, FLSHA1CRx/FLSHA2CRx/FLSHB1CRx/FLSHB2CRx register setting will be applied to Flash A1/A2/B1/B2 separately. In Parallel mode, FLSHA1CRx register setting will be applied to Flash A1 and B1, FLSHA2CRx register setting will be applied to Flash A2 and B2. FLSHB1CRx/ FLSHB2CRx register settings will be ignored. 1 - FLSHA1CR0/FLSHA1CR1/FLSHA1CR2 register settings will be applied to Flash A1/A2/B1/B2. FLSHA2CRx/FLSHB1CRx/FLSHB2CRx will be ignored.
14 CLRLEARNPHASE	The sampling clock phase selection will be reset to phase 0 when this bit is written with 0x1. This bit will be auto-cleared immediately.
13 —	Reserved
12 —	Reserved
11 CLRAHBBUFOPT	This bit determines whether AHB RX Buffer and AHB TX Buffer will be cleaned automatically when FlexSPI returns STOP mode ACK. Software should set this bit if AHB RX Buffer or AHB TX Buffer will be powered off in STOP mode. Otherwise AHB read access after exiting STOP mode may hit AHB RX Buffer or AHB TX Buffer but their data entries are invalid. 0 - AHB RX/TX Buffer will not be cleaned automatically when FlexSPI return Stop mode ACK. 1 - AHB RX/TX Buffer will be cleaned automatically when FlexSPI return Stop mode ACK.
10-9 —	Reserved
8-0 —	Reserved

8 —	Reserved
7 —	Reserved
6 READADDROPT	AHB Read Address option bit. This option bit is intend to remove AHB burst start address alignment limitation. When FlexSPI controller is used for FPGA application, there may be requirement that FlexSPI fetch exactly the byte number as AHB burst. In this case, FPGA device should be designed as non-wordaddressable and this option bit should be set 0. 0 - There is AHB read burst start address alignment limitation when flash is accessed in parallel mode or flash is word-addressable. 1 - There is no AHB read burst start address alignment limitation. FlexSPI will fetch more data than AHB burst required to meet the alignment requirement.
5 PREFETCHEN	AHB Read Prefetch Enable. When AHB read prefetch is enabled, FlexSPI will fetch more flash read data than current AHB burst needed so that the read latency for next AHB read access will be reduced.
4 BUFFERABLEEN	Enable AHB bus bufferable write access support. This field affects the last beat of AHB write access, refer AHB write access to Flash for more details about AHB bufferable write. 0 - Disabled. For all AHB write access (no matter bufferable or non-bufferable), FlexSPI will return AHB Bus ready after all data is transmitted to External device and AHB command finished. 1 - Enabled. For AHB bufferable write access, FlexSPI will return AHB Bus ready when the AHB command is granted by arbitrator and will not wait for AHB command finished.
3 CACHABLEEN	Enable AHB bus cachable read access support. 0 - Disabled. When there is AHB bus cachable read access, FlexSPI will not check whether it hit AHB TX Buffer. 1 - Enabled. When there is AHB bus cachable read access, FlexSPI will check whether it hit AHB TX Buffer first.
2 —	Reserved
1 —	Reserved
0 APAREN	Parallel mode enabled for AHB triggered Command (both read and write) . 0 - Flash will be accessed in Individual mode. 1 - Flash will be accessed in Parallel mode.

10.2.6.2.6 Interrupt Enable Register (INTEN)

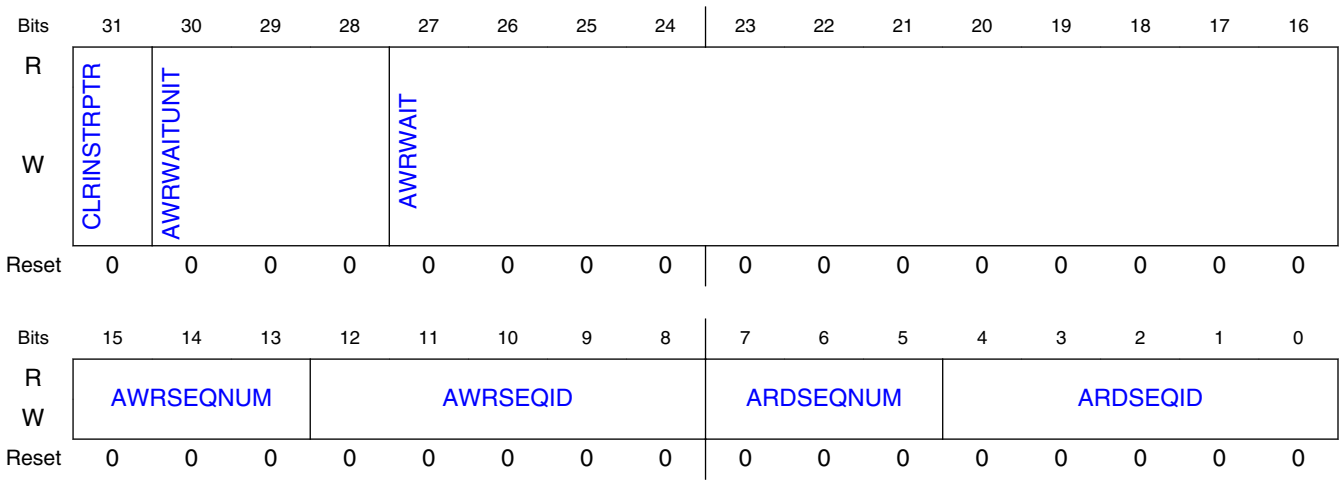
Reset	0	0	0	0	0	0	0	0	0	1	1	0	0	0	1	1

10.2.6.2.19.3 Fields

Field	Description
31-16 CSINTERVAL	This field is used to set the minimum interval between flash device Chip selection deassertion and flash device Chip selection assertion. If external flash has a limitation on the interval between command sequences, this field should be set accordingly. If there is no limitation, set this field with value 0x0. When CSINTERVALUNIT is 0x0, the chip selection invalid interval is: CSINTERVAL * 1 serial clock cycle; When CSINTERVALUNIT is 0x1, the chip selection invalid interval is: CSINTERVAL * 256 serial clock cycle. **NOTE:** The chip selection interval is 2 cycle at least even if CSINTERVAL is less than 2.
15 CSINTERVALUNIT	CS interval unit 0 - The CS interval unit is 1 serial clock cycle 1 - The CS interval unit is 256 serial clock cycle
14-11 CAS	Column Address Size. When external flash has separate address field for row address and column address, this field should be set to flash column address bit width. FlexSPI will automatically split flash mapped address to Row

Table continues on the next page...

Field	Description
	address and Column address according to CAS field and WA field setting. This bit should be set to 0x0 when external Flash don't support column address. FlexSPI will transmit all flash address bits as Row address. For flash address mapping, please refer to Flash memory map for more detail.
10 WA	Word Addressable. This bit should be set when external Flash is word addressable. If Flash is word addressable, it should be access in terms of 16 bits. At this time, FlexSPI will not transmit Flash address bit 0 to external Flash. For flash address mapping, please refer to Flash memory map for more detail.
9-5 TCSH	Serial Flash CS Hold time. This field is used to meet flash TCSH timing requirement. Serial flash CS Hold time promised by FlexSPI is: TCSH in serial root clock cycles (for both SDR and DDR mode). Please refer to FlexSPI Input Timing for more detail.
4-0 TCSS	Serial Flash CS setup time. This field is used to meet flash TCSS timing requirement. Serial flash CS Setup time promised by FlexSPI is: (TCSS + 1/2) serial root clock cycles (for both SDR and DDR mode). Please refer to FlexSPI Input Timing for more detail.



10.2.6.2.20 Flash Control Register 2 (FLSHA1CR2 - FLSHB2CR2)

Flash Control Register 2 contains setting field for AHB Bus access configuration. If the 4 external device are in different types, AHB read/write command may use different command sequences and AHB bus ready wait time may be also different.

10.2.6.2.20.1 Offset

Register	Offset
FLSHA1CR2	80h
FLSHA2CR2	84h
FLSHB1CR2	88h
FLSHB2CR2	8Ch

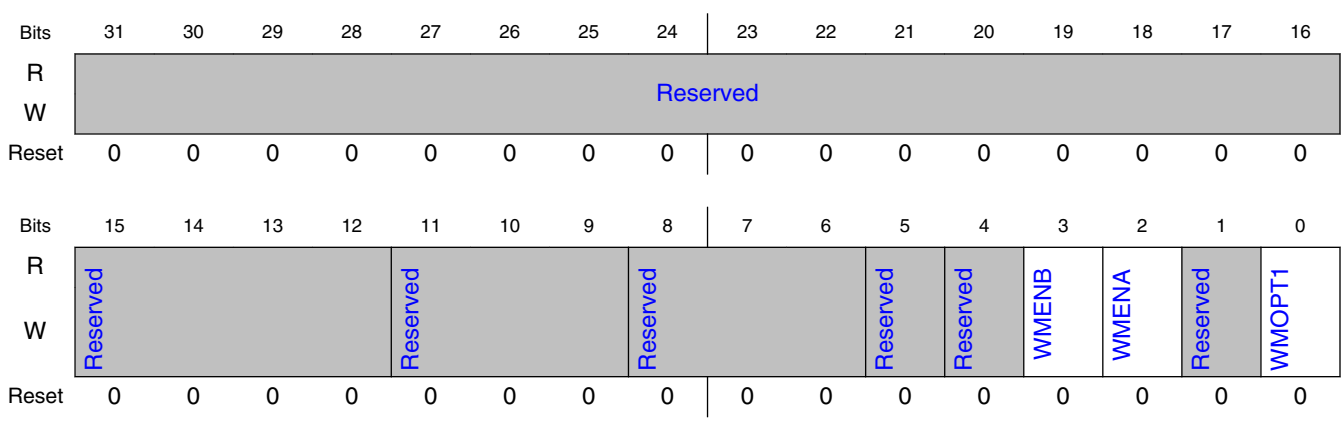
10.2.6.2.20.2 Diagram

10.2.6.2.20.3 Fields

Field	Description
31 CLRINSTRPTR	Clear the instruction pointer which is internally saved pointer by JMP_ON_CS. Refer Programmable Sequence Engine for details. This field is used for AHB Read access to external Flash supporting XIP (Execute-In-Place) mode.
30-28 AWRWAITUNIT	AWRWAIT unit 000 - The AWRWAIT unit is 2 ahb clock cycle 001 - The AWRWAIT unit is 8 ahb clock cycle 010 - The AWRWAIT unit is 32 ahb clock cycle 011 - The AWRWAIT unit is 128 ahb clock cycle 100 - The AWRWAIT unit is 512 ahb clock cycle 101 - The AWRWAIT unit is 2048 ahb clock cycle 110 - The AWRWAIT unit is 8192 ahb clock cycle 111 - The AWRWAIT unit is 32768 ahb clock cycle
27-16 AWRWAIT	For certain devices (such as FPGA), it need some time to write data into internal memory after the command sequences finished on FlexSPI interface. If another Read command sequence comes before previous programming finished internally, the read data may be wrong. This field is used to hold AHB Bus ready for AHB write access to wait the programming finished in external device. Then there will be no AHB read command triggered before the programming finished in external device. The Wait cycle between AHB triggered command sequences finished on FlexSPI interface and AHB return Bus ready: AWRWAIT * AWRWAITUNIT
15-13 AWRSEQNUM	Sequence Number for AHB Write triggered Command. For certain flash devices (e.g. HyperFlash/HyperRam/Serial NAND flash), a Flash programming access is done by several command sequences. AHB write Command will trigger (AWRSEQNUM+1) command sequences to external flash every time. FlexSPI executes the sequences in LUT incrementally.

Table continues on the next page...

Field	Description
	NOTE: • Software should make sure the last sequence index never exceed LUT sequence numbers: AWRSEQID+AWRSEQNUM < 32 • Software needs to make sure that the fields AWRSEQNUM and LUT are configured correctly according to external device spec. FlexSPI doesn't check the sequence and just executes them one by one.
12-8 AWRSEQID	Sequence Index for AHB Write triggered Command.
7-5 ARDSEQNUM	Sequence Number for AHB Read triggered Command in LUT. For certain flash devices (e.g. HyperFlash/HyperRam/Serial NAND flash), a Flash reading access is done by several command sequences. AHB read Command will trigger (ARDSEQNUM+1) command sequences to external flash every time. FlexSPI executes the sequences in LUT incrementally. **NOTE:** • Software should make sure the last sequence index never exceed LUT sequence numbers: ARDSEQID+ARDSEQNUM <= 32 • Software needs to make sure that the fields ARDSEQNUM and LUT are configured correctly according to external device spec. FlexSPI does't check the sequence and just executes them one by one.
4-0 ARDSEQID	Sequence Index for AHB Read triggered Command in LUT.



10.2.6.2.21 Flash Control Register 4 (FLSHCR4)

The flash control register 4 provide the configuration for all external devices.

10.2.6.2.21.1 Offset

Register	Offset
FLSHCR4	94h

10.2.6.2.21.2 Diagram

10.2.6.2.21.3 Fields

Field	Description
31-12 —	Reserved
11-9 —	Reserved
8-6 —	Reserved
5 —	Reserved
4 —	Reserved
3 WMENB	Write mask enable bit for flash device on port B. When write mask function is needed for memory device on port B, this bit must be set. 0 - Write mask is disabled, DQS(RWDS) pin will not be driven when writing to external device. 1 - Write mask is enabled, DQS(RWDS) pin will be driven by FlexSPI as write mask output when writing to external device.
2 WMENA	Write mask enable bit for flash device on port A. When write mask function is needed for memory device on port A, this bit must be set. 0 - Write mask is disabled, DQS(RWDS) pin will not be driven when writing to external device. 1 - Write mask is enabled, DQS(RWDS) pin will be driven by FlexSPI as write mask output when writing to external device.
1 —	Reserved
0 WMOPT1	Write mask option bit 1. This option bit could be used to remove AHB write burst start address alignment limitation. 0 - DQS pin will be used as Write Mask when writing to external device. There is no limitation on AHB write burst start address alignment when flash is accessed in individual mode. 1 - DQS pin will not be used as Write Mask when writing to external device. There is limitation on AHB write burst start address alignment when flash is accessed in individual mode.

10.2.6.2.22 IP Control Register 0 (IPCR0)

The IP control registers provide all the configuration required for IP commands. This register provides the flash device's start address, instead of SoC address, to be accessed for IP command. FlexSPI will determine the chip select automatically according to this start address.

NOTE

- It's not allowed to issue IP command crossing Flash device boundaries. Otherwise there will be IPCMDERR interrupt generated.
- This register should be set before IP command triggered.
- This register setting should not be changed while an IP command is in progress.

10.2.6.2.22.1 Offset

Register	Offset
IPCR0	A0h

10.2.6.2.24.3 Fields

Field	Description
31-1 —	Reserved
0 TRG	Setting this bit will trigger an IP Command. **NOTE:** • It's not allowed to trigger another IP command before previous IP command is finished on FlexSPI interface. Software need to poll register bit INTR_IP_CMD_DONE or wait for this interrupt in order to wait for IP command finished.

10.2.6.2.25 Data Learn Pattern Register (DLPR)

This register provides the pattern to be used during Data Learning in FlexSPI.

10.2.6.2.25.1 Offset

Register	Offset
DLPR	B4h

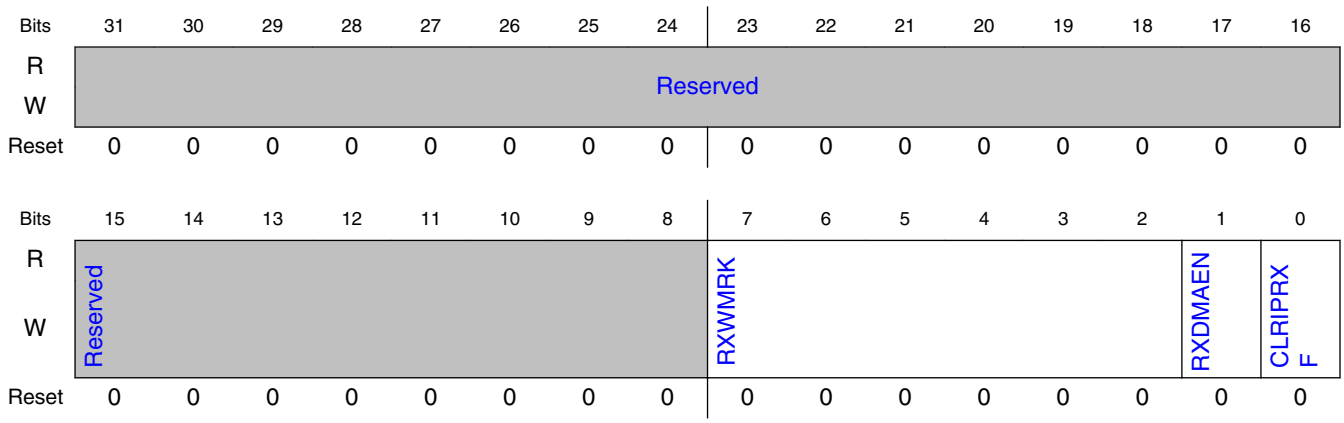
10.2.6.2.25.2 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	DLP															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DLP															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

10.2.6.2.25.3 Fields

Field	Description
31-0 DLP	Data Learning Pattern. The data learning pattern bit number is determined by operand in LEARN_SDR/LEARN_DDR Instruction Code. Data learning pattern bit number will be never more than 32 bits. If the operand in Instruction code is more than 32, 32 bits pattern will be used. If data learning pattern bit number is less than 32 bits, the lower pattern bits will be used. For more details, refer to Data Learning Feature.



10.2.6.2.26 IP RX FIFO Control Register (IPRXFCR)

This register provides the configuration fields for IP RX FIFO management.

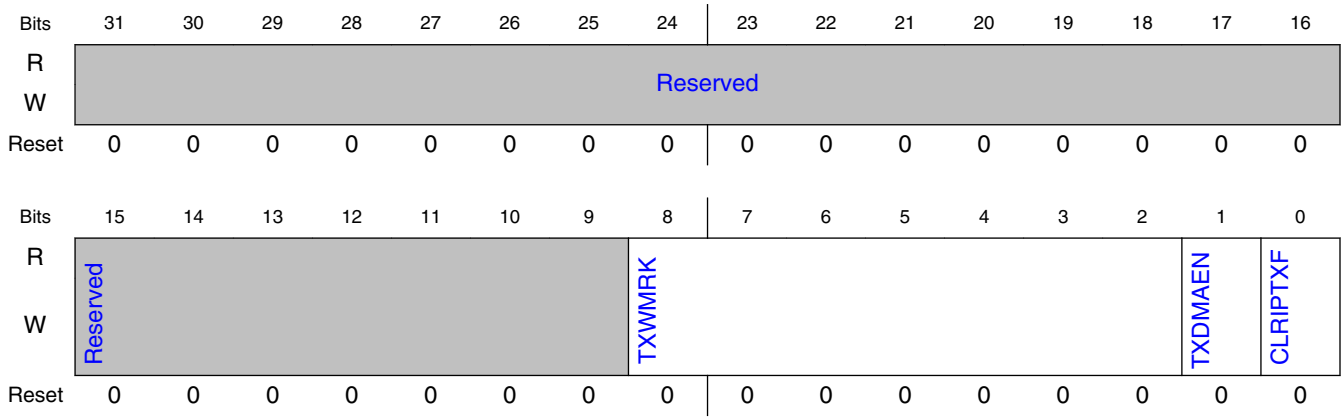
10.2.6.2.26.1 Offset

Register	Offset
IPRXFCR	B8h

10.2.6.2.26.2 Diagram

10.2.6.2.26.3 Fields

Field	Description
31-8 —	Reserved
7-2 RXWMRK	Watermark level is (RXWMRK+1)*64 Bits. Interrupt register bit IPRXWA is set when filling level in IP RX FIFO is no less than Watermark level by FlexSPI. There will be a DMA request when the filling level is no less than Watermark level and DMA read is enabled (register bit RXDMAEN is set). There will be an IPRXWA (IP RX FIFO watermark available) interrupt generated when the filling level is no less than Watermark level and IPRXWA interrupt is enabled (register bit INTEN_IPRXWA is set). **NOTE:** After write-1-clear to INTR[IPRXWA], read address should be rolled back to start address (memory mapped). If IP RX FIFO is read by IP bus, the read address to IP RX FIFO should roll back to RFDR0; If IP RX FIFO is read by AHB bus, the read address to IP RX FIFO should roll back to ARDF_BASE.
1 RXDMAEN	IP RX FIFO reading by DMA enabled. 0 - IP RX FIFO would be read by processor. 1 - IP RX FIFO would be read by DMA.
0 CLRIPRXF	Clear all valid data entries in IP RX FIFO. The read/write pointers in IP RX FIFO will be reset.



10.2.6.2.27 IP TX FIFO Control Register (IPTXFCR)

This register provides the configuration fields for IP TX FIFO management.

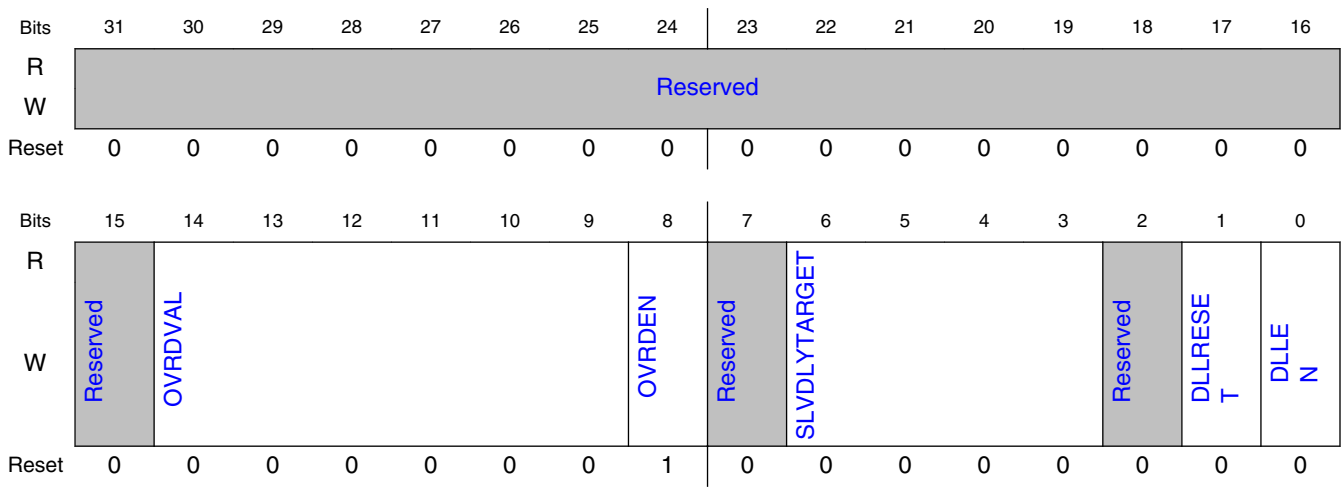
10.2.6.2.27.1 Offset

Register	Offset
IPTXFCR	BCh

10.2.6.2.27.2 Diagram

10.2.6.2.27.3 Fields

Field	Description
31-9 —	Reserved
8-2 TXWMRK	Watermark level is (TXWMRK+1)*64 Bits. Interrupt register bit IPTXWE is set when empty level in IP TX FIFO is no less than Watermark level by FlexSPI. There will be a DMA request when empty level is no less than Watermark level and DMA filling is enable (register bit TXDMAEN is set). There will be an IPTXWE (IP TX FIFO Watermark Empty) interrupt generated when empty level is no less than Watermark level and IPTXWE interrupt is enable (register bit INTEN_IPTXWE is set). **NOTE:** • The watermark level should be no more than the write window. • The watermark level should be no more than IP TX FIFO size. • The write address to IP RX FIFO should roll back to the start address of write window after pushing IP TX FIFO by writing-one-clear to INTR[IPTXWE].
1 TXDMAEN	IP TX FIFO filling by DMA enabled. 0 - IP TX FIFO would be filled by processor. 1 - IP TX FIFO would be filled by DMA.
0 CLRIPTXF	Clear all valid data entries in IP TX FIFO. The read/write pointers in IP TX FIFO will be reset.



10.2.6.2.28 DLL Control Register 0 (DLLACR - DLLBCR)

This register provides the configuration fields for Flash A/B sample clock DLL.

10.2.6.2.28.1 Offset

Register	Offset
DLLACR	C0h
DLLBCR	C4h

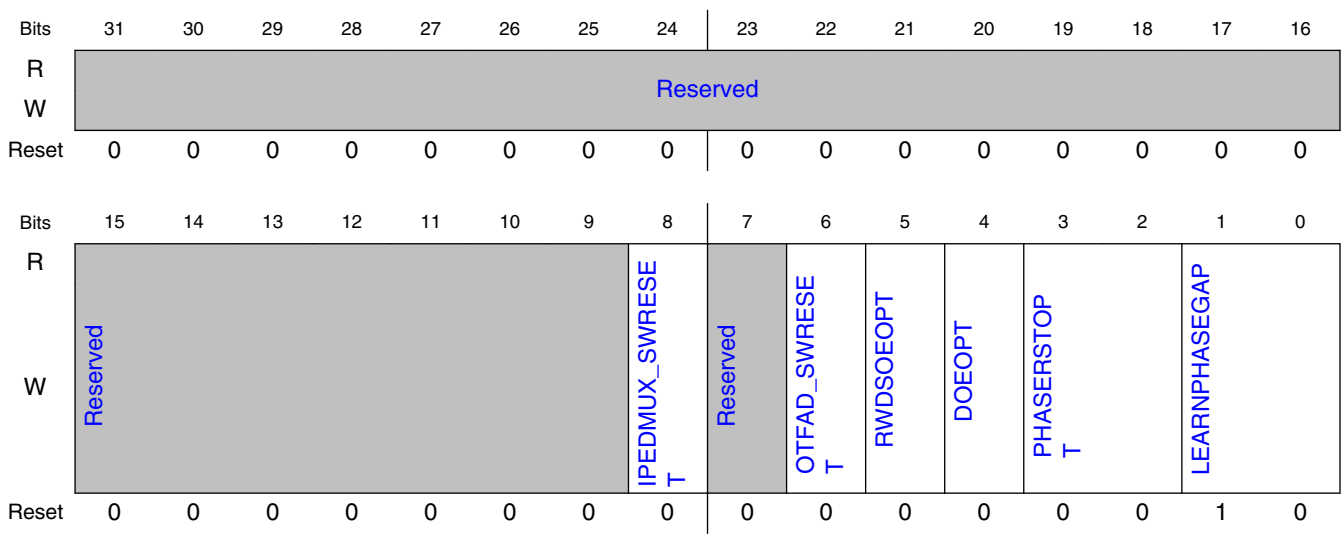
10.2.6.2.28.2 Diagram

10.2.6.2.28.3 Fields

Field	Description
31-15 —	Reserved
14-9 OVRDVAL	Slave clock delay line delay cell number selection override value. When OVRDEN is set 0x1, the delay cell number in DLL is OVRDVAL+1.
8 OVRDEN	Slave clock delay line delay cell number selection override enable.
7 —	Reserved
6-3 SLVDLYTARGET	The delay target for slave delay line is: ((SLVDLYTARGET+1) * 1/32 * clock cycle of reference clock (serial root clock). If serial root clock is >= 100 MHz, DLLEN set to 0x1, OVRDEN set to =0x0, then SLVDLYTARGET setting of 0xF is recommended.
2 —	Reserved
1 DLLRESET	Software could force a reset on DLL by setting this field to 0x1. This will cause the DLL to lose lock and re-calibrate to detect an ref_clock half period phase shift. The reset action is edge triggered, so software need to clear this bit after set this bit (no delay limitation).

Table continues on the next page...

Field	Description
0 DLLEN	DLL calibration enable. When this bit is cleared, DLL calibration is disabled and the delay cell number in slave delay line is always 1. Please note that SLV delay line is overridden when OVRDEN bit is set and this bit field setting is ignored.



10.2.6.2.29 Misc Control Register 2 (MISCCR2)

This register is reserved for future.

10.2.6.2.29.1 Offset

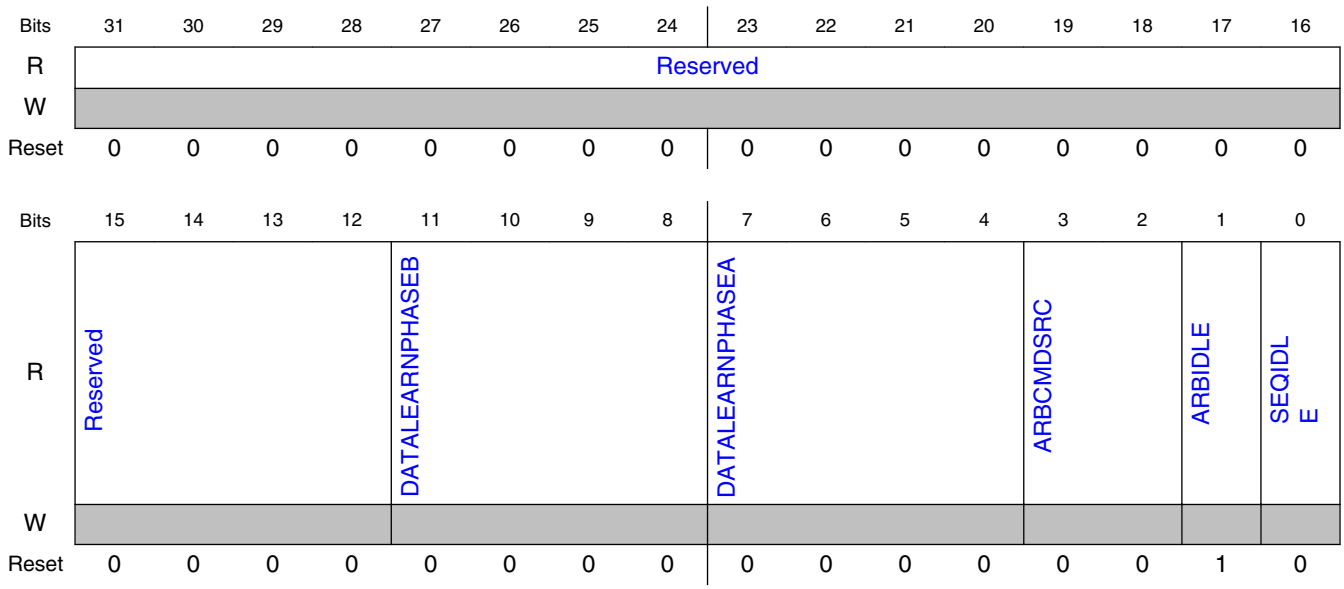
Register	Offset
MISCCR2	C8h

10.2.6.2.29.2 Diagram

10.2.6.2.29.3 Fields

Field	Description
31-9 —	Reserved
8	This bit is software reset for IPED MUX.This bit is not auto-cleared by hardware.

Table continues on the next page...



Field	Description
IPEDMUX_SWRESET	
7 —	Reserved
6 OTFAD_SWRESET	This bit is software reset for OTFAD.It is connected to output.This bit is not auto-cleared by hardware.
5 RWDSOEOPT	FlexSPI controller could delay the RWDS (write mask) output enable desertion by one cycle to relax transmit timing. 0 - RWDS output enable desertion is delayed by one cycle 1 - RWDS output enable desertion is not delayed by one cycle
4 DOEOPT	FlexSPI controller could delay the data lines output enable desertion by one cycle to relax transmit timing. **NOTE:** When there is no dummy cycle for transmit and receive trunaround and flash is not accessed in single mode, this option bit should be set 1. Otherwise, FlexSPI controller and flash device may drive data lines at the same time. 0 - Data line output enable desertion is delayed by one cycle 1 - Data line output enable desertion is not delayed by one cycle
3-2 PHASERSTOPT	SCLK/DQS output clock phase may need reset after a DDR sequence finished (high level). FlexSPI controller will auto reset the clock phase. 00 - SCLK/DQS output phase will be reset 0.5 cycle after CS de-assertion 01 - SCLK/DQS output phase will be reset 1.5 cycle after CS de-assertion 10 - SCLK/DQS output phase will be reset 2.5 cycle after CS de-assertion 11 - SCLK/DQS output phase will be reset 3.5 cycle after CS de-assertion
1-0 LEARNPHASEGAP	The clock phase gap for data learning is: N delay cells delay (75ps~200ps for each delay cell). 00 - N=2 01 - N=3 10 - N=4 11 - N=5

10.2.6.2.30 Status Register 0 (STS0)

10.2.6.2.30.1 Offset

Register	Offset
STS0	E0h

10.2.6.2.30.2 Diagram

10.2.6.2.30.3 Fields

Field	Description
31-12 —	Reserved
11-8 DATALEARNPHASEB	Indicate the sampling clock phase selection on Port B after Data Learning. This is similar as DATALEARNPHASEA field. The sampling clock phase is chosen separately for Port A and Port B.
7-4 DATALEARNPHASEA	Indicate the sampling clock phase selection on Port A after Data Learning. There are 16 clock phases for sampling clock which is generated by delay cell line. When data learning feature is not enabled, the default clock phase 0 will be used to sample Flash read data. When data learning feature is enabled and LEARN_SDR/LEARN_DDR instruction executed correctly on FlexSPI Interface, FlexSPI will determine the correct clock phase to sample Flash read data. Refer Data Learning Feature for more details.
3-2 ARBCMDSRC	This status field indicates the trigger source of current command sequence granted by arbitrator. This field value is meaningless when ARB_CTL is not busy (STS0[ARBIDLE]=0x1). 00 - Triggered by AHB read command (triggered by AHB read). 01 - Triggered by AHB write command (triggered by AHB Write). 10 - Triggered by IP command (triggered by setting register bit IPCMD.TRG). 11 - Triggered by suspended command (resumed).
1 ARBIDLE	This status bit indicates the state machine in ARB_CTL is busy and there is command sequence granted by arbitrator and not finished yet on FlexSPI interface. When ARB_CTL state (ARBIDLE=0x1) is idle, there will be no transaction on FlexSPI interface also (SEQIDLE=0x1). So this bit should be polled to wait for FlexSPI controller become idle instead of SEQIDLE.
0 SEQIDLE	This status bit indicates the state machine in SEQ_CTL is idle and there is command sequence executing on FlexSPI interface.

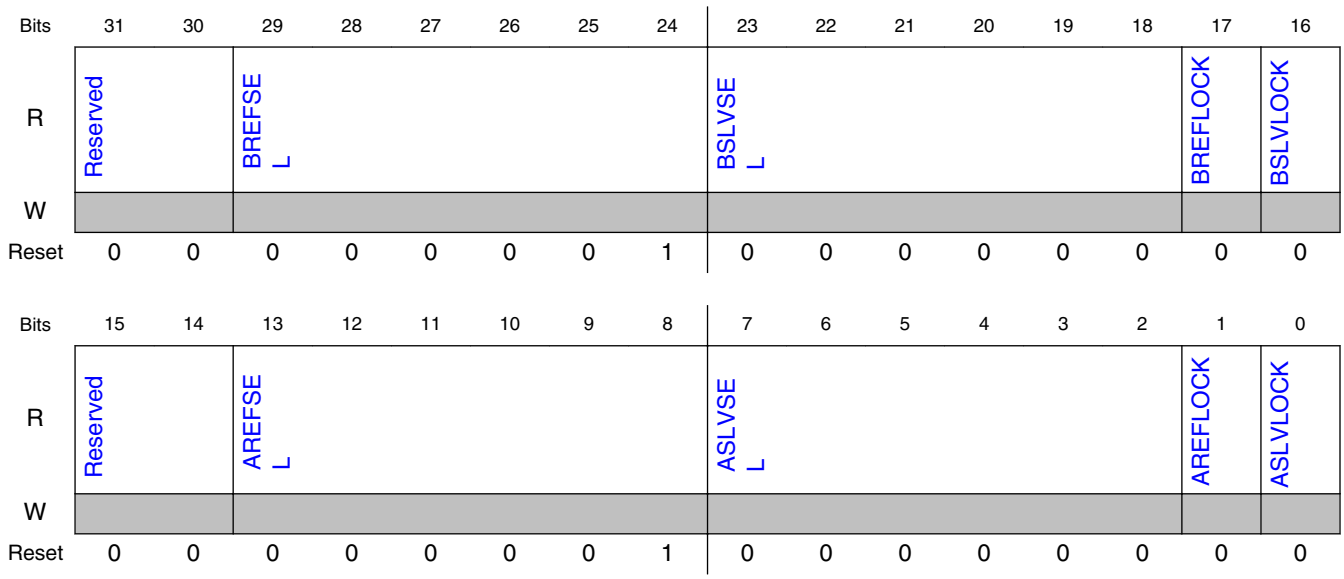
10.2.6.2.31.3 Fields

Field	Description
31-28 —	Reserved
27-24 IPCMDERRCODE	Indicates the Error Code when IP command Error detected. This field will be cleared when INTR[IPCMDERR] is write-1-clear(w1c). 0000 - No error. 0010 - IP command with JMP_ON_CS instruction used in the sequence. 0011 - There is unknown instruction opcode in the sequence. 0100 - Instruction DUMMY_SDR/DUMMY_RWDS_SDR used in DDR sequence. 0101 - Instruction DUMMY_DDR/DUMMY_RWDS_DDR used in SDR sequence. 0110 - Flash access start address exceed the whole flash address range (A1/A2/B1/B2).

Table continues on the next page...

Field	Description
	1110 - Sequence execution timeout. 1111 - Flash boundary crossed.
23-21 —	Reserved
20-16 IPCMDERRID	Indicates the sequence Index when IP command error detected. This field will be cleared when INTR[IPCMDERR] is write-1-clear(w1c).
15-12 —	Reserved
11-8 AHBCMDERRCODE	Indicates the Error Code when AHB command Error detected. This field will be cleared when INTR[AHBCMDERR] is write-1-clear(w1c). 0000 - No error. 0010 - AHB Write command with JMP_ON_CS instruction used in the sequence. 0011 - There is unknown instruction opcode in the sequence. 0100 - Instruction DUMMY_SDR/DUMMY_RWDS_SDR used in DDR sequence. 0101 - Instruction DUMMY_DDR/DUMMY_RWDS_DDR used in SDR sequence. 1110 - Sequence execution timeout.
7-5 —	Reserved
4-0 AHBCMDERRID	Indicates the sequence index when an AHB command error is detected. This field will be cleared when INTR[AHBCMDERR] is write-1-clear(w1c).



10.2.6.2.32 Status Register 2 (STS2)

This register indicates the status of Flash A and B sample clock DLLs.

10.2.6.2.32.1 Offset

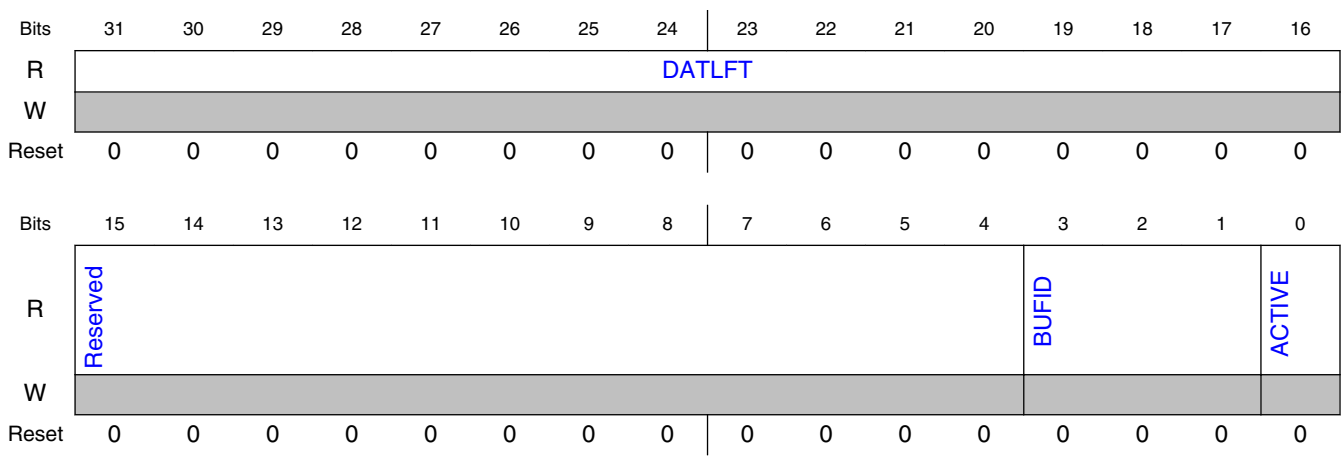
23-18 BSLVSEL	Flash B sample clock slave delay line delay cell number selection.
17 BREFLOCK	Flash B sample clock reference delay line locked.
16 BSLVLOCK	Flash B sample clock slave delay line locked.
15-14 —	Reserved
13-8 AREFSEL	Flash A sample clock reference delay line delay cell number selection.
7-2 ASLVSEL	Flash A sample clock slave delay line delay cell number selection .
1 AREFLOCK	Flash A sample clock reference delay line locked.
0 ASLVLOCK	Flash A sample clock slave delay line locked.



10.2.6.2.33 AHB Suspend Status Register (AHBSPNDSTS)

Indicates the status of Suspended AHB Read Prefetch command sequence. When there is IP/AHB command triggered and arbitrator is processing an AHB Read sequence (prefetching more data not for current AHB burst), the prefetch sequence will be suspended and may be resumed when there is no transaction on FlexSPI any more. FlexSPI saves only one AHB prefetch sequence. When a new prefetch sequence is suspended with an active sequence suspended already, previous suspended sequence will be removed and never resumed. Refer Command Abort and Suspend for more details.

9-8 NUM_PADS0	NUM_PADS0
7-0 OPERAND0	OPERAND0

10.2.7 AHB Memory Map definition

This section describes FlexSPI module AHB memory map in detail.

10.2.7.1 AHB Memory Map for Serial Flash memory access

AHB read/write access for serial flash memory is mapped to a specific address range. See the Memory Map and register definition for specific address ranges supported.

AHB Bus feature supported for Serial Flash memory reading:
- Cachable and Non-Cachable access
- Prefetch Enable/Disable
- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

AHB Bus feature for Serial Flash memory writing:
- Bufferable and Non-Bufferable access
- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

Refer Flash access by AHB Command for more details about AHB access to Serial Flash memory.

10.2.7.2 AHB Memory Map for IP RX FIFO read access

Following address range is mapped for AHB read access to IP RX FIFO: 0x34000000 - 0x34000200.

AHB Bus feature supported for IP RX FIFO reading:
- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

Refer Reading Data from IP RX FIFO for more details about IP RX FIFO reading.

10.2.7.3 AHB Memory Map for IP TX FIFO write access

Following address range is mapped for AHB write access to IP TX FIFO: 0x33008000 - 0x33008400.

AHB Bus feature supported for IP TX FIFO writing:
- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

Refer Filling Data to IP TX FIFO for more details about IP TX FIFO filling.

10.3 Ultra Secured Digital Host Controller (uSDHC)

10.3.1 Overview

The Ultra Secured Digital Host Controller (uSDHC) provides the interface between the host system and the SD/SDIO/MMC cards, as shown in Figure 10-57. The module acts as a bridge, passing host bus transactions to the SD/SDIO/MMC cards by sending commands and performing data accesses to/from the cards. It handles the SD/SDIO/MMC protocols at the transmission level.

10.3.1.1 Block Diagram

The following figure illustrates the block diagram for uSDHC.

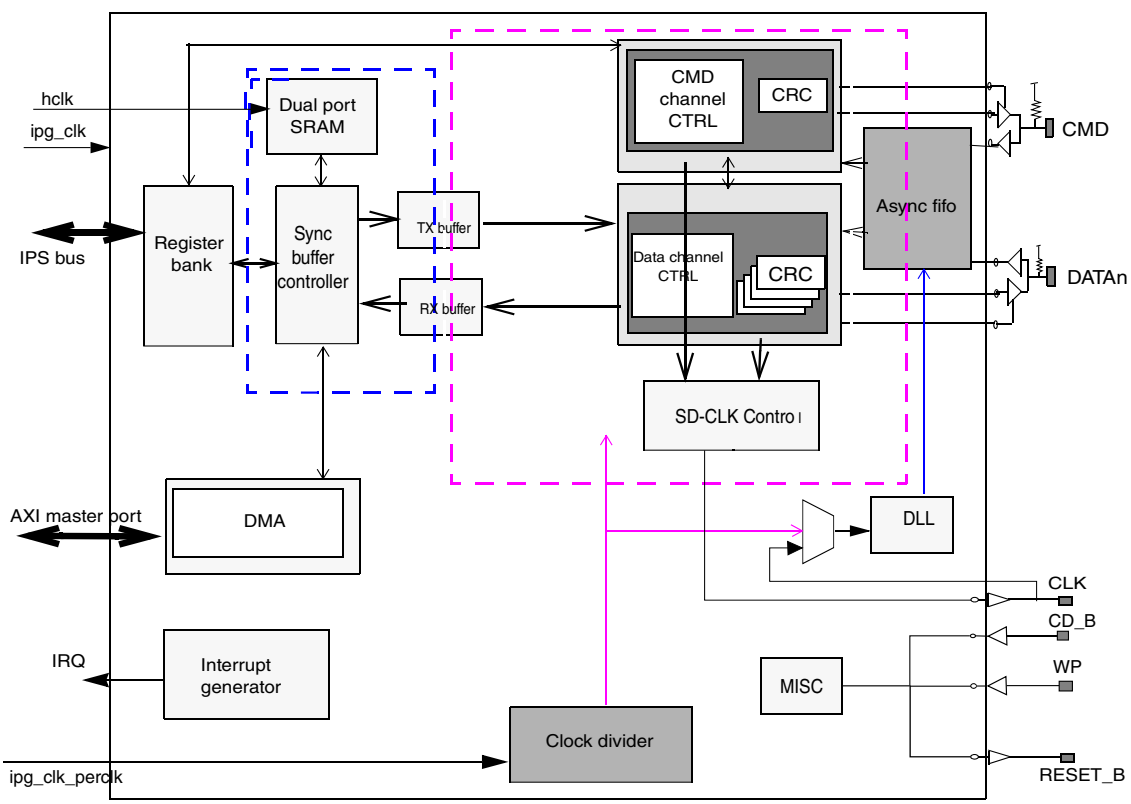

Figure 10-56. uSDHC block diagram

The figure below shows the System connection of uSDHC:

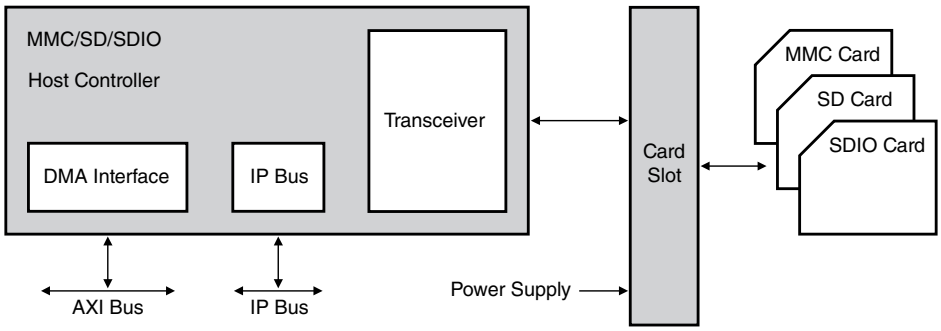

Figure 10-57. System connection of uSDHC

The following are brief descriptions of the cards supported by uSDHC:

- The Multi Media Card (MMC) is a universal low-cost data storage and communication media designed to cover a wide array of applications including mobile video and gaming. Previous MMC cards were based on a 7-pin serial bus with a single data pin, while the new high speed MMC communication is based on an advanced 11-pin serial bus designed to operate in the low-voltage range.
- The Secure Digital Card (SD) is an evolution of the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environmental requirements inherent in newly emerging audio and video consumer electronic devices. The physical form factor, pin assignment, and data transfer protocol are backward/downward compatible with the old MMC (with some additions).
- Under the SD protocol, system connection can be categorized into memory card, I/O card, and combo card, which have both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O card, which is also known as SDIO card, provides high-speed data I/O with low-power consumption for mobile electronic devices. For the sake of simplicity, the next figure does not show cards with reduced size or mini cards.

10.3.1.2 Features

The list given below shows the features of the uSDHC module:

- Conforms to the SD Host Controller Standard Specification version 2.0/3.0
- Compatible with the MMC System Specification version 4.2/4.3/4.4/4.41/4.5/5.0/5.1
- Compatible with the SD Memory Card Specification version 3.0 and supports the Extended Capacity SD Memory Card
- Compatible with the SDIO Card Specification version 2.0/3.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, and MMC RS cards

- Card bus clock frequency up to 208 MHz
- Supports 1-bit/4-bit SD and SDIO modes, and 1-bit/4-bit/8-bit MMC modes
  - Up to 832 Mbps of data transfer for SDIO cards using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDIO card using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 832 Mbps of data transfer for SDXC cards using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDXC card using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 1600 Mbps of data transfer for MMC cards using eight parallel data lines in the Single Data Rate (SDR) mode
  - Up to 3200 Mbps of data transfer for MMC cards using eight parallel data lines in the Dual Data Rate (DDR) mode
- Supports single block/multi-block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes; also supports interrupt period
- Embodies two fully configurable 256x32-bit FIFO for read/write data
- Supports internaland external DMA capabilities
- Support voltage selection by configuring vendor-specific register bit
- Supports Advanced DMA to perform linked memory access
- support Command queue mechanism

NOTE

This block can support all the above-listed speed mode and maximum data throughput. However, these may be specific to the device. See the corresponding chip-specific information or the device data sheet for accurate details.

10.3.2 Functional description

The following sections provide a brief functional description of the major system blocks, including the data buffer, DMA AXI interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock and reset manager, and clock generator.

10.3.2.1 Modes and operations

10.3.2.1.1 Data transfer modes

The uSDHC module can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- MMC 1-bit
- MMC 4-bit
- MMC 8-bit
- Identification mode (up to 400 kHz)
- MMC full-speed mode (up to 26 MHz)
- MMC high-speed mode (up to 52 MHz)
- MMC HS200 mode(up to 200 MHz)
- MMC HS400 mode (200 MHz both edges)
- MMC DDR mode (52 MHz both edges)
- SD/SDIO full-speed mode (up to 25 MHz)
- SD/SDIO high-speed mode (up to 50 MHz)
- SD/SDIO UHS-I mode(up to 208 MHz in SDR mode, up to 50 MHz in the DDR mode)

NOTE

This block can support all the above listed speed mode and maximum clock frequency. However, these may be specific to the device. See the corresponding chip-specific information or the device data sheet for accurate details.

10.3.2.2 Data buffer

The uSDHC module uses one configurable data buffer to transfer data between the system bus (IP bus or advanced extensible interface (AXI) bus) and the SD card in an optimized manner, maximizing throughput between the two clock domains (IP peripheral clock and the master clock).

The buffer is used as a temporary storage for transferring data between the host system and the card. The watermark levels for read and write are both configurable and can range between 1 to 128 words. When using internal DMA mode, The watermark level for read should be configured to 16 and watermark level for write should be configured to integral multiple of 16 to get max AXI bus throughput. The next figure provides the uSDHC buffer scheme.

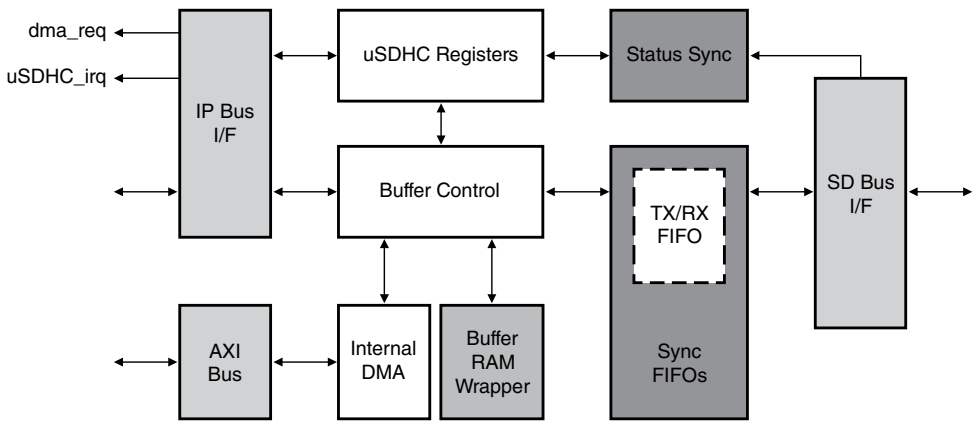

Figure 10-58. uSDHC buffer scheme

Here are 3 transfer modes to access the data buffer:

- CPU polling mode:
  - For a host-read operation, when the number of words received in the buffer meets or exceeds the RD_WML watermark value, by polling the BRR bit, the host driver can read the Buffer Data Port register to fetch the amount of words set in the RD_WML register from the buffer. The write operation is similar. For more information on the process of writing operation, see Write operation sequence.
- External DMA mode:
  - For a read operation, when there are more words received in the buffer than the amount set in the WTMK_LVL[RD_WML], a DMA request is sent out to inform the external DMA to fetch the data. The request will be immediately de-asserted when there is an access on the Buffer Data Port (DATA_BUFF_ACC_PORT) register. If the number of words in the buffer after the current burst meets or exceeds RD_WML value, the DMA request is asserted again. For instance, if there are twice as many words in the buffer as there are in

the WTMK_LVL[RD_WML] value, there are two successive DMA requests with only one cycle of de-assertion between. The write operation is similar. Note the accesses CPU polling mode and external DMA mode both use the IP bus, and if the external DMA is enabled, in both modes an external DMA request is sent when the buffer is ready.

- Internal DMA mode (includes simple and advanced DMA accesses):
  - The internal DMA access, either by simple or advanced DMA, is over the AXI bus. For internal DMA access mode, the external DMA request will never be sent out.

For a read operation, when there are more words in the buffer than the amount set in the RD_WML register, the internal DMA starts fetching data over the AXI bus.

The Write operation functions in a similar manner—sequential and contiguous access is necessary to ensure that the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actual byte order is swapped inside the buffer, according to the endian mode configured by software (see the following figures). For a host write operation, the byte order is swapped after the data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, the byte order is swapped before the data is stored in the buffer.

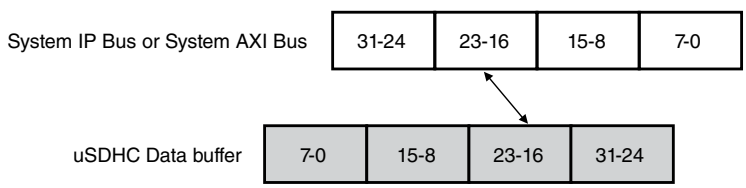

Figure 10-59. Data swap between system bus and uSDHC data buffer in the byte little endian mode

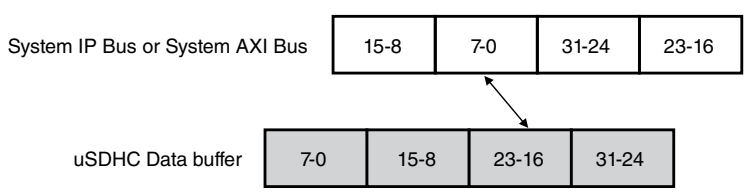

Figure 10-60. Data swap between system bus and uSDHC data buffer in half word big endian mode

10.3.2.2.1 Write operation sequence

There are 3 ways to write data into the buffer when the user transfers data to the card:

- External DMA through the uSDHC DMA request signal

- Processor core polling through the BWR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

When the internal DMA is not used, the DMAEN bit in the Transfer Type register is not set when the command is sent, uSDHC asserts a DMA request when the amount of buffer space exceeds the value set in the WTMK_LVL[WR_WML] bit field and is ready for receiving new data. At the same time, uSDHC sets the BWR bit. The buffer write ready interrupt is generated if it is enabled by software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC aborts the data transfer and abandons the current block. The host driver should read the contents of the DMA System Address register to obtain the starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the write operation from that address. It is recommended that a software reset for Data be applied before the transfer is restarted.

The uSDHC module does not start data transmission until the buffer has been filled with the number of words set in the WR_WML register. If the buffer is empty and the host system does not write data in time, uSDHC stops the CLK to avoid the data buffer underrun situation.

10.3.2.2.2 Read operation sequence

There are 3 ways to read data from the buffer when the data is received from the card:

- External DMA through uSDHC DMA request signal
- Processor core polling through the BRR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

When internal DMA is not used (DMAEN bit in Transfer Type register is not set when the command is sent), uSDHC asserts a DMA request when the amount of data exceeds the value set in the RD_WML register, which is available and ready for system fetching data. At the same time, uSDHC sets the BRR bit. The buffer read ready interrupt is generated if it is enabled by the software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC aborts the data transfer and abandons the current block. The host driver should read the content of the DMA System Address register to get the

starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the read operation from that address. It is recommended that a software reset for data be applied before the transfer is restarted.

For any write transfer mode, uSDHC does not start data transmission until the number of words set in the RD_WML register are in buffer. If the buffer is full and the host system does not read data in time, uSDHC stops the CLK to avoid the data buffer overrun situation.

10.3.2.2.3 Data buffer and block size

In the uSDHC module, the data buffer can hold up to 256 words (32-bit) and the watermark levels for write and read can be configured accordingly. The user needs to know the buffer size for the buffer operation during a data transfer to utilize it in the most optimized way.

The host driver may configure the value according to the system and requirement.

During a multi-block data transfer, the block length can be set to any value between 1 and 4096 bytes, satisfying the requirements of the external card. The only restriction is from the external card, which can be limited in size or support of a partial block access (which is not the integer times of 512 bytes).

As uSDHC treats each block individually, for block sizes which are not multiples of four (not word-aligned), stuffed bytes are required at the end of each block. For example, if the block size is 7 bytes and there are 12 blocks to write, the software side must write twice for each block. For each block, the ending byte is abandoned by uSDHC because it only sends 7 bytes to the card and picks data from the following system write, resulting in 24 beats of write access in total.

10.3.2.2.4 Dividing large data transfer

This SDIO command CMD53 definition limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in multiples of block size. If the total data length cannot be divided evenly into a multiple of the block size, then there are two options to transfer the data. These two options depend on the function and the card design. Option 1 is for the host driver to split the transaction. The remainder of the block

size data is then transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

See the figure below for an example showing the division of large data transfers, assuming a kind of WLAN SDIO card that only supports a block size of up to 64 bytes. Although uSDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size of less than 64 bytes, so the data must be divided (see the example below).

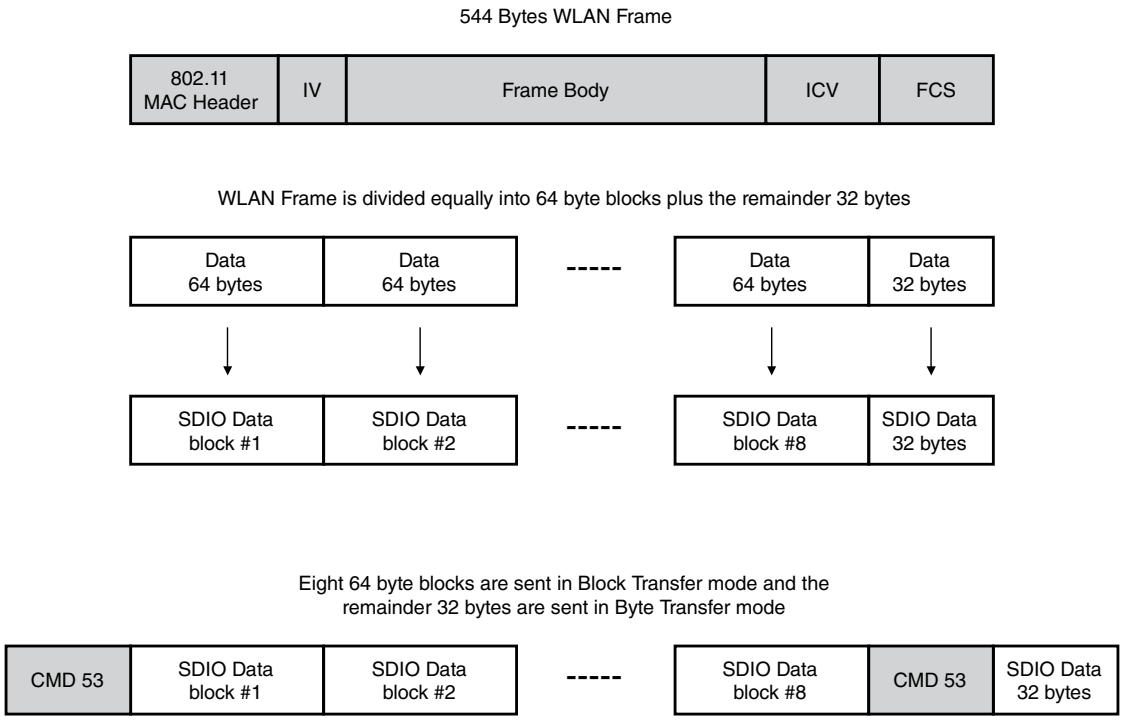

Figure 10-61. Example for dividing large data transfers

10.3.2.2.5 External DMA Request

When the internal DMA is not in use and external DMA is enabled, the Data Buffer will generate a DMA request to the system. During a write operation, when the number of WR_WML words can be held in the buffer free space, the signal uSDHC_dreq_b is asserted to 0, informing the Host System of a DMA write.

The BWR bit in the Interrupt Status register is also set, as long as the BWRSEN bit in the Interrupt Status Enable register is set. The DMA request is de-asserted after several accesses to the Data Port (DATA_BUFF_ACC_PORT) register are made while the buffer's free space can't meet the watermark condition (free space> write watermark level).

On read operation, when the number of RD_WML words are already in the buffer, the signal uSDHC_dreq_b is asserted to 0, informing the Host System for a DMA read. The BRR bit in the Interrupt Status register is also set, as long as the BRRSEN bit in the Interrupt Status Enable register is set. The DMA request is de-asserted after several accesses to the Data Port register are made while the buffer's data can't meet the watermark condition (the number of data in buffer > read watermark level).

If the DMA burst length can't change during a data transfer for an external DMA transfer, the watermark level (read or write) must be a divisor of the block size. If it is not, transferring the block may cause buffer under-run (read operation) or over-run (write operation). For example, if the block size is 512 bytes, the watermark level of read (or write) must be a power of two between 1 and 128. For processor core polling access there is no such issue, as the last access in the block transfer can be controlled by software. The watermark level can be any value, even larger than the block size (but no greater than 128 words) because the actual number of bytes transferred by the software can be controlled and does not exceed the block size in each transfer.

The uSDHC also supports non-word aligned block size, as long as the card supports that block size. In this case, the watermark level should be set as the number of words. For example, if the block size is 31 bytes, the watermark level can be set to any number of words. For this case, the BLKSIZE bits of the Block Attribute register will be set as 1fh. For the CPU polling access, the burst length can be 1 to 128 words, without restriction. This is because the software will transfer 8 words, and the uSDHC will also set the BWR or BRR bits when the remaining data does not violate data buffer. See for more details about the dynamic watermark level of the data buffer.

For the above example, even though 8 words are transferred via the DATA_BUFF_ACC_PORT register, the uSDHC will transfer only 31 bytes over the SD Bus, as required by the BLKSIZE bits. In this data transfer, with non-word aligned block size, the endian mode should be set cautiously or invalid data will be transferred to and from the card.

10.3.2.3 DMA AXI interface

The internal DMA implements a DMA engine and the AXI master. When the internal DMA is enabled, but the BWR and BRR bits are set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register.

See the figure below for an illustration of the DMA AXI interface block.

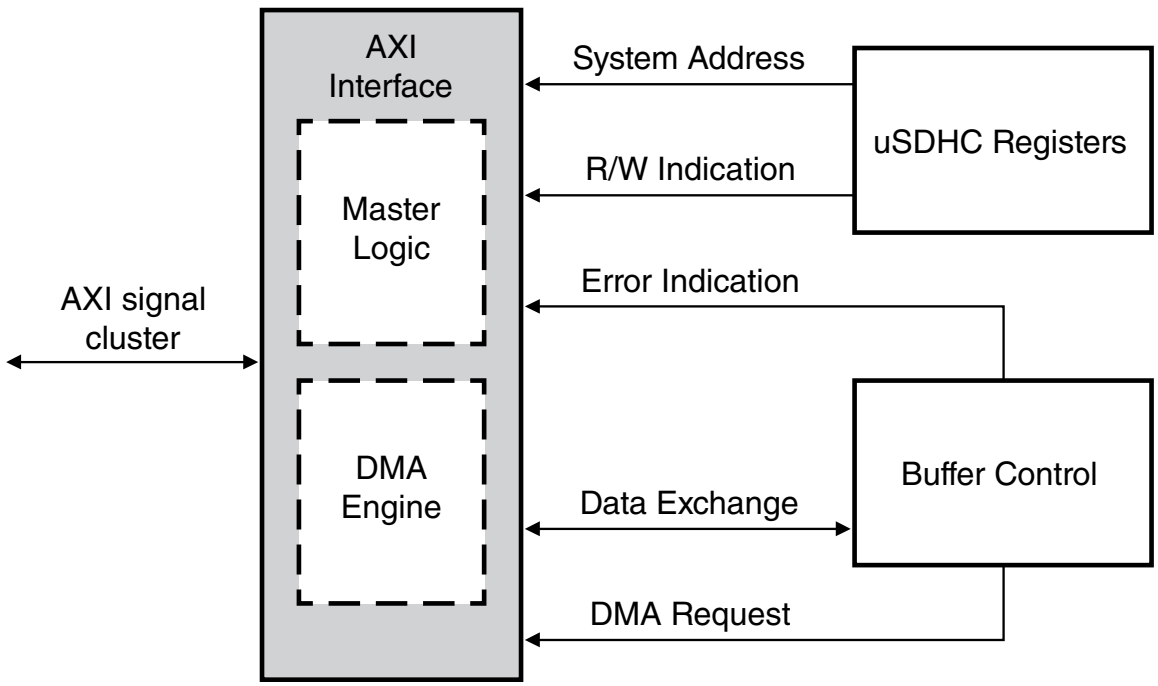

Figure 10-62. DMA AXI interface block

10.3.2.3.1 Internal DMA request

If the watermark level requirement is met in data transfer or if the last data of current block is ready in the data buffer, and the Internal DMA is enabled, the data buffer block sends a DMA request to AXI interface.Meanwhile, the external DMA request signal (uSDHC_dreq_b) is disabled.

The delay in response from the internal DMA engine depends on the system AXI bus loading and the priority assigned to uSDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The data buffer de-asserts the request if the data buffer space (for write) or bytes in data buffer is smaller than the watermark level. Upon access to the buffer by internal DMA, the data buffer updates its internal buffer pointer, and when the watermark level is satisfied or the last data of the current block is ready in the data buffer, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the watermark level set to six words (24 bytes). After the first burst transfer, if there are greater than or equal to two words in the buffer, which might contain some data of the next block), another DMA request is sent. This is because the remaining number of words to send for the current block is ceiling((31 - 6 * 4) / 4) = 2. The uSDHC module reads two words out of the buffer, with seven valid bytes and one stuffed byte.

10.3.2.3.2 AXI master interface

It is possible that the internal AXI DMA engine could fail during the data transfer. Upon detection of an AXI bus error during DMA transfer, the DMA engine stops the transfer and goes to the idle state. At that point, the internal data buffer stops receiving incoming data and sending out data. The DMAE bit in the Interrupt Status register is generated to host CPU to report a bus error condition.

After the DMAE interrupt is received, the software sends a CMD12 to abort the current transfer and read the DS_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and restart the transfer from this address to recover the corrupted block. DMA operation resumes when the interrupt is serviced by the software.

10.3.2.3.3 ADMA engine

In the SD host controller standard, a new DMA transfer algorithm called the Advanced DMA (ADMA) is defined. For simple DMA, after the page boundary is reached, a DMA interrupt is generated and the new system address is programmed by the host driver.

The ADMA defines the programmable descriptor table in the system memory. The host driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized because the host MCU intervention is not be needed during long DMA-based data transfers.

There are two types of ADMA in host controller: ADMA1 and ADMA2. ADMA1 can support data transfer of 4KB aligned data in system memory, and ADMA2 eliminates the restriction so that the data of any location and any size can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA can recognize all kinds of descriptors defined in SD host controller Standard, and if the "End" flag is detected in the descriptor, ADMA stops after this descriptor is processed.

10.3.2.3.3.1 ADMA concept and descriptor format

ADMA1 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Set data length descriptor
- Set data address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA2 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Rsv descriptor (new in ADMA2)
- Set data length and address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA starts read/write operation after it reaches the tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last set type descriptor before the tran type descriptor. Every tran type descriptor triggers a transfer, and the transfer data length is extracted from the most recent set type descriptor. If there is no set type descriptor after the previous Trans descriptor, the data length is the value for previous transfer, or 0 if no set descriptor is ever met.

For ADMA2, the tran type descriptor contains both data length and transfer data address, so the tran type descriptor itself can start a data transfer.

See the figure below for the format of the descriptor table for ADMA1.

Address/ Page Field		Address/ Page Field		Attribute Field					
31	12	11	6	5	4	3	2	1	0
Address or Data Length		000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	31- 28	27- 12
0	0	Nop	No Operation	Don't Care	
0	1	Set	Set Data Length	0000	Data Length
1	0	Tran	Transfer Data	Data Address	
1	1	Link	Link Descriptor	Descriptor Address	

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 10-63. Format of the ADMA1 descriptor table

See the figure below for the concept and access method of the descriptor table for ADMA1.

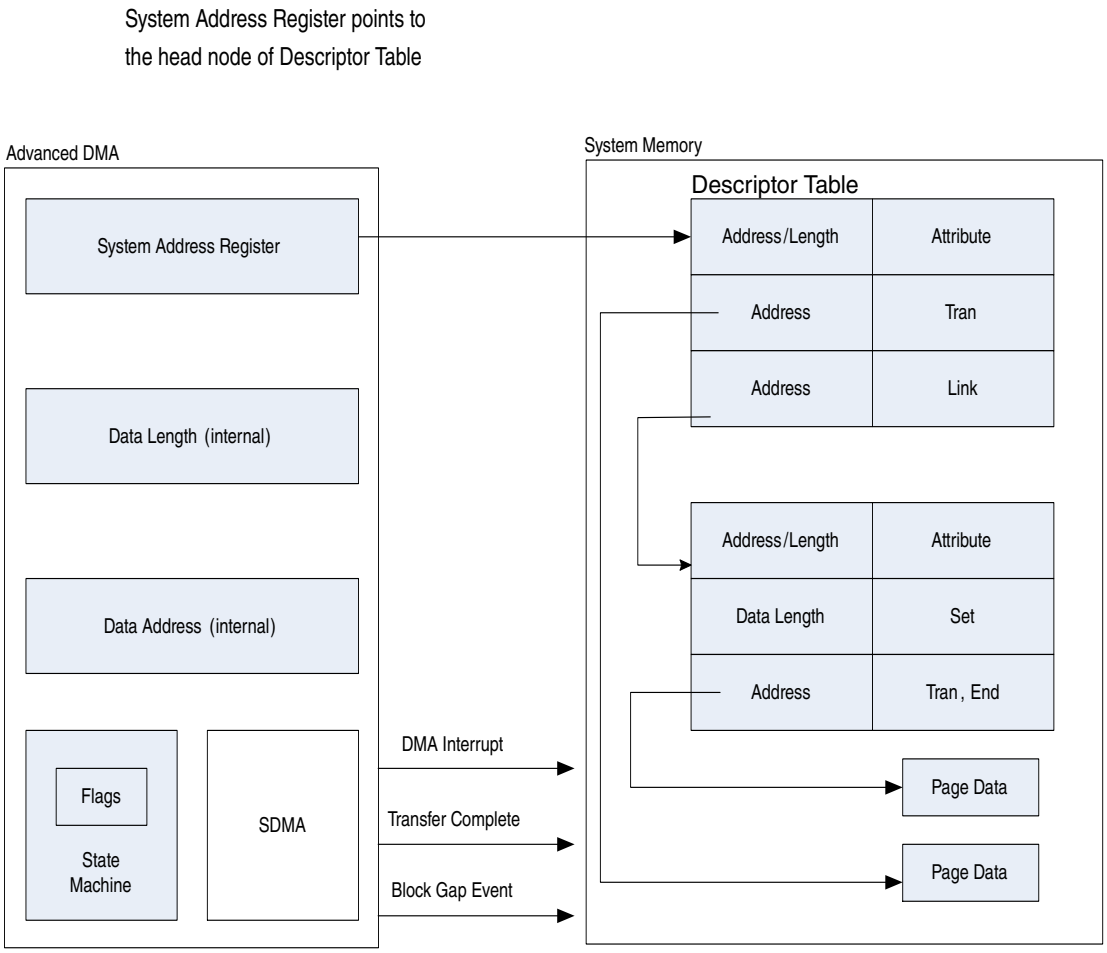

Figure 10-64. Concept and access method of the ADMA1 descriptor table

The figure below explains the ADMA2 format. ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it ignores the higher 32-bit. The Address field should be set to word aligned (lower 2-bit is always set to 0). Data length is in byte unit.

Address Field		Length		Reserved		Attribute Field					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit Address		16-bit length		0000000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	Operation
0	0	Nop	No Operation	Don't Care
0	1	Rsv	Reserved	Same as Nop. Read this line and go to next one
1	0	Tran	Transfer Data	Transfer data with address and length set in this descriptor line
1	1	Link	Link Descriptor	Link to another descriptor

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 10-65. Format of the ADMA2 descriptor table

See the figure below for the concept and access method of the descriptor table for ADMA2.

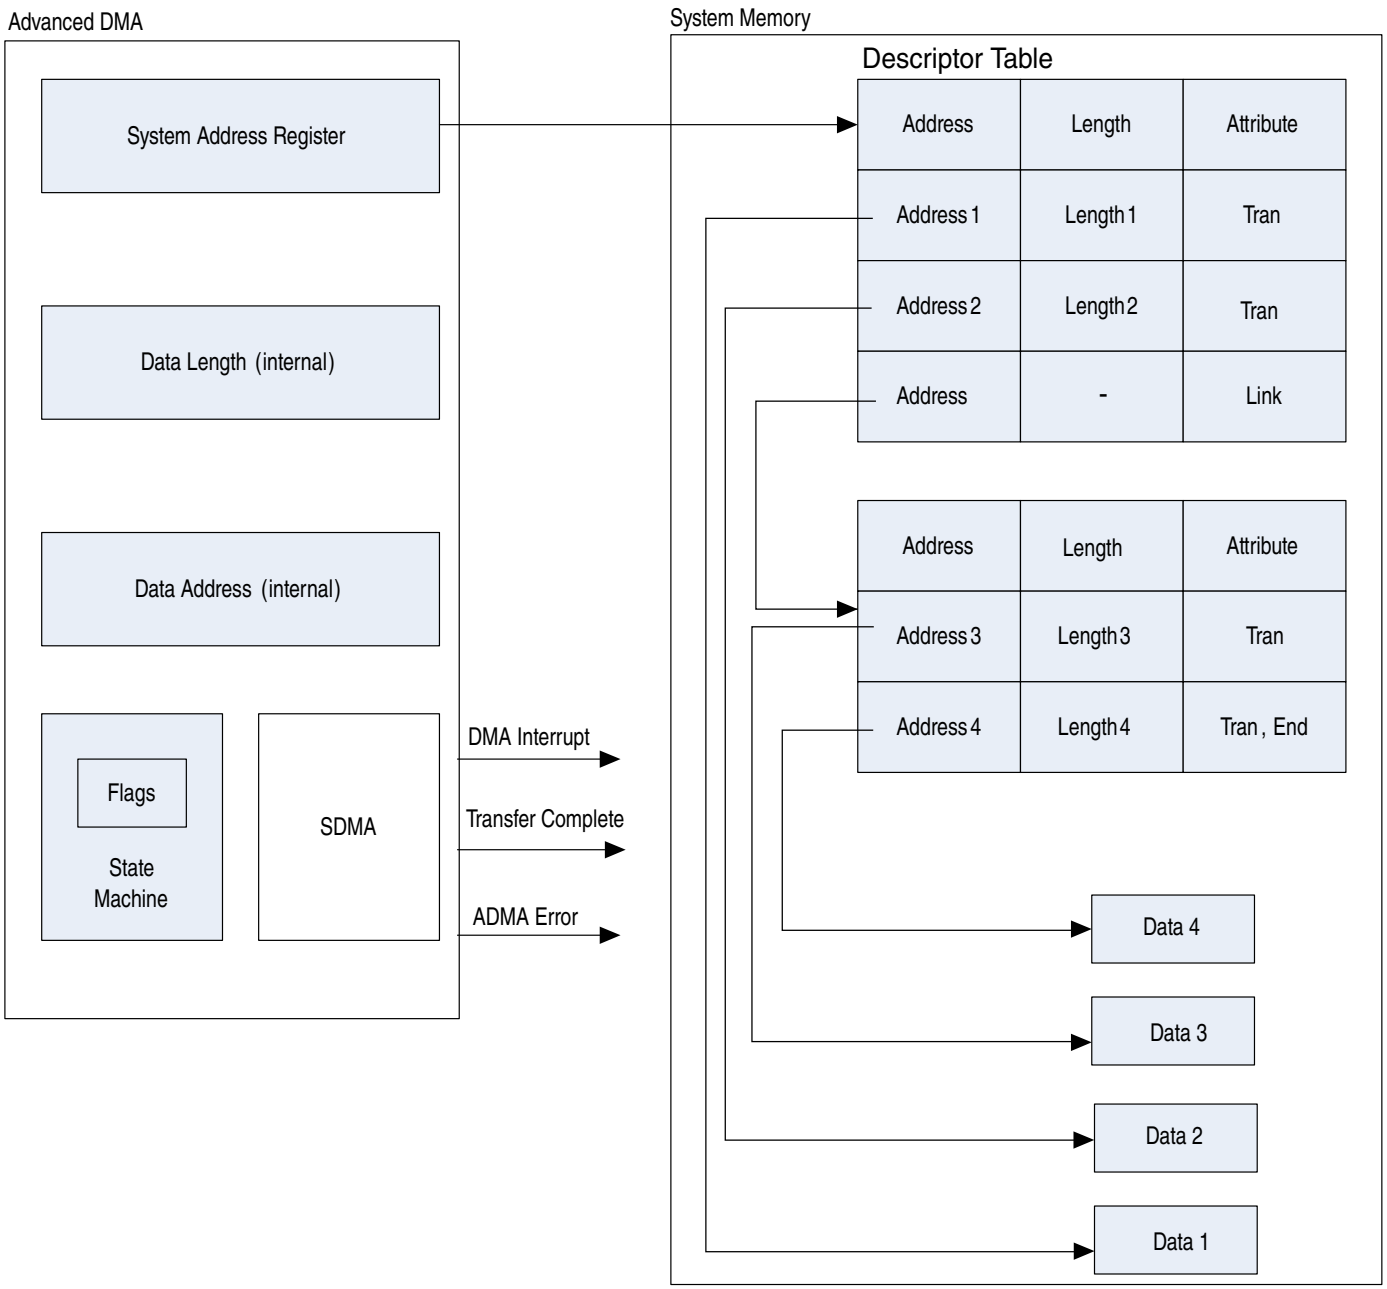

Figure 10-66. Concept and access method of the ADMA2 descriptor table

10.3.2.3.3.2 ADMA interrupt

If the interrupt flag descriptor is set, ADMA generates an interrupt according to various types of descriptors.

For ADMA1:

- Set type of descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop type of descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type of descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type of descriptor: interrupt is generated just after this descriptor is fetched.

10.3.2.3.3.3 ADMA error

The ADMA stops whenever an error is encountered. These errors include:

- Fetching descriptor error
- AXI response error
- Data length mismatch error

An ADMA descriptor error is generated when it fails to detect a "valid" flag in the descriptor. If an ADMA descriptor error occurs, the interrupt is not generated even if the "Interrupt" flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in buffer must be equal to the whole data length set in descriptor nodes, otherwise data length mismatch error is generated.

When BLKCNTEN bit is not set, then the whole data length set in descriptor is a multiple of block lengths; otherwise, when data set in the descriptor nodes are not performed at block boundaries, then data mismatch errors occur.

10.3.2.4 Register bank with IP bus interface

Register accesses through the IP bus interface are on the register bank.

See the figure below for the block diagram.

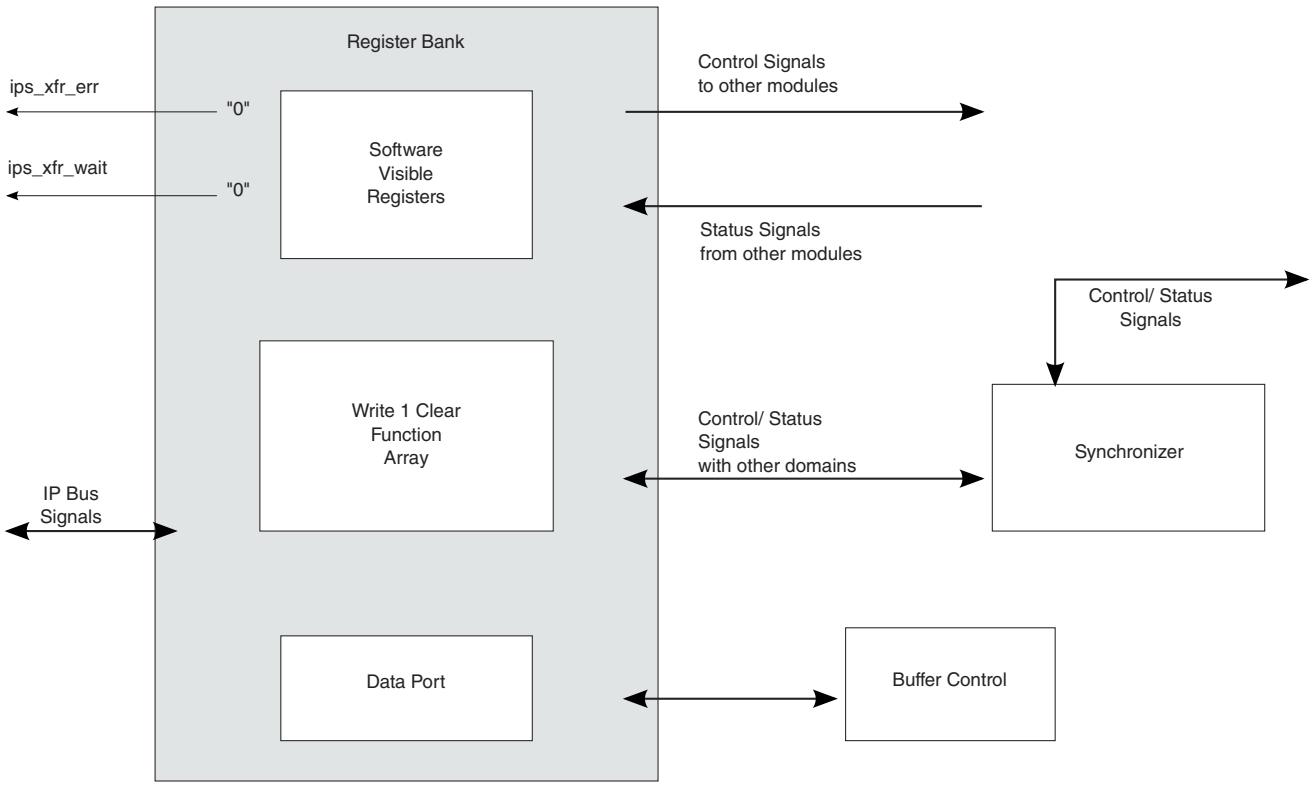

Figure 10-67. Register bank diagram

Only a 32-bit access is allowed, and no partial read/write is supported; therefore, all accesses are word aligned.

Access to an unimplemented address within the register memory map space does not generate a transfer error.

10.3.2.4.1 SD protocol unit

The SD protocol unit deals with all SD protocol affairs.

The SD protocol unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the CMD/DAT lines
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD protocol unit consists of four submodules:

- SD control misc
- Command control
- Data control
- Clock control

10.3.2.4.2 SD control misc

In the SD control misc unit:

- The card detection (including CD_B and DATA3 for card detection) and card interrupt are implemented.
- The module monitors the signal level on all the eight data lines and the command lines. It directly routes the level values into the register bank.
- The module also detects the Write Protect (WP) line. If WP is active, writes to the register bank are ignored.

10.3.2.4.3 SD clock control

If the internal data buffer is near full (for read) or near empty (for write), the SD clock must be gated off to avoid buffer over/under-run. This module asserts the gate of the output SD clock to shut the clock off. After the buffer has space (for read) or has data (for write), the clock gate of this module opens, and the SD clock is active again.

10.3.2.4.4 Command control

The Command Control module deals with the transactions on the CMD line.

See the figure below for an illustration of the structure for the Command CRC shift register.

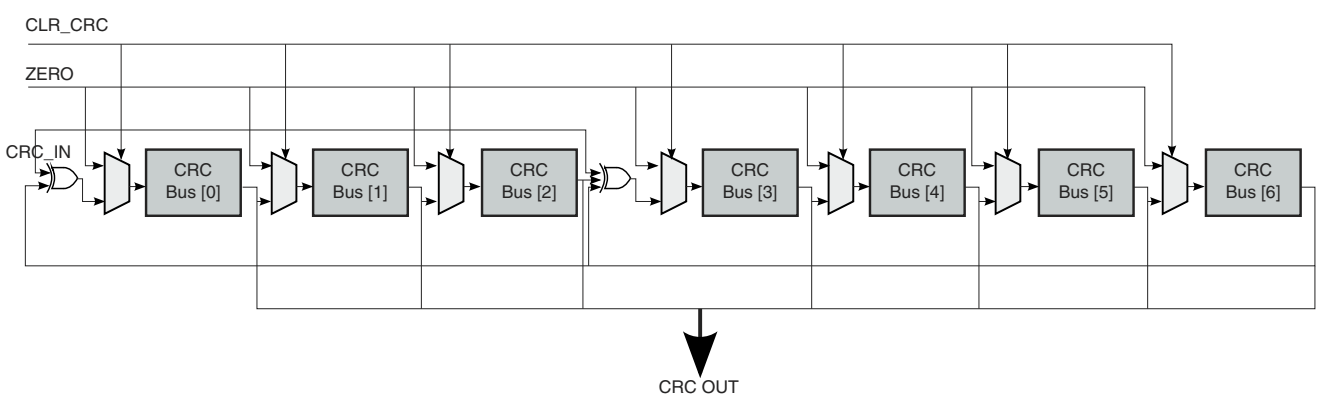

Figure 10-68. Command CRC shift register

The CRC polynomials for the CMD are as follows:

Generator polynomial: $G(x) = x^7 + x^3 + 1$
$M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + ... + (\text{last bit}) * x^0$
$CRC[6:0] = \text{Remainder } [(M(x) * x^7) / G(x)]$

10.3.2.4.5 Data control

The data agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DATA0 line and generates the read wait state by the request from the transceiver.

The CRC polynomials for the data are as follows:

Generator polynomial: $G(x) = x^{16} + x^{12} + x^5 + 1$

$M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + ... + (\text{last bit}) * x^0$

$CRC[15:0] = \text{Remainder } [(M(x) * x^{16}) / G(x)]$

10.3.2.5 Card insertion and removal detection

The uSDHC module uses either the DATA3 pin or the CD_B pin to detect card insertion or removal. When there is no card on the MMC/SD bus, the DATA3 is pulled to a low voltage level by default.

When any card is inserted to or removed from the socket, uSDHC detects the logic value changes on the DATA3 pin and generates an interrupt. When the DATA3 pin is not used for card detection (for example, it is implemented in GPIO), the CD_B pin must be connected for card detection. Whether DATA3 is configured for card detection or not, the CD_B pin is always a reference for card detection. Whether the DATA3 pin or the CD_B pin is used to detect card insertion, uSDHC sends an interrupt (if enabled) to inform the Host system that a card is inserted.

10.3.2.6 Power management and wakeup events

When there is no operation between uSDHC and the card through the SD bus, the user can completely disable the peripheral clock and base clock in the chip-level clock control module to save power. When the user needs to use uSDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to uSDHC are disabled, for instance, when the system is in low-power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The uSDHC module can generate these interrupts even when there are no clocks enabled. The three interrupts that can be used as wakeup events are these:

- Card removal interrupt
- Card insertion interrupt
- Interrupt from SDIO card (not available in multiple block data transfers)

The uSDHC module offers a power management feature. By clearing the clock enabled bits in the System Control (SYS_CTRL) register, the clocks are gated in the low position to uSDHC. For maximum power saving, the user can disable all the clocks to uSDHC when there is no operation in progress.

These three wakeup events (or wakeup interrupts) can also be used to wakeup the system from low-power modes.

NOTE

To make the interrupt a wakeup event, when all the clocks to uSDHC are disabled or when the entire system is in low power mode, the corresponding wakeup enabled bit needs to be set. Refer to Protocol Control (PROT_CTRL) for more information on the uSDHC Protocol Control register.

10.3.2.6.1 Setting wakeup events

For uSDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters the sleep mode.

Before the software disables the host clock, it should ensure that all the following conditions have been met:

- No read or write transfer is active
- Data and command lines are not active
- No interrupts are pending
- Internal data buffer is empty

10.3.2.7 MMC fast boot

The Embedded MultiMediaCard (eMMC4.3) specification adds a fast boot feature that requires hardware support. There are two types of fast boot modes in the eMMC4.3 specification: boot operation and alternative boot operation. Each type also has with-acknowledge and without-acknowledge modes.

In the boot operation mode, the master (MultiMediaCard host) can read boot data from the slave (MMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFA (optional for slave), before issuing CMD1.

NOTE

For the eMMC4.3 card setting, please see the eMMC4.3 specification.

10.3.2.7.1 Boot operation

If the CMD line is held low for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after the CMD line goes low, the slave starts to send the first boot data to the master on the DATA line(s). The master must keep the CMD line low to read all of the boot data.

NOTE

For the purposes of this documentation, fast boot is called "normal fast boot mode".

If boot acknowledge is enabled, the slave has to send acknowledge pattern '010' to the master within 50ms after the CMD line goes low. If boot acknowledge is disabled, the slave does not send out acknowledge pattern '010'.

The master can terminate the boot mode with the CMD line high.

The boot operation is terminated when all the contents of the enabled boot data are sent to the master. After the boot operation is executed, the slave gets ready for the CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

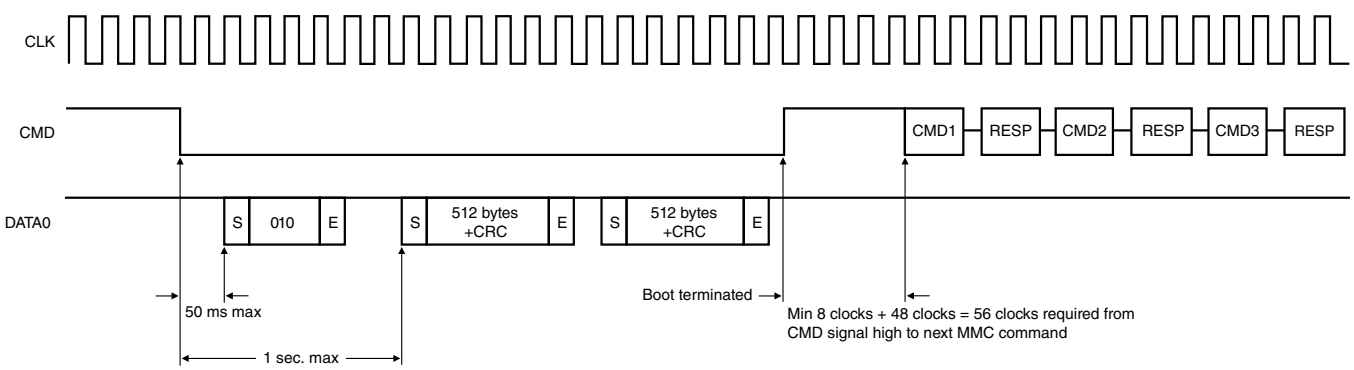

Figure 10-69. MultiMediaCard state diagram (normal boot mode)

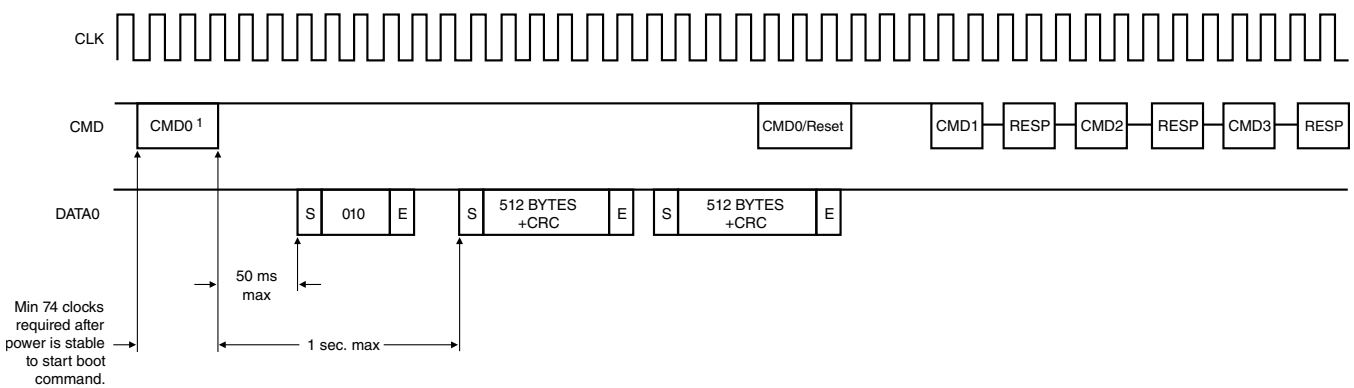
10.3.2.7.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.



After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFA after 74 clock cycles, before CMD1 is issued or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after CMD0 with the argument of 0xFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DATA line(s).

If boot acknowledge is enabled, the slave must send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFA is received. If boot acknowledge is disabled, the slave does not send out acknowledge pattern '010'.

The master can terminate the boot mode by issuing CMD0 (Reset).

Boot operation is terminated when all the contents of the enabled boot data are sent to the master. After the boot operation is executed, the slave gets ready for the CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

NOTE 1: CMD0 with argument 0xFFFFFFFA

Figure 10-70. MultiMediaCard state diagram (alternative boot mode)

10.3.2.8 Commands for MMC/SD/SDIO

A table containing the list of commands for the MMC/SD/SDIO cards is provided here.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the MultiMediaCard:

- Broadcast commands (bc), no response
- Broadcast commands with response (bcr), response from all cards simultaneously
- Addressed (point-to-point) commands (ac), no data transfer on the DATA
- Addressed (point-to-point) data transfer commands (adtc)

Response: A response is a token that is sent from the card to the host as an answer to a previously received command. A response is transferred serially on the CMD line.

Table 10-32. Commands for MMC/SD/SDIO cards

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all MMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all MMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3[1]	ac	[31:6] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_ADDR	Assigns relative address to the card.
CMD4	bc	[31:0] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO cards in idle state to send them operation conditions register contents in the response on the CMD line.
CMD6[2]	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.
CMD6[3]	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:6] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.

Table continues on the next page...

Table 10-32. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.
CMD13	ac	[31:6] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:6] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	adtc	[31:0] reserved bits(all 0)	R1	SEND_TUNING_BLOCK	64 bytes tuning pattern is sent for SDR50 and SDR104.
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISION follows.
CMD21	adtc	[31:0] stuff bits	R1	SEND_TUNING_BLOCK	128 clocks of tuning pattern (64 byte in 4 bit mode or 128 byte in 8 bit mode) is sent for HS200 optimal sampling point detection.
CMD22-23	Reserved				
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.

Table continues on the next page...

Table 10-32. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command is issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.
CMD39	ac	[31:0] RCA [15] register write flag	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if

Table continues on the next page...

Table 10-32. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
		[14:8] register address [7:0] register data			the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the MMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather than a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57-59	Reserved				
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 is used to read and write these registers.
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer.
CMD62-63	Reserved				

Table continues on the next page...

Table 10-32. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
ACMD6[4]	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13[4]	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.
ACMD22[4]	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23[4]	ac	[31:23] stuff bits [22:0] Number of blocks	R1	SET_WR_BLK_ERASE_COUNT	Set the number of write blocks to be pre-erased before writing (to be used for fast Multiple Block WR command). "1"=default(one write block).
ACMD41[4]	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42[4]	ac	[31:1] stuff bits [0] set_cd	R1	SET_CLR_CARD_DETECT	Connect(1)/Disconnect(0) the 50KOhm pull-up resistor on CD_B/DATA3 of the card.
ACMD51[4]	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high-speed SD cards. Command SWITCH_FUNC is for high-speed SD cards.
3. Command SWITCH is for high speed MMC cards. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 2.
4. ACMDs is preceded with the APP_CMD command. Commands listed are used for SD only, other SD commands not listed are not supported on this module.

The access bits for the EXT_CSD access modes are listed in the following table.

Table 10-33. EXT_CSD access modes

Bits	Access name	Operation
00	Command set	The command set is changed according to the Cmd Set field of the argument.
01	Set bits	The bits in the pointed byte are set, according to the bits set to 1 in the Value field.
10	Clear bits	The bits in the pointed byte are cleared, according to the bits set to 1 in the Value field.
11	Write byte	The Value field is written into the pointed byte.

10.3.2.9 Clocks

The table found here describes the clock sources for uSDHC. For more information on clocking, see the Clocking chapter.

Table 10-34. Clocks

Clock name	Description
hclk	Bus clock
ipg_clk	Peripheral clock
ipg_clk_s	Peripheral access clock for register access
ipg_clk_perclk	Base clock

10.3.2.10 Clock and reset manager

This module controls all four kinds reset signals within uSDHC:

- Hardware reset
- Software reset for all logic
- Software reset for the data logic
- Software reset for the command logic

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

10.3.2.11 Clock generator

The clock generator generates the card CLK by peripheral source clock in two stages. The clock divisor can be configured through register SYS_CTRL [SDCLKFS] for prescaler configuration while the [DVS] for divisor configuration. Details can be found in the register function description. See the following figure for the structure of the divider. The term "Base" represents the frequency of peripheral source clock.

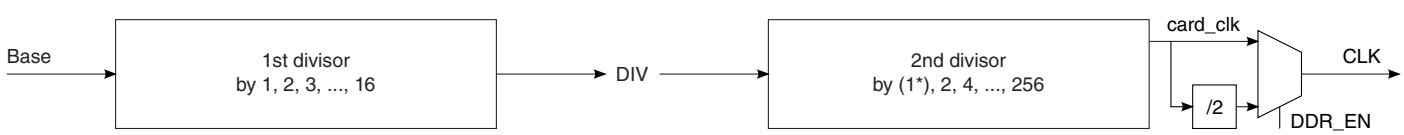


Figure 10-71. Two stages of the clock divider

The first stage outputs an intermediate clock (DIV) that can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler and outputs the actual internal working clock (card_clk). This clock is the driving clock for all the sub modules of the SD protocol unit, and helps in syncing FIFOs (see Figure 10-58) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage can be DIV, DIV/2, DIV/4,..., or DIV/256. Therefore, the highest frequency of the card_clk is base, and the next highest is Base/2, while the lowest frequency is Base/4096. If the duty cycle of the base clock is 50%, the duty cycle of card_clk is also 50%, even when the compound divisor is an odd value.

NOTE

CLK is different for the SDR and DDR modes.

- In the SDR mode, CLK is equal to the internal working clock (card_clk).

- In the DDR mode, CLK is equal to card_clk/2.

10.3.2.12 SDIO card interrupt

Information on interrupts in 1-bit mode, interrupts in 4-bit mode, and card interrupt handling are detailed in the sections below.

10.3.2.12.1 Interrupts in 1-bit mode

In this case, the DATA1 pin provides the interrupt function. An interrupt is asserted by pulling the DATA1 low from the SDIO card, until the interrupt service is finished to clear the interrupt.

10.3.2.12.2 Interrupt in 4-bit mode

As the interrupt and data line 1 share pin 8 in a 4-bit mode, an interrupt is only sent by the card and recognized by the host during a specific time. This is known as the interrupt period. The uSDHC module only provides samples the level on pin 8 during the interrupt period. At all other times, the host treats it as the data signal. The definition of the interrupt period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the interrupt period becomes active two clock cycles after the completion of a data packet. This interrupt period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in a 4-bit mode, there is only a limited period of time that the interrupt period can be active because of the limited period of data line availability between the multiple blocks of data. This requires stricter definition of the interrupt period. For this case, the interrupt period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DATA1 line holds low for one clock cycle, then pulls high for the next clock cycle . On completion of the interrupt period, the card releases the DATA1 line into the high Z state. The uSDHC module provides sample of the DATA1 during the interrupt period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Card Specification v1.10 for further information about the SDIO card interrupt.

10.3.2.12.3 Card interrupt handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, uSDHC clears the interrupt request to the host system. The host driver should clear this bit before servicing the SDIO interrupt, and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Card Interrupt Status can be cleared by writing 1 to this bit. But as the interrupt source from the SDIO card does not clear, this bit is set again. To clear this bit, it is required to reset the interrupt source from the external card followed by writing 1 to this bit. In a 1-bit mode, uSDHC detects the SDIO interrupt with or without the SD clock (to support wakeup). In a 4-bit mode, the interrupt signal is sampled during the interrupt period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the Host System Interrupt Controller. When the SDIO status is set and the host driver needs to service this interrupt, the SDIO bit in the Interrupt Control Register of SDIO card is cleared. This is required to clear the SDIO interrupt status latched in uSDHC and to stop driving the interrupt signal to the System Interrupt Controller. The host driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Status Enable bit is set to 1 and uSDHC starts sampling the interrupt signal again.

See the figure below for an illustration of the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

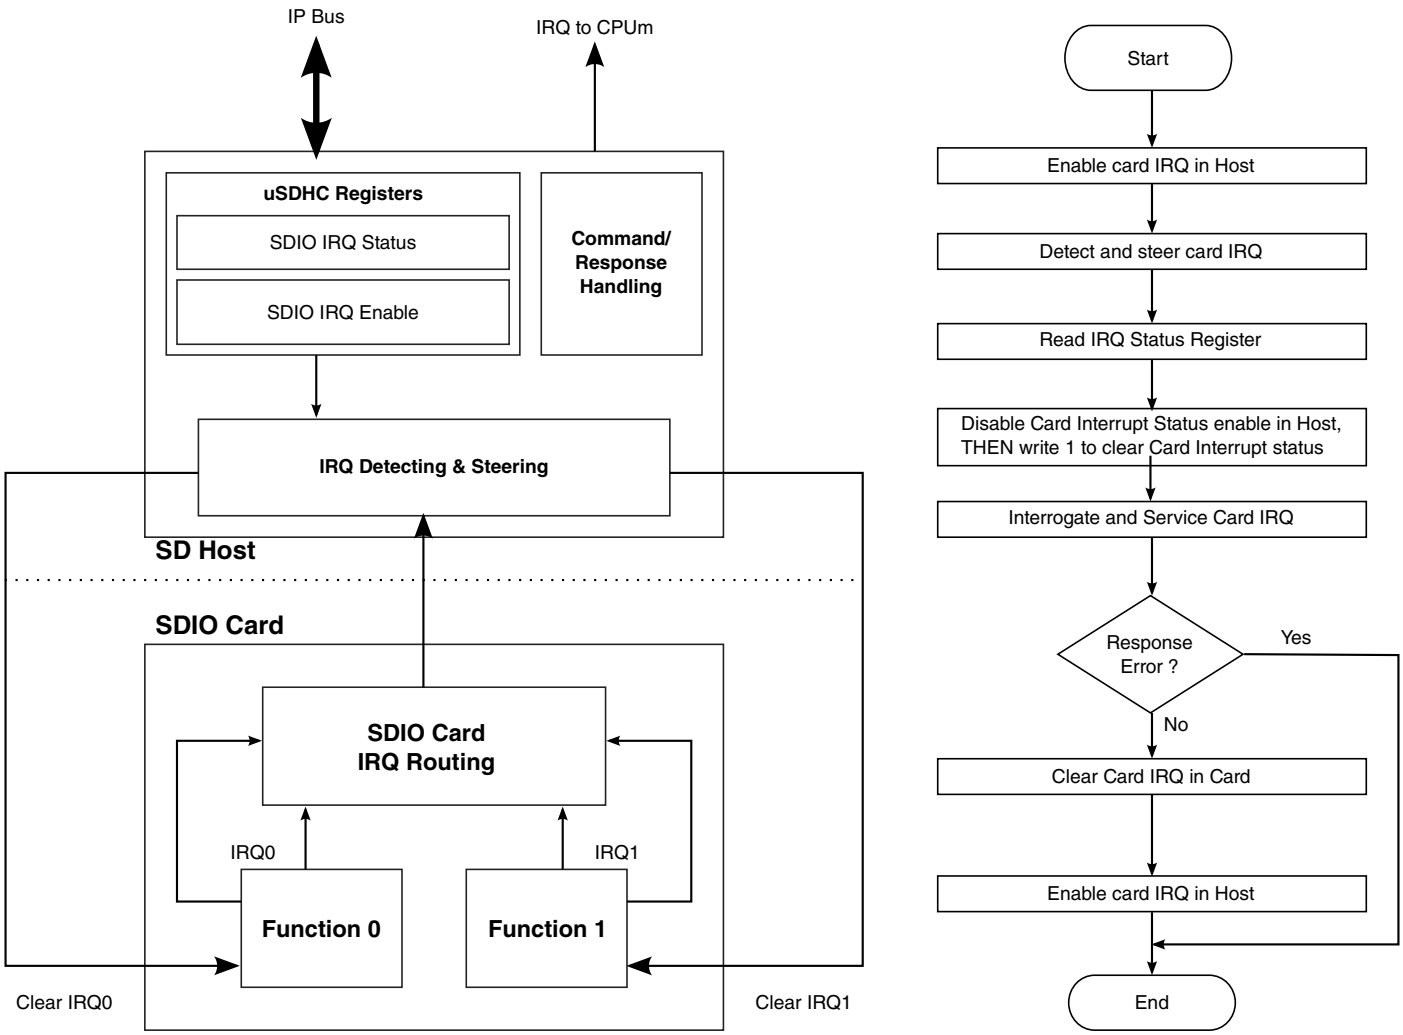

Figure 10-72. Card interrupt scheme, card interrupt detection, and handling procedure

10.3.3 External signals

The following table describes the uSDHC external signals:

Table 10-35. uSDHC external signals

Signal	Description	Direction
CLK	Clock for MMC/SD/SDIO card	O
CMD	CMD line connect to card	I/O
DATA7	DAT7 line in the 8-bit mode — Not used in other modes	I/O
DATA6	DAT6 line in the 8-bit mode — Not used in other modes	I/O

Table continues on the next page...

Table 10-35. uSDHC external signals (continued)

Signal	Description	Direction
DATA5	DAT5 line in the 8-bit mode — Not used in other modes	I/O
DATA4	DAT4 line in the 8-bit mode — Not used in other modes	I/O
DATA3	DAT3 line in the 4/8-bit mode or configured as card detection pin. The bit may be configured as card detection pin in the 1-bit mode.	I/O
DATA2	DAT2 line or Read Wait in the 4-bit mode Read Wait in 1-bit mode	I/O
DATA1	DAT1 line in the 4/8-bit mode Also, used to detect interrupt in 1/4-bit mode	I/O
DATA0	DAT0 line in all the modes Also, used to detect busy state	I/O
CD_B	Card detection pin If not used (for the embedded memory), tie low to indicate that there is a card attached.	I
WP	Card write protect detect If not used (for the embedded memory), tie low to indicate that it is not write protected.	I
RESET_B	Card hardware reset signal, active low	O
VSELECT	IO power voltage selection signal	O
STROBE	Input clock for eMMC HS400 mode	I

10.3.3.1 Signals overview

uSDHC has 15 associated I/O signals.

- The CLK is an internally generated clock used to drive the MMC, SD, and SDIO cards.
- The CMD I/O is used to send commands and receive responses to and from the card. Eight data lines (DAT7~DAT0) are used to perform data transfers between the uSDHC module and the card.
- The CD is card detection signal directly routed from the socket. This signal is active low (0). A low on CD# means that a card is inserted. It is optional for system implementation.
- The WP is write protection signals directly routed from the socket. This signal is active low (0). A high on WP means that the write protect switch is active. It is optional for system implementation.

- RST is an output signal used to reset the MMC card.
- VSELECT is an output signal used to change the voltage of the external power supplier. It is optional for system implementation.
- STROBE is input clock signal for eMMC HS400 mode.

If uSDHC needs to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high. If the uSDHC does not support the HS400 mode, STROBE can also be optional and tied to low.

10.3.4 Application of uSDHC

All communication between the system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as GO_IDLE_STATE, SEND_OP_COND, and ALL_SEND_CID. In the Broadcast mode, all cards are in the open-drain mode to avoid bus contention. Refer to Commands for MMC/SD/SDIO for the commands of bc and bcr categories.

After the broadcast command CMD3 is issued, the cards enter the standby mode. Addressed type commands are used from this point. In this mode, the CMD/DATA I/O pads turns to the push-pull mode to have the driving capability for maximum frequency operation. Refer to Commands for MMC/SD/SDIO for the commands of ac and adtc categories.

A uSDHC FIFO control problem exists with a software reset for a single block read. See MIX_CTRL[DTDSEL] for more information.

10.3.4.1 Command send & response receive basic operation

Assuming that the data type WORD is an unsigned 32-bit integer, the flow indicated below presents a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)
{
WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner
wCmd = (<cmd_index> & 0x3f) << 24; // set the first 8 bits as '00'+<cmd_index>
set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL accorind to the command index;
if (internal DMA is used) wCmd |= 0x1;
if (multi-block transfer) {
```

```
          set MSBSEL bit;
          if (finite block number) {
                    set BCEN bit;
                    if (auto12 command is to use) set AC12EN bit;
          }
}
write_reg(CMDARG, <cmd_arg>); // configure the command argument
write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
read IRQ Status register and check if any error bits about Command are set
if (any error bits are set) report error;
write 1 to clear CC bit and all Command Error bits;
}
```

For the sake of simplicity, the function wait_for_response is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. When doing this, make sure that the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and move to the Standby state no response to the Host when CMD2 is sent. The host driver deals with "fake" errors like this with caution.

10.3.4.2 Card identification mode

When a card is inserted to the socket or the card is reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for MMC cards.

10.3.4.2.1 Card detect

See the figure below for a flow diagram showing the detection of MMC, SD, and SDIO cards using uSDHC.

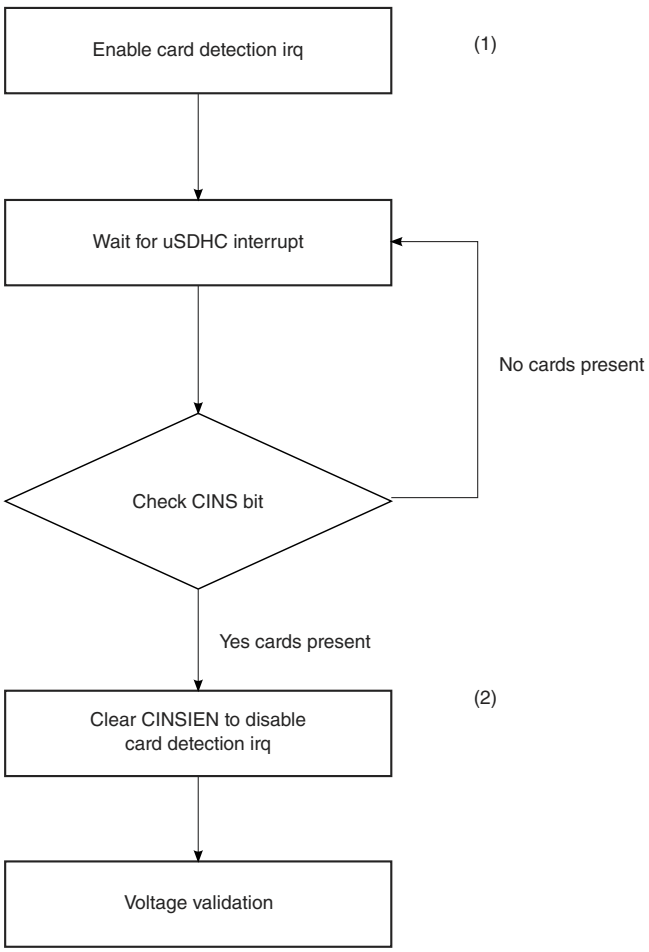

Figure 10-73. Flow diagram for card detection

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt.
- When an interrupt from uSDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion.
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards.

10.3.4.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) that is driven by Power On Reset (POR).

- Software reset (Host only) is initiated by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the host controller, respectively.
- Card reset (Card only): The command, "Go_Idle_State" (CMD0), is the software reset command for all types of MMC cards and SD memory cards. This command sets each card into the idle state regardless of the current card state. For an SDIO card, CMD52 is used to write an I/O reset in CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See the figure below for the software flow to reset both uSDHC and the card.

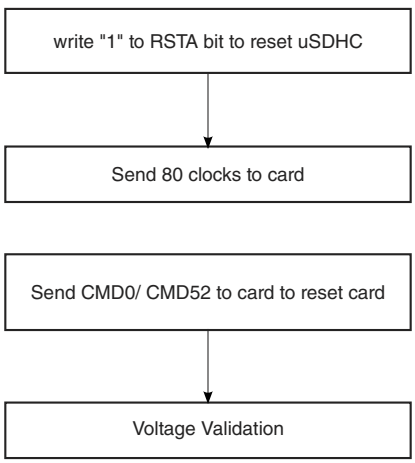

Figure 10-74. Flow chart for resetting uSDHC and SD I/O card

```
software_reset() { set_bit(SYSCTRL, RSTA); // software reset the Host set DTOCV and
      SDCLKFS bit fields to get the CLK of frequency around 400kHz configure IO pad to set
the power
      voltage of external card to around 3.0V poll bits CIHB and CDIHB bits of PRSSTAT to
wait both
      bits are cleared set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
      send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0 or
      send_command(CMD_IO_RW_DIRECT, <other parameters>); }
```

10.3.4.2.3 Voltage validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for VDD are defined in the Operation Conditions Register (OCR) and may not cover the whole range.

Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer VDD conditions. This means that if the host and card have non-common VDD ranges, the card is neither able to complete the identification cycle nor able to send CSD data.

Therefore, special commands Send_Op_Cont (CMD1 for MMC), SD_Send_Op_Cont (ACMD41 for SD Memory), and IO_Send_Op_Cont (CMD5 for SD I/O) are used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards that do not match the VDD range(s) desired by the host. This is accomplished when the host sends the desired VDD voltage window as the operand of this command. Cards that cannot perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive state. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive state. This query should be used if the host is able to select a common voltage range or if a notification is sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```
voltage_validation(voltage_range_arguement) { label the card as UNKNOWN;
      send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
      operation voltage, command argument is zero if (RESP_TIMEOUT !=
      wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted if (0 < number of IO
      functions) { label the card as SDIO; IORDY = 0; while (!(IORDY in IO OCR response))
{ // set
      voltage range for each IO function send_command(IO_SEND_OP_COND, <voltage range>,
      <other parameter>); wait_for_response(IO_SEND_OP_COND); } // end of while ... } // end
      of if (0 < ... if (memory part is present inside SDIO card) Label the card as
SDCombo; //
      this is an SD-Combo card } // end of if (RESP_TIMEOUT ... if (the card is labelled as
SDIO
      card) return; // card type is identified and voltage range is set, so exit the
function;
      send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application
      specific CMD prefix if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55
is
      accepted send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set
      voltage range for memory part or SD card wait_for_response(SD_APP_OP_COND); // voltage
range
      is set if (card type is UNKNOWN) label the card as SD; return; // } // end of if (no
error ...
      else if (errors other than time-out occur) { // command/response pair is corrupted
deal with
      it by program specific manner; } // of else if (response time-out else { // CMD55 is
refuse,
      it must be MMC card if (card is already labelled as SDCombo) { // change label re-
label the
      card as SDIO; ignore the error or report it; return; // card is identified as SDIO
card } //
      of if (card is ... send_command(SEND_OP_COND, <voltage range>, <...>); if
      (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted, either
label the
      card as UNKNOWN; return; } // of if (RESP_TIMEOUT ... } // of else }
```

10.3.4.2.4 Card registry

Card registry for the MMC and SD/SDIO/SD combo cards are different. For the SD card, the identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the card spec). Currently, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host requests the card to send their valid operation conditions.

The response to ACMD41 is the operation condition register of the card. The same command is sent to all the new cards in the system. Incompatible cards are put into the Inactive state. The host then issues the command, All_Send_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready state), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification state.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA is used to address the card for future data transfer operations. After the RCA is received, the card changes its state to the Standby state. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in the system.

For MMC operation, the host starts the card identification process in the open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line to allow parallel card operation during card identification. After the bus is activated, the host requests the cards to send their valid operation conditions (CMD1). The response to CMD1 is the "wired AND " operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive state. The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards (the cards in the Ready state) simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. As the CID is unique for each card, only one card can be successfully sent its full CID to the host. This card then goes into the Identification state. Thereafter, the host issues Set_Relative_Addr (CMD3) to assign a relative card address (RCA) to the card. After the RCA is received, the state of the card changes to standby, and the card does not react in further identification cycles. Also, its output driver switches

from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

The following steps show how to perform an operation using MMC cards:

```
card_registry() { do { // decide RCA for each card until response time-out
            if(card is labelled as SDCombo or SDIO) { // for SDIO card like device
            send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to publish its RCA
            retrieve RCA from response; } // end if (card is labelled as SDCombo ... else if
(card
            is labelled as SD) { // for SD card send_command(ALL_SEND_CID, <...>); if
            (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
send_command(SET_RELATIVE_ADDR,
            <...>); retrieve RCA from response; } // else if (card is labelled as SD ... else
            if (card is labelled as MMC) { send_command(ALL_SEND_CID, <...>); rca = 0x1; //
            arbitrarily set RCA, 1 here for example send_command(SET_RELATIVE_ADDR, 0x1 <<
16,
            <...>); // send RCA at upper 16 bits } // end of else if (card is labelled as MMC
            ... } while (response is not time-out); }
```

10.3.4.3 Card access

Information about Block Write, Block Read, Suspense Resume, ADMA Usage, Transfer Error, and Card Interrupt are detailed in the sections below.

10.3.4.3.1 Block write

Information on Normal Write, DDR Write, and Write with Pause are detailed in the sections below.

10.3.4.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card indicates that the failure on the DATA line. The transferred data is discarded and not written, and all further transmitted blocks (in multiple block write mode) are ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation is also aborted if the host tries to write over a write-protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card reports an error and does not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card begins writing and holds the DATA line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO cards at any time, and the card responds with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby state and release the DATA line without interrupting the write operation. When re-selecting the card, it reactivates the busy indication by pulling data to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other two methods (by means of external DMA orCPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
   - For SD/MMC cards, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or another error that occurred during the auto12 command sending and response receiving.

10.3.4.3.1.2 DDR write

uSDHC supports the dual data rate mode.

The software flow to write to a card in the DDR mode is described as below:

1. Check the card status and wait until the card is ready for data.

NOTE

For eMMC card, block length only can be set to 512byte.

2. Set the uSDHC number block register (NOB), where nob is 5, for instance.
3. Set the eMMC card to high-speed mode and use SWITCH(CMD6).
4. Set the eMMC card bus with 4-bit/8-bit DDR mode and use SWITCH(CMD6).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN and AC12EN bits should be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred or another error that occurred during the auto12 command sending and response receiving.

10.3.4.3.1.3 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the host driver, the driver can set the Stop At Block Gap Request (SABGREQ) bit in the Protocol Control register to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DATA0 line is not required to de-assert to release the busy state, no suspend command is needed.

Similar to the flow described in Normal Write, the write with pause is shown with the same kind of write operation:

1. Check the card status and wait until the card is ready for data.
2. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.

5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred or some another error that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The host driver reads the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt is received.

It is also possible that the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is the end of the transfer. These types of requests are ignored, the driver should treat these as a non-pause transfer, and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the host system is not stopped, and the transfer is active until the data buffer is full. Because of this, it is recommended to avoid using the Suspend command for the SDIO card. This is because when such a command is sent, uSDHC interprets the system that switches to another function on the SDIO card and flush the data buffer. uSDHC takes the Resume command as a normal command with data transfer, and it is left for the host driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set as well as the AC12EN bit. However, the uSDHC module automatically sends a CMD12 to mark the end of the multi-block transfer.

10.3.4.3.2 Block read

Information about Normal read, DDR read, Read with Pause, and Delay Line (DLL) in Read Path are detailed in the sections below.

10.3.4.3.2.1 Normal read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer state. For multi blocks read, data blocks are continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other two methods (by means of external DMA orCPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status and wait until card is ready for data.
2. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Disable the buffer read ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or another error occurred during the auto12 command sending and response receiving.

10.3.4.3.2.2 DDR read

The uSDHC module supports dual data rate mode.

The software flow to write to a card in the DDR mode is described below:

1. Check the card status and wait until the card is ready for data.

NOTE

For eMMC card, block length can be set to only 512 bytes.

2. Set the uSDHC number block register (NOB) where nob is 5, for instance.

3. Set the eMMC card to high-speed mode and use SWITCH (CMD6).
4. Set the eMMC card bus with 4-bit /8-bit DDR mode and use SWITCH(CMD6).
5. Disable the buffer write ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN and AC12EN bits should be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or another error that occurred during the auto12 command sending and response receiving.

10.3.4.3.2.3 Read with Pause

The read operation is not generally able to pause. Only the SDIO card (and SDCombo card working under I/O mode) supporting the Read Wait feature can pause during the read operation. If the SDIO card supports Read Wait (SRW bit in CCCR register is 1), the host driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks.

Before setting the SABGREQ bit, ensure that the RWCTL bit in the Protocol Control register is set, otherwise uSDHC does not assert the Read Wait signal during the block gap and data corruption occurs. It is recommended to set the RWCTL bit after the Read Wait capability of the SDIO card is recognized.

Similar to the flow described in Normal read, the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm that the card supports the Read Wait mode.
2. Set the RWCTL bit.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
5. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
6. Set the uSDHC number block register (NOB), where nob is 5, for instance.
7. Disable the buffer read ready interrupt, configure the DMA setting, and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
8. Set the SABGREQ bit.
9. Wait for the Transfer Complete interrupt.

10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or another error occurred during the auto12 command sending and response receiving.

Similar to the Write operation, it is possible to meet the ending block of the transfer when paused. In this case, uSDHC ignores the Stop At Block Gap Request and treats it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause is transferred to the host system. No matter if the Suspend command is sent or not, the internal data buffer is not flushed.

If the Suspend command is sent and the transfer is later resumed by means of a Resume command, uSDHC takes the command as a normal one accompanied with data transfer. It is left for the host driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the uSDHC automatically sends CMD12 to mark the end of multi-block transfer.

10.3.4.3.2.4 Delay Line (DLL) in read path

The DLL is newly added to assist in sampling read data. The DLL provides the ability to programmatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage, and temperature (PVT).

The reasons why DLL is needed for uSDHC are these:

- The path of read data traveling from card to host varies.
- In the SD/MMC DDR mode, the minimum input setup and hold time are both at 2.5 ns.

The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided card_clk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.

The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in the override mode. The override value set is the number of delay cells. In the override mode, there is no need to set the DLL_enable. Another DLL mode is target value mode. In this mode, the DLL automatically adjusts the number of delay cells according to the target value set by the user and PVT changes. Be aware that the target value is in units of

1/32 of the clock reference period. If the card_clk is 100Mhz, then the reference clock period is 10ns; setting target value of 16 means 5ns =(16/32)*10ns. The software can disable automatic update by the setting dll_gate_update bit.

As the user may change the frequency of card_clk from time to time by changing SDCLKFS[7:0]/DVS[3:0], the software must adjust the delay value to ensure it works correctly when the reference clock (card_clk) is changed. The following is the correct flow, which should be ignored if DLL_CTRL_ENABLE is not set.

Step 1: Set the DLL_CTRL_RESET bit

Step 2: Configure the SDCLKFS[7:0] and DVS[3:0]

Step 3: Wait until SDSTB is asserted

Step 4: Clear the DLL_CTRL_RESET bit

Step 5: Wait until both the DLL_STS_SLV_LOCK and DLL_STS_REF_LOCK are asserted

Step 6: Set the DLL_CTRL_SLV_FORCE_UPD

Step 7: Clear the DLL_CTRL_SLV_FORCE_UPD

NOTE

The software should make sure that the DLL_CTRL_SLV_FORCE_UPD lasts for at least one card_clk. So, the software may need to add some delay between step 6 and step 7.

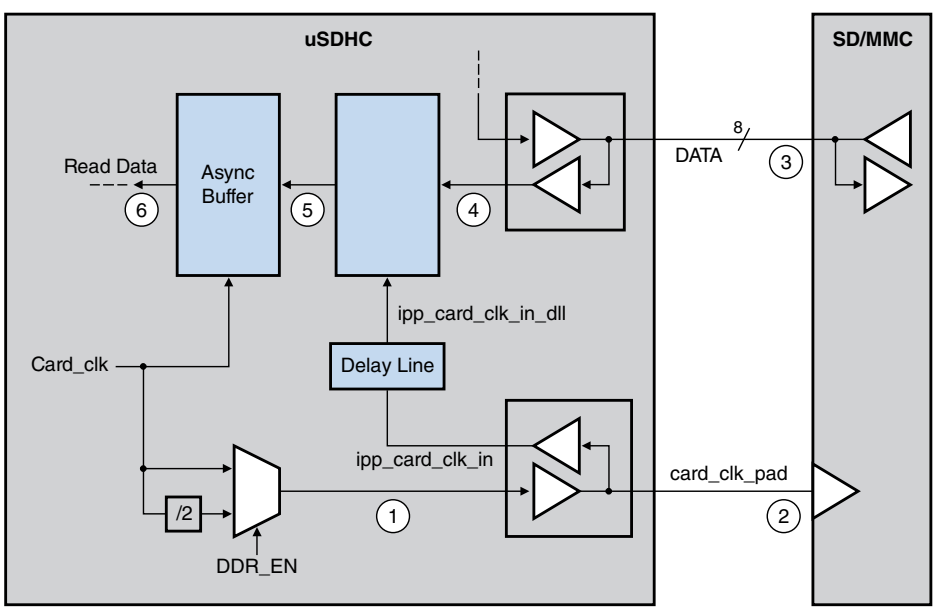

Figure 10-75. DLL in read path

10.3.4.3.3 Suspend Resume

The uSDHC module supports the Suspend Resume operations of SDIO cards, although slightly different than the suggested implementation of Suspend in the SDIO card specification.

10.3.4.3.3.1 Suspend

After setting the SABGREQ bit, the host driver may send a Suspend command to switch to another function of the SDIO card. The uSDHC module does not monitor the content of the response, so it does not know if the Suspend command succeeded or not. Accordingly, it does not de-assert Read Wait for read pause. To solve this problem, the host driver does not mark the Suspend command as "Suspend", (that is, setting the CMDTYP bits to 01). Instead, the driver sends this command as if it were a normal command, and only when the command succeeds, and the BS bit is set in the response, can the Driver send another command marked as "Suspend" to inform uSDHC that the current transfer is suspended. Here is the sequence for the Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so uSDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, uSDHC stops driving DATA2 and goes to the idle state.
5. Save the context registers in the system memory for later use, including the DMA System Address Register (for internal DMA operation), and the Block Attribute Register.
6. Begin operation for another function on the SDIO card.

10.3.4.3.3.2 Resume

To resume the data transfer, a Resume command is issued:

1. To resume the suspended function, restore the context register with the saved value in step #5 of the Suspend operation.
2. Send the Resume command: In the Transfer Type register, all the bit fields are set to the value as if this were another ordinary data transfer instead of a transfer resume (except the CMDTYP is set to 2'b10).

3. If the Resume command has responded, the data transfer is resumed.

10.3.4.3.4 ADMA usage

To use the ADMA in a data transfer, the host driver must prepare the correct descriptor chain prior to sending the read/write command.

The steps to prepare the correct descriptor chain are these:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4KB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.
4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors matches the product of the block size and block number configured in the Block Attribute Register.
6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

10.3.4.3.5 Transfer error

Information about CRC, Internal DMA, Transfer ADMA, and Auto CMD12 errors are detailed in the sections below.

10.3.4.3.5.1 CRC error

It is possible at the end of a block transfer that a write CRC status error or read CRC error occurs. For this type of error, the latest block received is discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one.

For a multi-block transfer, the host driver issues a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, uSDHC does not automatically send a CMD12 because the last

block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 is sent by uSDHC. In this case, the host driver re-sends or re-obtains the last block with a single block transfer.

10.3.4.3.5.2 Internal DMA error

During the data transfer with internal Simple DMA, if the DMA engine encounters an error on the AXI bus, the DMA operation is aborted, and the DMA error interrupt is sent to the host system. When acknowledged by such an interrupt, the host driver calculates the start address of data block in which the error occurs.

The start address can be calculated by either:

- Reading the DMA System Address register: The error occurs during the previous burst. Considering the block size, and the start address of the next burst transfer, it is straight forward to obtain the start address of the corrupted block.
- Reading the BLKCNT field of the Block Attribute register: Considering the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined.To use this method, MIX_CTRL[BCEN] bit has to be set to enable Block Attribute register update.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and restart the transfer from the corrupted block to recover from the error.

10.3.4.3.5.3 Transfer ADMA error

There are three kinds of possible ADMA errors: The AXI transfer, invalid descriptor, and data-length mismatch. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set.

For acknowledging the status, the host driver should recover the error as shown below and re-transfer from the place of interruption.

- AXI transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or to the next block if no block is corrupted.
- Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and recreate the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the

previous setting, the data length configured in the new descriptor chain should match the new value.
- Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

10.3.4.3.5.4 Auto CMD12 error

After the last block of the multi-block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, uSDHC automatically sends a CMD12 to the card to stop the transfer.

When errors with this command occur, it is recommended to the host driver to deal with the situations in the following manner:

- Auto CMD12 response time-out: It is not certain whether the command is accepted by the card or not. The host driver clears the auto CMD12 error status bits and re-send CMD12 until it is accepted by the card.
- Auto CMD12 response CRC error: As the card responds to CMD12, it aborts the transfer. The host driver may ignore the error and clear the error status bit.
- Auto CMD12 conflict error or not sent: The command is not sent; therefore, the host driver sends a CMD12 manually.

10.3.4.3.6 Card interrupt

The external cards can inform the host controller by means of some special signals. For the SDIO card, it can be the low-level on the DATA1 line during some special period. The uSDHC module only monitors the DATA1 line and supports the SDIO interrupt.

When the SDIO interrupt is captured by uSDHC, and the host system is informed by uSDHC asserting the uSDHC interrupt line, the interrupt service from the host driver is called.

As the interrupt source is controlled by the external card, the interrupt from the SDIO card must be serviced before the CINT bit is cleared by writing 1. Refer to Card interrupt handling for the card interrupt handling flow.

10.3.4.4 Switch function

A switch command is issued by the host driver to enable new features added to the SD/MMC spec. The SD/MMC cards can transfer data at bus widths other than 1-bit. Different speed modes are also defined. To enable these features, a switch command is issued by the host driver.

For SDIO cards, the high-speed mode/DDR50/SDR50/SDR104 are enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed. For SD cards, the high-speed mode/DDR50/SDR50/SDR104 are queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH_FUNC). For MMC cards, the high-speed mode/HS200/HS400 are queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The SDR4-bit, SDR8-bit, DDR4-bit, and DDR8-bit width of MMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO cards, it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following pseudocode examples do not show current capability check, which is recommended in the function switch process.

10.3.4.4.1 Query, enable, and disable SDIO high-speed mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is
cleared;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

10.3.4.4.2 Query, enable, and disable SD high-speed mode/DDR50/SDR50/SDR104

```
enable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
```

```
send CMD6, with argument 0xFFFFFx and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
wait data transfer done bit is set;
check if the bit x of received 512 bits is set;
if (bit 401 is '0') report the SD card does not support high speed mode and return;
if (bit 402 is '0') report the SD card does not support SDR50 mode and return;
if (bit 403 is '0') report the SD card does not support SDR104 mode and return;
if (bit 404 is '0') report the SD card does not support DDR50 mode and return;
send CMD6, with argument 0x80FFFFFx and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104 x=3; DDR50 x=4;)
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 50MHz for high speed mode, 100MHz for SDR50, 200MHz for SDR104, 50MHz for
DDR50;
(data transactions like normal peers)
}
disable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

10.3.4.4.3 Query, enable, and disable MMC high-speed mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and
return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

10.3.4.4.4 Set MMC bus width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
```

```
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and
return;
send CMD6 with argument 0x3B70x00; (8-bit(dual data rate), x=6; 4-bit(dual data rate), x=5;8-
bit, x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

10.3.4.5 ADMA operation

Here are the codes for the ADMA1 and ADMA2 operations.

10.3.4.5.1 ADMA1 operation

```
Set_adma1_descriptor
{
if (to start data transfer) {
// Make sure the address is 4KB align.
Set 'Set' type descriptor;
{
Set Act bits to 01;
Set [31:12] bits data length (byte unit);
}
Set 'Tran' type descriptor;
{
Set Act bits to 10;
Set [31:12] bits address (4KB align);
}
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to 11;
Set [31:12] bits the next descriptor address (4KB aligned);
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set End bit to 1;
}
if (to generate interrupt for this descriptor) {
Set Int bit to 1;
}
Set Valid bit to 1;
}
```

10.3.4.5.2 ADMA2 operation

```
Set_adma2_descriptor
{
if (to start data transfer) {
// Make sure the address is a 32-bit boundary (lower 2-bit are always '00').
Set higher 32-bit of descriptor for this data transfer initial address;
Set [31:16] bits data length (byte unit);
Set Act bits to '10';
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to '11';
// Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
Set higher 32-bit of descriptor for the next descriptor address;
}
else { // other types of descriptor
```

```
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set 'End' bit '1';
}
if (to generate interrupt for this descriptor) {
Set 'Int' bit '1';
}
Set the 'Valid' bit to '1';
}
```

10.3.4.6 Fast boot operation

10.3.4.6.1 Normal fast boot flow

Here are the steps for normal fast boot flow:

1. Software must configure the SYS_CTRL[INITA] bit to make sure that 74 card clocks are finished.
2. Software must configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 0 (normal fast boot), and bit 4 to select the ack mode. If the data is sent through the DMA mode, the software should configure bit 7 to enable the automatic stop at block gap feature, and configure bit 3-bit 0 to select the ack timeout value according to the SD CLK frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software must configure the Protocol control register to set Data Transfer Width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure the Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software must configure the Transfer Type Register to start the boot process. In normal boot mode, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN retain the default value, where DPSEL bit is set to 1, DTDSEL is set to 1 and MSBSEL is set to 1.
7. DMAEN should be configured as 0 in the polling mode and if BCEN is configured as 1, it is recommended to configure the number of blocks in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR_EN needs to be set to 1.
8. When step 6 is configured, the boot process begins. The software needs to poll the data buffer ready status to read the data from the buffer in time. If a boot timeout happens (ack times out or the first data read times out), an interrupt is triggered, and the software must configure MMC Boot Register to bit 6 to 0 to disable boot. This

makes CMD high, then after at least 56 clocks, it is ready to begin a normal initialization process.

9. If there is no timeout, software needs to determine when the data read is finished and then configure MMC Boot Register bit 6 to 0 to disable boot. This render CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin the normal initialization process.
10. You must reset the host and begin the normal process.

10.3.4.6.2 Alternative fast boot flow

Here are the steps for alternative fast boot flow:

1. Software needs to configure SYS_CTRL[INITA] to make sure 74 card clocks are finished.
2. Software needs to configure MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 1 (alternative boot), and bit 4 to select the ack mode or not. If data needs to be sent through the DMA mode, then configure bit 7 to enable the automatic stop at block gap feature. Software should also configure bit 3-bit 0 to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in the DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software needs to configure the Protocol control register to set the data transfer width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFA.
6. Software needs to configure the Transfer Type Register to start the boot process by CMD0 with the 0xFFFFFFFA argument. In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. Note DMAEN should be configured as 0 in the polling mode, and if BCEN is configured as 1 in polling mode, it is recommended to configure the block count in the Block Attributes Register to the maximum value. If in the DDR fast boot mode, DDR_EN needs to be set to 1.
7. When step 6 is configured, the boot process begins. Software needs to poll the data buffer ready status to read the data from the buffer in time. If there is a boot timeout (ack data timeout in 50ms or data timeout in 1s), the host sends out the interrupt and the software needs to send CMD0 with reset and then configure the boot enable bit to 0 to stop this process.
8. If there is no time out, the software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after the command is completed,

configure the MMC Boot Register bit 6 to stop the process. After 8 clocks from the command completion, the slave (card) is ready for the identification step.
9. You must reset the host and begin the normal process.

10.3.4.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the beginning of the image, it is necessary to switch DMA parameters on the fly during MMC fast boot.

In fast boot, the host can use Advanced DMA2 (ADMA2) with two destinations.

The detailed flow is described below:

1. The software needs to configure INIT_ACTIVE bit (system control register bit 27) to make sure that 74 card clocks are finished.
2. The software needs to configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot) or 1 (alternative boot); and bit 4 to select the ack mode. In DMA mode, configure bit 7 to 1 to enable the automatic stop at block gap feature. Also configure bits[31-16] to set the (BLK_CNT - VALUE1). Here VALUE1 is the value of the block count that needs to transfer the first time, so that the host stops at the block gap when the uSDHC controller gets VAULE1 blocks from the device. Also, configure bits[3-0] to select the ack timeout value according to the SD clock frequency.
3. The software then needs to configure the Block Attributes Register to set block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes. In DMA mode, it is recommended to set the block count (BLK_CNT) to the max value (16'hffff).
4. The software needs to configure Protocol Control Register to set DTW (data transfer width). If in DDR fast boot mode, the DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software enable ADMA2 by configuring Protocol Control Register bits [9-8].
6. The software needs to set at least three pairs of ADMA2 descriptor in boot memory (that is, in IRAM, at least six words). The first pair descriptor defines the start address (that is, IRAM) and data length (that is,512byte*VALUE1) of the first part boot code. The software also needs to set the second pair descriptor, the second start address (any value that is writable), and data length is suggested to set 1~2word (record as VALUE2). Note that the second couple desc also transfers useful data even at lease 1 word, because our ADMA2 cannot support 0 data_length data transfer descriptor.
7. The software needs to configure Command Argument Register to set argument to 0xFFFFFFFA in alternative fast boot and do not need to be set in normal fast boot.

8. The software needs to configure Transfer Type Register to start the boot process. CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. DMAEN is configured as 1 in the DMA mode. And, if BCEN is configured as 1, then configure blk no in Bock Attributes Register to the max value. And, if in the DDR fast boot mode, DDR_EN needs to be set to 1.
9. When step 8 is configured, boot process begins, the first VALUE1 block number data gets transferred. The software needs to poll the TC bit (bit1 in Interrupt Status Register) to determine first transfer is ended. Also, the software needs to polling the BGE bit (bit2 in Interrupt Status Register) to determine if the first transfer stops at the block gap.
10. When TC and BGE bits are set to 1, the software can analyze the first code of VALUE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of the boot code (VALUE3, the remain boot code block). Remember to set the last descriptor with END.
11. The software needs to configure the MMC Boot Register (offset 0xc4) again. Set bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot), to 1 (alternative boot); and bit 4 to select the ack mode or not. In the DMA mode, configure bit 7 to 1 for enabling the automatically stop at block gap feature. Also, configure bit31-bit16 to set the (BLK_CNT - (VALUE1+1+VALUE3)), that host stops at block gap when the uSDHC controller gets (VALUE1+1+VALUE3)) blocks from device totally include the blocks received in step 9. And need to configure bit 3-bit0 to select the ack timeout value according to the sd clk frequency. Note that the software does not need to configure the BLK_CNT again, because it is counted down automatically by the uSDHC controller.
12. The software needs to clear the TC and BGE bits and the software needs to clear SABGREQ (bit 16 in the Protocol control register) and set CREQ (bit17 in the Protocol control register) to 1 to resume the data transfer. Host transfers the VALUE2 and VALUE3 data to the destination that is set by descriptor.
13. The software needs to do poll BGE bit to determine if the fast boot is over.

Note:

- When ADMA boot flow starts, for uSDHC, it is like a normal ADMA read operation. So, set ADMA2 descriptor as the normal ADMA2 transfer.
- Need a few words length memory to keep descriptor.
- For the 1~2-word data in second descriptor setting, it is a useful data, so the software needs to deal the data because of the application case.

10.3.5 Software restrictions

10.3.5.1 Initialization active

The driver cannot set INITA bit in System Control register when any of the command line or data lines are active, so the driver must ensure both CDIHB and CIHB bits are cleared.

10.3.5.2 Software polling procedure

For polling read or write, after the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not a multiple of the value in the Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block.

For example, for a read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

10.3.5.3 Suspend operation

To suspend the data transfer, the software must inform uSDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform uSDHC that the transfer is suspended.

If software needs to resume the suspended transfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending such a 'suspend' command, uSDHC treats the current transfer is aborted and change the BLKCNT register to its original value, instead of retaining the remaining number of blocks.

10.3.5.4 Data length setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

ADMA1 is 4KB aligned.

10.3.5.5 (A)DMA address setting

To configure the ADMA1/ADMA2/DMA address register, when TC bit is set, the register always updates itself with the internal address value to support dynamic address synchronization, so the software must ensure that the TC bit is cleared prior to configuring the ADMA1/ADMA2/DMA address register.

10.3.5.6 Data port access

Data port does not support parallel access. For example, during an internal DMA access, it is not allowed to write any data to the data port by CPU; or during a CPU read operation, it is also prohibited to write any data to the data port, by either CPU or internal DMA. Otherwise the data is corrupted inside the uSDHC buffer.

10.3.5.7 Change clock frequency

The uSDHC module does not automatically gate off the card clock when the host driver changes the clock frequency. To prevent possible glitch on the card clock, clear the FRC_SDCLK_ON bit when changing the clock divisor value (SDCLKFS or DVS in System Control Register) or setting the RSTA bit.

Also, before changing the clock divisor value, the host driver should make sure that the SDSTB bit is high.

10.3.5.8 Multi-block read

For pre-defined multi-block read operation, that is, the number of blocks to read has been defined by previous CMD23 for MMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by uSDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode.

In this case, the card may not respond to this extra abort command and uSDHC gets response timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

10.3.6 uSDHC memory map/register definition

10.3.6.1 uSDHC register descriptions

This section includes the module memory map and detailed descriptions of all registers.

See the table below for the register memory map of uSDHC. All these registers only support 32-bit accesses.

NOTE

The uSDHC registers are 32-bit wide and only support 32-bit access.

10.3.6.1.1 uSDHC memory map

USDHC1 base address: 30B4_0000h

USDHC2 base address: 30B5_0000h

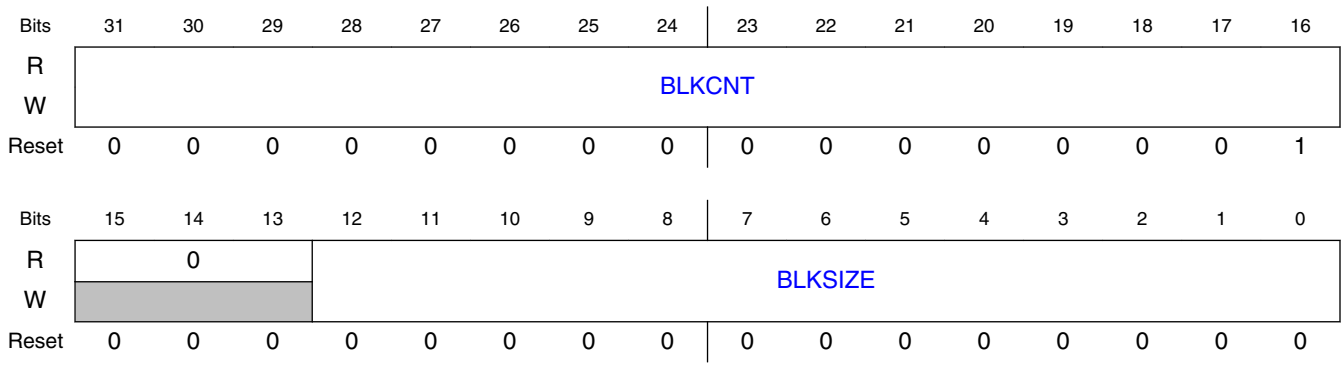
10.3.6.1.2.4 Fields

Field	Function
31-0 DS_ADDR	System address **DMA system address / argument 2** When ACMD23_ARGU2_EN is set to 0, SDMA uses this register as system address and supports only 32-bit addressing mode. Auto CMD23 cannot be used with SDMA. When ACMD23_ARGU2_EN is set to 1, SDMA uses ADMA System Address register (05Fh – 058h) instead of this register to support both 32-bit and 64-bit addressing. This register is used only for Argument2 and SDMA may use Auto CMD23. 1. **SDMA system address**

Field	Function
	Because the address must be word (4 bytes) aligned, the least two bits are reserved and always set to 0. When uSDHC stops a DMA transfer, this register points out the system address of the next contiguous data position. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operation during transfers may return an invalid value. The host driver initializes this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. This register is protected during a data transfer. When data lines are active, write to this register is ignored. The host driver waits until the DLA field in the Present State register is cleared, before writing to this register. The uSDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. Because this register supports dynamic address reflecting, when TC field is set, it automatically alters the value of internal address counter, so the software cannot change this register when TC field is set. Such restriction is also listed in Software restrictions. 2. **Argument 2** This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23. If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without ADMA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case.

10.3.6.1.3 Block Attributes (BLK_ATT)



10.3.6.1.3.1 Offset

Register	Offset
BLK_ATT	4h

10.3.6.1.3.2 Function

This register is used to configure the number of data blocks and the number of bytes in each block.

10.3.6.1.3.3 Diagram

10.3.6.1.3.4 Fields

Field	Function
31-16 BLKCNT	Blocks count for current transfer This field is enabled when the Block Count Enable field in the Transfer Mode register is set to 1 and is valid only for multiple block transfers. For single block transfer, this field always reads as 1. The host driver sets this field to a value between 1 and the maximum block count. The uSDHC module decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to zero results in no data blocks being transferred. This field should be accessed only when no transaction is executing (that is, after transactions are stopped). During data transfer, read operations on this field may return an invalid value and write operations are ignored. When saving transfer content because of a Suspend command, the number of blocks yet to be transferred can be determined by reading this field. The reading of this field should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when the Suspend command is sent out, uSDHC treats the current transfer as aborted and change the BLKCNT field back to its original value instead of keeping the dynamical indicator of the remaining block count. When restoring transfer content prior to issuing a Resume command, the host driver restores the previously saved block count. **NOTE:** Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when MSBSEL field is indicating a single block transfer, the read value of BLKCNT is always 1. 0000000000000000b - Stop count 0000000000000001b - 1 block 0000000000000010b - 2 blocks 1111111111111111b - 65535 blocks
15-13 —	Reserved
12-0 BLKSIZE	Transfer block size This field specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations are ignored. 0000000000000b - No data transfer 0000000000001b - 1 byte

Field	Function
	0000000000010b - 2 bytes 0000000000011b - 3 bytes 0000000000100b - 4 bytes 0000111111111b - 511 bytes 0001000000000b - 512 bytes 0100000000000b - 2048 bytes 1000000000000b - 4096 bytes

10.3.6.1.4 Command Argument (CMD_ARG)

10.3.6.1.4.1 Offset

Register	Offset
CMD_ARG	8h

10.3.6.1.4.2 Function

This register contains the SD/MMC command argument.

10.3.6.1.4.4 Fields

Field	Function
31-0 CMDARG	Command argument The SD/MMC command argument is specified as bits 39-8 of the command format in the SD or MMC specification. This field is write protected when the Command Inhibit (CMD) field in the Present State register is set.

10.3.6.1.5 Command Transfer Type (CMD_XFR_TYP)

10.3.6.1.5.1 Offset

Register	Offset
CMD_XFR_TYP	Ch

10.3.6.1.5.2 Function

This register is used to control the operation of data transfers. The host driver sets this register before issuing a command followed by a data transfer or before issuing a Resume command. To prevent data loss, uSDHC prevents writing to the bits, which are involved in the data transfer of this register, when data transfer is active. These fields are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

The host driver checks the Command Inhibit DAT field (PRES_STATE[CDIHB]) and the Command Inhibit CMD field (PRES_STATE[CIHB]) in the Present State register before writing to this register. When the CDIHB field in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB field is set, any write to this register is ignored.

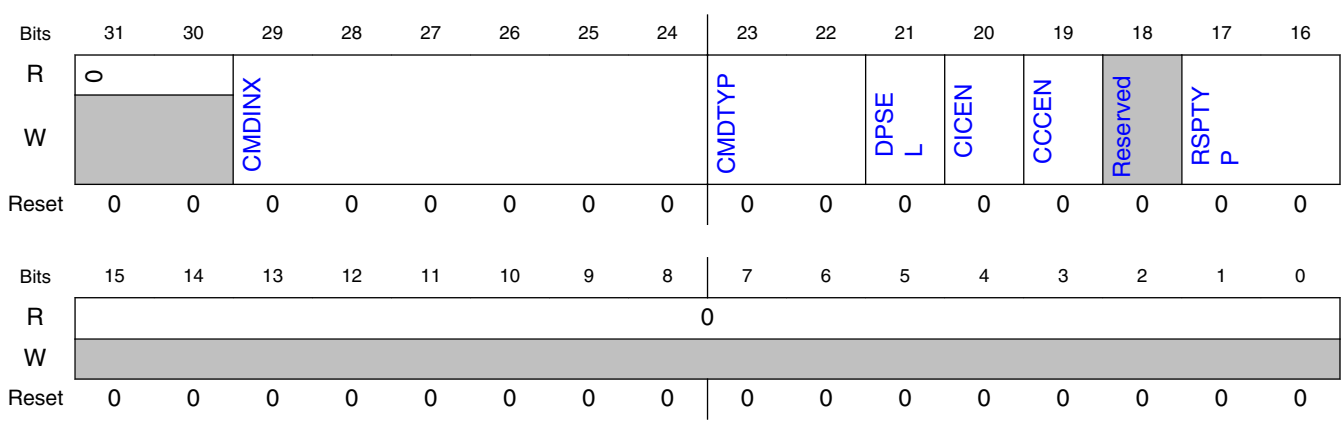
On sending commands with data transfer involved, it is mandatory that the block size is non-zero. Block count must also be non-zero, or indicated as a single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise uSDHC ignores the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (PRES_STATE[WPSPL] field of Present State register is '1'); otherwise, uSDHC also ignores the command.

If the commands with data transfer do not receive the response in 64 clock cycles, that is, if response time-out happens, uSDHC treats the external device, does not accept the command, and aborts the data transfer. In this scenario, the driver should issue the command again to retry the transfer. It is also possible that for some reason the card responds to the command but uSDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The table below shows the summary of how register settings determine the type of data transfer.

Table 10-36. Transfer type register setting for various transfer types

Multi/single block select	Block count enable	Block count	Function
0	Do not care	Do not care	Single transfer
1	0	Do not care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer



The table below shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, regarding the Response Type bits as well as the name of the response type.

Table 10-37. Relationship between parameters and the name of the response type

Response type	Index check enable	CRC check enable	Name of response type
00	0	0	No response
01	0	1	R2
10	0	0	R3, R4
10	1	1	R1, R5, R6
11	1	1	R1b,R5b

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification, but R5b is defined in this specification to specify that uSDHC checks the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command is used with R5b.
- The CRC fields for R3 and R4 are expected to be all 1 bits. The CRC check is disabled for these response types.

10.3.6.1.5.3 Diagram

10.3.6.1.5.4 Fields

Field	Function
31-30 —	Reserved
29-24 CMDINX	Command index These fields are set to the command number that is specified in bits 45-40 of the command-format in the SD Memory Card Physical Layer Specification and SDIO Card Specification.
23-22 CMDTYP	Command type There are three types of special commands: Suspend, Resume, and Abort. These fields are set to 00b for all other commands. • Suspend command: If the Suspend command succeeds, uSDHC assumes that the card bus has been released and that it is possible to issue the next command that uses the DATA line. Because uSDHC does not monitor the content of command response, it does not know if the Suspend command succeeded or not. It is the host driver's responsibility to check the status of the Suspend command and send another command marked as Suspend to inform uSDHC that a Suspend command was successfully issued. See Suspend Resume for more details. After the end bit of command is sent, uSDHC deasserts Read Wait for read transactions and stops checking busy for write transactions. In a 4-bit mode, the interrupt cycle starts. If the Suspend command fails, uSDHC maintains its current state, and the host driver restarts the transfer by setting the Continue Request field in the Protocol Control register. • Resume command: The host driver re-starts the data transfer by restoring the registers saved before sending the Suspend command and then sends the Resume command. The uSDHC module checks for a pending busy state before starting write transfers. • Abort command: If this command is set when executing a read transfer, uSDHC stops reads to the buffer. If this command is set when executing a write transfer, uSDHC stops driving the DATA line. After issuing the Abort command, the host driver should issue a software reset (Abort Transaction). 00b - Normal other commands 01b - Suspend CMD52 for writing bus suspend in CCCR 10b - Resume CMD52 for writing function select in CCCR 11b - Abort CMD12, CMD52 for writing I/O Abort in CCCR
21 DPSEL	Data present select This field is set to 1 to indicate that data is present and is transferred using the DATA line. It is set to 0 for the following: • Commands using only the CMD line (for example, CMD52) • Commands with no data transfer, but using the busy signal on DATA0 line (R1b or R5b (for example, CMD38)) **NOTE:** In resume command, this field is set, and other bits in this register is set the same as when the transfer was initially launched. When the write protect switch is on, (that is, the WPSPL field is active as '0'), any command with a write operation ignored. When this field is set, while the DTDSEL field is 0, writes to the register Transfer Type are ignored. 0b - No data present 1b - Data present
20 CICEN	Command index check enable If this field is set to 1, uSDHC checks the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this field is set to 0, the Index field is not checked. 0b - Disable command index check 1b - Enables command index check

Table continues on the next page...

Field	Function
19 CCCEN	Command CRC check enable If this field is set to 1, uSDHC checks the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this field is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. See RSPTYP[1:0] and Command Transfer Type (CMD_XFR_TYP). 0b - Disables command CRC check 1b - Enables command CRC check
18 —	Reserved
17-16 RSPTYP	Response type select 00b - No response 01b - Response length 136 10b - Response length 48 11b - Response length 48, check busy after response
15-0 —	Reserved

10.3.6.1.9 Command Response3 (CMD_RSP3)

10.3.6.1.9.1 Offset

Register	Offset
CMD_RSP3	1Ch

10.3.6.1.9.2 Function

This register is used to store part 3 of the response bits from the card.

The table below describes the mapping of command responses from the SD bus to Command Response registers for each response type. In this table, R[ ] refers to a bit range within the response data as transmitted on the SD bus.

Table 10-38. Response bit definition for each response type

Response type	Meaning of response	Response field	Response register
R1,R1b (normal response)	Card status	R[39:8]	CMDRSP0
R1b (auto CMD12 response)	Card status for auto CMD12	R[39:8]	CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{CMDRSP3[23:0], CMDRSP2, CMDRSP1, CMDRSP0}
R3 (OCR register)	OCR register for memory	R[39:8]	CMDRSP0
R4 (OCR register)	OCR register for I/O etc.	R[39:8]	CMDRSP0
R5, R5b	SDIO response	R[39:8]	CMDRSP0
R6 (publish RCA)	New published RCA[31:16] and card status[15:0]	R[39:9]	CMDRSP0

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, uSDHC only stores part of the response data in the Command Response registers. This enables the host driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by uSDHC (as specified by the Command Index Check Enable and the Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, uSDHC checks R[47:1], and if the response length is 136 the uSDHC checks R[119:1].

Because uSDHC may have a multiple block data transfer executing concurrently with a CMD_wo_DAT command, uSDHC stores the Auto CMD12 response in the CMDRSP3 register. The CMD_wo_DAT response is stored in CMDRSP0. This allows uSDHC to

avoid overwriting the Auto CMD12 response with the CMD_wo_DAT and vice versa. When uSDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

10.3.6.1.9.3 Diagram

10.3.6.1.11 Present State (PRES_STATE)

10.3.6.1.11.1 Offset

Register	Offset
PRES_STATE	24h

10.3.6.1.11.2 Function

The host driver can get status of uSDHC from this 32-bit read only register.

The host driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DATA lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands are issued when Command Inhibit (DATA) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.

NOTE

The reset value of Present State register depends on board connectivity.

10.3.6.1.11.4 Fields

Field	Function
31-24 DLSL	DATA[7:0] line signal level This field is used to check the DATA line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DATA0. The reset value is affected by the external pull-up / pull-down resistors. By default, the read value of this field after reset is 8'b11110111, when DATA3 is pulled down and the other lines are pulled up. 00000000b - Data 0 line signal level 00000001b - Data 1 line signal level 00000010b - Data 2 line signal level 00000011b - Data 3 line signal level 00000100b - Data 4 line signal level 00000101b - Data 5 line signal level 00000110b - Data 6 line signal level 00000111b - Data 7 line signal level
23 CLSL	CMD line signal level This field is used to check the CMD line level to recover from errors, and for debugging. The reset value is affected by the external pull-up / pull-down resistor, by default, the read value of this field after reset is 1'b1, when the command line is pulled up.
22-20 —	Reserved
19 WPSPL	Write protect switch pin level The Write Protect switch is supported for memory and combo cards. This field reflects the inverted value of the WP pin of the card socket. A software reset does not affect this field. The reset value is affected by the external write protect switch. If the WP pin is not used, it should be tied low, so that the reset value of this field is high and write is enabled. 0b - Write protected (WP = 1) 1b - Write enabled (WP = 0)
18	Card detect pin level

Table continues on the next page...

Field	Function
CDPL	This field reflects the inverse value of the CD_B pin for the card socket. Debouncing is not performed on this field. This field may be valid, but is not guaranteed, because of propagation delay. Use of this field is limited to testing because it must be debounced by software. A software reset does not affect this field. A write to the Force Event Register does not affect this field. The reset value is affected by the external card detection pin. This field shows the value on the CD_B pin (that is, when a card is inserted in the socket, it is 0 on the CD_B input, and consequently, the CDPL reads 1. 0b - No card present (CD_B = 1) 1b - Card present (CD_B = 0)
17 —	Reserved
16 CINST	Card inserted This field indicates whether a card has been inserted. The uSDHC module debounces this signal so that the host driver does not need to wait for it to stabilize. Changing from a 0 to 1 generates a Card Insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a Card Removal interrupt in the Interrupt Status register. A write to the Force Event Register does not affect this field. The Software Reset For All in the System Control register does not affect this field. A software reset does not affect this field. 0b - Power on reset or no card 1b - Card inserted
15 TSCD	Tap select change done This field indicates the delay setting is effective after write CLK_TUNE_CTRL_STATUS register. 0b - Delay cell select change is not finished. 1b - Delay cell select change is finished.
14-13 —	Reserved
12 RTR	Re-Tuning Request (only for SD3.0 SDR104 mode,and EMMC HS200 mode) Host controller may request host driver to execute re-tuning sequence by setting this field when the data window is shifted by temperature drift and a tuned sampling point does not have a good margin to receive correct data. This field is cleared when a command is issued with setting Execute Tuning field in MIX_CTRL register. Changing of this field from 0 to 1 generates Re-Tuning Event. See Interrupt status registers for more detail. This field isn't set to 1 if Sampling Clock Select in the MIX_CTRL register is set to 0 (using fixed sampling clock). 0b - Fixed or well tuned sampling clock 1b - Sampling clock needs re-tuning
11 BREN	Buffer read enable This status field is used for non-DMA read transfers. The uSDHC module implements an internal buffer to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this field is high, valid data greater than the watermark level exist in the buffer. A change of this field from 1 to 0 occurs when some reads from the buffer (read DATPORT (Base + 0x20)) are made and the buffer hasn't valid data greater than the watermark level. A change of this field from 0 to1 occurs when there is enough valid data ready in the buffer and the Buffer Read Ready interrupt has been generated and enabled. 0b - Read disable 1b - Read enable
10	Buffer write enable

Table continues on the next page...

Field	Function
BWEN	This status field is used for non-DMA write transfers. The uSDHC module implements an internal buffer to transfer data efficiently. This read only flag indicates if space is available for write data. If this field is 1, valid data greater than the watermark level can be written to the buffer. A change of this field from 1 to 0 occurs when some writes to the buffer (write DATPORT (Base + 0x20)) are made and the buffer hasn't valid space greater than the watermark level. A change of this field from 0 to 1 occurs when the buffer can hold valid data greater than the write watermark level and the Buffer Write Ready interrupt is generated and enabled. 0b - Write disable 1b - Write enable
9 RTA	Read transfer active This status field is used for detecting completion of a read transfer. This field is set for either of the following conditions: • After the end field of the read command • When writing a 1 to the Continue Request field in the Protocol Control register to restart a read transfer A transfer complete interrupt is generated when this field changes to 0. This field is cleared for either of the following conditions: • When the last data block as specified by block length is transferred to the System, that is, all data are read away from uSDHC internal buffer. • When all valid data blocks have been transferred from uSDHC internal buffer to the System and no current block transfers are being sent because of the Stop At Block Gap Request being set to 1. 0b - No valid data 1b - Transferring data
8 WTA	Write transfer active This status field indicates a write transfer is active. If this field is 0, it means no valid write data exists in uSDHC. This field is set in either of the following cases: • After the end field of the write command • When writing 1 to the Continue Request field in the Protocol Control register to restart a write transfer This field is cleared in either of the following cases: • After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple) • After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request During a write transaction, a Block Gap Event interrupt is generated when this field is changed to 0, as result of the Stop At Block Gap Request being set. This status is useful for the host driver in determining when to issue commands during Write Busy state. 0b - No valid data 1b - Transferring data
7 SDOFF	SD clock gated off internally This status field indicates that the SD clock is internally gated off, because of buffer over / under-run or read pause without read wait assertion, or the driver set FRC_SDCLK_ON field is 0 to stop the SD clock in idle status. This field is for the host driver to debug data transaction on the SD bus. 0b - SD clock is active. 1b - SD clock is gated off.

Table continues on the next page...

Field	Function
6 PEROFF	IPG_PERCLK gated off internally This status field indicates that the IPG_PERCLK is internally gated off. This field is for the host driver to debug transaction on the SD bus. When IPG_CLK_SOFT_EN is cleared, IPG_PERCLK is gated off, otherwise IPG_PERCLK is always active. 0b - IPG_PERCLK is active. 1b - IPG_PERCLK is gated off.
5 HCKOFF	HCLK gated off internally This status field indicates that the HCLK is internally gated off. This field is for the host driver to debug during a data transfer. 0b - HCLK is active. 1b - HCLK is gated off.
4 IPGOFF	Peripheral clock gated off internally This status field indicates that the peripheral clock is internally gated off. This field is for the host driver to debug. 0b - Peripheral clock is active. 1b - Peripheral clock is gated off.
3 SDSTB	SD clock stable This status field indicates that the internal card clock is stable. This field is for the host driver to poll clock status when changing the clock frequency. It is recommended to clear FRC_SDCLK_ON field in System Control register to remove glitches on the card clock when the frequency is changing. Before changing clock divisor value (SDCLKFS or DVS), host driver should make sure the SDSTB field is high. 0b - Clock is changing frequency and not stable. 1b - Clock is stable.
2 DLA	Data line active This status field indicates whether one of the DATA lines on the SD bus is in use. In the case of read transactions: This status indicates if a read transfer is executing on the SD bus. Changes in this value from 1 to 0, between data blocks, generates a Block Gap Event interrupt in the Interrupt Status register. This field is set in either of the following cases: • After the end field of the read command • When writing a 1 to the Continue Request field in the Protocol Control register to restart a read transfer This field is cleared in either of the following cases: • When the end field of the last data block is sent from the SD bus to uSDHC. • When the Read Wait state is stopped by a Suspend command and the DATA2 line is released. The uSDHC module waits at the next block gap by driving Read Wait at the start of the interrupt cycle. If the Read Wait signal is already driven (data buffer cannot receive data), uSDHC can wait for a current block gap by continuing to drive the Read Wait signal. It is necessary to support Read Wait to use the suspend / resume function. This field remains 1 during Read Wait. In the case of write transactions: This status indicates that a write transfer is executing on the SD bus. Changes in this value from 1 to 0 generate a Transfer Complete interrupt in the Interrupt Status register. This field is set in either of the following cases:

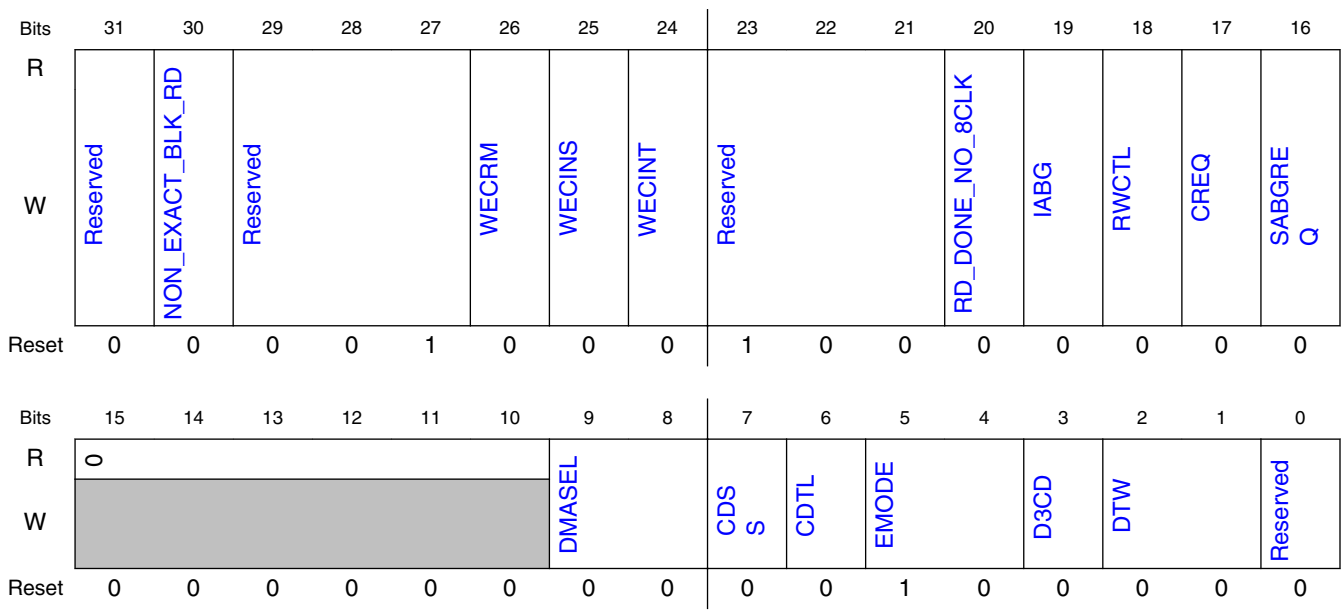
Table continues on the next page...

Field	Function
	• After the end field of the write command • When writing to 1 to the Continue Request field in the Protocol Control register to continue a write transfer This field is cleared in either of the following cases: • When the SD card releases Write Busy of the last data block, uSDHC also detects if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, uSDHC assumes the card drive "Not Busy". • When the SD card releases write busy, prior to waiting for write transfer, and because of a Stop At Block Gap Request. In the case of command with busy pending: This status indicates that a busy state follows the command and the data line is in use. This field is cleared when the DATA0 line is released. 0b - DATA line inactive 1b - DATA line active
1 CDIHB	Command Inhibit Data (DATA) This status field is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this field is 0, it indicates that uSDHC can issue the next SD / MMC Command. Commands with a busy signal belong to Command Inhibit (DATA) (for example. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register. **NOTE:** The SD host driver can save registers for a suspend transaction after this field has changed from 1 to 0. 0b - Can issue command that uses the DATA line 1b - Cannot issue command that uses the DATA line
0 CIHB	Command inhibit (CMD) If this status bit is 0, it indicates that the CMD line is not in use and uSDHC can issue a SD / MMC command using the CMD line. This field is set also immediately after the Transfer Type register is written. This field is cleared when the command response is received. Even if the Command Inhibit (DATA) is set to 1, commands using only the CMD line can be issued if this field is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If uSDHC cannot issue the command because of a command conflict error (see Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this field remains 1 and the Command Complete is not set. The Status of issuing an auto CMD12 does not show on this field. 0b - Can issue command using only CMD line 1b - Cannot issue command

10.3.6.1.12 Protocol Control (PROT_CTRL)

10.3.6.1.12.1 Offset

Register	Offset
PROT_CTRL	28h



10.3.6.1.12.2 Function

This register controls three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether uSDHC issues a Suspend command or the SD card accepts the Suspend command.

- If the host driver does not issue a Suspend command, the Continue request is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card accepts it, a Resume command is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card does not accept it, the Continue request is used to restart the transfer.

Any time stop at block gap request stops the data transfer, the host driver waits for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the host driver clears the Stop At Block Gap Request before or simultaneously.

10.3.6.1.12.3 Diagram

10.3.6.1.12.4 Fields

Field	Function
31	Reserved
—	Always write as 0
30	Non-exact block read

Table continues on the next page...

Field	Function
NON_EXACT_BLK_RD	Current block read is non-exact block read. It is only used for SDIO. 0b - The block read is exact block read. Host driver does not need to issue abort command to terminate this multi-block read. 1b - The block read is non-exact block read. Host driver needs to issue abort command to terminate this multi-block read.
29-27 —	Reserved
26 WECRM	Wakeup event enable on SD card removal This field enables a wakeup event, via a card removal, in the Interrupt Status register. FN_WUS (Wakeup Support) in CIS does not affect this field. When this field is set, the Card Removal Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Removal Status and uSDHC interrupt. 0b - Disables wakeup event enable on SD card removal 1b - Enables wakeup event enable on SD card removal
25 WECINS	Wakeup event enable on SD card insertion This field enables a wakeup event, via a card insertion, in the Interrupt Status register. FN_WUS (Wakeup Support) in CIS does not affect this field. When this field is set, the Card Insertion Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Insertion Status and uSDHC interrupt. 0b - Disable wakeup event enable on SD card insertion 1b - Enable wakeup event enable on SD card insertion
24 WECINT	Wakeup event enable on card interrupt This field enables a wakeup event, via a card interrupt, in the Interrupt Status register. This field can be set to 1 if FN_WUS (Wakeup Support) in CIS is set to 1. When this field is set, the Card Interrupt Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Interrupt Status and uSDHC interrupt. 0b - Disables wakeup event enable on card interrupt 1b - Enables wakeup event enable on card interrupt
23-21 —	Reserved Always write as 3'b100
20 RD_DONE_NO_8CLK	Read performed number 8 clock According to the SD/MMC spec, for read data transaction, 8 clocks are needed after the end field of the last data block. So, by default(RD_DONE_NO_8CLK=0), eight clocks are active after the end field of the last read data transaction. However, these 8 clocks should not be active if user wants to use stop at block gap (include the auto stop at block gap in boot mode) feature for read and the RWCTL field (bit18) is not enabled. In this case, software should set RD_DONE_NO_8CLK to avoid these 8 clocks. Otherwise, the device might send extra data to uSDHC while uSDHC ignores these data. In a summary, this field should be set only if the use case needs to use stop at block gap feature while the device can't support the read wait feature.
19 IABG	Interrupt at block gap This field is valid only in 4-bit mode, of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card cannot signal an interrupt during a multiple block transfer, this field should be set to 0 to avoid an inadvertent interrupt. When the host driver detects an SDIO card insertion, it sets this field according to the CCCR of the card. 0b - Disables interrupt at block gap 1b - Enables interrupt at block gap

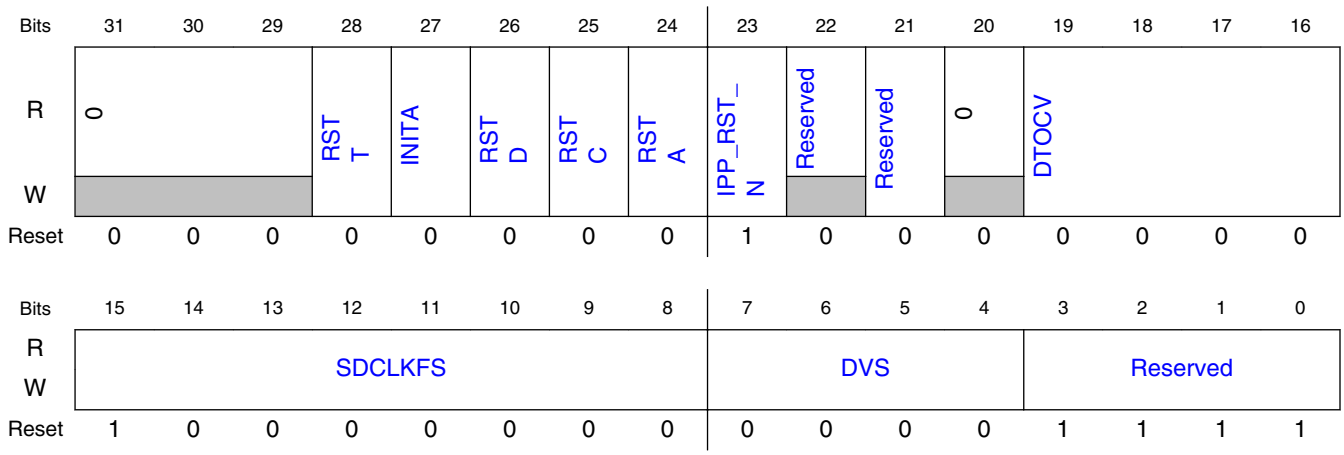
Table continues on the next page...

Field	Function
18 RWCTL	Read wait control The read wait function provided by this field is optional for SDIO cards. If the card supports read wait, set this field to enable use of the read wait protocol to stop read data using the DATA2 line. Otherwise, uSDHC has to stop the SD clock to hold read data, which restricts commands generation. When the host driver detects an SDIO card insertion, it sets this field according to the CCCR of the card. If the card does not support read wait, this field should never be set to 1; otherwise, DATA line conflicts might occur. If this field is set to 0, stop at block gap during read operation is also supported, but uSDHC stops the SD clock to pause reading operation. 0b - Disables read wait control and stop SD clock at block gap when SABGREQ field is set 1b - Enables read wait control and assert read wait without stopping SD clock at block gap when SABGREQ field is set
17 CREQ	Continue request This field is used to restart a transaction which was stopped using the stop at block gap request. When a suspend operation is not accepted by the card, it is also by setting this field to restart the paused transfer. To cancel stop at the block gap, set stop at block gap request to 0 and set this field to 1 to restart the transfer. The uSDHC module automatically clears this field, therefore it is not necessary for the host driver to set this field to 0. If both stop at block gap request and this field are 1, the continue request is ignored. 0b - No effect 1b - Restart
16 SABGREQ	Stop at block gap request This field is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the transfer complete is set to 1, indicating a transfer completion, the host driver leaves this field set to 1. Clearing both the stop at block gap request and continue request does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The uSDHC module supports the stop at block gap request for write transfers, but for read transfers it requires that the SDIO card support read wait. Therefore, the host driver does not set this field during read transfers unless the SDIO card supports Read Wait and has set the read wait control to 1; otherwise, uSDHC stops the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the host driver writes data to the Data Port register, the host driver sets this field after all block data is written. If this field is set to 1, the host driver does not write data to the Data Port register after a block is sent. Once this field is set, the host driver does not clear this field before the Transfer Complete field in Interrupt Status register is set, otherwise uSDHC's behavior is undefined. This field effects read transfer active, write transfer active, DATA Line Active and Command Inhibit (DATA) in the Present State register. 0b - Transfer 1b - Stop
15-10 —	Reserved
9-8 DMASEL	DMA select This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation. 00b - No DMA or simple DMA is selected. 01b - ADMA1 is selected. 10b - ADMA2 is selected. 11b - Reserved
7 CDSS	Card detect signal selection This field selects the source for the card detection. 0b - Card detection level is selected (for normal purpose). 1b - Card detection test level is selected (for test purpose).

Table continues on the next page...

Field	Function
6 CDTL	Card detect test level This field is enabled while the card detection signal selection is set to 1 and it indicates card insertion. 0b - Card detect test level is 0, no card inserted 1b - Card detect test level is 1, card inserted
5-4 EMODE	Endian mode This field supports all three endian modes in data transfer. See Data buffer for more details. 00b - Big endian mode 01b - Half word big endian mode 10b - Little endian mode 11b - Reserved
3 D3CD	DATA3 as card detection pin If this field is set, DATA3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DATA3 is also a chip-select for the SPI mode. A pull-down on this pin and CMD0 might set the card into the SPI mode, which uSDHC does not support. 0b - DATA3 does not monitor card insertion 1b - DATA3 as card detection pin
2-1 DTW	Data transfer width This field selects the data width of the SD bus for a data transfer. The host driver sets it to match the data width of the card. Possible data transfer width is 1-bit, 4-bits or 8-bits. 00b - 1-bit mode 01b - 4-bit mode 10b - 8-bit mode 11b - Reserved
0 —	Reserved

10.3.6.1.13 System Control (SYS_CTRL)



10.3.6.1.13.1 Offset

Register	Offset
SYS_CTRL	2Ch

10.3.6.1.13.2 Function

This register provides control of the system. See detail in the field description.

10.3.6.1.13.3 Diagram

10.3.6.1.13.4 Fields

Field	Function
31-29 —	Reserved
28 RSTT	Reset tuning When set this field to 1, it resets tuning circuit. After tuning circuits are reset, bit value is 0. Clearing execute_tuning field in AUTOCMD12_ERR_STATUS also sets this field to 1 to reset tuning circuit
27 INITA	Initialization active When this field is set, 80 SD-clocks are sent to the card. After the 80 clocks are sent, this field is self cleared. This field is very useful during the card power-up period when 74 SD-clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this field is already 1 has no effect. Writing 0 to this field at any time has no effect. When either of the CIHB and CDIHB fields in the Present State register are set, writing 1 to this field is ignored (that is, when command line or data lines are active, write to this field is not allowed). On the other-hand, when this field is set, that is, during initialization active period, it is allowed to issue command, and the command bit stream appears on the CMD pad after all 80 clock cycles are done. So, when this command ends, the driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs to send 80 cycles to the card and does not want to wait till this field is self cleared.

26
RSTD
	Software reset for data line
	Only part of the data circuit is reset. DMA circuit is also reset. After this field is set, the software waits for self-clear.
	The following registers and bits are cleared by this field:
	• Data Port register
	  • Buffer is cleared and initialized
	• Present State register
	  • Buffer read enable
	  • Buffer write enable
	  • Read transfer active
	  • Write transfer active
	  • DATA line active
	  • Command Inhibit (DATA)
	• Protocol Control register

Table continues on the next page...

Field	Function
	• Continue request • Interrupt Status register • Buffer read ready • Buffer write ready • DMA interrupt • Block gap event • Transfer complete **NOTE:** When reset, the software must make sure there is no incomplete data transferring. If there is data transfer going on, the software needs to wait TC or DC INT_STATUS register is set. 0b - No reset 1b - Reset
25 RSTC	Software reset for CMD line Only part of the command circuit is reset. After this field is set, the software waits for self-clear. The following registers and bits are cleared by this field: • Present State Register • Command Inhibit (CMD) • Interrupt Status Register • Command Complete 0b - No reset 1b - Reset
24 RSTA	Software reset for all This reset affects the entire host controller except for the card detection circuit. RSTA resets all the registers that can be reset by RSTC/RSTD. During its initialization, the host driver is set this field to 1 to reset uSDHC. The uSDHC module resets this field to 0 when the capabilities registers are valid and the host driver can read them. Additional use of Software Reset For All does not affect the value of the capabilities registers. After this field is set, it is recommended that the host driver reset the external card and re-initialize it. After this field is set, the software should wait for self-clear. In tuning process, after every CMD19 is finished, this field is set to retest uSDHC. **NOTE:** When reset, the software must make sure there is no incomplete data transferring. If there is data transfer going on, the software needs to wait TC or DC INT_STATUS register is set. 0b - No reset 1b - Reset
23 IPP_RST_N	Hardware reset This field's value is output to card through pad directly to hardware reset pin of the card if the card supports this feature.
22 —	Reserved
21 —	Reserved
20 —	Reserved
19-16 DTOCV	Data timeout counter value This value determines the interval by which DAT line timeouts are detected. See the Data Timeout Error field in the Interrupt Status register for information on factors that dictate time-out generation. Time-out clock frequency is generated by dividing the base clock SDCLK value by this value. The host driver can clear the Data Timeout Error Status Enable (in the Interrupt Status Enable register) to prevent inadvertent time-out events.

Table continues on the next page...

Field	Function
	0000b - SDCLK x 2^{32} 0001b - SDCLK x 2^{33} 0010b - SDCLK x 2^{18} 0011b - SDCLK x 2^{19} 1101b - SDCLK x 2^{29} recommend to use for other speed mode except HS400/HS200/SDR104 mode 1110b - SDCLK x 2^{30} recommend to use for HS200/SDR104 mode 1111b - SDCLK x 2^{31} recommend to use for HS400 mode
15-8 SDCLKFS	SDCLK frequency select This field is used to select the frequency of the SDCLK pin. The frequency is not programmed directly, rather this field holds the prescaler (of this register) and divisor (next register) of the Base Clock Frequency register. In Single Data Rate mode (DDR_EN field of MIXERCTRL is '0') Only the following settings are allowed: 80h) Base clock divided by 256 40h) Base clock divided by 128 20h) Base clock divided by 64 10h) Base clock divided by 32 08h) Base clock divided by 16 04h) Base clock divided by 8 02h) Base clock divided by 4 01h) Base clock divided by 2 00h) Base clock divided by 1 While in Dual Data Rate mode (DDR_EN field of MIXERCTRL is '1') Only the following settings are allowed: 80h) Base clock divided by 512 40h) Base clock divided by 256 20h) Base clock divided by 128 10h) Base clock divided by 64 08h) Base clock divided by 32 04h) Base clock divided by 16 02h) Base clock divided by 8 01h) Base clock divided by 4 00h) Base clock divided by 2 When the software changes the DDR_EN field, SDCLKFS might need to be changed also. In Single Data Rate mode, setting 00h bypasses the frequency prescaler of the SD clock. Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits. The frequency of SDCLK is set by the following formula: Clock Frequency = (Base Clock) / (prescaler x divisor)

Table continues on the next page...

Field	Function
	For example, in Single Data Rate mode, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h yields 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz. The reset value of this field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD clock after reset is 375 kHz. According to the SD Physical Specification Version 1.1 and the SDIO Card Specification Version 1.2, the maximum SD clock frequency is 50 MHz and is never exceed this limit. Before changing clock divisor value (SDCLKFS or DVS), host driver should make sure the SDSTB field is high. If setting SDCLKFS and DVS can generate the same clock frequency,(for example, in SDR mode, SDCLKFS = 01h is same as DVS = 01h.), SDCLKFS is highly recommended.
7-4 DVS	Divisor This field is used to provide a more exact divisor to generate the desired SD clock frequency. Note the divider can even support odd divisors without deterioration of duty cycle. Before changing clock divisor value (SDCLKFS or DVS), Host driver should make sure the SDSTB field is high. The settings are as follows: 0000b - Divide-by-1 0001b - Divide-by-2 1110b - Divide-by-15 1111b - Divide-by-16
3-0 —	Reserved Always write as 1.

10.3.6.1.14 Interrupt Status (INT_STATUS)

10.3.6.1.14.1 Offset

Register	Offset
INT_STATUS	30h

10.3.6.1.14.2 Function

An interrupt is generated when the normal interrupt signal enable is enabled and at least one of the status fields is set to 1. For all fields, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For card interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the card driver services the interrupt condition; otherwise, the CINT field is asserted again.

The table below shows the relationship between the command timeout error and the command complete.

Table 10-39. uSDHC status for command timeout error/command complete bit combinations

Command CRC Error	Command timeout error	Meaning of the status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

The table below shows the relationship between the transfer complete and the data timeout error.

Table 10-40. uSDHC status for data timeout error/transfer complete bit combinations

Transfer complete	Data timeout error	Meaning of the status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data transfer complete

The table below shows the relationship between the command CRC error and command timeout error.

Table 10-41. uSDHC status for command CRC error/command timeout error bit combinations

Command complete	Command timeout error	Meaning of the status
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

10.3.6.1.14.4 Fields

Field	Function
31-29 —	Reserved
28 DMAE	DMA error Occurs when an Internal DMA transfer has failed. This field is set to 1, when some error occurs in the data transfer. This error can be caused by either simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. Because any error corrupts the whole data block, the host driver restarts the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size. 0b - No error 1b - Error
27 —	Reserved
26 TNE	Tuning error: (only for SD3.0 SDR104 mode and EMMC HS200 mode) This field is set when an unrecoverable error is detected in a tuning circuit. By detecting Tuning Error, host driver needs to abort a command executing and perform tuning.
25 —	Reserved
24 AC12E	Auto CMD12 error Occurs when detecting that one of the fields in the Auto CMD12 Error Status register has changed from 0 to 1. This field is set to 1, not only when the errors in Auto CMD12 occur, but also, when the Auto CMD12 is not executed due to the previous command error. 0b - No error 1b - Error
23	Reserved

Table continues on the next page...

Field	Function
—	
22 DEBE	Data end bit error Occurs either when detecting 0 at the end field position of read data that uses the DATA line, or at the end field position of the CRC. This field is not asserted in tuning process. 0b - No error 1b - Error
21 DCE	Data CRC error Occurs when detecting a CRC error when transferring read data that uses the DATA line, or when detecting the Write CRC status having a value other than 010. This field is not asserted in tuning process. 0b - No error 1b - Error
20 DTOE	Data timeout error Occurs when detecting one of following time-out conditions. • Busy time-out for R1b, R5b type • Busy time-out after Write CRC status • Read Data time-out. This field is not asserted in tuning process. 0b - No error 1b - Time out
19 CIE	Command index error Occurs if a command index error occurs in the command response. This field is not asserted in tuning process. 0b - No error 1b - Error
18 CEBE	Command end bit error Occurs when detecting that the end field of a command response is 0. This field is not asserted in tuning process. 0b - No error 1b - End bit error generated
17 CCE	Command CRC error Command CRC Error is generated in two cases. • If a response is returned and the Command Timeout Error is set to 0 (indicating no time-out), this field is set when detecting a CRC error in the command response. • The uSDHC module detects a CMD line conflict by monitoring the CMD line when a command is issued. If uSDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then uSDHC aborts the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error should also be set to 1 to distinguish CMD line conflict. This field is not asserted in tuning process. 0b - No error 1b - CRC error generated
16	Command timeout error

Table continues on the next page...

Field	Function
CTOE	Occurs only if no response is returned within 64 SDCLK cycles from the end field of the command. If uSDHC detects a CMD line conflict, in which case a Command CRC Error is also be set (as shown in Interrupt Status (INT_STATUS)), this field is set without waiting for 64 SDCLK cycles. This is because the command is aborted by uSDHC. This field is not asserted in tuning process. 0b - No error 1b - Time out
15 —	Reserved
14 CQI	Command queuing interrupt This interrupt is asserted when at least one of the bits in CQIS register is set. This interrupt is cleared only by clearing the source interrupt in CQIS register.
13 TP	Tuning pass:(only for SD3.0 SDR104 mode and EMMC HS200 mode) Current CMD19 transfer is done successfully. That is, current sampling point is correct.
12 RTE	Re-tuning event: (only for SD3.0 SDR104 mode and EMMC HS200 mode) This status is set if Re-Tuning Request in the Present State register changes from 0 to 1. host controller requests host driver to perform re-tuning for next data transfer. Current data transfer (not large block count) can be completed without re-tuning. 0b - Re-tuning is not required. 1b - Re-tuning should be performed.
11-9 —	Reserved
8 CINT	Card interrupt This status field is set when an interrupt signal is detected from the external card. In 1-bit mode, uSDHC detects the Card Interrupt without the SD clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from the SDIO card and the interrupt to the host system. Writing this field to 1 can clear this field, but as the interrupt source from the SDIO card does not clear, this field is set again. to clear this field, it is required to reset the interrupt source from the external card followed by a writing 1 to this field. When this status has been set, and the host driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the host system. After completion of the card interrupt service (It should reset the interrupt sources in the SDIO card and the interrupt signal might not be asserted), write 1 to clear this field, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again. 0b - No card interrupt 1b - Generate card interrupt
7 CRM	Card removal This status field is set if the Card Inserted field in the Present State register changes from 1 to 0. When the host driver writes this field to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state might possibly be changed when the host driver clears this field and the interrupt event might not be generated. When this field is cleared, it is set again if no card is inserted. to leave it cleared, clear the Card Removal Status Enable field in Interrupt Status Enable register. 0b - Card state unstable or inserted 1b - Card removed
6	Card insertion

Table continues on the next page...

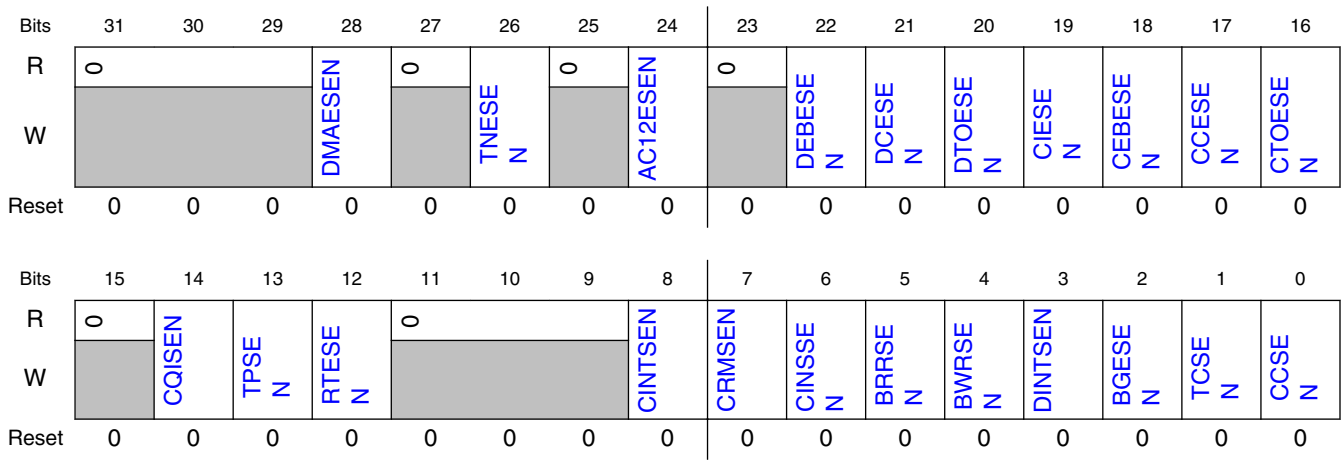
Field	Function
CINS	This status field is set if the Card Inserted field in the Present State register changes from 0 to 1. When the host driver writes this field to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state might possibly be changed when the host driver clears this field and the interrupt event might not be generated. When this field is cleared, it is set again if a card is inserted. to leave it cleared, clear the Card Inserted Status Enable field in Interrupt Status Enable register. 0b - Card state unstable or removed 1b - Card inserted
5 BRR	Buffer read ready This status field is set if the Buffer Read Enable field, in the Present State register, changes from 0 to 1. See the Buffer Read Enable field in the Present State register for additional information. This field indicates that cmd19 is finished in tuning process. 0b - Not ready to read buffer 1b - Ready to read buffer
4 BWR	Buffer write ready This status field is set if the Buffer Write Enable field, in the Present State register, changes from 0 to 1. See the Buffer Write Enable field in the Present State register for additional information. 0b - Not ready to write buffer 1b - Ready to write buffer
3 DINT	DMA interrupt Occurs only when the internal DMA finishes the data transfer successfully. Whenever errors occur during data transfer, this field does not be set. Instead, the DMAE field is set. Either Simple DMA or ADMA finishes data transferring, this field is set. 0b - No DMA interrupt 1b - DMA interrupt is generated.
2 BGE	Block gap event If the Stop At Block Gap Request field in the Protocol Control register is set, this field is set when a read or write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this field is not set to 1. In the case of a Read Transaction: This field is set at the falling edge of the DATA Line Active Status (When the transaction is stopped at SD bus timing). The Read Wait must be supported to use this function. In the case of Write Transaction: This field is set at the falling edge of Write Transfer Active Status (After getting CRC status at SD Bus timing). 0b - No block gap event 1b - Transaction stopped at block gap
1 TC	Transfer complete This field is set when a read or write transfer is completed. In the case of a Read Transaction: This field is set at the falling edge of the Read Transfer Active Status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length (after the last data has been read to the host system). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request field in the Protocol Control register (after valid data has been read to the host system). In the case of a Write Transaction: This field is set at the falling edge of the DATA Line Active Status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as specified by the data length and the busy signal is released. The second is when data

Table continues on the next page...

Field	Function
	transfers are stopped at the block gap, by setting the Stop At Block Gap Request field in the Protocol Control register, and the data transfers are completed. (after valid data is written to the SD card and the busy signal released). In the case of a command with busy, this field is set when busy is deasserted. This field is not asserted in tuning process. 0b - Transfer does not complete 1b - Transfer complete
0 CC	Command complete This field is set when you receive the end field of the command response (except auto CMD12). See the Command Inhibit (CMD) in the Present State register. This field is not asserted in tuning process. 0b - Command not complete 1b - Command complete

10.3.6.1.15 Interrupt Status Enable (INT_STATUS_EN)

10.3.6.1.15.1 Offset



Register	Offset
INT_STATUS_EN	34h

10.3.6.1.15.2 Function

Setting any bit in this register to 1 enables the corresponding interrupt status be requested to the system. If any bit is set to 0, the corresponding interrupt request gets blocked.

- Depending on IABG field setting, uSDHC might be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There are some delays on the Card Interrupt, asserted from the card, to the time the host system is informed.
- To detect a CMD line conflict, the host driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

10.3.6.1.17 Auto CMD12 Error Status (AUTOCMD12_ERR_STATUS)

10.3.6.1.17.1 Offset

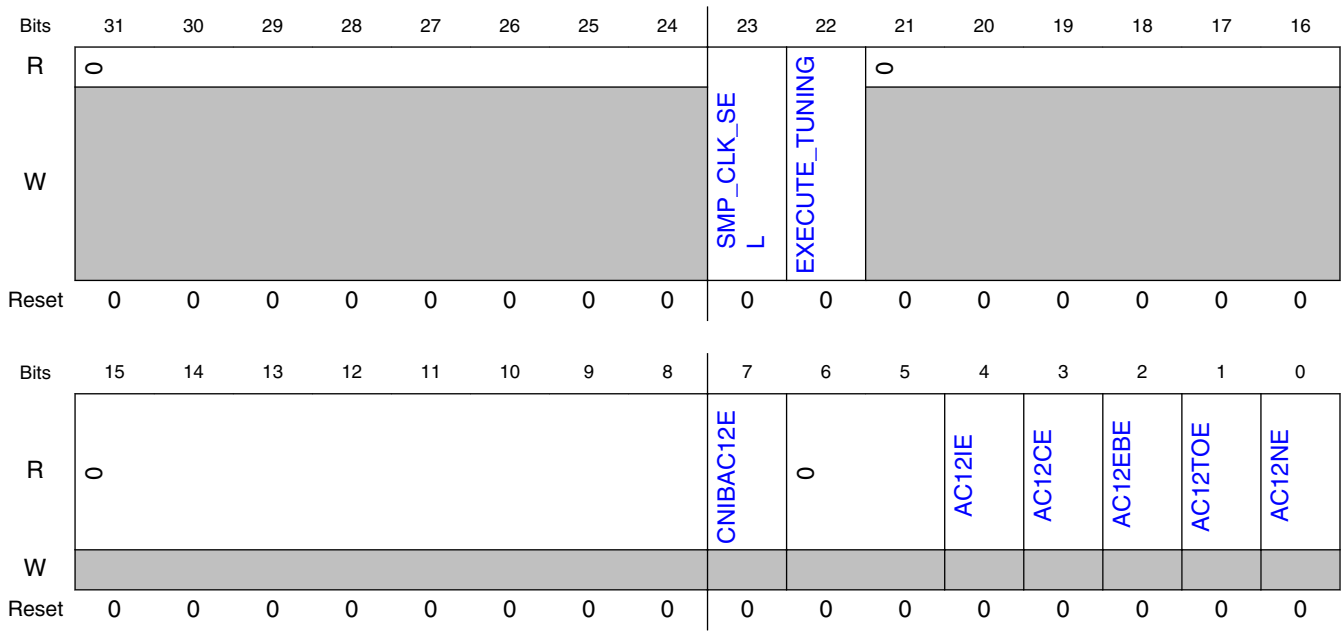
Register	Offset
AUTOCMD12_ERR_STATUS	3Ch

10.3.6.1.17.2 Function

When the Auto CMD12 Error Status field in the Status register is set, the host driver checks this register to identify what kind of error the Auto CMD12 / CMD 23 indicated. Auto CMD23 errors are indicated in field 04-01. This register is valid only when the Auto CMD12 Error status field is set.

The table below shows the relationship between the Auto CMGD12 CRC Error and the Auto CMD12 Command Timeout Error.

Table 10-42. Relationship between command CRC error and command timeout error for auto CMD12



Auto CMD12 CRC error	Auto CMD12 timeout error	Type of error
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

- When uSDHC is going to issue an Auto CMD12
  - Set field 0 to 1 if the Auto CMD12 cannot be issued due to an error in the previous command
  - Set field 0 to 0 if the Auto CMD12 is issued
- At the end field of an Auto CMD12 response
  - Check errors correspond to fields 1-4
  - Set fields 1-4 corresponding to detected errors
  - Clear fields 1-4 corresponding to detected errors
- Before reading the Auto CMD12 Error Status field 7
  - Set field 7 to 1 if there is a command that can't be issued
  - Clear field 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, field 7 is sampled when the driver is not writing to the Command register. So, it is suggested to read this register only when the AC12E field in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error fields (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

10.3.6.1.17.3 Diagram

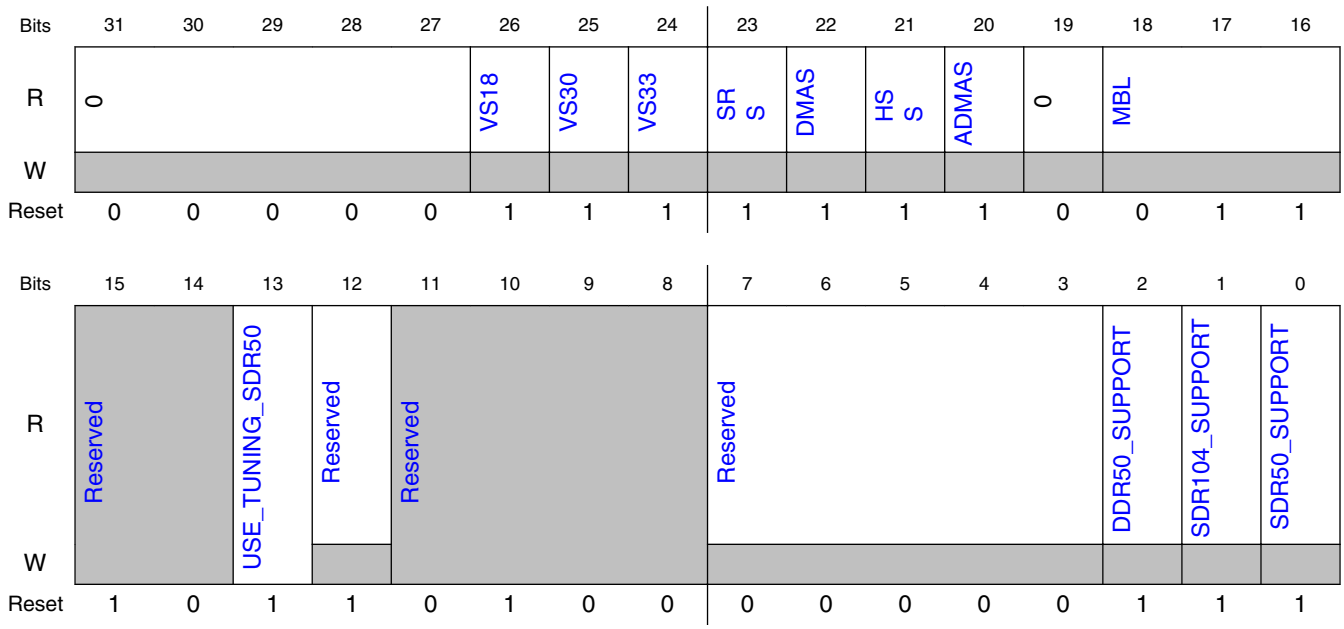
10.3.6.1.17.4 Fields

Field	Function
31-24 —	Reserved
23 SMP_CLK_SEL	Sample clock select This field is used to select sampling clock to receive CMD and DATA. This field is functional only when TUNING_CTRL[STD_TUNING_EN] is set. Otherwise, this field is reserved. This field is controlled by re-tuning procedure and is valid after the tuning procedure is complete (AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]=0). A value of '1' means that tuning has been completed successfully and a value of '0' implies the tuning has failed. Writing '1' to this field is meaningless and ignored when the tuning has failed. The tuning circuit is reset by writing '0' to this field. This field can be cleared by setting AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]=1. Once the tuning circuit is reset, it takes time to complete tuning sequence. Therefore, host driver should keep this field as 1 to perform the re-tuning sequence in a short time. This field cannot be changed while the Host controller is receiving response or a read data block. 0b - Fixed clock is used to sample data 1b - Tuned clock is used to sample data
22 EXECUTE_TUNING	Execute tuning This field is used to start the tuning procedure. This field is functional only when TUNING_CTRL[STD_TUNING_EN] is set. Otherwise, this field is reserved. This field is set to start tuning procedure and automatically cleared when tuning procedure is completed. The result of tuning is indicated to AUTOCMD12_ERR_STATUS[SMP_CLK_SEL]. 0b - Tuning procedure is aborted 1b - Start tuning procedure
21-8	Reserved

Table continues on the next page...

Field	Function
—	
7 CNIBAC12E	Command not issued by Auto CMD12 error Setting this field to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 error (D04-D01) in this register. 0b - No error 1b - Not issued
6-5 —	Reserved
4 AC12IE	Auto CMD12 / 23 index error Occurs if the command index error occurs in response to a command. 0b - No error 1b - Error, the CMD index in response is not CMD12/23
3 AC12CE	Auto CMD12 / 23 CRC error Occurs when detecting a CRC error in the command response. 0b - No CRC error 1b - CRC error met in Auto CMD12/23 response
2 AC12EBE	Auto CMD12 / 23 end bit error Occurs when detecting that the end field of command response is 0 which should be 1. 0b - No error 1b - End bit error generated
1 AC12TOE	Auto CMD12 / 23 timeout error Occurs if no response is returned within 64 SDCLK cycles from the end field of the command. If this field is set to1, the other error status fields (2-4) have no meaning. 0b - No error 1b - Time out
0 AC12NE	Auto CMD12 not executed If memory multiple block data transfer is not started, due to a command error, this field is not set because it is not necessary to issue an Auto CMD12. Setting this field to 1 means uSDHC cannot issue the Auto CMD12 to stop a memory multiple block data transfer due to some error. If this field is set to 1, other error status fields (1-4) have no meaning. 0b - Executed 1b - Not executed

10.3.6.1.18 Host Controller Capabilities (HOST_CTRL_CAP)



10.3.6.1.18.1 Offset

Register	Offset
HOST_CTRL_CAP	40h

10.3.6.1.18.2 Function

This register provides the host driver with information specific to uSDHC implementation. The value in this register is the power-on-reset value and does not change with a software reset.

10.3.6.1.18.3 Diagram

10.3.6.1.18.4 Fields

Field	Function
31-27 —	Reserved
26 VS18	Voltage support 1.8 V This field depends on the host system ability. 0b - 1.8 V not supported 1b - 1.8 V supported

Field	Function
31-29 —	Reserved
28-24	Reserved

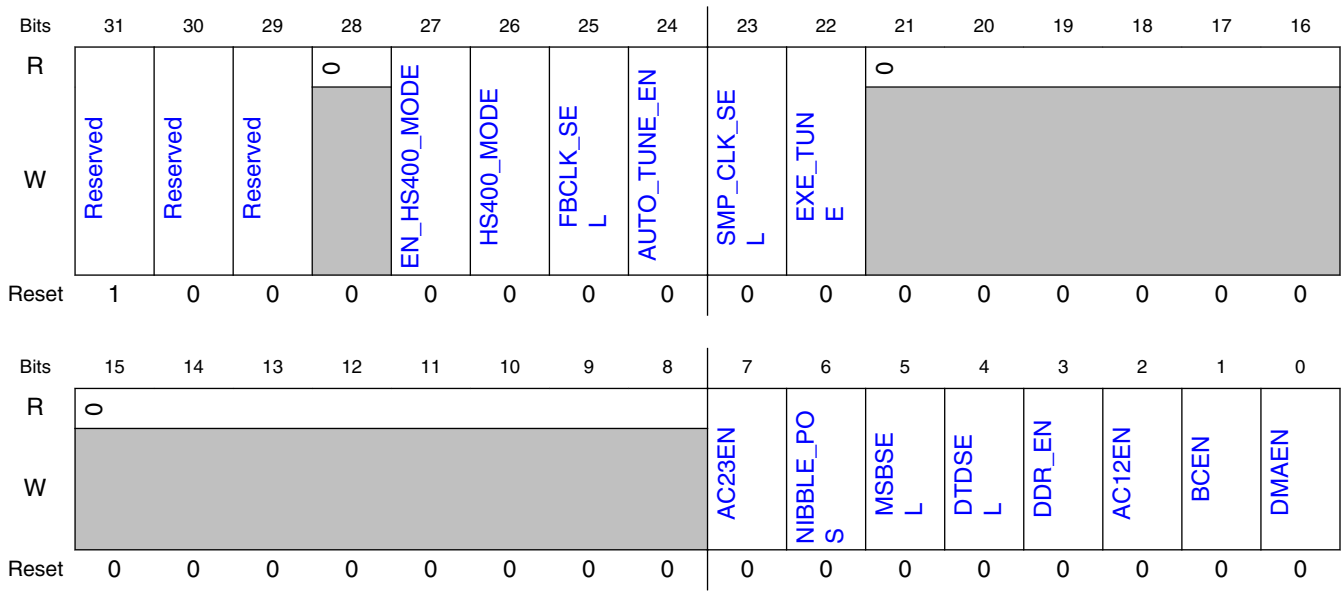
Table continues on the next page...

Field	Function
—	
23-16 WR_WML	Write watermark level This field indicates the number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also, the number of words as a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128.When using internal DMA, WR_WML can be set any value between 1 and 128. To get max AXI throughput, we recommend to use integer multiple of 16.
15-13 —	Reserved
12-8 —	Reserved
7-0 RD_WML	Read watermark level This field indicates the number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also, the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128.When using internal DMA mode, RD_WML must be set to the value less than 16. To get max AXI throughput, recommend to use 16.

10.3.6.1.20 Mixer Control (MIX_CTRL)

10.3.6.1.20.1 Offset

Register	Offset
MIX_CTRL	48h



10.3.6.1.20.2 Function

This register is used to DMA and data transfer. To prevent data loss, the software should check if data transfer is active before writing this register. These fields are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

Table 10-43. Transfer type register setting for various transfer types

Multi/single block select	Block count enable	Block count	Function
0	Do not care	Do not care	Single transfer
1	0	Do not care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer

10.3.6.1.20.3 Diagram

10.3.6.1.20.4 Fields

Field	Function
31 —	Reserved Always write as 1.
30 —	Reserved Always write as 0.
29 —	Reserved Always write as 0.
28 —	Reserved
27 EN_HS400_MODE	Enable enhance HS400 mode Enhance HS400 enable
26 HS400_MODE	Enable HS400 mode HS400 Enable
25 FBCLK_SEL	Feedback clock source selection (Only used for SD3.0, SDR104 mode and EMMC HS200 mode) 0b - Feedback clock comes from the loopback CLK 1b - Feedback clock comes from the ipp_card_clk_out
24 AUTO_TUNE_EN	Auto tuning enable (Only used for SD3.0, SDR104 mode and and EMMC HS200 mode) 0b - Disable auto tuning 1b - Enable auto tuning
23 SMP_CLK_SEL	Clock selection When TUNING_CTRL[STD_TUNING_EN] is 0, this field is used to select Tuned clock or Fixed clock to sample data / cmd (Only used for SD3.0, SDR104 mode and EMMC HS200 mode)

Table continues on the next page...

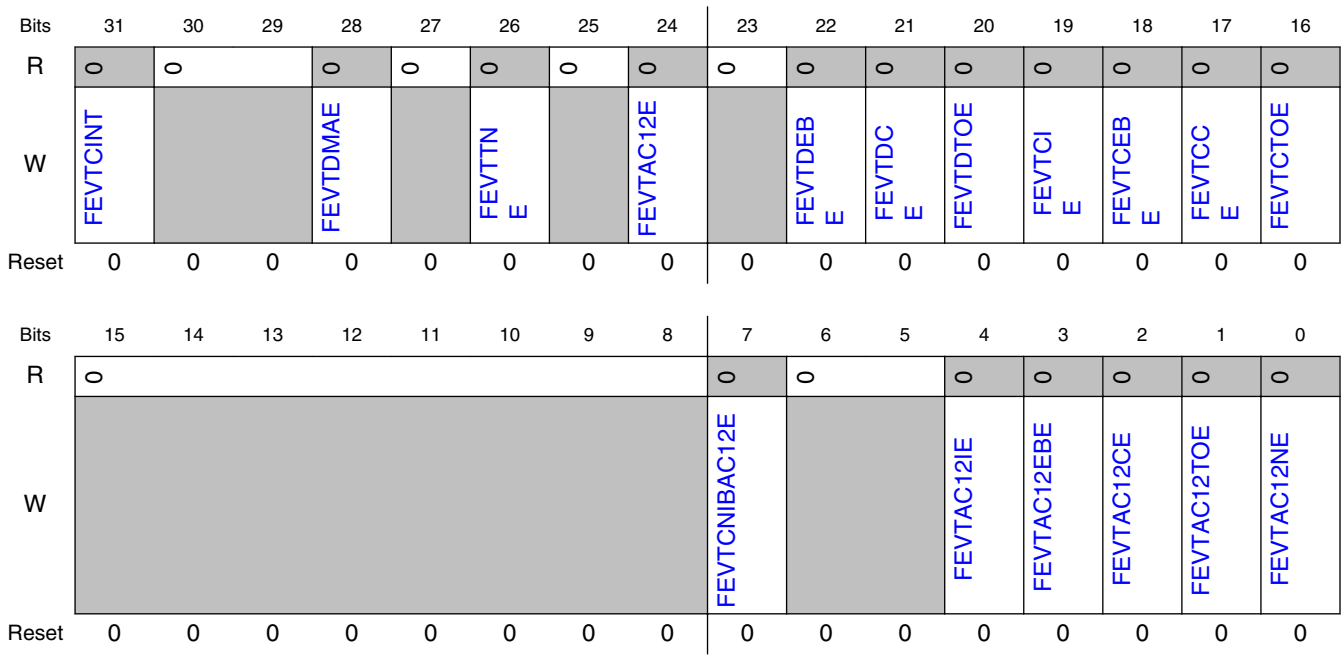
Field	Function
	0b - Fixed clock is used to sample data / cmd 1b - Tuned clock is used to sample data / cmd
22 EXE_TUNE	Execute tuning: (Only used for SD3.0, SDR104 mode and EMMC HS200 mode) When TUNING_CTRL[STD_TUNING_EN] is 0, this field is set to 1 to indicate the host driver is starting tuning procedure. Tuning procedure is aborted by writing 0. 0b - Not tuned or tuning completed 1b - Execute tuning
21-8 —	Reserved
7 AC23EN	Auto CMD23 enable When this field is set to 1, the host controller issues a CMD23 automatically before issuing a command specified in the Command Register.
6 NIBBLE_POS	Nibble position indication This field indicates the nibble position in the DDR 4-bit mode. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'.
5 MSBSEL	Multi / Single block select This field enables multiple block DATA line data transfers. For any other commands, this field can be set to 0. If this field is 0, it is not necessary to set the Block Count register. See Command Transfer Type (CMD_XFR_TYP). 0b - Single block 1b - Multiple blocks
4 DTDSEL	Data transfer direction select This field defines the direction of DATA line data transfers. The field is set to 1 by the host driver to transfer data from the SD card to uSDHC and is set to 0 for all other commands. If a CMD with the response data size cannot be divided by 64 bytes, is given without a STOP CMD, and is followed by a software reset, then you must write a 0 to DTDSEL before inserting a software reset. This is necessary to avoid any issue during the SD card reinitialization. Read multiple blocks will not be affected as it is required to have a STOP CMD. 0b - Write (Host to card) 1b - Read (Card to host)
3 DDR_EN	Dual data rate mode selection
2 AC12EN	Auto CMD12 enable Multiple block transfers for memory require a CMD12 to stop the transaction. When this field is set to 1, uSDHC issues a CMD12 automatically when the last block transfer has completed. The host driver is not set this field to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, uSDHC ignores this field no matter it is set or not. 0b - Disable 1b - Enable
1 BCEN	Block count enable This field is used to enable the Block Count register, which is only relevant for multiple block transfers. When this field is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 0b - Disable

Table continues on the next page...

Field	Function
	1b - Enable
0 DMAEN	DMA enable This field enables DMA functionality. If this field is set to 1, a DMA operation begins when the host driver sets the DPSEL field of this register. Whether the simple DMA or the advanced DMA is active depends on the DMA Select field of the Protocol Control register. 0b - Disable 1b - Enable

10.3.6.1.21 Force Event (FORCE_EVENT)

10.3.6.1.21.1 Offset



Register	Offset
FORCE_EVENT	50h

10.3.6.1.21.2 Function

This register is not a physically implemented register. Rather, it is an address at which the Interrupt Status register can be written if the corresponding field of the Interrupt Status Enable Register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register sets the corresponding field of Interrupt Status register. A read from this register always results in 0's. to change the corresponding status fields in the Interrupt Status register, make sure to set IPGEN field in System Control Register so that peripheral clock is always active.

Forcing a card interrupt generates a short pulse on the DATA1 line, and the driver might treat this interrupt as a normal interrupt. The interrupt service routine might skip polling the card interrupt factor as the interrupt is self cleared.

10.3.6.1.21.3 Diagram

10.3.6.1.21.4 Fields

Field	Function
31 FEVTCINT	Force event card interrupt Writing 1 to this field generates a short low-level pulse on the internal DATA1 line, as if a self-clearing interrupt was received from the external card. If enabled, the CINT field is set and the interrupt service routine might treat this interrupt as a normal interrupt from the external card.

1 FEVTAC12TOE	Force event auto command 12 time out error Forces the AC12TOE field in the Auto Command12 Error Status register to be set
0 FEVTAC12NE	Force event auto command 12 not executed Forces the AC12NE field in the Auto Command12 Error Status register to be set

10.3.6.1.22 ADMA Error Status (ADMA_ERR_STATUS)

10.3.6.1.22.1 Offset

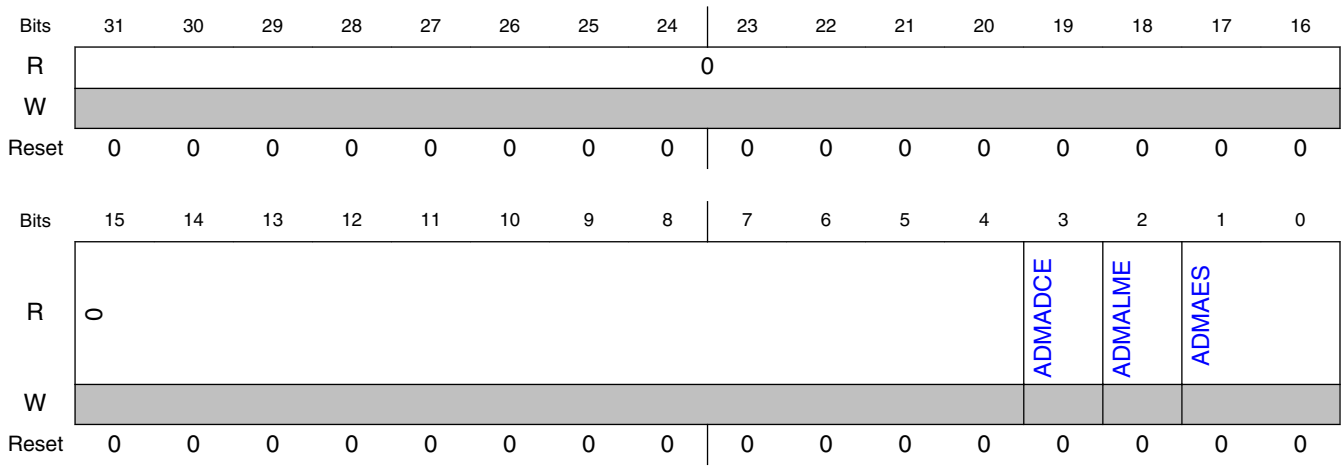
Register	Offset
ADMA_ERR_STATUS	54h

10.3.6.1.22.2 Function

When an ADMA Error Interrupt has occurred, the ADMA error sates field in this register holds the ADMA state and the ADMA System Address register holds the address around the error descriptor.

For recovering from this error, the host driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address.
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address.
- ST_CADR: This state is never set because it only increments the descriptor pointer and does not generate an ADMA error.
- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address.



In case of a write operation, the host driver should use the ACMD22 to get the number of the written block, rather than using this information, because unwritten data might exist in the host controller.

The host controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST_FDS state. The host driver can distinguish this error by reading the Valid field of the error descriptor.

Table 10-44. ADMA error state coding

D01-D00	ADMA error state (when error has occurred)	Contents of ADMA System Address register
00	ST_STOP (Stop DMA)	Holds the address of the next executable descriptor command
01	ST_FDS (Fetch descriptor)	Holds the valid descriptor address
10	ST_CADR (Change address)	No ADMA error is generated
11	ST_TFR (Transfer data)	Holds the address of the next executable descriptor command

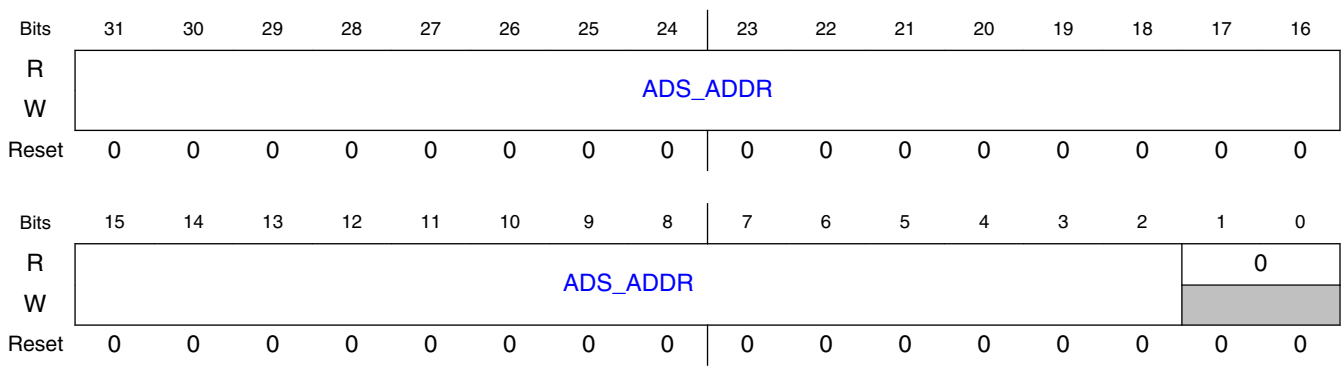
10.3.6.1.22.3 Diagram

10.3.6.1.22.4 Fields

Field	Function
31-4 —	Reserved
3 ADMADCE	ADMA descriptor error This error occurs when invalid descriptor fetched by ADMA. 0b - No error 1b - Error
2 ADMALME	ADMA length mismatch error This error occurs in the following two cases: • While the block count enable is being set, the total data length specified by the descriptor table is different from that specified by the block count and block length. • Total data length cannot be divided by the block length. 0b - No error 1b - Error
1-0 ADMAES	ADMA error state (when ADMA error is occurred) This field indicates the state of the ADMA when an error has occurred during an ADMA data transfer. See ADMA Error Status (ADMA_ERR_STATUS) for more details.

10.3.6.1.23 ADMA System Address (ADMA_SYS_ADDR)

10.3.6.1.23.1 Offset



Register	Offset
ADMA_SYS_ADDR	58h

10.3.6.1.23.2 Function

This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the host driver sets the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register holds the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned.

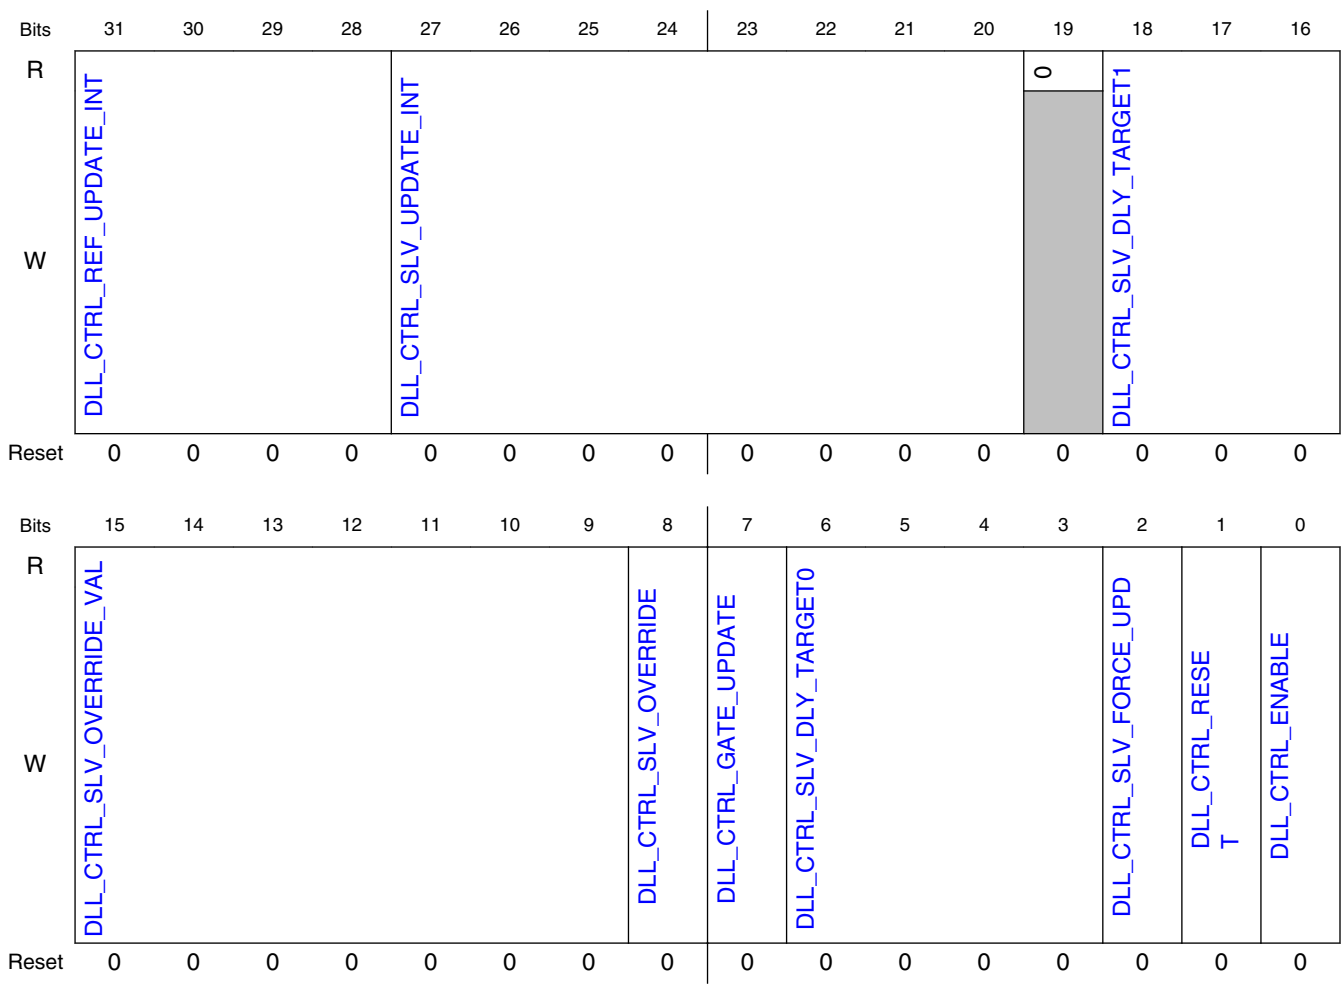
Because this register supports dynamic address reflecting, when TC field is set, it automatically alters the value of internal address counter, so the software cannot change this register when TC field is set. Such restriction is also listed in Software restrictions.

10.3.6.1.23.3 Diagram

10.3.6.1.23.4 Fields

Field	Function
31-2 ADS_ADDR	ADMA system address This field contains the physical system memory address used for ADMA transfers.
1-0 —	Reserved

10.3.6.1.24 DLL (Delay Line) Control (DLL_CTRL)



10.3.6.1.24.1 Offset

Register	Offset
DLL_CTRL	60h

10.3.6.1.24.2 Function

This register contains control fields for DLL.

10.3.6.1.24.3 Diagram

10.3.6.1.24.4 Fields

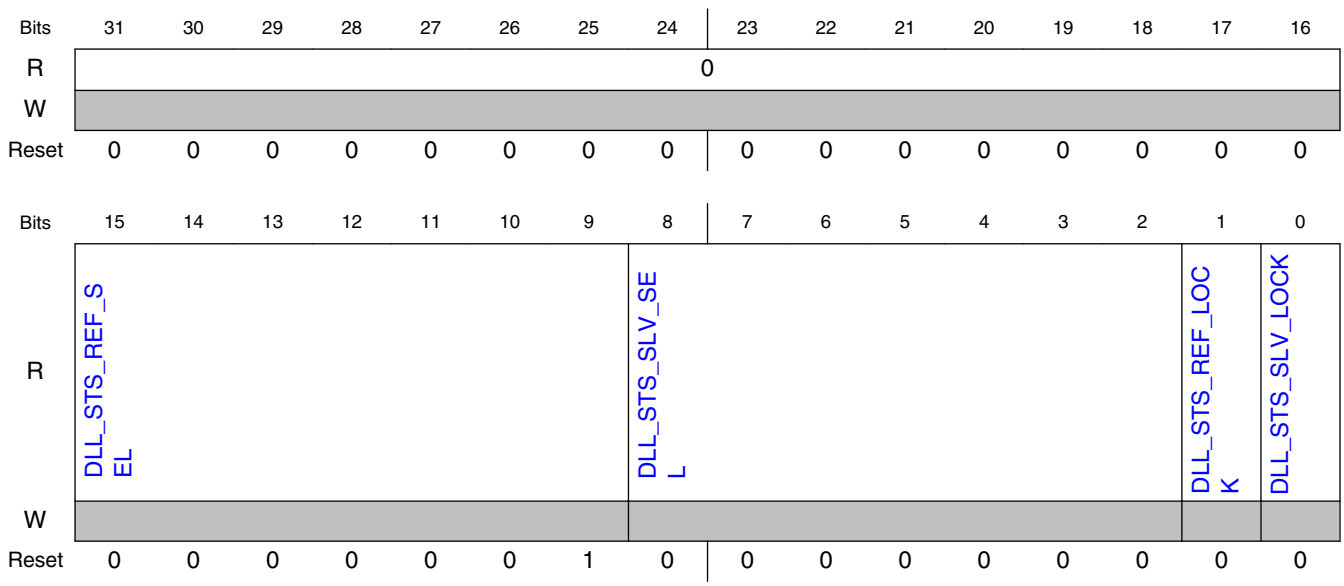
Field	Function
31-28	DLL control loop update interval

Table continues on the next page...

Field	Function
DLL_CTRL_REF_UPDATE_INT	The interval cycle is (2 + REF_UPDATE_INT) * REF_CLOCK. By default, the DLL control loop updates every two REF_CLOCK cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that might effect the delay (such as voltage and temperature)
27-20 DLL_CTRL_SLV_UPDATE_INT	Slave delay line update interval If default 0 is used, it means 256 cycles of REF_CLOCK. A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line also updates automatically when the reference DLL transitions to a locked state (from an un-locked state).
19 —	Reserved
18-16 DLL_CTRL_SLV_DLY_TARGET1	DLL slave delay target1 See DLL_CTRL_SLV_DLY_TARGET0 below.
15-9 DLL_CTRL_SLV_OVERRIDE_VAL	DLL slave override val When SLV_OVERRIDE = 1, this field is used to select 1 of 128 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 128.
8 DLL_CTRL_SLV_OVERRIDE	DLL slave override Set this field to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE field. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0
7 DLL_CTRL_GATE_UPDATE	DLL gate update Set this field to 1 to prevent the DLL from updating (because when clock_in exists, glitches might appear during DLL updates). This field might be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.
6-3 DLL_CTRL_SLV_DLY_TARGET0	DLL slave delay target0 The delay target for uSDHC loopback read clock can be programmed in 1/16th increments of an ref_clock half-period. The delay is (({DLL_CTRL_SLV_DLY_TARGET1,DLL_CTRL_SLV_DLY_TARGET0} +1)* REF_CLOCK / 2) / 16 So the input read-clock can be delayed relative input data from (REF_CLOCK / 2) / 16 to REF_CLOCK * 4. **NOTE:** For the restrictions of delay cell implementation, the delay target must be set between REF_CLOCK/16 and REF_CLOCK*2 when REF_CLOCK is running at 200 MHz. When REF_CLOCK frequency is slower than 100 MHz, the maximum delay target might not reach REF_CLOCK*2.
2 DLL_CTRL_SLV_FORCE_UPD	DLL slave delay line Setting this field to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line updates automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function might not work when uSDHC is working on data / cmd / response.
1 DLL_CTRL_RESET	DLL reset Setting this field to 1 force a reset on DLL. This causes the DLL to lose lock and re-calibrate to detect an REF_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, so to create a subsequent reset, RESET must be taken low and then asserted again.
0	DLL and delay chain

Field	Function
DLL_CTRL_ENABLE	Set this field to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.

10.3.6.1.25 DLL Status (DLL_STATUS)



10.3.6.1.25.1 Offset

Register	Offset
DLL_STATUS	64h

10.3.6.1.25.2 Function

This register contains the DLL status information. All fields are read only and reads the same as the power-reset value.

10.3.6.1.25.3 Diagram

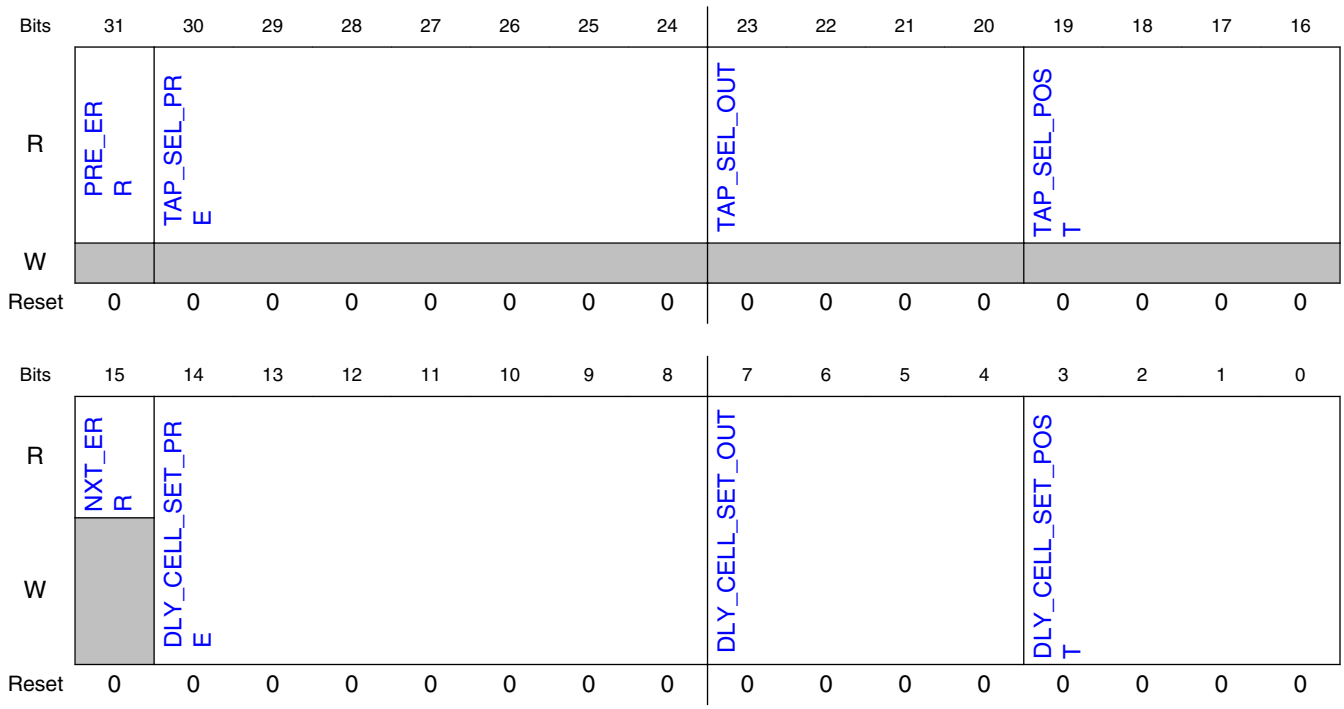
10.3.6.1.25.4 Fields

Field	Function
31-16	Reserved

Table continues on the next page...

Field	Function
—	
15-9 DLL_STS_REF_SEL	Reference delay line select taps This is encoded by 7 fields for 127 taps.
8-2 DLL_STS_SLV_SEL	Slave delay line select status This is the instant value generated from reference chain. Because the reference chain can only be updated when REF_CLOCK is detected, this value should be the right value to be updated when the reference is locked.
1 DLL_STS_REF_LOCK	Reference DLL lock status This signifies that the DLL has detected and locked to a half-phase ref_clock shift, allowing the slave delay-line to perform programmed clock delays
0 DLL_STS_SLV_LOCK	Slave delay-line lock status This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value

10.3.6.1.26 CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS)



10.3.6.1.26.1 Offset

Register	Offset
CLK_TUNE_CTRL_STATUS	68h

10.3.6.1.26.2 Function

This register contains the Clock Tuning Control status information. All fields are read only and reads the same as the power-reset value. This register is added to support SD3.0 UHS-I SDR104 mode and EMMC HS200 mode.

10.3.6.1.26.3 Diagram

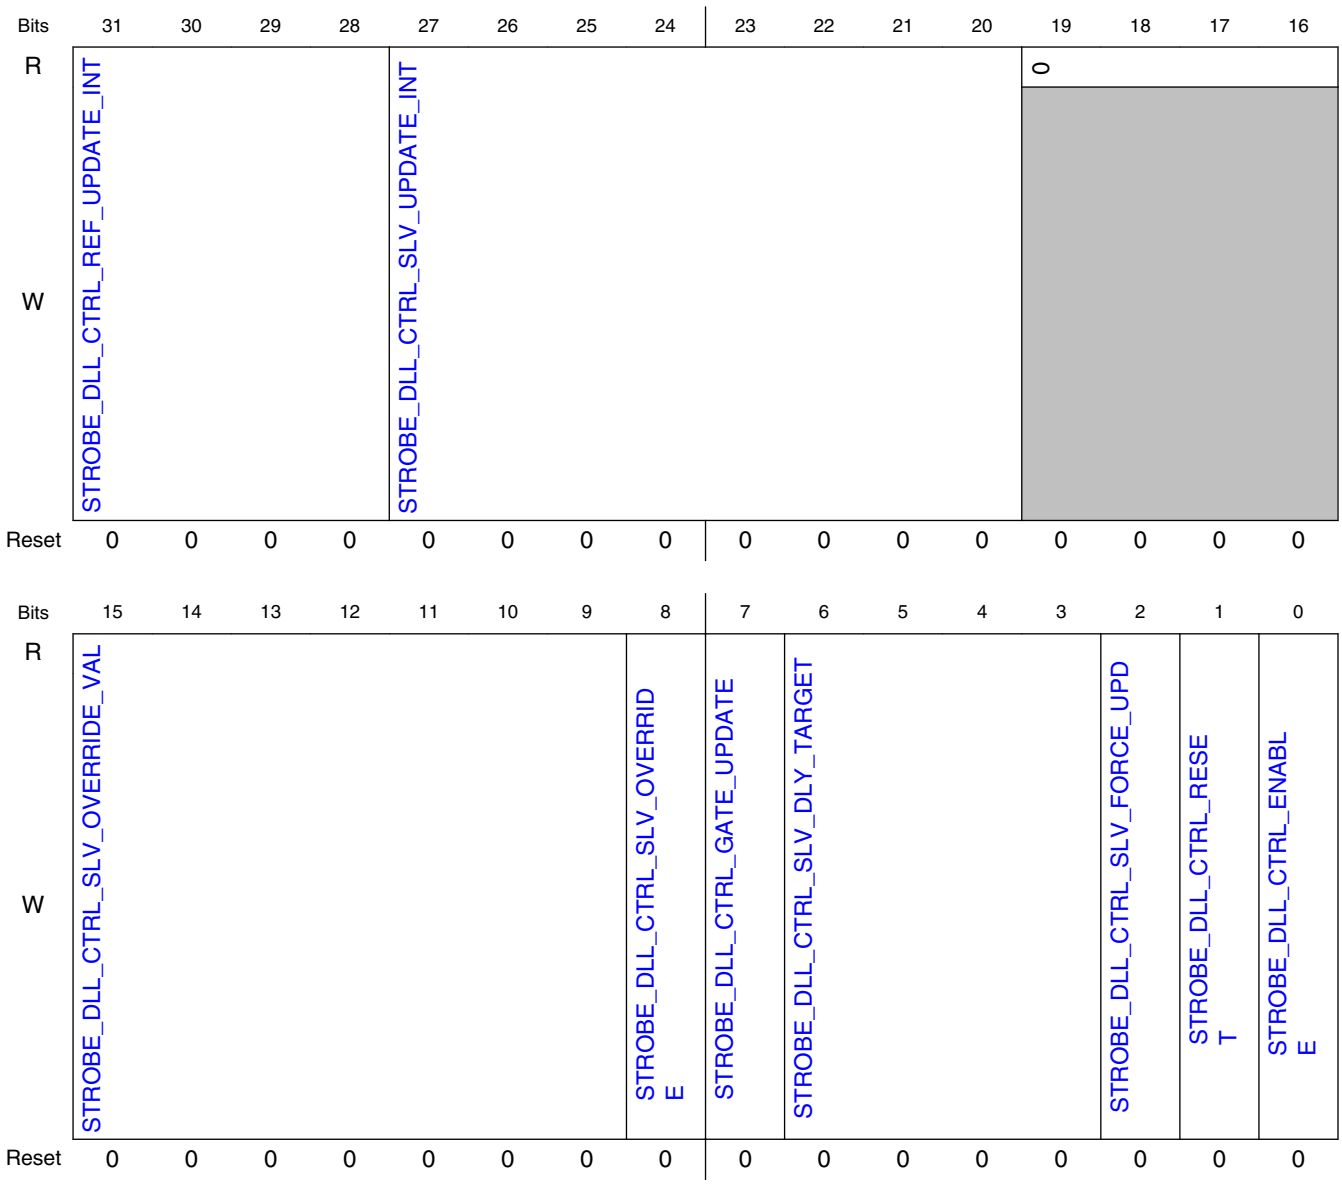
10.3.6.1.26.4 Fields

Field	Function
31 PRE_ERR	PRE error PRE error which means the number of delay cells added on the feedback clock is too small. It is valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
30-24 TAP_SEL_PRE	TAP_SEL_PRE Reflects the number of delay cells added on the feedback clock between the feedback clock and CLK_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is disabled, TAP_SEL_PRE is always equal to DLY_CELL_SET_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is enabled, TAP_SEL_PRE is updated automatically according to the status of the auto tuning circuit to adjust the sample clock phase.
23-20 TAP_SEL_OUT	Delay cells added on the feedback clock between CLK_PRE and CLK_OUT Reflects the number of delay cells added on the feedback clock between CLK_PRE and CLK_OUT.
19-16 TAP_SEL_POST	Delay cells added on the feedback clock between CLK_OUT and CLK_POST Reflects the number of delay cells added on the feedback clock between CLK_OUT and CLK_POST.
15 NXT_ERR	NXT error NXT error which means the number of delay cells added on the feedback clock is too large. It's valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
14-8	delay cells on the feedback clock between the feedback clock and CLK_PRE

Table continues on the next page...

Field	Function
DLY_CELL_SET_PRE	Set the number of delay cells on the feedback clock between the feedback clock and CLK_PRE.
7-4 DLY_CELL_SET_OUT	Delay cells on the feedback clock between CLK_PRE and CLK_OUT Set the number of delay cells on the feedback clock between CLK_PRE and CLK_OUT.
3-0 DLY_CELL_SET_POST	Delay cells on the feedback clock between CLK_OUT and CLK_POST Set the number of delay cells on the feedback clock between CLK_OUT and CLK_POST.

10.3.6.1.27 Strobe DLL control (STROBE_DLL_CTRL)



10.3.6.1.27.1 Offset

Register	Offset
STROBE_DLL_CTRL	70h

10.3.6.1.27.2 Function

This register contains the strobe DLL control information.

10.3.6.1.27.3 Diagram

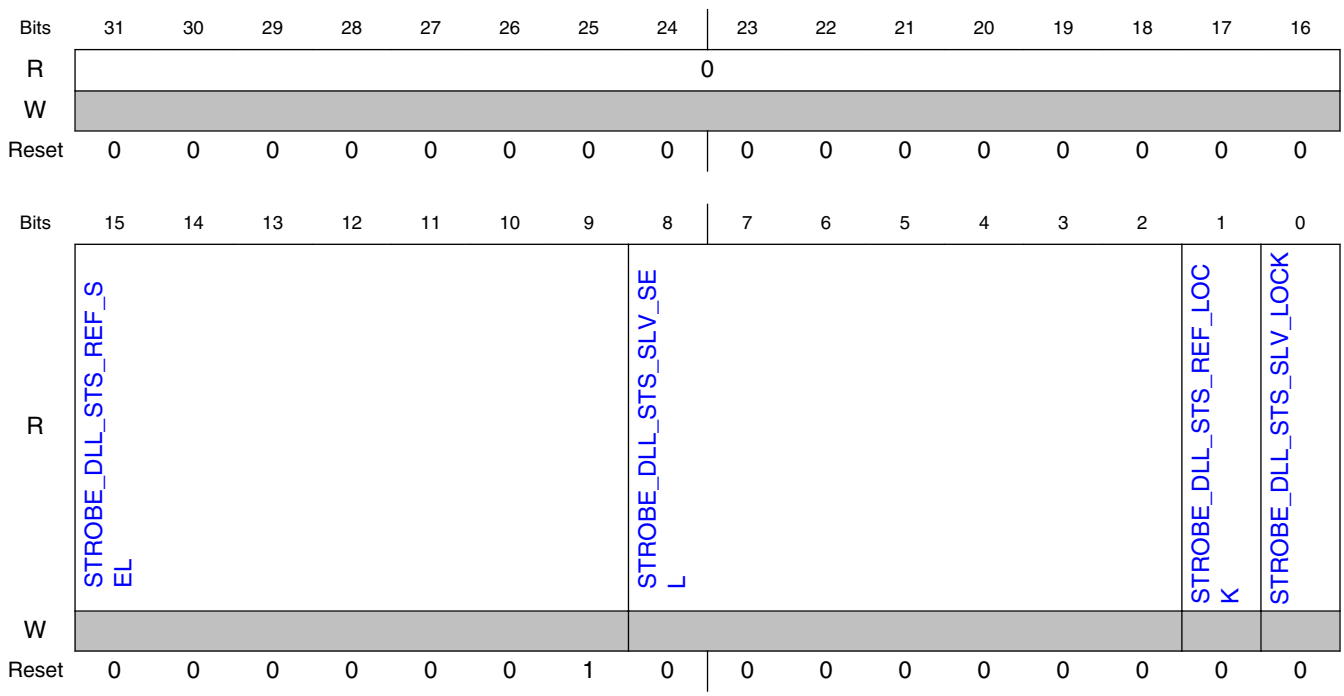
10.3.6.1.27.4 Fields

Field	Function
31-28	Strobe DLL control reference update interval
STROBE_DLL_CTRL_REF_UPDATE_INT	The interval cycle is (2 + STROBE_REF_UPDATE_INT) * STROBE_REF_CLOCK. By default, the DLL control loop updates every two STROBE_REF_CLOCK cycles. **NOTE:** Increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that might effect the delay (such as voltage and temperature)
27-20	Strobe DLL control slave update interval

Table continues on the next page...

Field	Function
STROBE_DLL_CTRL_SLV_UPDATE_INT	Slave delay line update interval. If default 0 is used, it means 256 cycles of STROBE_REF_CLOCK. A value of 0x0F results in 15 cycles and so on. **NOTE:** software can always cause an update of the slave-delay line using the STROBE_SLV_FORCE_UPDATE register. The slave delay line also updates automatically when the reference DLL transitions to a locked state (from an un-locked state).
19-16 —	This field is reserved. This read-only field is reserved and always has the value 0.
15-9 STROBE_DLL_CTRL_SLV_OVERRIDE_VAL	Strobe DLL control slave Override value When STROBE_SLV_OVERRIDE = 1, this field is used to manually select one of 128 physical taps. A value of 0 selects tap 1, and a value of 0x7F selects tap 128.
8 STROBE_DLL_CTRL_SLV_OVERRIDE	Strobe DLL control slave override Set this field to 1 to Enable manual override for slave delay chain using STROBE_SLV_OVERRIDE_VAL; set this field to 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE field. In fact to reduce power, if STROBE_SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0.
7 STROBE_DLL_CTRL_GATE_UPDATE	Strobe DLL control gate update Set this field to 1 to prevent the DLL from updating (because when STROBE_CLOCK_IN exists, glitches might appear during DLL updates). This field can be used by software if such a condition occurs. Clear the field to 0 to allow the DLL to update automatically.
6-3 STROBE_DLL_CTRL_SLV_DLY_TARGET	Strobe DLL Control Slave Delay Target The delay target for uSDHC loopback read clock can be programmed in 1/16th increments of an STROBE_REF_CLOCK half-period. The delay is ((STROBE_DLL_CTRL_SLV_DLY_TARGET + 1) * STROBE_REF_CLOCK / 2) / 16, So the input read-clock can be delayed relative input data from (STROBE_REF_CLOCK / 2) / 16 to (STROBE_REF_CLOCK *4)/16. **NOTE:** For the restrictions of delay cell implementation, the minimum delay target that can be set is REF_CLOCK/16.
2 STROBE_DLL_CTRL_SLV_FORCE_UPD	Strobe DLL control slave force updated Setting this field to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line should automatically update the STROBE_SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if STROBE_SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function might not work when uSDHC is working on data / cmd / response.
1 STROBE_DLL_CTRL_RESET	Strobe DLL control reset Setting this field to 1 to force a reset on DLL. This causes the DLL to lose lock and re-calibrate to detect an REF_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, to create a subsequent reset, RESET must be taken low and then asserted again.
0 STROBE_DLL_CTRL_ENABLE	Strobe DLL control enable Set this field to 1 to enable the DLL and delay chain; otherwise, set to 0 to bypasses DLL. **NOTE:** Using the slave delay line override feature with STROBE_SLV_OVERRIDE and STROBE_SLV_OVERRIDE VAL, the DLL does not need to be enabled.

10.3.6.1.28 Strobe DLL status (STROBE_DLL_STATUS)



10.3.6.1.28.1 Offset

Register	Offset
STROBE_DLL_STATUS	74h

10.3.6.1.28.2 Function

This register contains the strobe DLL status information. All fields are read only and read the same as the power-reset value.

10.3.6.1.28.3 Diagram

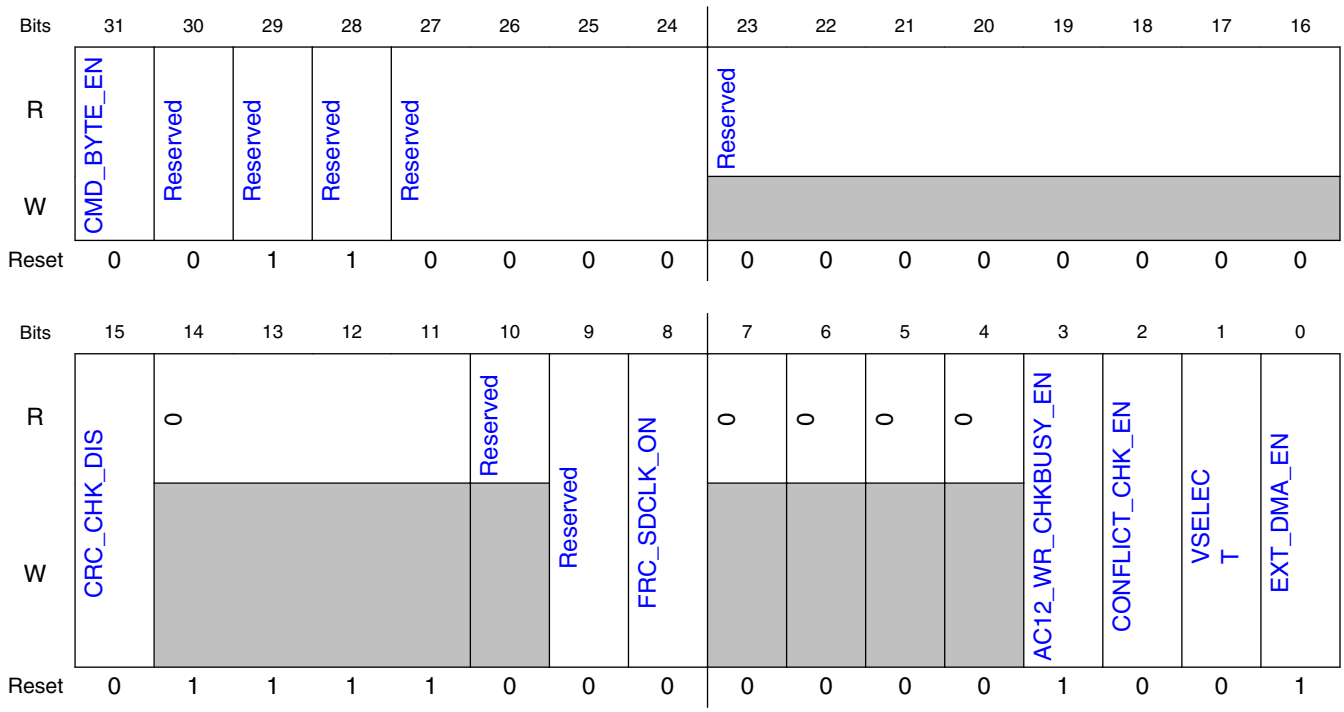
10.3.6.1.28.4 Fields

Field	Function
31-16	This field is reserved.
—	This read-only field is reserved and always has the value 0.
15-9	Strobe DLL status reference select
STROBE_DLL_STS_REF_SEL	Reference delay line select taps. This is encoded by 7 fields for 127 taps.
8-2	Strobe DLL status slave select

Table continues on the next page...

Field	Function
STROBE_DLL_STS_SLV_SEL	Slave delay line select status. This is the instant value generated from reference chain. Because the reference chain can only be updated when STROBE_REF_CLOCK is detected, this value can be updated with the right value when the reference is locked.
1 STROBE_DLL_STS_REF_LOCK	Strobe DLL status reference lock This signifies that the DLL has detected and locked to a half-phase REF_CLOCK shift, it allows the slave delay-line to perform programmed clock delays.
0 STROBE_DLL_STS_SLV_LOCK	Strobe DLL status slave lock Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line, and the slave-delay line is implementing the programmed delay value.

10.3.6.1.29 Vendor Specific Register (VEND_SPEC)



10.3.6.1.29.1 Offset

Register	Offset
VEND_SPEC	C0h

10.3.6.1.29.2 Function

This register contains the vendor specific control/status register.

10.3.6.1.29.3 Diagram

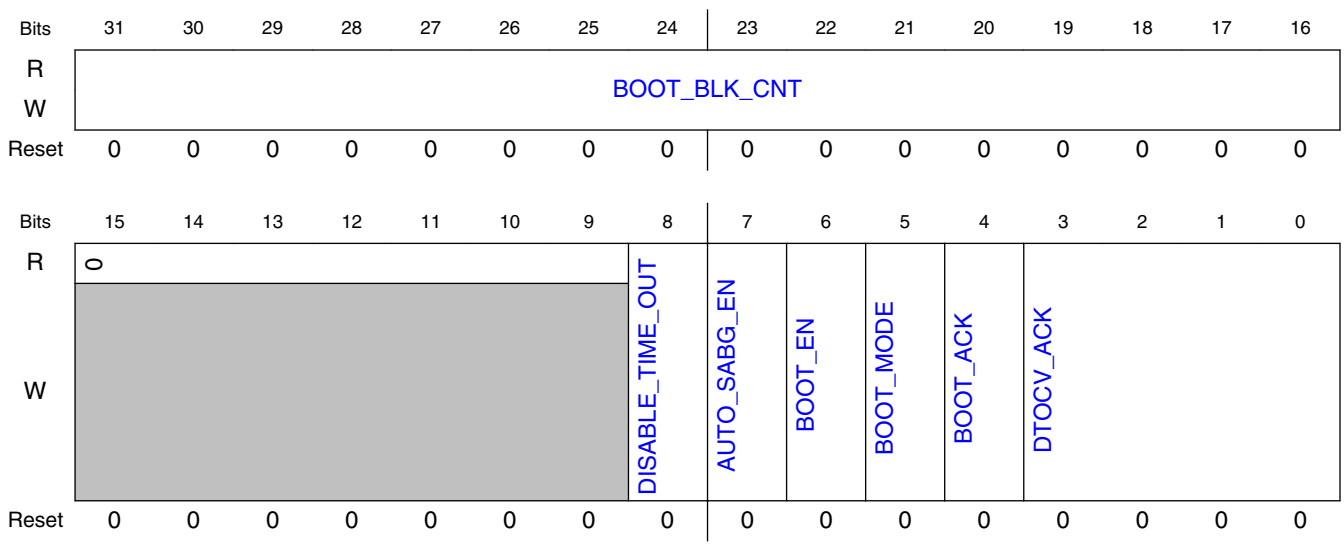
10.3.6.1.29.4 Fields

Field	Function
31 CMD_BYTE_EN	Byte access This field controls the byte access. 0b - Disable 1b - Enable
30 —	Reserved Always write as 0.
29 —	Reserved Always write as 1
28 —	Reserved Always write as 0.
27-24 —	Reserved Always write as 4'b0000.
23-16 —	Reserved Always write as 8'h00.
15 CRC_CHK_DIS	CRC Check Disable 0b - Check CRC16 for every read data packet and check CRC fields for every write data packet 1b - Ignore CRC16 check for every read data packet and ignore CRC fields check for every write data packet
14-11	Reserved

Table continues on the next page...

Field	Function
—	Reserved
10 —	Reserved Always write as 0.
9 —	Reserved Always write as 0.
8 FRC_SDCLK_ON	Force CLK Force CLK output active Do not set this bit to 1 unless it is necessary. Also, make sure that this bit is cleared when uSDHC's clock is about to be changed (frequency change, clock source change, or delay chain tuning). 0b - CLK active or inactive is fully controlled by the hardware. 1b - Force CLK active
7 —	Reserved
6 —	Reserved
5 —	Reserved
4 —	Reserved
3 AC12_WR_CHK BUSY_EN	Check busy enable Check busy enable after auto CMD12 for write data packet 0b - Do not check busy after auto CMD12 for write data packet 1b - Check busy after auto CMD12 for write data packet
2 CONFLICT_CHK_EN	Conflict check enable It is not implemented in uSDHC IP. 0b - Conflict check disable 1b - Conflict check enable
1 VSELECT	Voltage selection Change the value of output signal VSELECT to control the voltage on pads for external card. There must be a control circuit out of uSDHC to change the voltage on pads. 0b - Change the voltage to high voltage range, around 3.0 V 1b - Change the voltage to low voltage range, around 1.8 V
0 EXT_DMA_EN	External DMA request enable Enable the request to external DMA. When the internal DMA (either Simple DMA or Advanced DMA) is not in use, and this field is set, uSDHC sends out DMA request when the internal buffer is ready. This field is particularly useful when transferring data by Arm platform polling mode, and it is not allowed to send out the external DMA request. By default, this field is set. 0b - In any scenario, uSDHC does not send out external DMA request. 1b - When internal DMA is not active, the external DMA request is sent out.

10.3.6.1.30 MMC Boot (MMC_BOOT)



10.3.6.1.30.1 Offset

Register	Offset
MMC_BOOT	C4h

10.3.6.1.30.2 Function

This register contains the MMC Fast Boot control register.

10.3.6.1.30.3 Diagram

10.3.6.1.30.4 Fields

Field	Function
31-16 BOOT_BLK_CNT	Stop At Block Gap value of automatic mode The value defines the Stop At Block Gap value of automatic mode. When received, card block cnt is equal to (BLK_CNT - BOOT_BLK_CNT) and AUTO_SABG_EN is 1, then Stop At Block Gap. Here, BLK_CNT is defined in the Block Attributes Register, field 31 - 16 of 0x04.
15-9 —	Reserved
8 DISABLE_TIME_OUT	Time out **NOTE:** When this field is set, there is no timeout check no matter whether BOOT_EN is set or not. 0b - Enable time out

Table continues on the next page...

Field	Function
	1b - Disable time out
7 AUTO_SABG_EN	Auto stop at block gap During boot, enable auto stop at block gap function. This function is triggered, and host stops at block gap when received card block cnt is equal to (BLK_CNT - BOOT_BLK_CNT).
6 BOOT_EN	Boot enable Boot mode enable 0b - Fast boot disable 1b - Fast boot enable
5 BOOT_MODE	Boot mode Boot mode select 0b - Normal boot 1b - Alternative boot
4 BOOT_ACK	BOOT ACK Boot ACK mode select 0b - No ack 1b - Ack

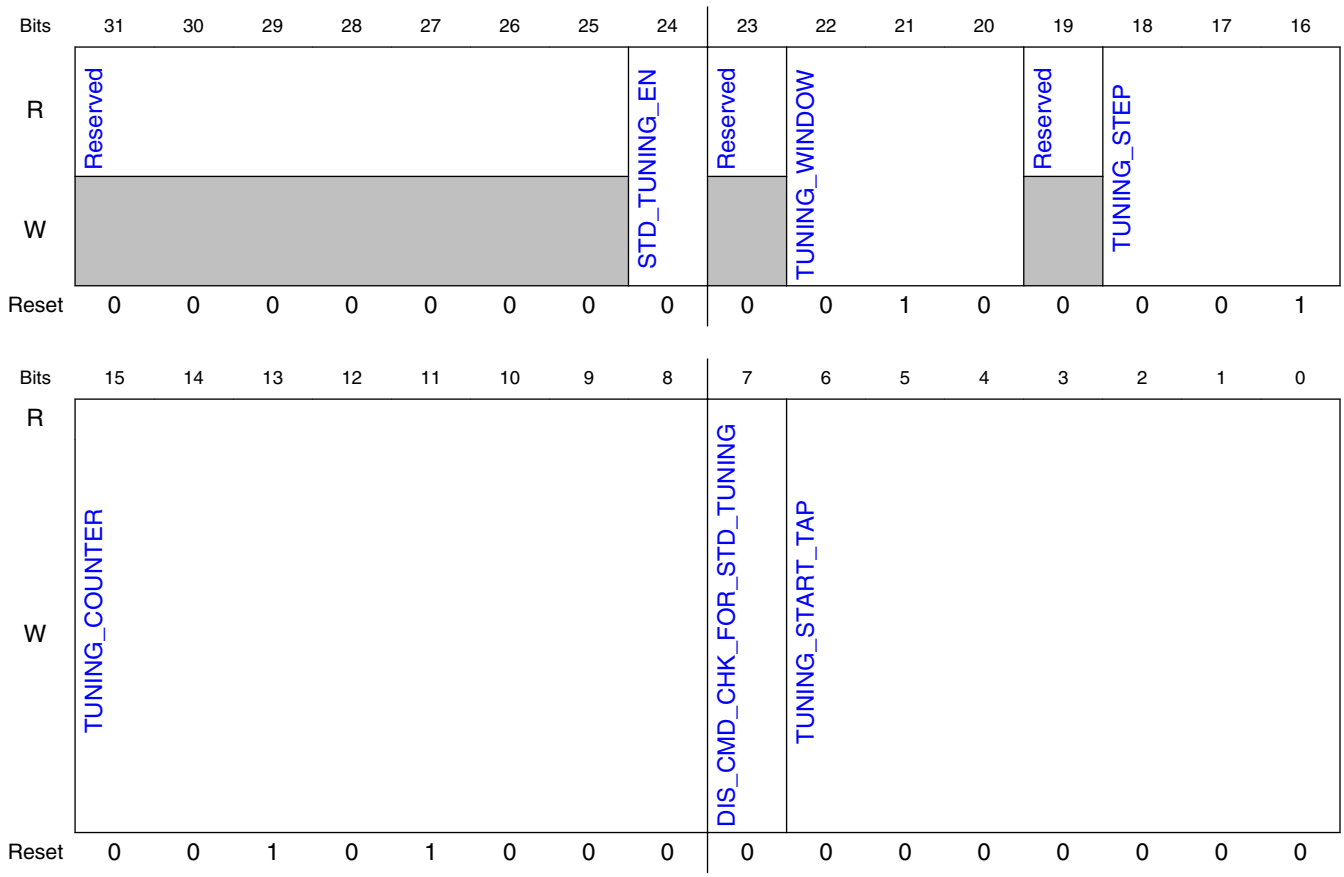
10.3.6.1.31.4 Fields

Field	Function
31-16 FBCLK_TAP_SEL	Enable extra delay on internal feedback clock
15 EN_32K_CLK	Enable 32khz clock for card detection Use 32khz clock for card detection
14 —	Reserved
13 —	Reserved
12 ACMD23_ARGU2_EN	Argument2 register enable for ACMD23 0b - Disable 1b - Argument2 register enable for ACMD23 sharing with SDMA system address register. Default is enabled.
11 HS400_RD_CLK_STOP_EN	HS400 read clock stop enable Only stop clock at read block gap.
10 HS400_WR_CLK_STOP_EN	HS400 write clock stop enable Only stop clock at write block gap.
9 —	Reserved

Table continues on the next page...

Field	Function
8-7 —	Reserved
6 TUNING_CMD_EN	Tuning command enable Enable the auto tuning circuit to check the CMD line. 0b - Auto tuning circuit does not check the CMD line. 1b - Auto tuning circuit checks the CMD line.
5 TUNING_1bit_EN	Tuning 1bit enable Enable the auto tuning circuit to check the DATA0 only. It is used with the TUNING_8bit_EN together.
4 TUNING_8bit_EN	Tuning 8bit enable Enable the auto tuning circuit to check the DATA[7:0]. It is used with the TUNING_1bit_EN together. 0b00 - Tuning circuit only checks the DATA[3:0] 0b01 - Tuning circuit only checks the DATA0 0b10 - Tuning circuit checks the whole DATA[7:0] 0b11 - Invalid **NOTE:** The format of these two fields are [TUNNING_8bit_EN:TUNNING_1bit_EN].
3 CARD_INT_D3_TEST	Card interrupt detection test This field is used only for debugging. 0b - Check the card interrupt only when DATA3 is high. 1b - Check the card interrupt by ignoring the status of DATA3.
2-0 —	Reserved

10.3.6.1.32 Tuning Control (TUNING_CTRL)



10.3.6.1.32.1 Offset

Register	Offset
TUNING_CTRL	CCh

10.3.6.1.32.2 Function

The register contains configuration of tuning circuit.

10.3.6.1.32.3 Diagram

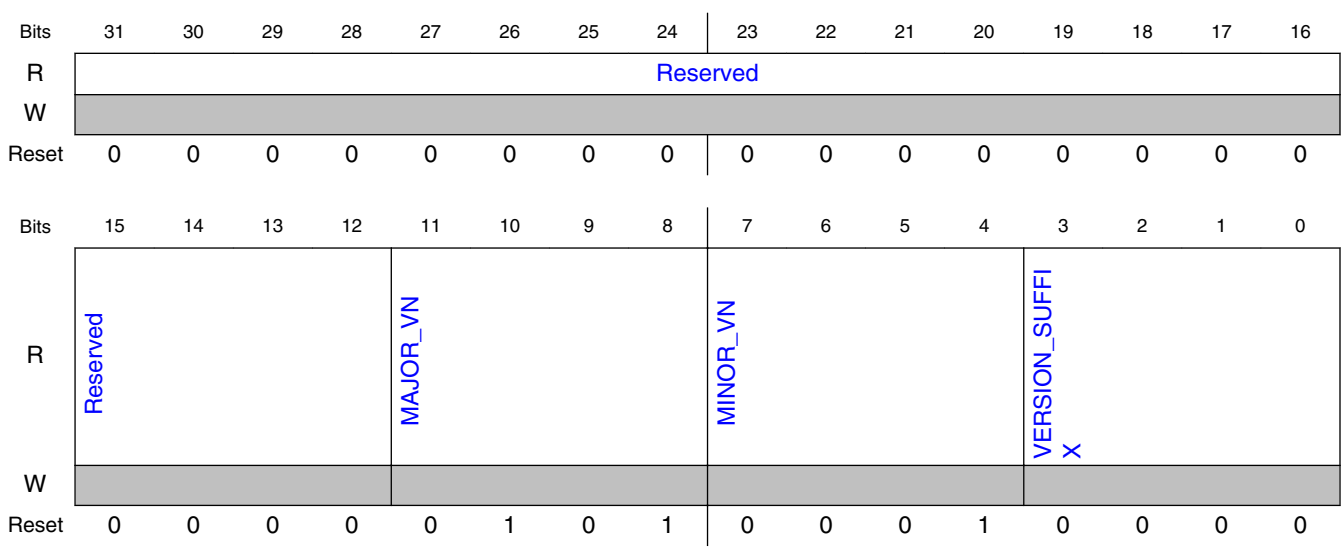
10.3.6.1.32.4 Fields

Field	Function
31-25 —	Reserved
24 STD_TUNING_EN	Standard tuning circuit and procedure enable This field is used to enable standard tuning circuit and procedure.
23 —	Reserved
22-20 TUNING_WINDOW	Data window Select data window value for auto tuning
19 —	Reserved
18-16 TUNING_STEP	TUNING_STEP The increasing delay cell steps in tuning procedure.

Table continues on the next page...

Field	Function
15-8 TUNING_COUNTER	Tuning counter The MAX repeat CMD19 times in tuning procedure.
7 DIS_CMD_CHK_FOR_STD_TUNING	Disable command check for standard tuning Writing 1 to this field disables command check (command CRC, CMD end bit error, and CMD index error or CMD timeout error) for standard tuning flow after each tuning command is sent.
6-0 TUNING_START_TAP	Tuning start The start delay cell point when send first CMD19 in tuning procedure.

10.3.6.1.33 Command Queuing Version (CQVER)



10.3.6.1.33.1 Offset

Register	Offset
CQVER	100h

10.3.6.1.33.2 Function

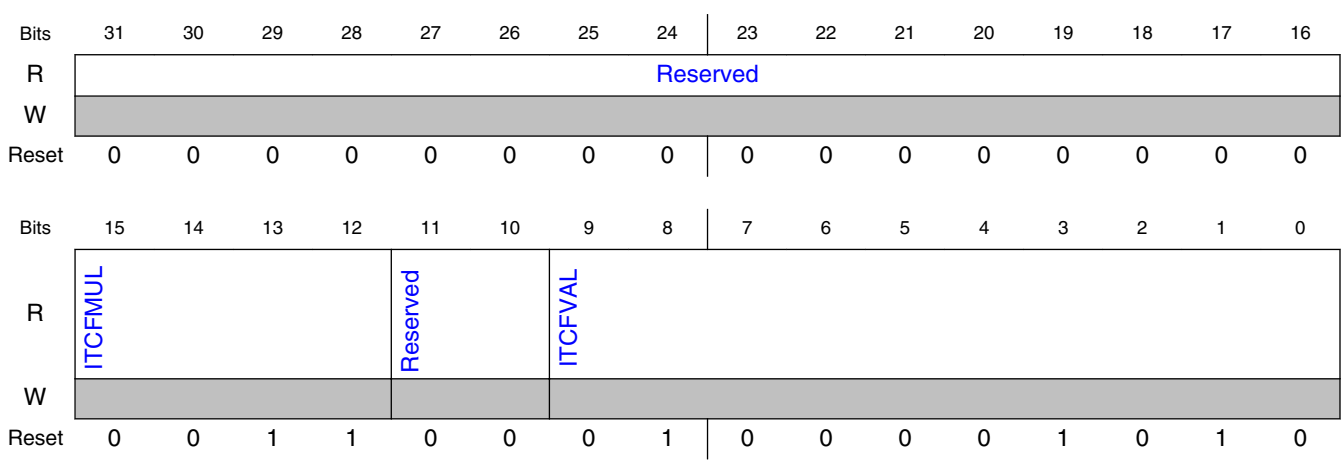
This register provides information about the version of the e•MMC CQ standard that is implemented by CQE, in BCD format. The current version is 5.1.

10.3.6.1.33.3 Diagram

10.3.6.1.33.4 Fields

Field	Function
31-12 —	Reserved
11-8 MAJOR_VN	e •MMC major version number Digit right of decimal point, in BCD format
7-4 MINOR_VN	e •MMC minor version number Digit right of decimal point, in BCD format
3-0 VERSION_SUFFIX	e •MMC version suffix The second digit right of decimal point, in BCD format

10.3.6.1.34 Command Queuing Capabilities (CQCAP)



10.3.6.1.34.1 Offset

Register	Offset
CQCAP	104h

10.3.6.1.34.2 Function

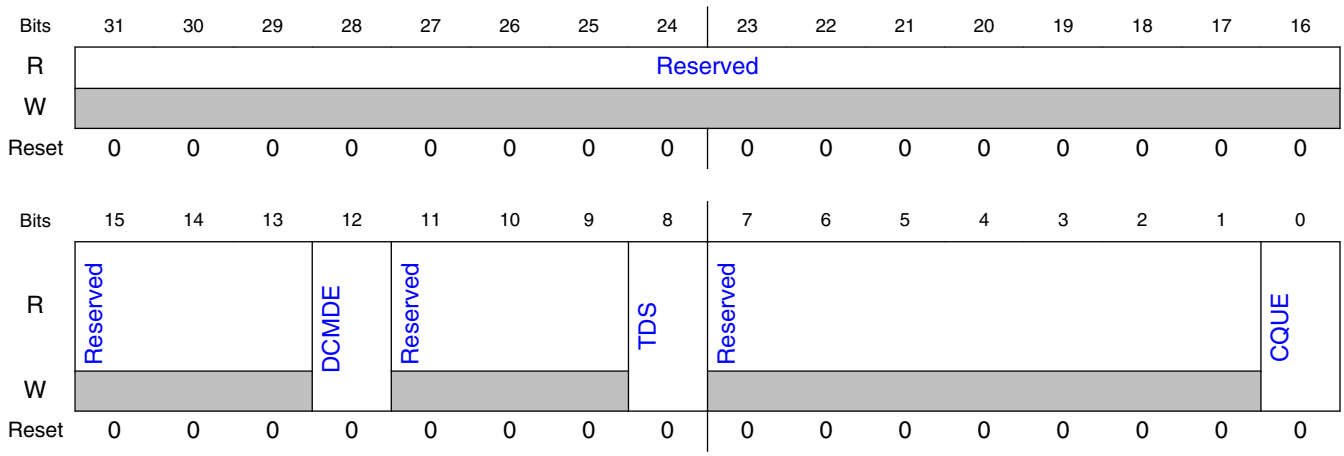
This register indicates hardware capabilities.

10.3.6.1.34.3 Diagram

10.3.6.1.34.4 Fields

Field	Function
31-16 —	Reserved
15-12 ITCFMUL	Internal timer clock frequency multiplier ITCFMUL and ITCFVAL indicate the frequency of the clock used for interrupt coalescing timer and for determining the SQS polling period. See ITCFVAL definition for details. 0001b - 0.001 MHz 0010b - 0.01 MHz 0011b - 0.1 MHz 0100b - 1 MHz 0101b - 10 MHz 0110-1001b - Reserved
11-10 —	Reserved
9-0 ITCFVAL	Internal timer clock frequency value ITCFMUL and ITCFVAL indicate the frequency of the clock used for interrupt coalescing timer and for determining the polling period when using periodic SEND_QUEUE_ STATUS (CMD13) polling. The clock frequency is calculated as ITCFVAL* ITCFMUL. For example, to encode 19.2 MHz, ITCFVAL is C0h (= 192 decimal) and ITCFMUL is 2h (0.1 MHz): 192 * 0.1 MHz = 19.2 MHz.

10.3.6.1.35 Command Queuing Configuration (CQCFG)



10.3.6.1.35.1 Offset

Register	Offset
CQCFG	108h

10.3.6.1.35.2 Function

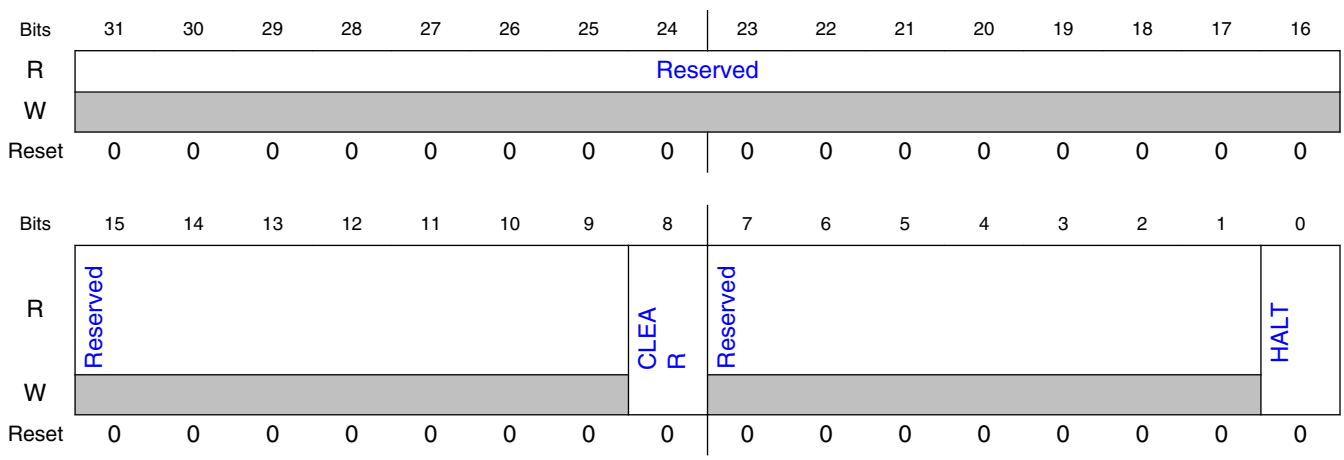
This register controls CQE behavior affecting the general operation of command queuing module or operation of multiple tasks in the same time.

10.3.6.1.35.3 Diagram

10.3.6.1.35.4 Fields

Field	Function
31-13 —	Reserved
12 DCMDE	Direct command (DCMD) enable This bit indicates to the hardware whether the Task Descriptor in slot #31 of the TDL is a Data Transfer Task Descriptor, or a Direct Command Task Descriptor. CQE uses this bit when a task is issued in slot #31, to determine how to decode the Task Descriptor. 0b - Task descriptor in slot #31 is a Data Transfer Task Descriptor 1b - Task descriptor in slot #31 is a DCMD Task Descriptor
11-9 —	Reserved
8 TDS	Task descriptor size This bit indicates whether the task descriptor size is 128 bits or 64 bits as detailed in Data Structures section. This bit can only be configured when Command Queuing Enable bit is ‘0’ (command queuing is disabled) 0b - Task descriptor size is 64 bits 1b - Task descriptor size is 128 bits
7-1 —	Reserved
0 CQUE	Command queuing enable Software shall write '1' this bit when in order to enable command queuing mode (for example, enable CQE). When this bit is 0, CQE is disabled and software controls the e•MMC bus using the legacy e•MMC host controller. Before software writes '1' to this bit, software shall verify that the e•MMC host controller is in idle state and there are no commands or data transfers ongoing. When software wants to exit command queuing mode, it shall clear all previous tasks if such exist before setting this bit to 0.

10.3.6.1.36 Command Queuing Control (CQCTL)



10.3.6.1.36.1 Offset

Register	Offset
CQCTL	10Ch

10.3.6.1.36.2 Function

This register controls CQE behavior affecting the general operation of command queuing module or operation of multiple tasks in the same time.

10.3.6.1.36.3 Diagram

10.3.6.1.36.4 Fields

Field	Function
31-9 —	Reserved
8 CLEAR	Clear all tasks Software shall write '1' this bit when it wants to clear all the tasks sent to the chip. This bit can only be written when CQE is in halt state (for example, Halt bit is 1). When software writes 1, the value of the register is updated to '1', and CQE shall reset CQTDBR register and all other context information for all unfinished tasks. Then CQE will clear this bit.

Table continues on the next page...

Field	Function
	Software should poll on this bit until it is set to back 0 and may then resume normal operation, by clearing the Halt bit. CQE does not communicate to the chip that the tasks were cleared. It is software's responsibility to order the chip to discard the tasks in its queue using CMDQ_TASK_MGMT command. Writing '0' to this register shall have no effect.
7-1 —	Reserved
0 HALT	Halt Host software shall write '1' to the bit when it wants to acquire software control over the e•MMC bus and disable CQE from issuing commands on the bus. For example, issuing a Discard Task command (CMDQ_TASK_MGMT) When software writes '1', CQE shall complete the ongoing task if such a task is in progress. Once the task is completed and CQE is in idle state, CQE shall not issue new commands and shall indicate so to software by setting this bit to 1. Software may poll on this bit until it is set to 1, and may only then send commands on the e•MMC bus. In order to exit halt state (for example, resume CQE activity), software shall clear this bit (write '0'). Writing '0' when the value is already '0' shall have no effect.

10.3.6.1.37 Command Queuing Interrupt Status (CQIS)

10.3.6.1.37.1 Offset

Register	Offset
CQIS	110h

10.3.6.1.37.2 Function

This register indicates pending interrupts that require service. Each bit in this registers is asserted in response a specific event, only if the respective bit is set in CQISTE register.

10.3.6.1.37.3 Diagram

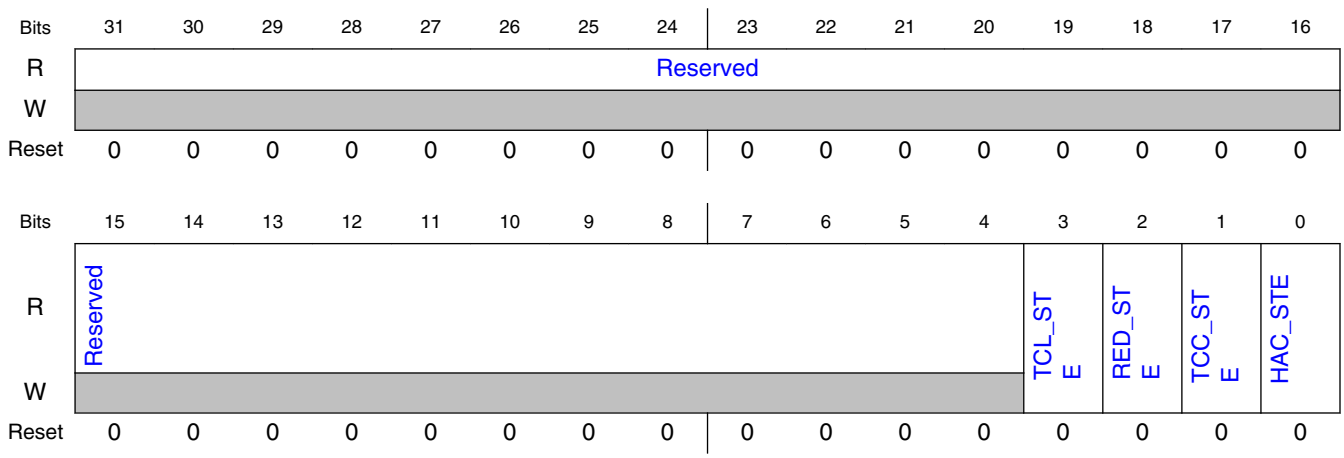
Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved												TCL	RED	TCC	HAC
W													W1C	W1C	W1C	W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

10.3.6.1.37.4 Fields

Field	Function
31-4 —	Reserved
3 TCL	Task cleared This status bit is asserted (if CQISTE[TCL_STE] =1) when a task clear operation is completed by CQE. The completed task clear operation is either an individual task clear (CQTCLR) or clearing of all tasks (CQCTL).
2 RED	Response error detected interrupt This status bit is asserted (if CQISTE[RED_STE] =1) when a response is received with an error bit set in the device status field. The contents of the device status field are listed in 6.13. Software uses CQRMEM register to configure which device status bit fields may trigger an interrupt, and which are masked.
1 TCC	Task complete interrupt This status bit is asserted (if CQISTE[TCC_STE] =1) when at least one of the following two conditions are met: • A task is completed and the INT bit is set in its Task Descriptor • Interrupt caused by Interrupt Coalescing logic (see 0)
0 HAC	Halt complete interrupt This status bit is asserted (if CQISTE[HAC_STE] =1) when halt bit in CQCTL register transitions from 0 to 1 indicating that host controller has completed its current ongoing task and has entered halt state.

10.3.6.1.38 Command Queuing Interrupt Status Enable (CQISTE)



10.3.6.1.38.1 Offset

Register	Offset
CQISTE	114h

10.3.6.1.38.2 Function

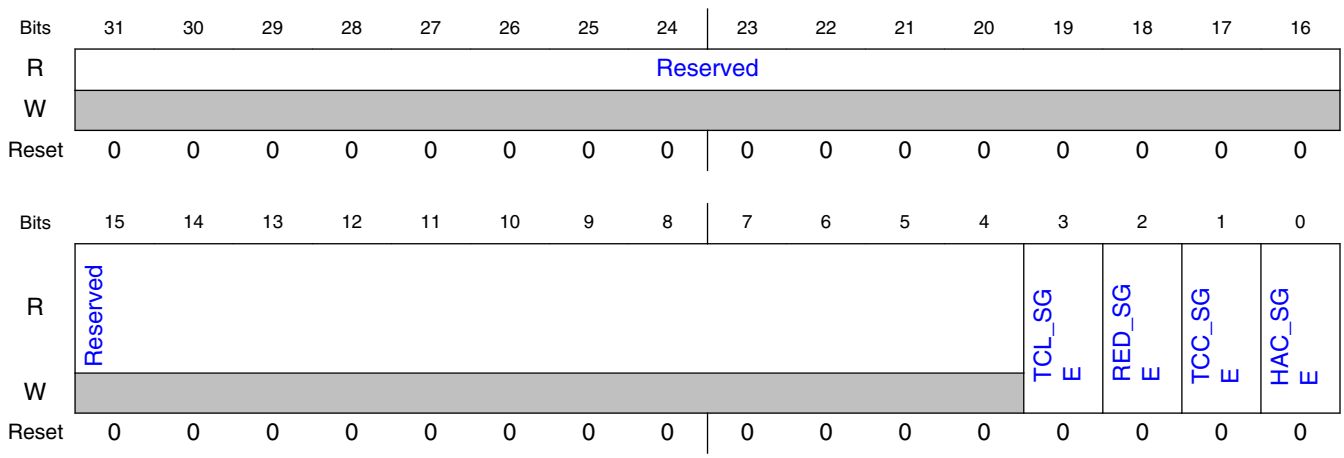
This register enables and disables the reporting of the corresponding interrupt to host software in CQIS register. When a bit is set ('1') and the corresponding interrupt condition is active, then the bit is CQIS is asserted. Interrupt sources that are disabled (‘0’) are not indicated in the CQIS register. This register is bit-index matched to CQIS register.

10.3.6.1.38.3 Diagram

10.3.6.1.38.4 Fields

Field	Function
31-4 —	Reserved
3 TCL_STE	Task cleared status enable 0b - CQIS[TCL] is disabled 1b - CQIS[TCL] is set when its interrupt condition is active
2 RED_STE	Response error detected status enable 0b - CQIS[RED] is disabled 1b - CQIS[RED] is set when its interrupt condition is active
1 TCC_STE	Task complete status enable 0b - CQIS[TCC] is disabled 1b - CQIS[TCC] is set when its interrupt condition is active
0 HAC_STE	Halt complete status enable 0b - CQIS[HAC] is disabled 1b - CQIS[HAC] is set when its interrupt condition is active

10.3.6.1.39 Command Queuing Interrupt Signal Enable (CQISGE)



10.3.6.1.39.1 Offset

Register	Offset
CQISGE	118h

10.3.6.1.39.2 Function

This register enables and disables the generation of interrupts to host software. When a bit is set ('1') and the corresponding bit in CQIS is set, then an interrupt is generated. Interrupt sources that are disabled (‘0’) are still indicated in the CQIS register. This register is bit-index matched to CQIS register.

10.3.6.1.39.3 Diagram

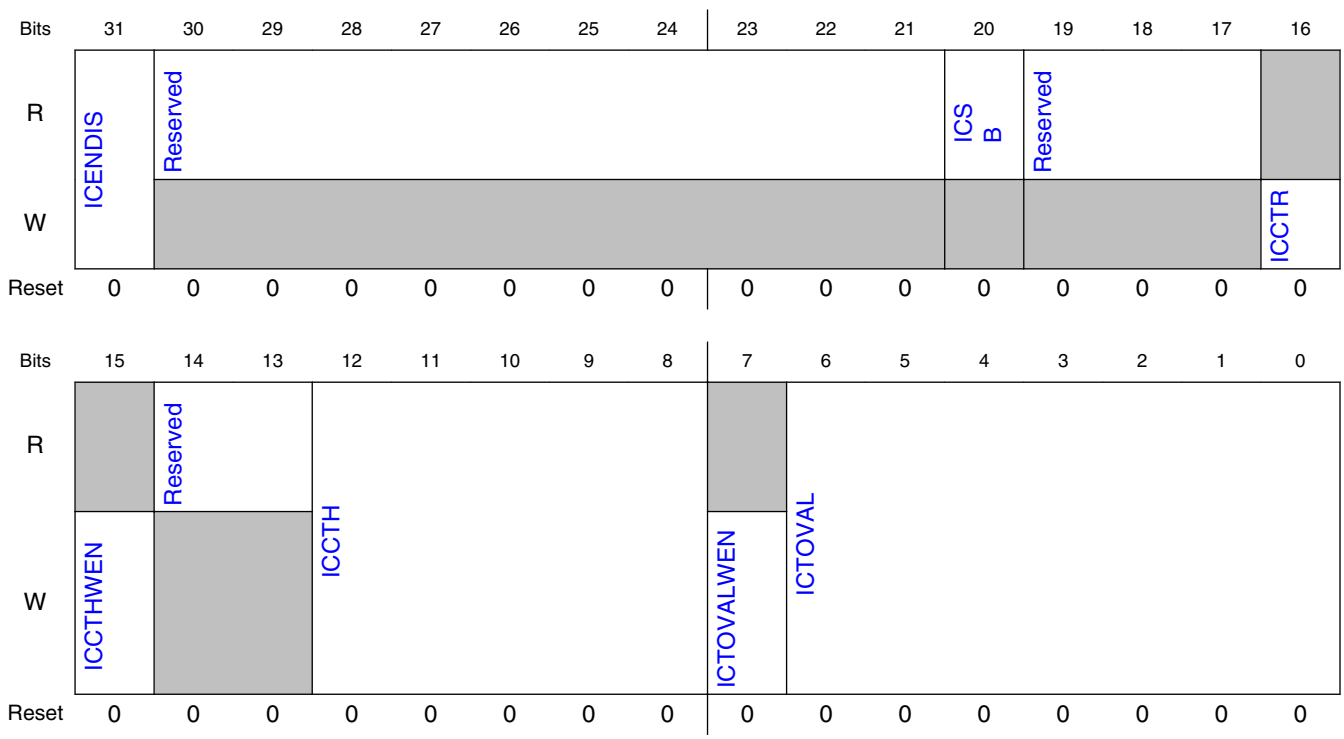
10.3.6.1.39.4 Fields

Field	Function
31-4 —	Reserved
3 TCL_SGE	Task cleared signal enable When set and CQIS[TCL] is asserted, the CQE generates an interrupt.
2 RED_SGE	Response error detected signal enable When set and CQIS[RED] is asserted, the CQE generates an interrupt.
1 TCC_SGE	Task complete signal enable When set and CQIS[TCC] is asserted, the CQE generates an interrupt.

Table continues on the next page...

Field	Function
0 HAC_SGE	Halt complete signal enable When set and CQIS[HAC] is asserted, the CQE generates an interrupt.

10.3.6.1.40 Command Queuing Interrupt Coalescing (CQIC)



10.3.6.1.40.1 Offset

Register	Offset
CQIC	11Ch

10.3.6.1.40.2 Function

This register controls the interrupt coalescing feature.

10.3.6.1.40.3 Diagram

10.3.6.1.40.4 Fields

Field	Function
31 ICENDIS	Interrupt coalescing enable/disable When host driver writes ‘1’, the interrupt coalescing timer and counter are reset.
30-21 —	Reserved
20 ICSB	Interrupt coalescing status This bit indicates to software whether any tasks (with INT=0) have completed and counted towards interrupt coalescing (for example, ICSB is set if and only if IC counter > 0). 0b - No task completions have occurred since last counter reset (IC counter =0) 1b - At least one task completion has been counted (IC counter >0)
19-17 —	Reserved
16 ICCTR	Counter and timer reset When host driver writes ‘1’, the interrupt coalescing timer and counter are reset.
15 ICCTHWEN	Interrupt coalescing counter threshold write enable When software writes ‘1’, the value ICCTH is updated with the contents written at the same cycle. When software writes ‘0’, the value in ICCTH is not updated. **NOTE:** Write operations to ICCTH are only allowed when the task queue is empty.
14-13 —	Reserved
12-8 ICCTH	Interrupt coalescing counter threshold Software uses this field to configure the number of task completions (only tasks with INT=0 in the Task Descriptor) which are required in order to generate an interrupt. Counter Operation: As data transfer tasks with INT=0 complete, they are counted by CQE. The counter is reset by software during the interrupt service routine. The counter stops counting when it reaches the value configured in ICCTH. The maximum allowed value is 31. **NOTE:** When ICCTH is 0, task completions are not counted, and counting-based interrupts are not generated. In order to write to this field, the ICCTHWEN field must be set at the same write operation.
7 ICTOVALWEN	Interrupt coalescing timeout value write enable When software writes ‘1’, the value ICTOVAL is updated with the contents written at the same cycle. When software writes ‘0’, the value in ICTOVAL is not updated. **NOTE:** Write operations to ICTOVAL are only allowed when the task queue is empty.
6-0 ICTOVAL	Interrupt coalescing timeout value Software uses this field to configure the maximum time allowed between the completion of a task on the bus and the generation of an interrupt. Timer Operation: The timer is reset by software during the interrupt service routine. It starts running when a data transfer task with INT=0 is completed, after the timer was reset. When the timer reaches the value configured in ICTOVAL field it generates an interrupt and stops.

Field	Function
	The timer's unit is equal to 1024 clock periods of the clock whose frequency is specified in the Internal Timer Clock Frequency field CQCAP register. The minimum value is 01h (1024 clock periods) and the maximum value is 7Fh (127*1024 clock periods). For example, a CQCAP field value of 0 indicates a 19.2 MHz clock frequency (period = 52.08 ns). If the setting in ICTOVAL is 10h, the calculated polling period is 16*1024*52.08 ns= 853.33 us **NOTE:** When ICTOVAL is 0, the timer is not running, and timer-based interrupts are not generated. In order to write to this field, the ICTOVALWEN bit must be set at the same write operation.

10.3.6.1.41 Command Queuing Task Descriptor List Base Address (CQTDLBA)

10.3.6.1.41.1 Offset

Register	Offset
CQTDLBA	120h

10.3.6.1.41.2 Function

This register is used for configuring the lower 32 bits of the byte address of the head of the Task Descriptor List in the host memory.

10.3.6.1.41.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	TDLBA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

10.3.6.1.41.4 Fields

Field	Function
31-0	Task descriptor list base address

Field	Function
TDLBA	This register stores the LSB bits (bits 31:0) of the byte address of the head of the Task Descriptor List in system memory. The size of the task descriptor list is 32 * (Task Descriptor size + Transfer Descriptor size) as configured by Host driver. This address shall be set on 1 KByte boundary: The lower 10 bits of this register shall be set to 0 by software and shall be ignored by CQE.

10.3.6.1.42 Command Queuing Task Descriptor List Base Address Upper 32 Bits (CQTDLBAU)

10.3.6.1.42.1 Offset

Register	Offset
CQTDLBAU	124h

10.3.6.1.42.2 Function

This register is used for configuring the upper 32 bits of the byte address of the head of the Task Descriptor List in the host memory.

10.3.6.1.42.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	TDLBAU															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

10.3.6.1.42.4 Fields

Field	Function
31-0 TDLBAU	Task descriptor list base address This register stores the MSB bits (bits 63:32) of the byte address of the head of the Task Descriptor List in system memory.

Field	Function
	The size of the task descriptor list is 32 * (Task Descriptor size + Transfer Descriptor size) as configured by Host driver. This register is reserved when using 32-bit addressing mode.

10.3.6.1.43 Command Queuing Task Doorbell (CQTDBR)

10.3.6.1.43.1 Offset

Register	Offset
CQTDBR	128h

10.3.6.1.43.2 Function

Using this register, software triggers CQE to process a new task.

10.3.6.1.43.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	TDBR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TDBR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

10.3.6.1.43.4 Fields

Field	Function
31-0 TDBR	Task doorbell Software configures TDLBA and TDLBAU, and enable CQE in CQCFG before using this register. Writing 1 to bit n of this register triggers CQE to start processing the task encoded in slot n of the TDL. CQE always processes tasks in-order according to the order submitted to the list by CQTDBR write transactions. CQE processes Data Transfer tasks by reading the Task Descriptor and sending QUEUED_TASK_PARAMS (CMD44) and QUEUED_TASK_ADDRESS (CMD45) commands to the device.

Field	Function
	CQE processes DCMD tasks (in slot #31, when enabled) by reading the Task Descriptor, and generating the command encoded by its index and argument. The corresponding bit is cleared to '0' by CQE in one of the following events: 1. When a task execution is completed (with success or error) 2. The task is cleared using CQTCLR register 3. All tasks are cleared using CQCTL register 4. CQE is disabled using CQCFG register Software may initiate multiple tasks at the same time (batch submission) by writing 1 to multiple bits of this register in the same transaction. In the case of batch submission: CQE shall process the tasks in order of the task index, starting with the lowest index. If one or more tasks in the batch are marked with QBR, the ordering of execution will be based on said processing order. Writing 0 by software shall have no impact on the hardware, and will not change the value of the register bit.

10.3.6.1.44 Command Queuing Task Completion Notification (CQTCN)

10.3.6.1.44.1 Offset

Register	Offset
CQTCN	12Ch

10.3.6.1.44.2 Function

This register is used by CQE to notify software about completed tasks.

10.3.6.1.44.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	TCN															
W	W1C															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

10.3.6.1.44.4 Fields

Field	Function
31-0 TCN	Task complete notification CQE shall set bit n of this register (at the same time it clears bit n of CQTDBR) when a task execution is completed (with success or error). When receiving interrupt for task completion, software may read this register to know which tasks have finished. After reading this register, software may clear the relevant bit fields by writing 1 to the corresponding bits.

10.3.6.1.45 Command Queuing Device Queue Status (CQDQS)

10.3.6.1.45.1 Offset

Register	Offset
CQDQS	130h

10.3.6.1.45.2 Function

This register stores the most recent value of the device's queue status.

10.3.6.1.45.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

10.3.6.1.45.4 Fields

Field	Function
31-0 DQS	Device queue status

Field	Function
	Every time the Host controller receives a queue status register (QSR) from the device, it updates this register with the response of status command (For example, the chip's queue status).

10.3.6.1.46 Command Queuing Device Pending Tasks (CQDPT)

10.3.6.1.46.1 Offset

Register	Offset
CQDPT	134h

10.3.6.1.46.2 Function

This register indicates to software which tasks are queued in the device, awaiting execution.

10.3.6.1.46.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	DPT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DPT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

10.3.6.1.46.4 Fields

Field	Function
31-0 DPT	Device pending tasks Bit n of this register is set if and only if QUEUED_TASK_PARAMS (CMD44) and QUEUED_TASK_ADDRESS (CMD45) were sent for this specific task and if this task hasn't been executed yet. CQE shall set this bit after receiving a successful response for CMD45. CQE shall clear this bit after the task has completed execution.

Field	Function
	Software needs to read this register in the task-discard procedure, when the controller is halted, to determine if the task is queued in the device. If the task is queued, the driver sends a CMDQ_TASK_MGMT (CMD48) to the device ordering it to discard the task. Then software clears the task in the CQE. Only then the software orders CQE to resume its operation using CQCTL register.

10.3.6.1.47 Command Queuing Task Clear (CQTCLR)

10.3.6.1.47.1 Offset

Register	Offset
CQTCLR	138h

10.3.6.1.47.2 Function

This register is used for removing an outstanding task in the CQE. The register should be used only when CQE is in Halt state.

10.3.6.1.47.3 Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	TCLR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TCLR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

10.3.6.1.47.4 Fields

Field	Function
31-0 TCLR	Task clear Writing 1 to bit n of this register orders CQE to clear a task which software has previously issued. This bit can only be written when CQE is in Halt state as indicated in CQCFG register Halt bit. When software writes ‘1’ to a bit in this register, CQE updates the value to ‘1’, and starts clearing the data structures related to the task. CQE clears the bit fields (sets a value of 0) in CQTCLR and in CQTDBR once clear operation is complete.

Field	Function
	Software should poll on the CQTCLR until it is cleared to verify clear operation was complete. Writing to this register only clears the task in the CQE and does not have impact on the device. In order to discard the task in the device, host software shall send CMDQ_TASK _MGMT while CQE is still in Halt state. Host driver is not allowed to use this register to clear multiple tasks at the same time. Clearing multiple tasks can be done using CQCTL register. Writing 0 to a register bit shall have no impact.

10.3.6.1.48 Command Queuing Send Status Configuration 1 (CQSSC1)

10.3.6.1.48.1 Offset

Register	Offset
CQSSC1	140h

10.3.6.1.48.2 Function

The register controls the when SEND_QUEUE_STATUS commands are sent.

10.3.6.1.48.3 Diagram

10.3.6.1.48.4 Fields

Field	Function
31-20 —	Reserved
19-16	Send status command block counter

Table continues on the next page...

Field	Function
CBC	This field indicates to CQE when to send SEND_QUEUE_STATUS (CMD13) command to inquire the status of the device's task queue. A value of *n* means CQE sends status command on the CMD line, during the transfer of data block BLOCK_CNT-n, on the data lines, where BLOCK_CNT is the number of blocks in the current transaction. A value of 0 means that SEND_QUEUE_STATUS (CMD13) command is not sent during the transaction. Instead it will be sent only when the data lines are idle. A value of 1 means that STATUS command is to be sent during the last block of the transaction.
15-0 CIT	Send status command idle timer This field indicates to CQE the polling period to use when using periodic SEND_QUEUE_STATUS (CMD13) polling. Periodic polling is used when tasks are pending in the device, but no data transfer is in progress. When a SEND_QUEUE_STATUS response indicating that no task is ready for execution, CQE counts the configured time until it issues the next SEND_QUEUE_STATUS. Timer units are clock periods of the clock whose frequency is specified in the Internal Timer Clock Frequency field CQCAP register. The minimum value is 0001h (1 clock period) and the maximum value is FFFFh (65535 clock periods). Default interval is: 4096 clock periods. For example, a CQCAP field value of 0 indicates a 19.2 MHz clock frequency (period = 52.08 ns). If the setting in CQSSC1.CIT is 1000h, the calculated polling period is 4096*52.08 ns= 213.33 us

10.3.6.1.49 Command Queuing Send Status Configuration 2 (CQSSC2)

10.3.6.1.49.1 Offset

Register	Offset
CQSSC2	144h

10.3.6.1.49.2 Function

This register is used for configuring RCA field in SEND_QUEUE_STATUS command argument.

10.3.6.1.49.3 Diagram

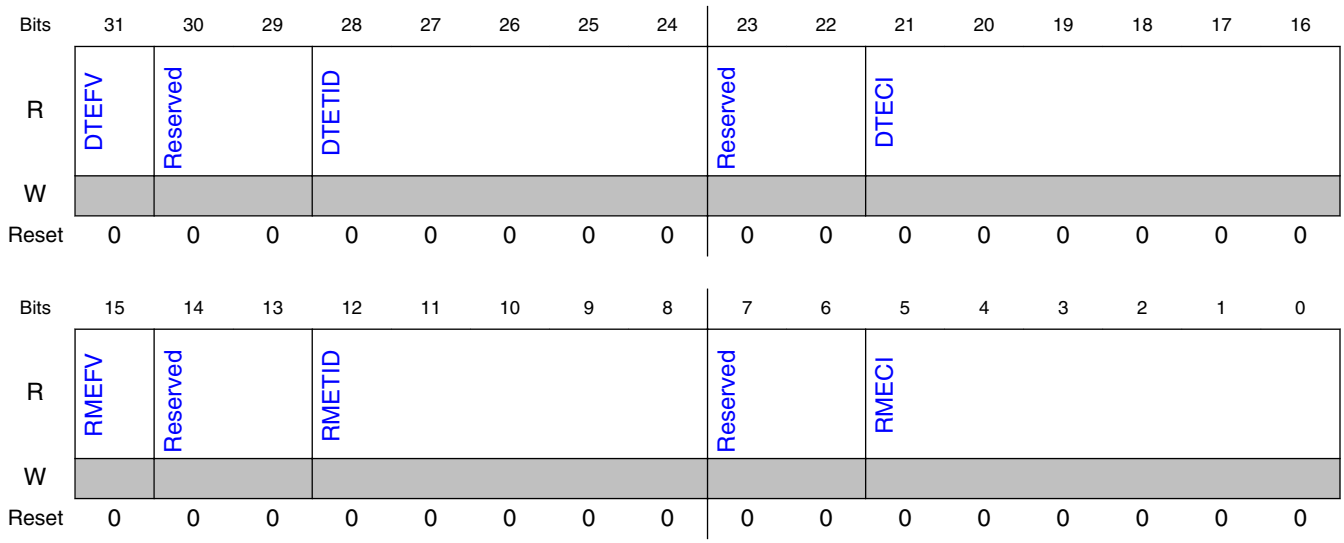
10.3.6.1.51.4 Fields

Field	Function
31-0 RMEM	Response mode error mask This bit is used as in interrupt mask on the device status filed which is received in R1/R1b responses. The reset value of this register is set to trigger an interrupt on all “Error” type bits in the device status, as defined in 6.13. **NOTE:** Responses to CMD13 (SQS) encode the QSR, so they are ignored by this logic. 00000000000000000000000000000000b - When a R1/R1b response is received, bit i in the device status is ignored 00000000000000000000000000000001b - When a R1/R1b response is received, with bit i in the device status set, a RED interrupt is generated

10.3.6.1.52 Command Queuing Task Error Information (CQTERRI)

10.3.6.1.52.1 Offset

Register	Offset
CQTERRI	154h



10.3.6.1.52.2 Function

This register is updated by CQE when an error occurs on data or command related to a task activity.

When such error is detected by CQE or indicated by the e•MMC controller CQE stores in CQTERRI the task IDs and the command indices of the commands which were executed on the command line and data lines when the error occurred.

Software is expected to use this information in the error recovery procedure. See B.2.8 for more details.

10.3.6.1.52.3 Diagram

10.3.6.1.52.4 Fields

Field	Function
31 DTEFV	Data transfer error fields valid This bit is updated when an error is detected by CQE, or indicated by e•MMC controller. If a data transfer is in progress when the error is detected/indicated, the bit is set to 1. If a no data transfer is in progress when the error is detected/indicated, the bit is cleared to 0.
30-29 —	Reserved
28-24 DTETID	Data transfer error task ID This field indicates the ID of the task which was executed on the data lines when an error occurred. The field is updated if a data transfer is in progress when an error is detected by CQE, or indicated by e•MMC controller.
23-22 —	Reserved
21-16 DTECI	Data transfer error command index This field indicates the index of the command which was executed on the data lines when an error occurred. The index shall be set to EXECUTE_READ_TASK (CMD46) or EXECUTE_WRITE_TASK (CMD47) according to the data direction. The field is updated if a data transfer is in progress when an error is detected by CQE, or indicated by e•MMC controller.

Table continues on the next page...

Field	Function
15 RMEFV	Response mode error fields valid This bit is updated when an error is detected by CQE, or indicated by e•MMC controller. If a command transaction is in progress when the error is detected/indicated, the bit is set to 1. If a no command transaction is in progress when the error is detected/indicated, the bit is cleared to 0.
14-13 —	Reserved
12-8 RMETID	Response mode error task ID This field indicates the index of the command which was executed on the command line when an error occurred. The field is updated if a command transaction is in progress when an error is detected by CQE, or indicated by e•MMC controller.
7-6 —	Reserved
5-0 RMECI	Response mode error command index This field indicates the index of the command which was executed on the command line when an error occurred. The field is updated if a command transaction is in progress when an error is detected by CQE, or indicated by e•MMC controller.

Chapter 11
Connectivity

11.1 HSIO BLK_CTRL

11.1.1 Overview

The HSIOMIX domain contains control and status registers known as HSIO Block Control (HSIO BLK_CTRL). These registers have miscellaneous top-level controls for peripherals within the HSIOMIX domain. Some of these controls includes clocking, interrupt, and reset sources. Please see the clock control chapter and interrupt chapter for more information regarding the clock input sources and IRQ event mapping to HSIOMIX.

11.1.1.1 Block Diagram

The HSIO BLK_CTRL interface connects to the HSIOMIX domain peripherals. A block diagram illustrating the HSIOMIX domain is shown below.

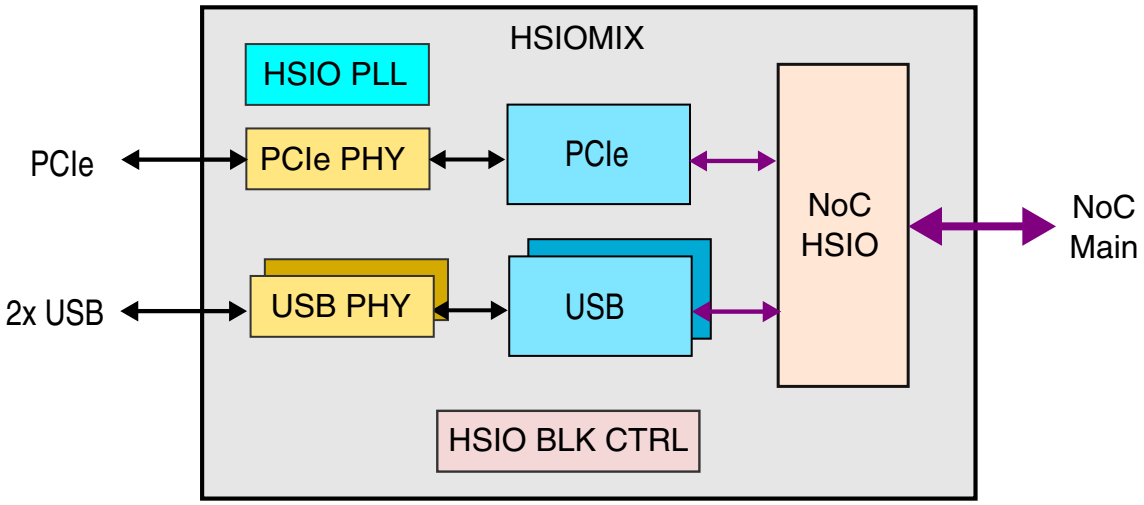

Figure 11-1. HSIOMIX Block Diagram

11.1.2 Clocks and Resets

The HSIO BLK_CTRL contains clock distribution and gating controls, as well as reset handling to several of the HSIOMIX peripherals. Please see related clock and reset controls in the BLK_CTRL register description. For more information about the input clocks and resets to the domain, please see the clock control chapter, system reset chapter, and system-level IRQ assignments.

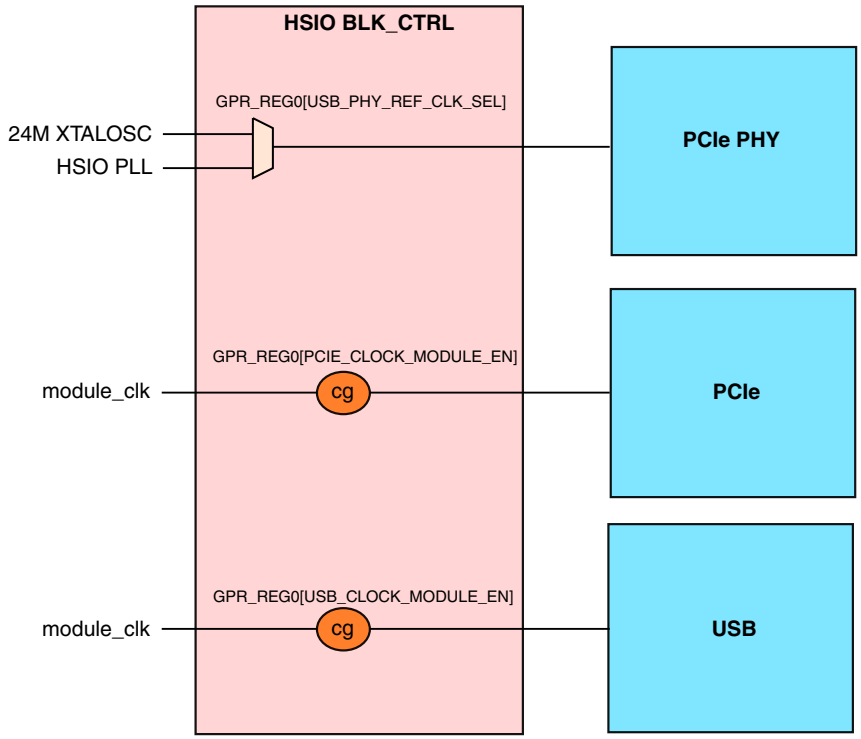

Figure 11-2. HSIO BLK_CTRL Clocks

11.1.3 Memory Map and register definition

This section includes the HSIO BLK_CTRL module memory map and descriptions of all registers.

11.1.3.1 register descriptions

11.1.3.1.1 HSIO_BLK_CTL memory map

Field	Function
OTG_VBUS_SESSVLD_WAKEUP_INTERRUPT	
0 OTG_DP_DM_WAKEUP_INTERRUPT	Interrupt status of dm or dp, otg_dp_wakeup_interrupt | otg_dm_wakeup_interrupt

11.2 Universal Serial Bus Controller (USB)

11.2.1 Overview

The USB module is a USB 3.0-compliant serial interface engine for implementing a USB interface. This module may be connected to an external port. Collectively the module and external port are called the USB 3.0 interface. USB 3.0 supports Super-speed (SS), High-speed (HS), Full-speed (FS), and Low-speed (LS) operations.

- The upper layer is common for USB 2.0 and USB 3.0 operation. This has the bus interface, buffer management block, list processor for scheduling, and control and status register (CSR) functions
- USB 2.0 PHY and MAC layers
- USB 3.0 PHY, LINK, and MAC layers

11.2.1.1 Block diagram

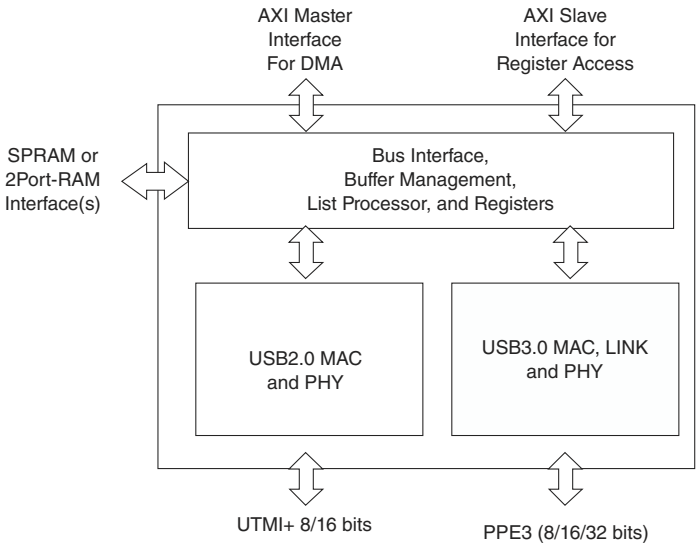

Figure 11-3. Block diagram

11.2.1.2 Features

The USB 3.0 module includes the following features:

- Complies with USB specification rev 3.0 (xHCI compatible)
- Supports operation as a standalone USB host controller
- USB dual-role operation and can be configured as host or device
- Super-speed (5 Gbit/s), high-speed (480 Mbit/s), full-speed (12 Mbit/s), and low-speed (1.5 Mbit/s) operations.
- Supports operation as a standalone single port USB
- Supports four programmable, bidirectional USB endpoints
- Supports system memory interface with 40-bit addressing capability

11.2.2 Functional description

11.2.2.1 Modes of operation

The USB 3.0 module operates in following modes.

- Host Mode: SS/HS/FS/LS
- Device Mode: SS/HS/FS

11.2.2.2 System memory descriptor and data buffers

The software creates transfer request blocks (TRBs), and four DWORDs each, that point to the data buffers. Normally, the TRBs are allocated consecutively in system memory; only the data buffers can be scattered. In the case of a circular buffer, the link-TRB points to the next TRB. Once the TRBs and data buffers are set up in the system memory, the software driver issues a start transfer command that points to the location of the first TRB in the system memory to start the DMA operation. TRBs, though small (only four DWORDs), provide a rich set of features for the software to schedule transfers, isochronous, control, interrupt moderation, and so on.

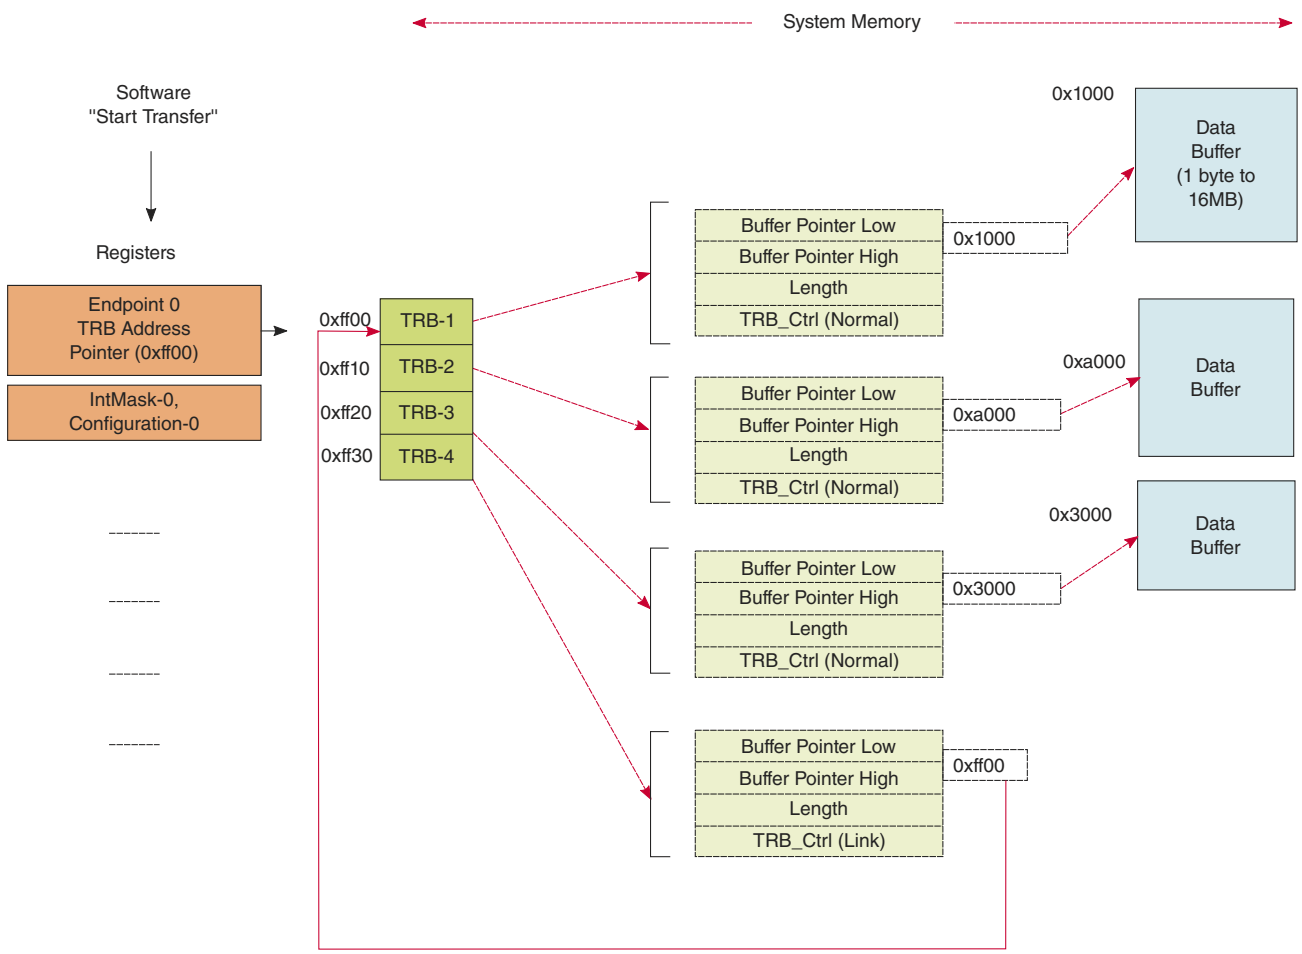

Figure 11-4. System Memory Descriptor and Data Buffers

11.2.2.3 Device descriptor structures

Device mode transfer request blocks (TRBs) are small 4 DWORDs and at the same time provide a rich set of features so that the software can efficiently manage the USB core, memory buffers, and MIPS requirements.

The following is a list of device mode TRB characteristics:

- TRBs provide support for scattered data structures. The scattered data buffers can be zero bytes to 16 MB in length.
- TRBs must be placed in system memory aligned to a 16-byte boundary.
- TRBs are kept in linear memory to enhance descriptor caching performance. If the data buffers are small (as in an Ethernet application) the core can efficiently collect the scattered data to build USB packets without wasting bus efficiency that collecting scattered descriptors requires.
- Supports TRB linking. This allows software to set up a circular ring of TRBs with the last TRB linking to the first one.
- Supports system memory interface with 40-bit addressing capability
- Supports byte-aligned buffers for each TRB of a transfer. This feature prevents the need for buffer copying in cases where the USB device driver receives unaligned data buffers from other applications (for example, Ethernet). Whenever the application controls buffer allocation, it must allocate SoC bus width and burst-aligned buffers to facilitate efficient bus and memory utilization. For transmitting, the core supports byte-aligned buffers on all TRBs.

  For example: To use 16 bursts in a 64-bit system, you must try to allocate buffers that are 16 * 8 = 128 bytes aligned. This is the normal buffer structure because Linux-like OSs allocate 4 KB buffers. SDR/DDR memory controllers also provide better performance when requests are burst aligned.

- Supports software queueing of multiple USB transfers (LST bit for IN/OUT transfers and CSP bit for OUT transfers control this function).
- Provides interrupt moderation capability, allowing software to selectively enable events on TRB completion, as controlled by the IOC (Interrupt on completion) bit. The IOC event is also used by software to reallocate the released buffers, allowing software to re-use just a few buffers in a circular fashion. This helps when the memory is limited but have enough MIPS to process interrupts. Larger buffers can be allocated to reduce the number of interrupts.
  - In USB 3.0 larger transfers are recommended because the raw transfer rate is almost 10 times faster, unlike USB 2.0, where drivers set up only 64 KB or 128 KB transfers. For example, a 64 KB transfer that takes 1.3 ms in USB 2.0 requires only 164 µS in USB 3.0. If you set up buffers of 64 KB and enable the transfer completion event, then you receive an interrupt every 164 µS.
- Supports streaming (Stream ID field used for this purpose).

11.2.2.3.1 Structures

This figure shows the control and status field of a transfer request block.

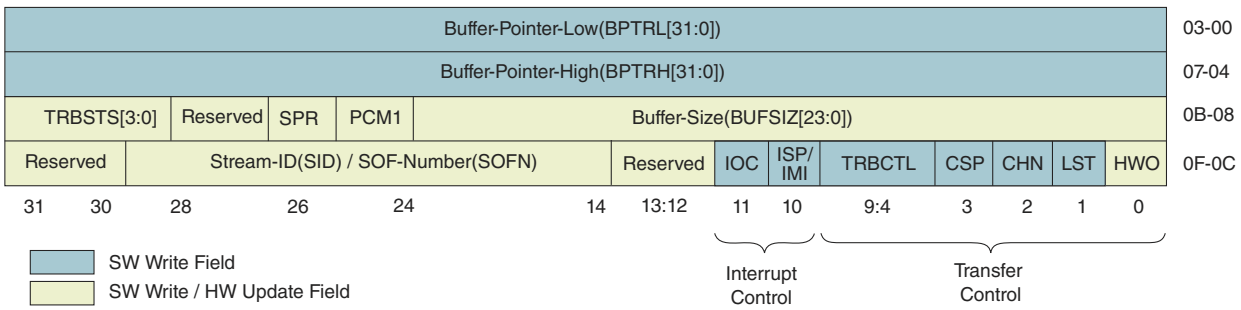

Figure 11-5. TRB control and status fields

Table 11-1. Device descriptor structure field definitions

Field	Description	Hardware access
DW 03-00		
31:0	Buffer pointer low (BPTRL) Data buffer pointer to low 32 bit address (BPTR[31:0]). Hardware may also update this field (implementation specific).	R/W
DW 07-04		
31:0	Buffer pointer high (BPTRH) Data buffer pointer to high 32-bit address (BPTR[63:32]).	R/W
DW 0B-08		
31:28	TRB status (TRBSTS) Hardware updates this field with transfer status information before releasing the TRB. • 4'h0: OK • 4'h1: MissedIsoc: Isochronous interval missed or incomplete • 4'h2: SetupPending - During the current control transfer data/status phase, another SETUP was received. • 4'h4: TransferInProgress - During the current transfer, an end transfer command was received.	R/W
27	Reserved. Hardware may update these bits for internal usage.	R/W
26	SPR • If GUCTL1[DEV_TRB_OUT_SPR_IND] is 1'b1, this field indicates the short packet received for the last processed TRB for the transfer. If a short packet has been received, this TRB field is set during an OUT transfer TRB write back if this is the last TRB used for that transfer descriptor. • If GUCTL1[DEV_TRB_OUT_SPR_IND] is 1'b0, this field is reserved. Hardware may update these bits for internal usage.	R/W
25:24	Packet count M1 (PCM1) For high-speed, High bandwidth isochronous IN endpoints, this field in an Isoc-First TRB represents the total number of packets in the Buffer Descriptor minus 1.	R/W

Table continues on the next page...

Table 11-1. Device descriptor structure field definitions (continued)

Field	Description	Hardware access
23:0	Buffer size (BUFSIZ) If CHN=0 and HWO=0 for the TRB, this field represents the total remaining Buffer Descriptor buffer size in bytes. Valid Range: 0 bytes to (16 MB - 1 byte). The hardware decrements this field to represent the remaining buffer size after data is transferred. For a Link TRB, the buffer size should be "0".	R/W
DW 0F-0C		
31:30	Reserved.	R/W
29:14	Stream ID / SOF Number For stream-based bulk endpoints: The Stream ID of the transfer this TRB is associated with. Stream ID must be the same in all TRBs (R/W). For isochronous endpoints: The (micro)frame number in which the last packet of this TRB's buffer was transmitted or received (debug purposes only) (RO).	R/W
13:12	Reserved.	R/W
11	Interrupt on Complete (IOC) When IOC is set in a TRB, and once the transfer for this buffer is completed, the core will issue XferInProgress event with IOC bit set in the event's status. This indicates the buffer is available for software to reuse or release.	R
10	Interrupt on Short Packet / Interrupt on Missed ISOC (ISP/IMI) Applicable to OUT endpoints when a short packet is received, and CSP=1 and LST=0. If this bit is 1, the core generates an XferInProgress event. For Isochronous endpoints: If this bit is 1, the core generates an XferInProgress event when the interval represented by the Buffer Descriptor completes with a "Missed Isoc" status.	R
9:4	TRB Control (TRBCTL) Indicates the type of TRB: 1: Normal (Control-Data-2+ / Bulk / Interrupt) - Set TRBCTL to 1 for all TRBs used in data stage except the first TRB 2: Control-Setup 3: Control-Status-2 - Set TRBCTL to 3 for a SETUP request without data stage 4: Control-Status-3 - Set TRBCTL to 4 for a SETUP request with data stage 5: Control-Data - Set TRBCTL to 5 for the first TRB of a data stage 6: Isochronous-First - Set TRBCTL to 6 for the first TRB of a Service Interval 7: Isochronous 8: Link TRB Others: Reserved	R
3	Continue on Short Packet (CSP) Applicable to OUT endpoints only when a short packet is received. If this bit is 1, the core will continue to the next Buffer Descriptor. This setting is required for isochronous endpoints. If this bit is 0, the core will generate an XferComplete event and remove the stream.	R
2	Chain Buffers (CHN)	R

Table continues on the next page...

Table 11-1. Device descriptor structure field definitions (continued)

Field	Description	Hardware access
	Applicable to IN and OUT endpoints. Set to 1 by software to associate this TRB with the next TRB. A Buffer Descriptor is defined as one or more TRBs. The CHN bit is used to identify the TRBs that comprise a Buffer Descriptor. The CHN bit is always 0 in the last TRB of a Buffer Descriptor and when the LST field is set to 1.	
1	Last TRB (LST) Indicates this is the last TRB in a list. After completing the transfer for the associated buffer the core will stop the transfer for the endpoint / bulk-stream and issues an XferComplete event. The stream is automatically removed by the hardware.	R
0	Hardware Owner of Descriptor (HWO) Indicates that hardware owns the TRB. Software sets this bit to 1 when it creates the TRB, and cannot modify it until hardware resets this bit to 0. However, there are exceptions for short packets on OUT endpoints and Link TRBs. Because the hardware autonomously checks this bit to determine if the entire TRB is valid, software must set this field to '1' after preparing the other three DWORDs of the TRB with valid information.	R/W

11.2.2.3.1.1 Normal (Control-Data/Bulk/Interrupt), Isochronous, and Status Transfer Request Block Structure

The Normal TRB is used for Bulk/Control-Data/Interrupt endpoint transfers. The data buffers can be scattered anywhere and each may have different sizes. The TRB Buffer Pointer and the Buffer Size fields point to buffer address and size respectively. The Stream ID for bulk endpoints will be programmed by the application.

For isochronous endpoints, the first TRB in a service interval must have the Isoc-First type, the last TRB in a service interval must have CHN=0, and any other TRBs have CHN=1. The starting (micro)frame time is communicated via the Start Transfer command, and the core tracks the (micro)frame times of the subsequent Buffer Descriptors.

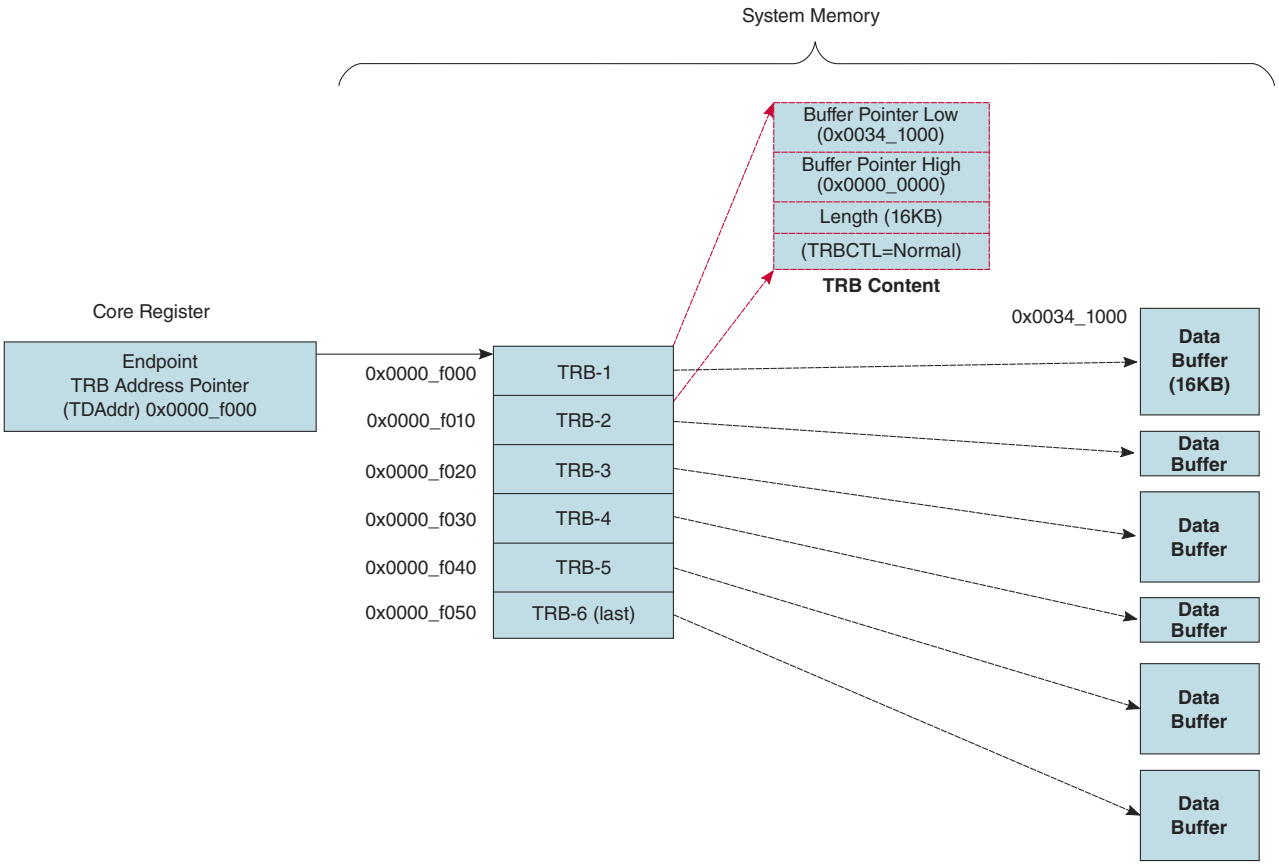

Figure 11-6. Normal (Control-Data/Bulk/Interrupt) Descriptor Structure

11.2.2.3.1.2 Setup and Status TRB Structure

To receive a SETUP packet, the driver queues up a single Setup TRB, whose buffer pointer value may be set to any address, including the address of the TRB. The buffer size must be set to 8. The core will write the 8 bytes of the received SETUP to the address requested. If the address of the TRB is used, there is no need for a separate data buffer to receive a SETUP packet. After completing Setup stage, driver will schedule Data stage and Status stage transfers. For more information, see Control transfer programming model.

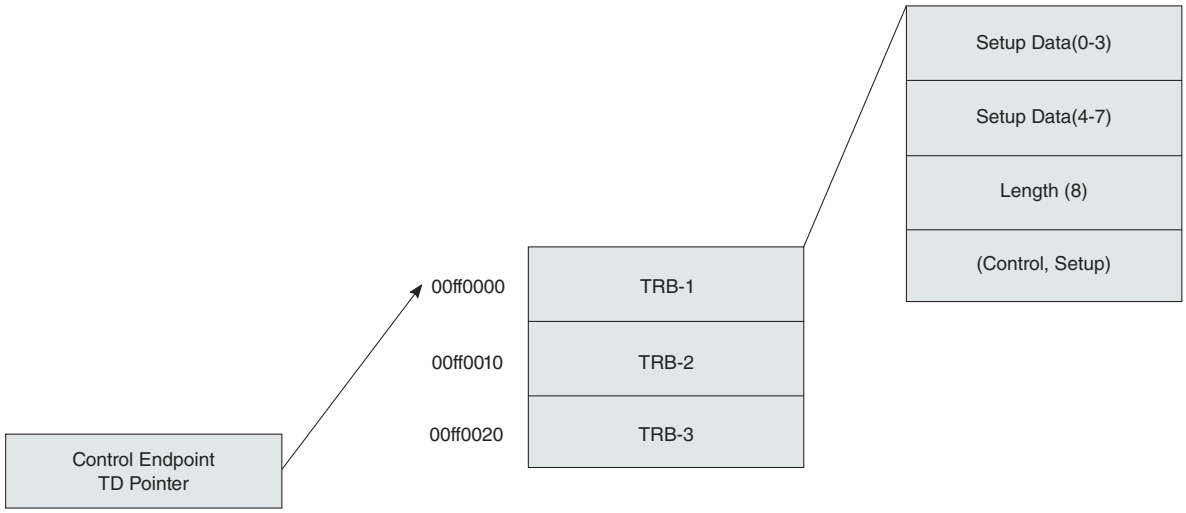

Figure 11-7. SETUP Descriptor Structure with Buffer Pointing to Setup TRB

After interpreting the SETUP bytes, software will determine if the next stage of the control transfer is a data stage or status stage.

If the SETUP bytes require a 3-stage control transfer, the TRB type used in the Data stage must be Control- Data for the first TRB of the Buffer Descriptor. When the host moves on to the Status stage, the TRB Type must be Control-Status-3.

If the SETUP bytes require a 2-stage control transfer, the TRB Type must be Control-Status-2.

The Status TRB is a zero-length TRB, with an unspecified Buffer Pointer value and a Buffer Size of zero. There is no data buffer associated with a Status TRB.

11.2.2.3.1.3 Link TRB Structure

The Link TRB is used to link back to the starting TRB for reusing TRBs in a circular fashion.

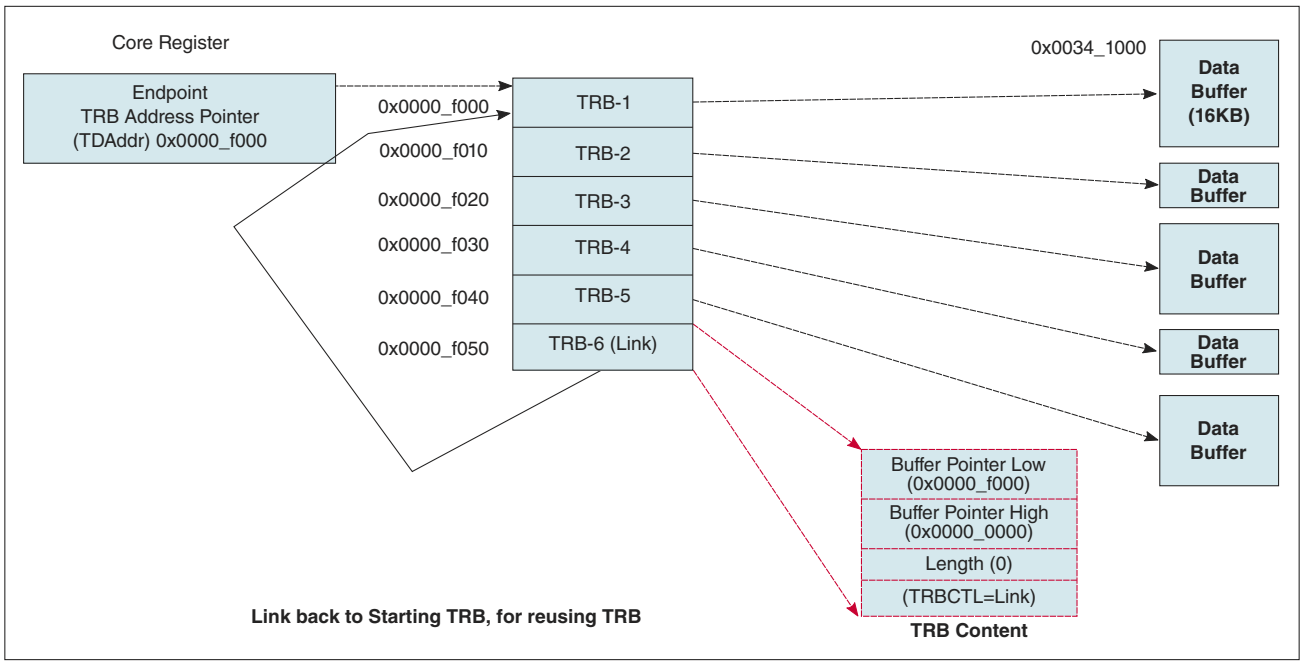

Figure 11-8. Link TRB Structure

If software prepares a circular TRB list which is shorter than the number of cached TRBs (four), the core automatically detects the loop and will not re-fetch a TRB that has already been fetched. For example, for four cached TRBs the software setup three TRBs in the following way:

- TRB-1: Normal, HWO=1
- TRB-2: Normal, HWO=1
- TRB-3: Link to TRB 1

The core will fetch TRBs 1, 2, and 3. Then the core will follow the link to TRB-1, note that its address is the same as the TRB-1 that has already been fetched into the cache, and will temporarily stop fetching TRBs. When TRB-1 completes due to traffic on the USB, the core will write TRB-1 back to memory with the HWO field set to '0', generate a XferInProgress event if necessary, and will automatically attempt to fetch TRB-1 again. In most cases, the core will see the HWO field set to '0' and will stop fetching until software updates the TRB, sets the HWO field back to '1', and issues an Update Transfer command.

11.2.2.3.1.4 Chaining buffers (CHN) and interrupt on completion (IOC) usage

This figure shows a chaining buffer example for an isochronous IN and a bulk IN transaction.

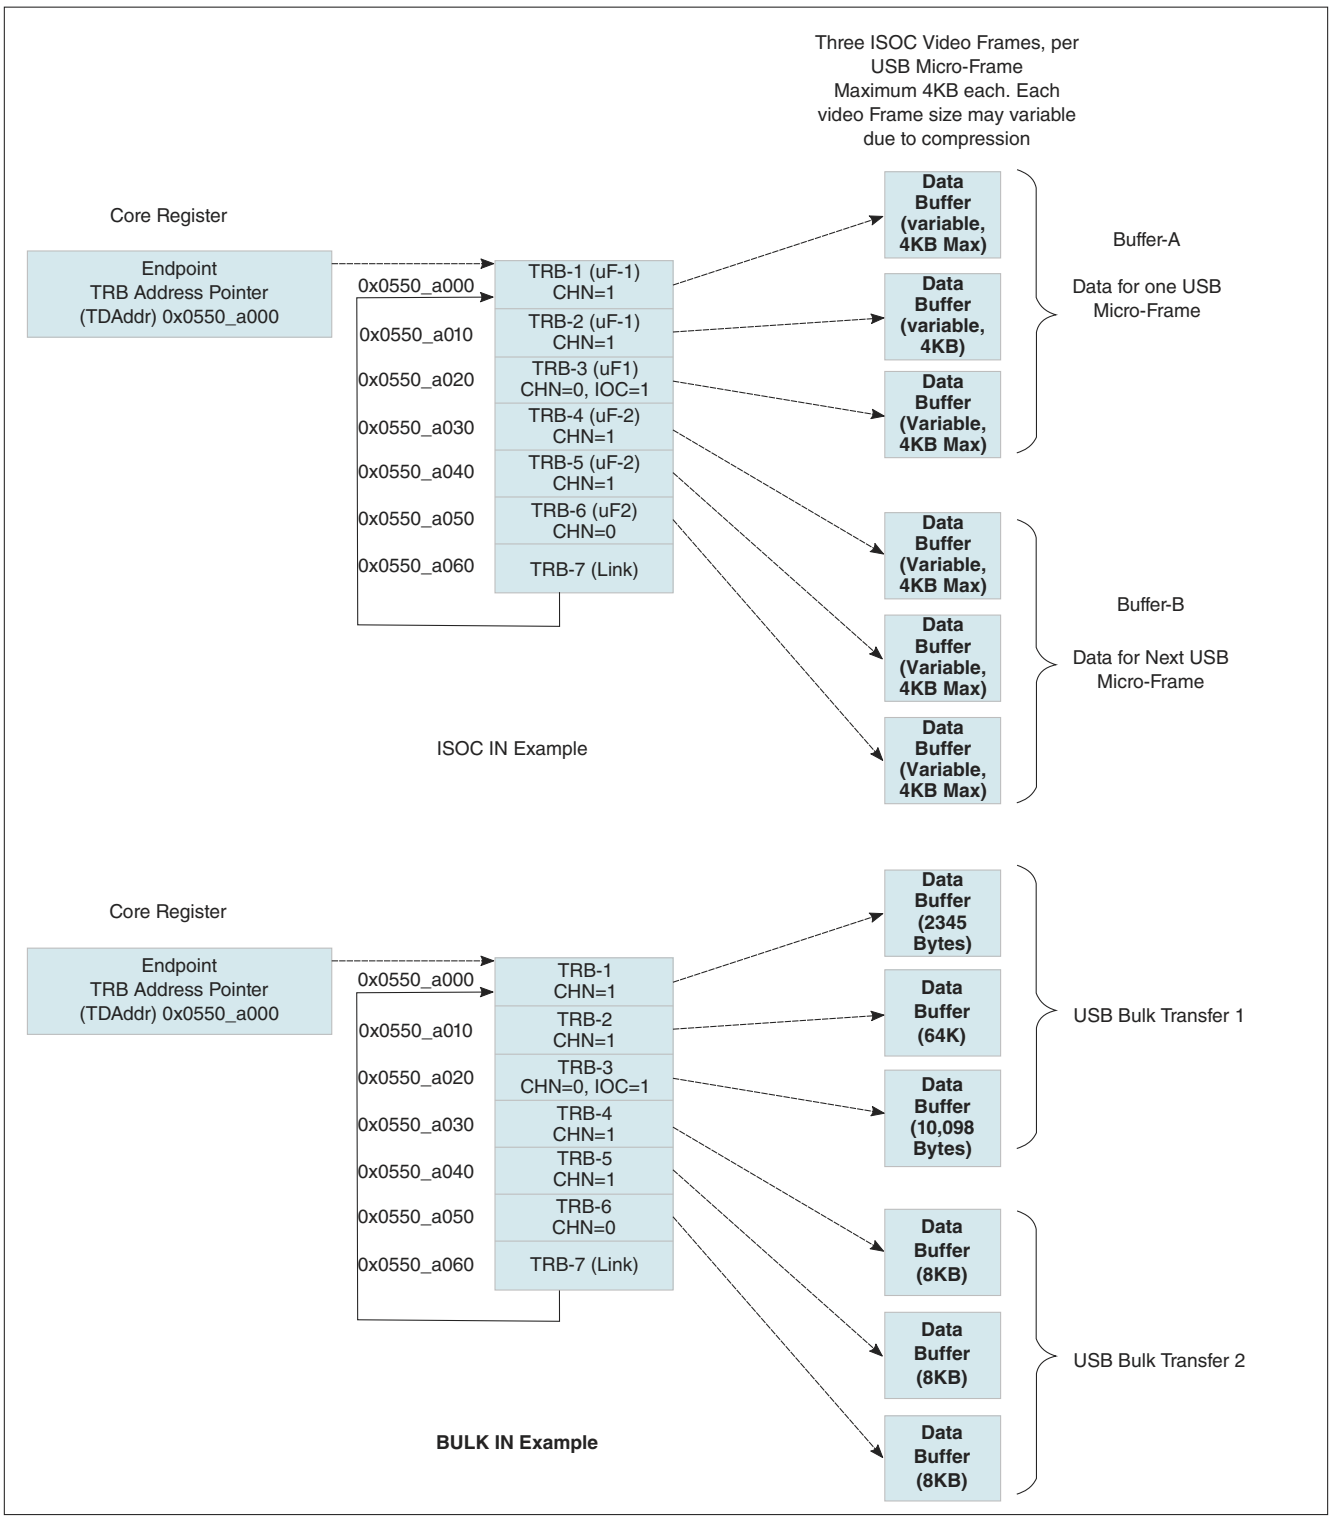

Figure 11-9. Chaining buffers for isochronous and bulk IN

In the isochronous IN application shown in the above figure, there are three video frames to be sent to the host in each microframe. Each video buffer size is maximum of 4 KB and the size may vary for each microframe depending on the compression. The CHN bit

in the TRB-3 is 0, which indicates this is the last buffer of a transfer for the given microframe. The device schedules TRB-1, 2, and 3 in the first bInterval. Similarly, TRB-6 indicates (CHN=0) microframe boundary, and TRB-4, 5, and 6 will be sent during the next bInterval.

For the last packet of last transfer in a microframe, the device internally sets last packet flag when responding at SuperSpeed for isochronous IN transfers.

The application can also use the IOC bit to receive an interrupt when the buffer-A transfer is completed, so it can use buffer-A to send data on the bInterval following the next bInterval. As long as the driver can service the interrupt and set up data before another bInterval, the USB transfers can continue without interruption. Depending upon the system interrupt latency, the buffer size can be adjusted.

If interrupt latency is high occasionally, the software may not have time to set up the linked TRB before the next bInterval. In this case, the core, on seeing HWO bit set to 0 in the TRB, stops processing further TRBs of this endpoint. When hardware receives the Update Transfer command from software, it will re-fetch the TRB. In the case of bulk application, the core will issue the NRDY signal. In isochronous transfers, zero- length packets are sent to the host until software enables the transfer again.

In the bulk IN example, the CHN bit indicates USB Transfer boundary. During a TRB transfer, CHN indicates whether to send the bytes from next TRB buffer as part of the current transfer. For example, even though TRB-1 has 2,345 bytes, the last 297 (2345 - 2 * 1024 = 297) bytes will be combined with the data in TRB-2 and sent as a 1,024 byte packet on the USB since CHN=1. On the other hand, when there is a short packet left in TRB-3, the short packet will be sent separately, since CHN=0.

Figure 11-10 and Figure 11-11 shows examples of chaining buffers, with the fetch on the SoC bus and the transfer on the USB.

Figure 11-12 shows a bulk OUT application where two transfers are set up. The device writes data into TRB-1 and TRB-2 for the first transfer. The CHN bit (CHN=0) in TRB-2 indicates that this is the last buffer of the transfer, then TRB-3 and TRB-4 are written for the second transfer. Similarly, the CHN bit (CHN=0) in TRB-4 indicates the second transfer boundary.

If an interrupt latency is high, software may not have time to set up the TRB. In this case, the core, on seeing the HWO bit set to 0 in the TRB, will stop processing further TRBs for the endpoint. Hardware will re-fetch the TRB when software issues the update transfer command. In the case of bulk, control, or interrupt endpoints, the core will issue NRDY. In the case of isochronous endpoints, packets will be dropped until software enables the transfer again.

In the bulk OUT example below, when a short packet is received for TRB-1, TRB-3 will be used for the next OUT transfer and TRB-2 will be closed.

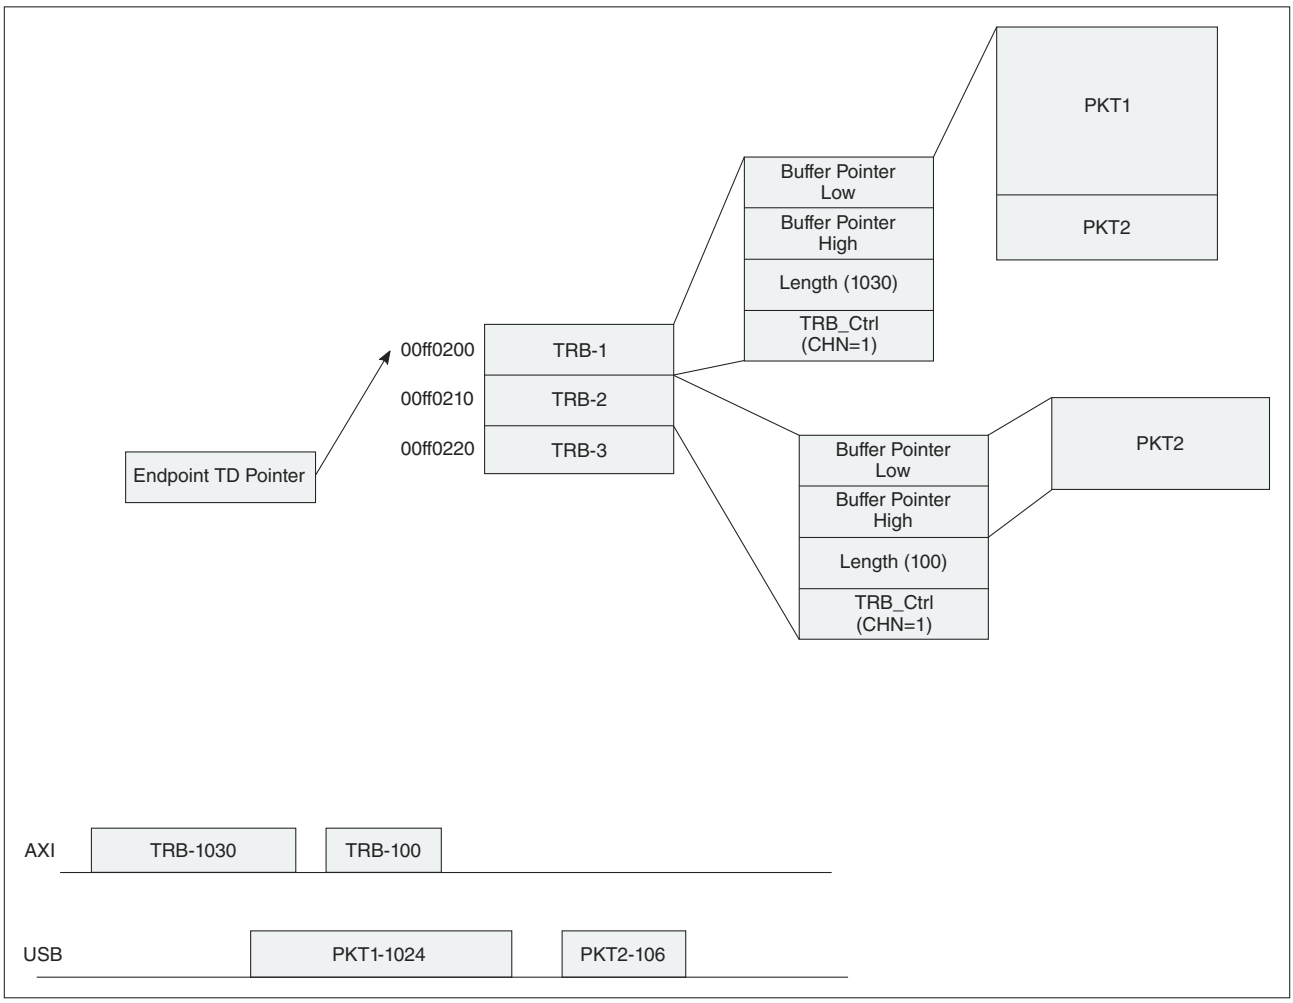

Figure 11-10. Chaining buffers, example 1

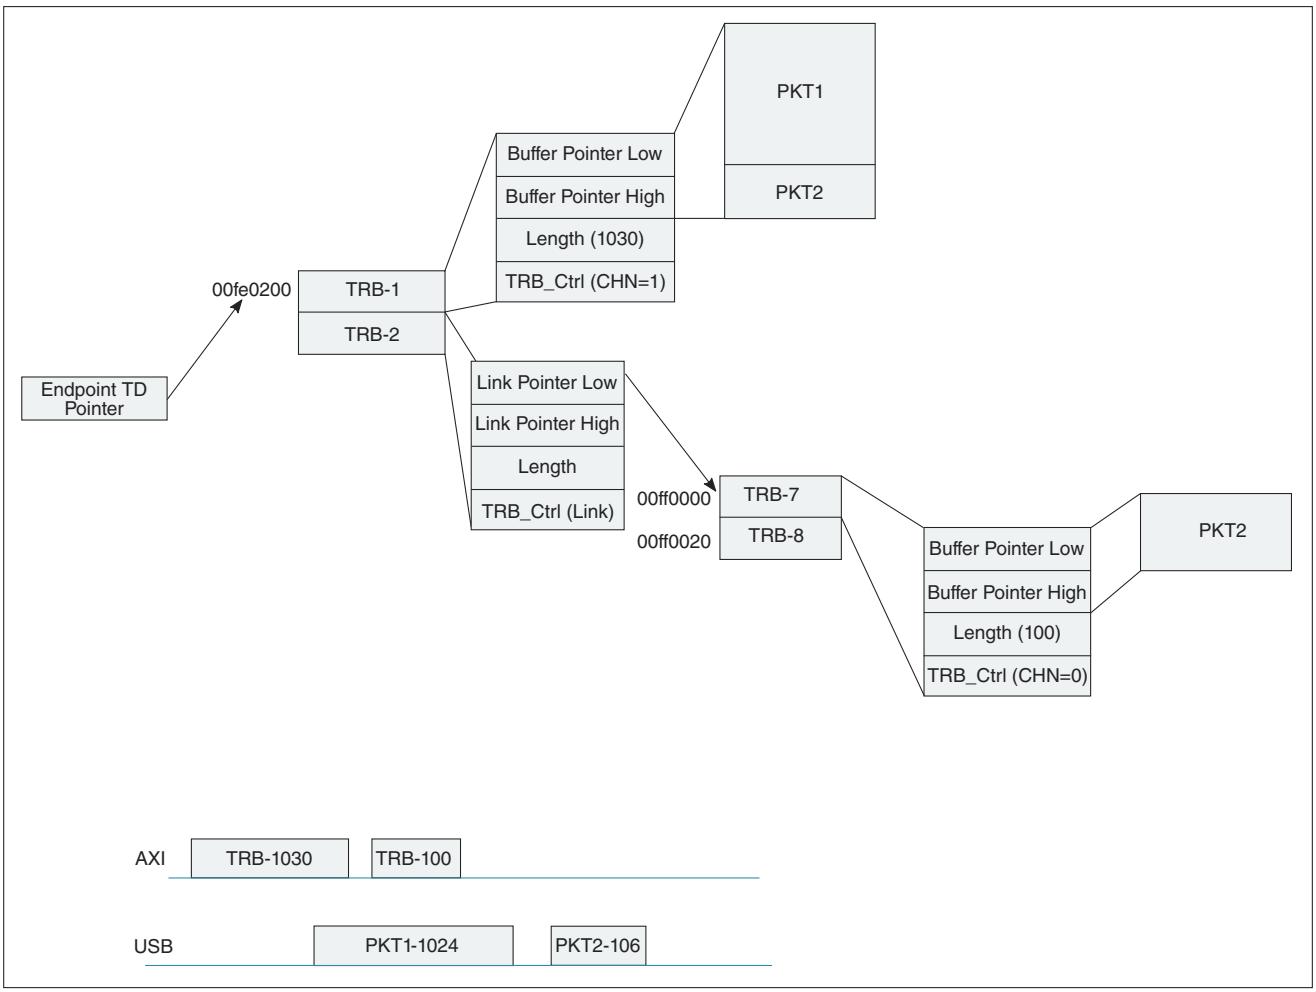

Figure 11-11. Chaining buffers, example 2

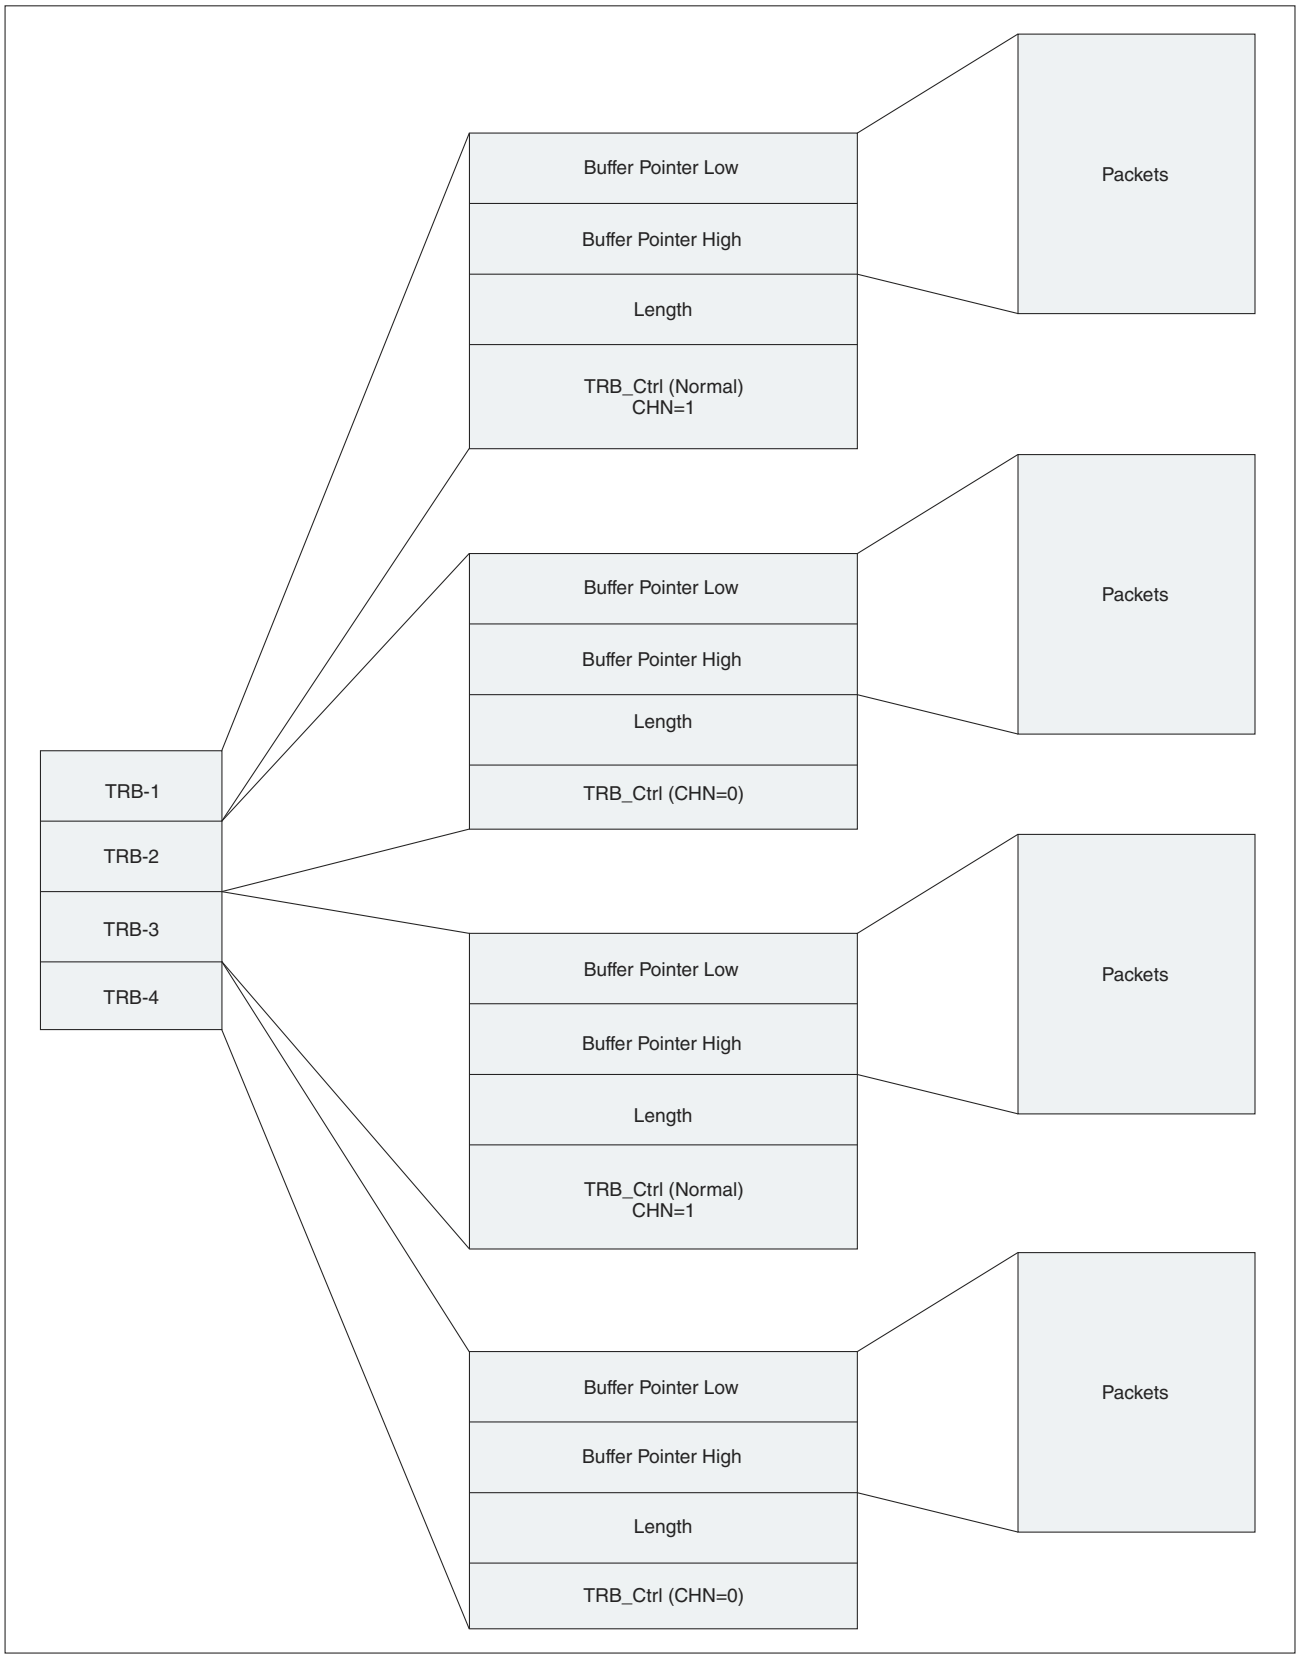

Figure 11-12. Bulk OUT with two transfers

11.2.2.3.1.5 Interrupt on Short Packet (ISP) and Continue on Short Packet (CSP) Usage

These two bits are used to schedule single or multiple OUT transfer. In most applications where only one OUT transfer per endpoint is scheduled, the software always sets ISP=1 and CSP=0. If the device receives a short packet, then it indicates a USB transfer completion through XferComplete events.

In an Ethernet-over-USB application, where software knows it is going to receive short packets, it can set up multiple transfer size buffers in one step by setting CSP=1 in all the TRBs. On a short packet, the device will update the byte count and move to next TRB. Software can also set ISP once in n number of TRBs to receive an XferInProgress event so it can process the previous short packets.

The following example shows software setting multiple 1500-byte Ethernet transfers and enabling the XferInProgress event once for four Ethernet packets to reduce the number of interrupts.

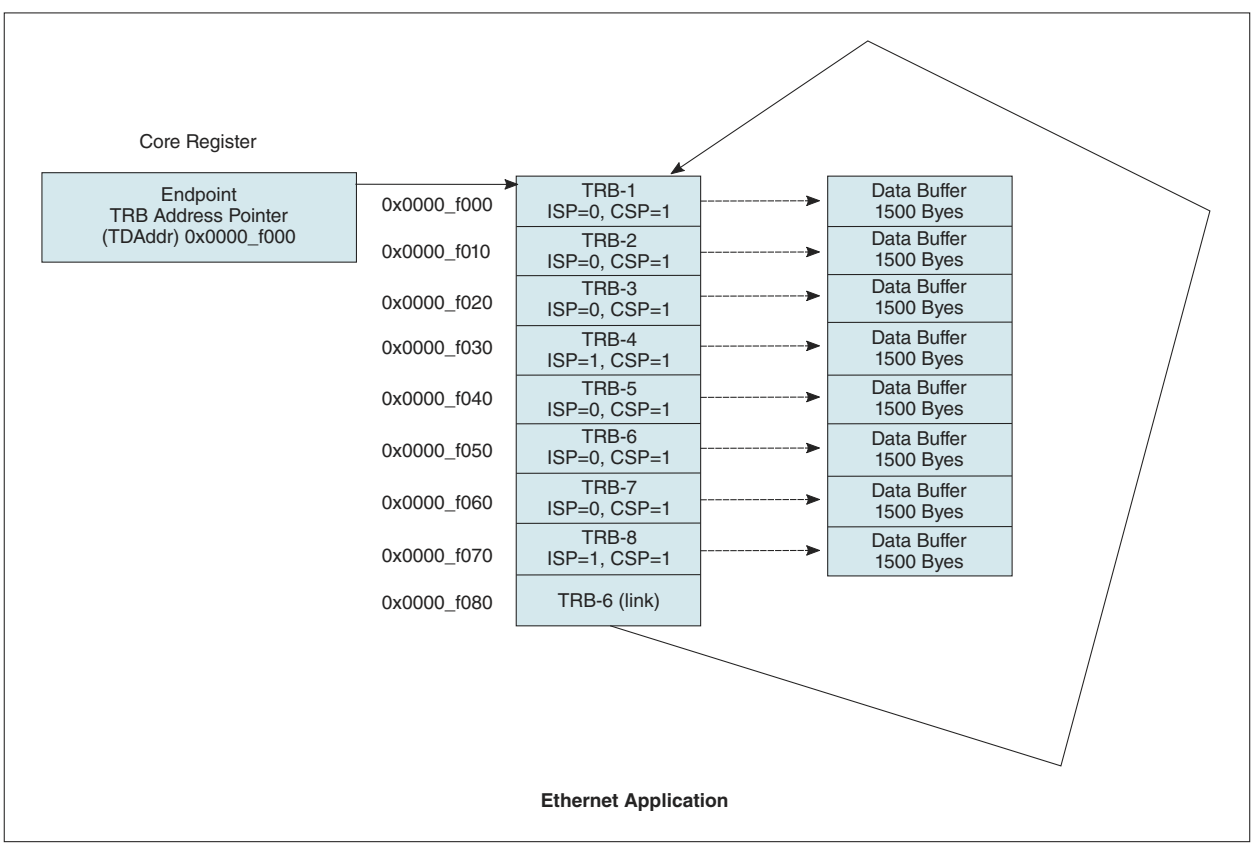

Figure 11-13. ISP and CSP Usage

11.2.2.4 Device generic command structure

Software can program the controller using DGCMD and DGCMDPAR registers to send link management packets and notifications.

DGCMD[7:0] specifies the type of generic command that the software needs the controller to perform. This section discusses the commands present in the following table.

Any command that is not present in the table is considered Reserved.

Table 11-2. device generic command types

Command	Description
02h	Set Periodic Parameters

Table continues on the next page...

Table 11-2. device generic command types (continued)

Command	Description
	Parameter[9:0] (SystemExitLatency): Software should set this to the same value programmed by the host through the Set SEL device request, in microseconds. The Set SEL control transfer has six bytes of data and contains four values; Refer to Section 9.4.12 of the *USB 3.0 Specification*. Offset: Name (Meaning) • 0: U1SEL (Time in µs for U1 System Exit Latency) • 1: U1PEL (Time in µs for U1 Device to Host Exit Latency) • 2: U2SEL (Time in µs for U2 System Exit Latency) • 4: U2PEL (Time in µs for U2 Device to Host Exit Latency) If the device is enabled for U1 and U2, then the U2PEL should be programmed. If the device is enabled only for U1, then U1PEL should be programmed into this parameter. If the value is greater than 125 µs, then the software must program a value of zero into this register. coreConsultant configuration provides the default value, assuring the register contains a valid setting when software does not set the register value. The coreConsultant parameter is DWC_USB3_PERIODIC_PARAMS. **NOTE:** Currently, the controller does not use the programmed value.
04h	Set Scratchpad Buffer Array Address Lo This command sets bits [31:0] of the external address of the scratchpad buffer array used for save/restore. If either this command or command 05h is issued while the controller is stopped (RunStop=0), the CmdIOC bit must be set to '0'. The device scratchpad buffer array has the same format as the xHCI scratchpad buffer array; it contains an array of 64-bit pointers to data buffers that will be used to save the controller state.
05h	Set Scratchpad Buffer Array Address Hi This command sets bits [63:32] of the external address of the scratchpad array buffer used for save/restore. If either this command or command 04h is issued while the controller is stopped (RunStop=0), the CmdIOC bit must be set to '0'. The device scratchpad buffer array has the same format as the xHCI scratchpad buffer array; it contains an array of 64-bit pointers to data buffers that will be used to save the controller's state.
07h	Transmit Device Notification

Table continues on the next page...

Table 11-2. device generic command types (continued)

Command	Description
	This command allows any device notification to be transmitted, using the notification type and notification parameters specified in the DGCMDPAR register. DGCMDPAR[3:0] = Notification Type DGCMDPAR[31:4] = Notification parameters, depends on the notification type For example, to transmit a Function Wake, software sets DGCMDPAR[3:0] to 1, and DGCMDPAR[10:4] to the Interface Number. This field relates to the “Notification Type Specific” field in a Device Notification Transaction Packet as described in Section 8.5.6 of the *USB 3.0 Specification*. The following bits of the DGCMDPAR register have been put into the corresponding DWORD described in Section 8.5.6 of the *USB 3.0 Specification*: DGCMDPAR[3:0] into DWORD 1[7:4] (Notification Type) DGCMDPAR[27:4] into DWORD 1[31:8] (Notification Type Specific) DGCMDPAR[31:28] into DWORD 2[3:0] (Notification Type Specific) There is one exception for the Bus Interval Adjustment Device Notification: DGCMDPAR[19:4] represents the Bus Interval Adjustment field; however, in the *USB 3.0 Specification*, the Bus Interval Adjustment field is actually at 31:16 of DWORD 1. In the case of Host Role Request, DGCMDPAR[3:0] = 4, and DGCMDPAR[5:4] = RSP Phase.
09h	Selected FIFO Flush • Parameter[4:0] = FIFO Number • Paramer[5] = ‘1’ for TX FIFO or ‘0’ for RX FIFO
0Ah	All FIFO Flush No Parameter
0Ch	Set Endpoint NRDY Issuing this command will make the controller think that the given endpoint is in an NRDY state. If there are buffers available in that endpoint, the controller will immediately transmit an ERDY. Parameter[4:0]: Physical Endpoint Number
10h	Run SoC Bus LoopBack Test When enabled, executes an SoC Bus Loopback test, which allows the data flow from transmit to receive to be tested without any connection to a PHY. 1. Configure Physical EP0 as a non-stream capable Bulk OUT endpoint (USB Endpoint Number field set to 5'h0) with the desired MaxPacketSize. 2. Configure Physical EP1 as a non-stream capable Bulk IN endpoint (USB Endpoint Number field set to 5'h1) assigned to TxFIFO 0 with the desired MaxPacketSize.

Table 11-2. device generic command types

Command	Description
	3. Issue this command with Parameter[0] set to '1', enabling Loopback mode. 4. Issue Start Transfer to EP0 (Command 6: Start transfer (DEPSTRTXFER)). 5. Issue Start Transfer to EP1. 6. The controller reads data from the IN buffers and writes it back to the OUT buffers. The Tx-FIFO 0 default value of ((512/'DWC_USB3_MBYTES) + 2) should be changed to ((1024/'DWC_USB3_MBYTES) + 2) for loopback mode. Parameter[0]: When 1, enables Loopback mode. When 0, disables Loopback mode.

11.2.2.5 Device programming model

11.2.2.5.1 Register initialization

The USB3 core contains global registers (prefixed by G*) and device registers (prefixed by D*) that are programmed to start operation and handle certain events. This section describes which registers must be accessed depending on the event that software is attempting to handle:

- Power-On or Soft Reset
- USB Reset Event
- Connect Done Event
- SetAddress Device Request
- SetConfiguration Device Request
- Disconnect Event
- Device-Initiated Disconnect and Reconnect
- Device U3 Exit

11.2.2.5.1.1 Device power-on or soft reset

This section explains device core initialization after power-on or soft reset. The application must follow this initialization sequence for device mode operation.

When the core is first powered on, software initializes the following registers. The order of operations is not important, except for the first and last steps (DCTL[CSFTRST]=1 and DCTL[RUN_STOP]=1).

Table 11-3. Power-on or soft reset register initialization

Register	Description
DCTL	Set the CSftRst field to '1' and wait for a read to return '0'. This resets the device core.
GSBUSCFG0/1	Leave the default values, refer Global SoC Bus Configuration Register 0 (GSBUSCFG0) and Global SoC Bus Configuration Register 1 (GSBUSCFG1)
GTXTHRCFG/ GRXTHRCFG	This is required only if threshold is enabled.
GUSB2PHYCFG	Program PHY as per Global USB2 PHY Configuration Register (GUSB2PHYCFG) or leave the default values if the correct power-on values were selected. Note: The PHY must not be enabled for auto-resume in device mode.
GUSB3PIPECTL	Program the following PHY [DatWidth] or leave the default values if the correct power-on values were selected.
GTXFIFOSIZn	Write these registers to allocate prefetch buffers for each Tx endpoint. Unless the packet sizes of the endpoints are application-specific, it is recommended to use the default value.
GRXFIFOSIZ0	Write this register to allocate the receive buffer for all endpoints. Unless the packet sizes of the endpoints are application-specific, it is recommended to use the default value.
GEVNTADR/ GEVNTSIZ/ GEVNTCOUNT	Depending on the number of interrupts allocated, program the Event Buffer Address and Size registers to point to the Event Buffer locations in system memory, the sizes of the buffers, and unmask the interrupt. Note: USB operation stops if the Event Buffer memory is insufficient, because the core stops receiving/ transmitting packets.
GCTL	Program this register to override scaledown, RAM clock select, and clock gating parameters.
DCFG	Program device speed and periodic frame interval
DEVTEN	At a minimum, enable USB Reset, Connection Done, and USB/Link State Change events
DEPCMD0	Issue a DEPSTARTCFG command with DEPEVT.XferRscIdx set to 0 and CmdIOC set to 0 to initialize the transfer resource allocation. Poll CmdAct for completion.
DEPCMD0/ DEPCMD1	Issue a DEPCFG command for physical endpoints 0 & 1 with the following characteristics, and poll CmdAct for completions: USB Endpoint Number = 0 or 1 (for physical endpoint 0 or 1) FIFONum= 0 XferNRdyEn and XferCmplEn = 1 Maximum Packet Size = 512 Burst Size = 0 EPType = 2'b00 (Control)
DEPCMD0/ DEPCMD1	Issue a DEPXFERCFG command for physical endpoints 0 & 1 with DEPCMDPAR0_0/1 set to 1, and poll CmdAct for completions
DEPCMD0	Prepare a buffer for a setup packet, initialize a setup TRB, and issue a DEPSTRTXFER command for physical endpoint 0, pointing to the setup TRB. Poll CmdAct for completion. Note: The core attempts to fetch the setup TRB via the master interface after this command completes.
DALEPENA	Enable physical endpoints 0 & 1 by writing 0x3 to this register
DCTL	Set DCTL[RunStop] to '1' to allow the device to attach to the host. At this point, the device is ready to receive SOF packets, respond to control transfers on control endpoint 0, and generate events.

After the controller has been started, wait for the following events:

- Wait for a DEVT.USBReset event. This indicates that a reset is detected on the USB.
- Wait for a DEVT.ConnectionDone event. This event indicates the end of the reset on the USB. On this event, read the DSTS register to get the connection speed.

11.2.2.5.1.2 Initialization on USB reset

To initialize the core as a device, during USB Reset, the application must perform the following steps:

Table 11-4. Initialization on USB reset

Register	Description
DEPCMD0	If a control transfer is still in progress, complete it and get the core into the "Setup a Control-Setup TRB / Start Transfer" state
DEPCMDn	Issue a DEPENDXFER command for any active transfers (except for the default control endpoint 0)
DEPCMDn	Issue a DEPCSTALL (ClearStall) command for any endpoint in STALL mode prior to the USB Reset (excluding control endpoints)
DCFG	Set DevAddr to '0'

NOTE

- Special Reset Considerations for Default Control Endpoint 0: The default control endpoint is not affected by a USB Reset, so software must continue following the software flow for control transfers explained in "Control Transfer Programming Model" even across a USB Reset event. Resources can only be assigned to the default control endpoint once after a power on or soft reset.

11.2.2.5.1.3 Initialization on connect done

When this event is received, software must perform the following steps:

Table 11-5. Initialization on connect done

Register	Description
DSTS	Read this register to obtain the connection speed
GCTL	Program the RAMClkSel field to select the correct clock for the RAM clock domain. This field is reset to 0 after USB reset, so it must be reprogrammed each time on Connect Done.
DEPCMD0/ DEPCMD1	Issue a DEPCFG command (with Config Action set to "Modify") for physical endpoints 0 & 1 using the same endpoint characteristics from Power-On Reset, but set MaxPacketSize to 512 (SuperSpeed), 64 (High-Speed), 8/16/32/64 (Full-Speed), or 8 (Low-Speed).
GTXFIFOSIZn	(optional) Based on the new MaxPacketSize of IN endpoint 0, software may choose to re-allocate the TXFIFO sizes by writing to these registers.

11.2.2.5.1.4 Initialization on SetAddress request

When the application receives a SetAddress request in a SETUP packet, it performs the following steps:

Table 11-6. Initialization on SetAddress request

Register	Description
DCFG	Program the DCFG register with the device address received as part of the SetAddress request when SETUP packet is decoded.
DEPCMD1	After receiving the XferNotReady(Status) event, acknowledge the status stage by issuing a DEPSTRTXFER command pointing to a Status TRB. This step must be done after the DCFG register is programmed with the new device address.

At this point, the device is ready to receive micro-SOF/ITP and is configured to receive control transfers on control endpoint 0 with a new address assigned.

11.2.2.5.1.5 Initialization on SetConfiguration or SetInterface Request

When the application receives a SetConfiguration or SetInterface request in a SETUP packet, it performs the following steps:

Table 11-7. Initialization on SetConfiguration or SetInterface Request

Register	Description
DALEPENA	Set this register to 0x3 to disable all endpoints other than the default control endpoint 0.
DEPCMDn	Issue a DEPENDXFER command for any active transfers (except for the default control endpoint 0).
DEPCMD1	Issue a DEPCFG command (with Config Action field set to "Modify") for physical endpoint 1 using the current endpoint characteristics to re-initialize the TXFIFO allocation.
DEPCMD0	Issue a DEPSTARTCFG command with DEPCMD0.XferRscIdx set to 2 to re-initialize the transfer resource allocation.
DEPCMDn	Issue a DEPCFG command (with the Config Action field set to "Initialize") for each endpoint that is present in the new configuration (except for the default control endpoint). Note: Control endpoints are bi-directional and must use consecutive even/odd physical endpoint numbers for the OUT/IN direction (such as 2/3, or 4/5), and the FIFONum must be configured to the same value in both directions.
DEPCMDn	Issue a DEPXFERCFG command for each endpoint that is present in the new configuration (except for the default control endpoint 0).
GTXFIFOSIZn	(optional) Based on the new configuration of IN endpoints, software may choose to re-allocate the TXFIFO sizes by writing to these registers.
DALEPENA	Enable the logical endpoints that are active in the new configuration.
DEPCMD1	After receiving the XferNotReady(Status) event, acknowledge the status stage by issuing a DEPSTRTXFER command pointing to a Status TRB. This step must be done after the previous steps to ensure the host does not access any other endpoints that are being set up.

At this point, the core is prepared to accept Start Transfer commands for the newly-configured endpoints. For information on how to set up transfers, see the Operational model.

11.2.2.5.1.6 Alternate initialization on SetInterface request

When handling a SetInterface device request, another possibility is that software may reconfigure existing endpoints instead of starting the configuration from the beginning. This is only possible if no TXFIFOs need to be reassigned. This flow also assumes that the endpoints that are being removed or reconfigured in the new interface have halted their traffic prior to the host issuing the SetInterface request.

Table 11-8. Alternate initialization on SetInterface request

Register	Description
DEPCMDn	Make sure there are no transfers still active on the endpoints that are changing in the new interface. This is normally ensured by the host prior to issuing the SetInterface, but if not, issue an End Transfer command for the transfer on each endpoint that is changing.
DEPCMDn	Issue a DEPCFG command (with the Config Action field set to "Initialize") for each endpoint that is changing in the new configuration. The side effect of the DEPCFG command is that the endpoint's sequence number is automatically set to 0.
DALEPENA	Write this register with all the endpoints that are enabled (including the ones that are not changing).
DEPCMDn	Using the StartXfer command, acknowledge the status stage response for the SetInterface request.

11.2.2.5.1.7 Initialization on disconnect event

When the application receives a Disconnect event, it must set DCTL[ULSTCHNGREQ] to 5. Other than this, the core does not require any initialization. Because the DCTL[RUN_STOP] bit is still '1', the device attempts to reconnect to the host, at which time a USB Reset and Connect Done event occurs. However, if the application does not want to attempt to reconnect to the host, it should perform the steps in the next section.

NOTE

When DCFG[DEVSPD] is programmed for 2.0 only mode (such as, High-Speed or Full-Speed), and if the application wants to issue any commands to clear any pending transfers during a Disconnect interrupt, then it has to disable USB_GUSB2PHYCFG[SUSPENDUSB20] before issuing any commands and re-enable it after the commands have completed.

11.2.2.5.1.8 Device-initiated disconnect

If the application wants to disconnect from the host, it should perform the following actions:

Table 11-9. Initialization on device-initiated disconnect

Register	Description
DEPCMD0	If a control transfer is still in progress, complete it and get the core into the "Setup a Control-Setup TRB / Start Transfer" state
DEPCMDn	Issue a DEPENDXFER command for any active transfers (except for the default control endpoint 0)
DCTL	Set DCTL[RUN_STOP] to '0' to disconnect from the host
DSTS	Poll [DEVCTRLHLT] until it is '1'

At this point, the device is disconnected from the host and will not attempt to reconnect.

11.2.2.5.1.9 Reconnect after device-initiated disconnect

If the application decides to reconnect to the host, it must follow the steps in Device power-on or soft reset.

11.2.2.5.1.10 Initialization after U3 exit

When a device exits from U3 to U0, if there is an active transfer on an endpoint prior to the entry into U3, then software needs to issue a ‘Set Endpoint NRDY’ command. This makes the device endpoint send ERDY.

NOTE

The Set Endpoint NRDY command should be used only for device initialization after U3 exit. It should not to be used in any other scenario.

Typically, the host does not transition the device to U3 during transfers. However, when the following conditions occur, the host may send LGO_U3 request:

- Endpoint enters flow control because transfer is not ready, and
- Host decides to enter a low power state due to user interaction

In such a scenario, the device accepts the LGO_U3 request and enters the U3 state. Because SS is full duplex, the device may have sent ERDY while receiving the LGO_U3 request. As a result,

- On the host side, this ERDY is not processed
- On device side, there is no information stored that this corner case occurred and the host did not process ERDY

Therefore, when coming out of U3, the device needs to send ERDY again so that the host continues the transfer for that endpoint. This is achieved by the device software driver issuing Set Endpoint NRDY command.

When the device software receives a link state change event with the link indicating that the device is entering U3, then the device software tracks and waits for the link state change event with the link indicating U0 entry. When the device software detects this condition and also detects that there are transfers still active on the endpoint, it issues the Set EndPoint NRDY command.

11.2.2.5.2 Operational model

The following sections describes the processes and data structures that the core uses to implement the USB 3.0 specification.

11.2.2.5.2.1 USB and physical endpoints

Endpoints are referred to in two ways:

- As a USB endpoint number: USB endpoints are defined in the USB specification.
- As a physical endpoint resource number: The hardware has a fixed number of physical endpoint resources. Each resource is unidirectional and can be configured to refer to either direction of any USB endpoint.

The software always works on physical endpoints and it knows how physical endpoint corresponds to USB endpoints. DALEPENA is the only register that has one enable bit per USB endpoint.

During SetConfiguration, software maps physical endpoint resources to the required USB endpoints. When a USB request comes in, the USB endpoint number gets converted to a physical endpoint number in the core. Similarly, when a USB packet is sent out, the physical endpoint number is converted to the USB endpoint and sent out.

A USB control endpoint requires two physical endpoints. One physical endpoint is mapped to the OUT direction of the Control endpoint, and the other one is mapped to the IN direction of the Control endpoint. Specifically the two physical endpoints are used as the following:

- The Setup stage of any control transfer uses the OUT direction physical endpoint.

- For a control write or 2-stage transfer, the Data stage (if present) uses the OUT direction physical endpoint and the Status stage uses the IN direction physical endpoint.
- For a control read transfer, the Data stage uses the IN direction physical endpoint and the Status stage uses the OUT direction physical endpoint.

11.2.2.5.2.2 Event buffers

Hardware passes command completion, transfer progress, and asynchronous events to software through one or more Event Buffers.

To configure an Event Buffer, the software performs the following steps:

1. Sets up an empty buffer in system memory.
2. Writes the address of the beginning of the buffer into GEVNTADR. This address must be aligned to the Event Buffer size.
3. Writes the size of the buffer and interrupt mask into GEVNTSIZ. Depending on your system interrupt latency, enough Event Buffer space must be allocated to avoid lost interrupts or reduced performance.
4. Write a 0 into the GEVNTCOUNT register. This must be the last step, as it enables the Event Buffer. After the Event Buffer has been configured, software must not change the size or address.

There is one interrupt line per Event Buffer that indicates there are one or more events present. Software reads one or more events out of the buffer and indicates to hardware how many events it processed by writing the byte count to the GEVNTCOUNT register.

Clock crossing delays may result in the interrupt's continual assertion after software acknowledges the last event. Therefore, when the interrupt line is asserted, software must read the GEVNTCOUNT register and only process events if the GEVNTCOUNT is greater than 0.

The first event produced by the core after the Event Buffer is configured will be written to the address specified in GEVNTADR. Most events are 32 bits, and subsequent events will be written to the address (PreviousEventAddress + 4). When that address exceeds the sum of GEVNTADR and GEVNTSIZ, the core wraps around to the first GEVNTADR value. In this way, the Event Buffer operates like a circular buffer with hardware writing to the "tail" of the buffer and software reading from the "head."

Most events are exactly 4 bytes in size, but there is one exception: The Vendor Device Test LMP Received Event (VndrDevTstRcved) is a 12 byte event that includes a header in the first 4 bytes and the contents of the LMP in the following 8 bytes.

When an event occurs within the core, hardware checks the enable bit that corresponds to the event to decide whether the event will be written to the Event Buffer or not. The Event Buffer contains one of the following types of information, depending on the value of the lower bits of the event:

- Device Endpoint-Specific Event (DEPEVT) (Event[0] = 0x0)
  - The DEPCFG endpoint-specific command specifies the bits that are enabled and which Event Buffer to use for these events.
- Device-Specific Event (DEVT) (Event[0] = 0x1, Event[7:1] = 0x00)
  - The Generic Command Complete event is enabled through the DGCMD[CmdIOC] field when the command is issued.
  - The Event Buffer Overflow Event cannot be disabled and is written to the Event Buffer that encounters the overflow.
  - The rest of the Device-Specific events are enabled through the DEVTEN register.
  - Except for the Event Buffer Overflow Event, these events are written to the Event Buffer specified in the DCFG[IntrNum] field.

The core always leaves one entry free in each Event Buffer. When the Event Buffer is almost full, hardware writes the Event Buffer Overflow event and the USB will eventually get stalled when endpoints start responding NRDY or the link layer will stop returning credits (in SuperSpeed). This event is an indication to software that it is not processing events quickly enough. During this time, events will be queued up internally. When software frees up Event Buffer space, the queued up events will be written out and the USB will return to normal operation.

Event Buffer Content for Device Endpoint-Specific Events (DEPEVT)

Table 11-10. Device Endpoint-n Events: DEPEVT

Field	Description
31–16	Event Parameters (EventParam) For XferNotReady, XferComplete, and Stream events on Bulk Endpoints: [31-16]StreamID. Applies only to bulk endpoints that support streams. This indicates the Stream ID [1] of the transfer for which the event is generated For XferInProgress: [31-16] Isochronous Microframe Number (IsocMicroFrameNum). Indicates the microframe number of the beginning of the interval that generated the XferInProgress event (debug purposes only) For XferNotReady events on Isochronous Endpoints: [31-16] Isochronous Microframe Number (IsocMicroFrameNum). Indicates the microframe number during which the endpoint was not ready **NOTE:** USB 3.0 core represents USB bus time as a 14-bit value on the bus and also in the DSTS register (DSTS[SOFFN]), but as a 16-bit value in the XferNotReady event. Use the 16-bit value to interact with Isochronous endpoints via the StartXfer command. The extra two bits that the USB 3.0 core produces will be necessary for handling wrap-around conditions in the interaction between software and hardware.

Table continues on the next page...

Table 11-10. Device Endpoint-n Events: DEPEVT (continued)

Field	Description
	EPCmdCmplt events For all EPCmdCmplt events [27-24]- Command Type. The command type that completed (Valid only in a DEPEVT event. Undefined when read from the DEPCMD.EventParam field). For EPCmdCmplt event in response to Start Transfer command. [22-16] Transfer Resource Index (XferRscIdx). The internal hardware transfer resource index assigned to this transfer. This index must be used in all Update Transfer and End Transfer commands.
15–12	Event Status (EventStatus) Within an XferNotReady event- [15]: Indicates the reason why the XferNotReady event is generated: 0- XferNotActive- Host initiated a transfer, but the requested transfer is not present in the hardware 1- XferActive- Host initiated a transfer, the transfer is present, but no valid TRBs are available [14]: Not Used [13:12]: For control endpoints, indicates what stage was requested when the transfer was not ready: 2'b01- Control Data Request 2'b10- Control Status Request Within an XferComplete or XferInProgress event- [15]: LST bit of the completed TRB (XferComplete only) [15]: MissedIsoc: Indicates the interval did not complete successfully (XferInProgress only) [14]: IOC bit of the TRB that completed [13]: Indicates the TRB completed with a short packet reception or the last packet of an isochronous interval [12]: Reserved If the host aborts the data stage of a control transfer, software may receive a XferComplete event with the EventStatus field equal to '0'. This is a valid event that must be processed as a part of the Control transfer programming model. Within a Stream Event- [15:12]: - 4'h2- StreamNotFound- This stream event is issued when the stream-capable endpoint performed a search in its transfer resource cache, but could not find an active and ready stream. - 4'h1- StreamFound- This stream event is issued when the stream-capable endpoint found an active and ready stream in its transfer resource cache, and initiated traffic for that stream to the host. The ID of the selected Stream is in the EventParam field. In response to a Start Transfer command- 4'h2- Indicates expiry of the bus time reflected in the Start Transfer command. 4'h1- Indicates there is no transfer resource available on the endpoint. In response to a Set Transfer Resource (DEPXFERCFG) command- 4'h1- Indicates an error has occurred because software is requesting more transfer resources to be assigned than have been configured in the hardware. In response to a End Transfer command-

Table continues on the next page...

Table 11-10. Device Endpoint-n Events: DEPEVT (continued)

Field	Description
	4'h1- Indicates an invalid transfer resource was specified.
11–10	This field is reserved.
9–6	4'h7- Endpoint Command Complete (EPCmdCmplt) Indicates software may issue another Device Endpoint command to the endpoint. When issued in response to an End Transfer command, indicates that DMA stopped for the endpoint. For all other commands, this event does not imply that all effects of the commandtook place. The DEPCMD register contains the same status information present in the Event Status Bits field. 4'h6- Stream Event (StreamEvt) Indicates that a stream-capable endpoint initiated a search within its transfer resource cache. The result of the search is in the EventStatus field (Found or NotFound). 4'h5- Reserved 4'h4 - Reserved 4'h3- XferNotReady Event (XferNotReady) Indicates receipt of a transaction when no TRBs are available for the endpoint. For isochronous IN endpoints, a zero-length packet is automatically sent by hardware and NRDY for non-isochronous endpoints. The application must enable this event if it plans to issue Start Transfer on demand. This event can happen when software issues a Start Transfer or Update Transfer. In this case, software must ignore this event because it has already issued the Start Transfer or Update Transfer. XferNotReady is generated when the core responds NRDY to the host on the USB. It is useful in the beginning of a transfer when software wants to wait for the host to start polling the endpoint before setting up TRBs, but it is not efficient to use this event to determine when the core has run out of TRBs. For determining when the core has processed TRBs and needs software to setup more, use the IOC field in a TRB along with the XferInProgress event that is generated when the core completes a TRB with IOC=1. For non-stream-capable endpoints, the hardware filters multiple events if the host continues transactions, even after the core responds with NRDY. This internal filter is reset after software issues any endpoint command to this endpoint. For stream-capable endpoints, this event is generated each time the host attempts a transaction, even if the core responds with NRDY. For isochronous endpoints, this event is generated only once prior to the Start Transfer command to communicate the current bus time. For additional information, see the Event Status field. 4'h2- XferInProgress Event (XferInProgress) Applies to IN and OUT endpoints. Indicates an EP/Stream specific event happened and it is continuing the transfer. For additional information, see the Device programming model. 4'h1- XferComplete Event (XferComplete) Applies to IN and OUT endpoints. Indicates that a EP/Stream transfer completed and the core stopped the transfer. For additional information, see the Device programming model. 4'h0- Reserved
5–1	Physical Endpoint Number (0-31)

Table 11-10. Device Endpoint-n Events: DEPEVT (continued)

Field	Description
0	1'b0- Indicates that this is an endpoint-specific event.

1. Note that term Stream ID used in USB chapter is different from Arm SMMU terminology.

Event Buffer Content for Device-Specific Events (DEVT)

Table 11-11. Device-specific events: DEVT

Field	Description
31-25	Reserved
24-16	Event Information Bits (EvtInfo) For a USB/Link State change Event, this field indicates the state of the link- EvtInfo[8:5] - HIRD value received from the LPM token (valid for a Hibernation Request Event) EvtInfo[4] - SuperSpeed event. Set to 1 for SS; Set to 0 for non-SS. EvtInfo[3:0] - Link State. Indicates link state at the time of the event. Follows same encoding as DSTS link state bits.
15-12	Reserved
11-8	11- Event Buffer Overflow Event (EvntOverflow) The core writes this event to indicate there is no space in the event buffer, and one or more Device-specific events may have been dropped after this event. Endpoint-Specific events will not be dropped, but they will be delayed which can cause a drop in performance on the USB. Software uses this event as a warning that the Event Buffer is too small and the core should be reconfigured with a larger Event Buffer or software needs to process events more quickly. In order to avoid repeated Event Buffer Overflow Events, software must free up space in the Event Buffer by acknowledging more than 1 event (writing a value greater than 4 to the GEVNTCOUNT register). This event cannot be disabled, and is always written to the Event Buffer that encounters the overflow. 10- Generic Command Complete Event (CmdCmplt) The core writes this event to indicate the generic command is complete. 9- Erratic Error Event (ErrticErr) The core writes this event to report erratic errors (phy_rxvalid_i/phy_rxvldh_i or phy_rxactive_i is asserted for at least 2 ms, due to PHY error) seen on the UTMI+. Due to erratic errors, the USB 3.0 core goes into Suspended state and a USB/Link state change event (ULStChng) is generated to the application. If the early suspend is asserted due to an erratic error, the application can only perform a soft disconnect recover. For SuperSpeed operation, the PHY erratic error event indicates that the PIPE is not responding to the PHY command (for example, pipe3_PowerDown change or receiver detection). After the core requested any PHY command, if it did not receive pipe3_PhyStatus within 100ms, the core will timeout and generate the erratic error event. After generating the erratic error, the core assumes that the PHY command is completed successfully and proceeds with the next pending PHY command. Software must reset the controller on receiving the erratic error. 8- Reserved 7- Start of (micro)Frame (Sof) 6- USB Suspend Entry Event

Table continues on the next page...

Table 11-11. Device-specific events: DEVT (continued)

Field	Description
	This event provides a notification that the link has gone to a suspend state (L2, U3, or L1). This event is generated when hibernation mode is disabled. The existing Link State Change event (3) provides the same information, but is generated for every link state change. 5- Hibernation Request Event This event provides a notification that the link has gone to a suspend state where hibernation is supported (L2, U3, or L1) and requires software intervention - When DCTL.KeepConnect=1 and L1HibernationEn=0, this event is generated only when the link goes to L2 or U3 - When DCTL.KeepConnect=1, L1HibernationEn=1, and the core is configured to support LPM (DCTL.LPMCap=1 and DCTL.HIRD_Thres[4]=1), this event is generated when the link goes to L2, U3, or L1 with an HIRD value greater than the DCTL.HIRD_Thres[3-0] value The existing Link State Change event (3) provides the same information, but is generated for every link state change. If both events are enabled, only the Hibernation Request event will be generated if the conditions are met. When this event occurs, software is required to start the hibernation process EvtInfo[4:0] indicates the Link State and Speed which caused the Hibernation Event (using the same encoding as the Link State Change event. Suspend is 3, and L1 is 2)EvtInfo[8:5] provides the HIRD value from the host's LPM tokenFor L2 and U3, this event is only generated when DCTL.KeepConnect=1For L1, this event is only generated when DCTL.L1HibernationEn=1 and DCTL.KeepConnect=1In addition to the suspend states that trigger this event, hibernation is also supported when the link is disconnected. See 'Device-Initiated Disconnect and Low Power While Disconnected' for details. 4- Resume/Remote Wakeup Detected Event (WkUpEvt) This event is generated when the host initiates a resume condition on the USB bus. This event is not generated by the device initiating a remote wakeup to the host. 3- USB/Link State Change (ULStChng) The core writes this event to indicate a change of USB or Link state. Bits 23-16 (EvtInfo) of this event indicate the Link Status. The event is generated in SuperSpeed when the link LTSSM state changes, except when LTSSM exits from HOT_RESET, POLL or LTSSM enters into RECOVERY. 2- Connection Done (ConnectDone) 1- USB Reset (USBRst) 0- Disconnect Detected Event (DisconnEvt) Note: This event is generated only if VBUS is off.
7-1	7’h00 - Device Specific Event
0	1’b1 - Non-Endpoint-Specific Event

11.2.2.5.2.3 Transfer and buffer rules

Buffers that are used to transfer data to and from an endpoint are defined using a Buffer Descriptor, which consists of one or more Transfer Request Blocks (TRBs). A CHN flag in the TRB is used to identify the TRBs that comprise a Buffer Descriptor. Therefore, a

Buffer Descriptor refers to a consecutive set of TRB data structures where the CHN flag is set in all TRBs, except the last. Note that a Buffer Descriptor may consist of a single TRB, whose CHN flag will not be set.

Software communicates the location of the first TRB by using the Start Transfer command on an endpoint. Even endpoints that are not stream-capable use this command.The core fetches TRBs from external memory starting at the address provided in the Start Transfer command parameters, continuing in a linear fashion and following the Link TRB until a TRB is encountered that has its LST bit set to '1' or HWO bit set to '0'. Therefore, software must ensure that it has valid TRBs prepared before issuing the Start Transfer command to prevent the core from reading uninitialized memory.

Descriptor fetch requests are buffered within the hardware and handled separately from the progress of the current transfer. Therefore, it is possible that the core completes a transfer with XferComplete but still continues reading TRBs that it has not cached yet. If software is immediately de-allocating the memory for TRBs based on the XferComplete event, it is recommended that software issue an End Transfer command for the endpoint/ transfer resource prior to de-allocating the memory. The completion of the End Transfer command flushes out any pipelined descriptor fetches and avoids a potential bus error.

While processing TRBs, two conditions may cause the core to write out an event and raise an interrupt line:

- TRB Complete:
  - For OUT endpoints, a packet is received which reduces the remaining byte count in the TRB buffer to zero.
  - For IN endpoints, an acknowledgement is received for a transmitted packet which reduces the remaining byte count in the TRB buffer to zero.
- Short Packet Received:
  - For OUT endpoints only. While writing to a TRB buffer, the endpoint receives a packet that is smaller than the endpoint's MaxPacketSize.

This table shows the USB 3.0 Core Actions Based on TRB Control Bits.

Table 11-12. USB 3.0 Core Actions Based on TRB Control Bits

Direction	TRB Complete Packet	ISP	IOC	CHN	LST	CSP	Action
IN	Yes	-	X	0	1	-	XferComplete event
IN	Yes	-	0	X	0	-	No event
IN	Yes	-	1	X	0	-	XferInProgress event
OUT	Yes No	-	X	0	1	-	XferComplete event
OUT	Yes No	-	0	X	0	-	No event

Table continues on the next page...

Table 11-12. USB 3.0 Core Actions Based on TRB Control Bits (continued)

OUT	Yes No	-	1	X	0	-	XferInProgress event
OUT	X Yes	X	X	X	X	0	XferComplete event [1]
OUT	X Yes	X	X	0	1	1	XferComplete event
OUT	X Yes	X	X	1	0	1	Search for CHN=0, accumulate IOC and ISP, then follow CHN=0 rules [2]
OUT	X Yes	X	1	0	0	1	XferInProgress event
OUT	X Yes	0	0	0	0	1	No event
OUT	X Yes	1	0	0	0	1	XferInProgress event

1. When a TRB receives whose CSP bit is 0 and CHN bit is 1 receives a short packet, the chained TRBs that follow it are not written back (for example, the BUFSIZ and HWO fields remain the same as the software-prepared value)
2. In the case of an OUT endpoint, if the CHN bit is set (and CSP is also set), and a short packet is received, the core retires the TRB in progress and skip past the TRB where CHN=0, accumulating the ISP and IOC bits from each TRB. If ISP or IOC is set in any TRB, the core generates an XferInProgress event. Hardware does not set the HWO bit to 0 in skipped TRBs. If the endpoint type is isochronous, the CHN=0 TRB will also be retired and its buffer size field updated with the total number of bytes remaining in the BD.

On XferComplete and XferInProgress events, status bits in the event indicate LST, IOC, Short Packet Received, or Bus Error status. In the "fast-forward" case, the IOC status is accumulated from the skipped TRBs, not just the TRB that received the short packet.

When the hardware writes back the TRBs, it updates the BUFSIZ field to represent the remaining unused buffer.

11.2.2.5.2.3.1 Number of TRBs rule

- Software must set up only one TRB for a control setup or status stage.
- If software is preparing multiple transfers for an IN endpoint, it may be necessary to place a 0-length TRB between transfers that are MaxPacketSize aligned to indicate transfer boundaries to the host. This is not necessary, if the class driver and the host can handle bursting between transfers.
- If software is preparing multiple transfers for an OUT endpoint, it needs to place a MaxPacketSize TRB between transfers, if it expects the host to transmit a 0-length packet between transfers.

11.2.2.5.2.3.2 TRB control bit rules

Transfer control bits must conform to the following restrictions:

For OUT endpoints, the CSP bit must be the same in every TRB within a Buffer Descriptor (either set or clear).

- The core autonomously checks the HWO field of a TRB to determine if the entire TRB is valid.

- Therefore, software must ensure that the rest of the TRB is valid before setting the HWO field to '1'. In most systems, this means that software must update the fourth DWORD of a TRB last. Every time software validates a TRB by setting HWO=1, it must also issue an Update Transfer command to the core.
- Software sets the HWO bit to 1 when it creates the TRB, and cannot modify it until hardware resets it to 0. However,
  - Software must detect when a "fast-forward" occurs on an OUT endpoint that receives a short packet, since some TRBs in a chain may still have their HWO bit set to 1 while belonging to software.
  - Hardware will not clear the HWO bit of a Link TRB. Therefore, software can only modify a Link TRB if the TRB prior to the Link TRB has its HWO bit set to 0.
- The LST bit must not be set to 1 for isochronous endpoints.
- For a Setup or Status TRB, set CHN=0, LST=1, and CSP=0.
- For the data stage of a control transfer, set CSP=0 in all TRBs and LST=1 in the last TRB of the data stage.
- For Link TRBs, the LST, CHN, IOC, ISP, CSP, and Stream ID fields are ignored and must be set to 0.
- The Link TRB's chain bit is implicitly equal to the chain bit of the TRB before it. If the TRB before it has CHN=1, then the Link acts as if it's CHN=1. If the TRB before it has CHN=0, then the Link acts as if it's CHN=0. A Link TRB cannot be the last TRB in a Buffer Descriptor.
- When CSP=1 and the core receives a short packet, it searches for the end of the Buffer Descriptor by finding the Normal TRB that has CHN=0. Therefore, it is illegal to setup a circular buffer with all Normal TRBs with CHN=1.

11.2.2.5.2.3.3 Buffer size rules and zero-length packets

The hardware contains a cache that holds four TRBs per transfer.

For IN endpoints, the following rules apply:

- The number of chained TRBs necessary to construct a single packet must never exceed 3 . A maximum of one link TRB can be present in the chain.
- If software wants to indicate a transfer completion to the host by sending a zero-length packet after a multiple of MAXPACKETSIZE, it must set up a zero-length TRB following the last TRB in the transfer.

For OUT endpoints, the following rules apply:

- If the first TRB has CHN=1, its buffer size must be ≥ 1 byte

- The total size of a buffer descriptor must be a multiple of MAXPACKETSIZE
- A received zero-length packet still requires a MAXPACKETSIZE buffer. Therefore, if the expected amount of data to be received is a multiple of MAXPACKETSIZE, software should add MAXPACKETSIZE bytes to the buffer to sink a possible zero-length packet at the end of the transfer.

For IN and OUT endpoints, the following rule applies:

- The BUFSIZ field in a link TRB must be set to 0.

11.2.2.5.2.3.4 Transfer setup recommendations

Software can either set up transfers before the host attempts to move data on an endpoint ("preset" transfers) or can set up transfers on demand ("on-demand" transfers). When using preset transfers, software can safely disable the XferNotReady event in the endpoint configuration. However, when using on-demand transfers, the XferNotReady event must be enabled and software may not use the "No Response" variant of the Update Transfer command. The XferNotReady event is issued when the host attempts to move data on an endpoint when one of the following conditions is present:

- No previous transfer was started with Start Transfer.
- Not enough hardware-owned (HWO=1) TRBs are available to handle the requested data movement. The XferNotReady event must not be disabled for control endpoints because the event is an integral part ofcontrol transfer handling.

Although there are many valid ways to set up transfers, it is recommended that you choose one of three general mechanisms:

- When software wants to set up one transfer at a time and has the entire buffer available for transfer, it must set up TRBs that point to the data buffers and in the last TRB it must set the LST bit and issue Start Transfer, which points to the first TRB location.
  - When the USB transfer completes, the core will notify the software through the XferComplete event. The LST bit will be set in the status field of the event. The XferComplete will also release the Transfer Resource.
  - A premature XferComplete event can happen before all the data buffers are exhausted, if there is a Bus Error or, in an OUT transfer a short packet has been received and CSP=0. During these conditions the TRB will have an updated BUFSIZ field which represents the amount of buffer remaining after the successful part of data transfer.
  - Software can also set up an IOC bit TRB, so that it gets notified when data buffers are used up and can free them up sooner than waiting for the entire transfer to complete. On completing a TRB with IOC set, and not the last one,

the core will issue an XferInProgress event with IOC set in the status field of the event.

- When software wants to set up one transfer at a time, but it has fewer data buffers available than the full transfer size, it must set up circular TRBs (using a Link TRB), and also set up IOC bits in the TRBs. Depending on buffer allocation and interrupt frequency it can set IOC for once in "x" number of TRBs.
  - As soon as the USB transfer for a TRB is completed, and if IOC is set, the core will generate an XferInProgress event with IOC set in the status field.
  - On seeing the event, software reuses the TRB and updates it with the next data buffer. It also issues an Update Transfer command, indicating it has updated a TRB.
  - If software is slow and hardware finds a TRB with HWO reset to 0, it waits for an Update Transfer command. Upon seeing the Update Transfer, it prefetches the TRB and continues the transfer.
  - When software reaches the end of the transfer, it sets the TRB LST bit. When hardware completes the TRB, it issues an XferComplete event and releases the Transfer Resource.
- When the Device software has multiple transfers to set up, it must set up circular TRBs and also set up CHN bits in all TRBs, except the last of each transfer. For OUT endpoints, multiple transfers can be supported when the CSP field is set to '0' if each transfer has a multiple of MaxPacketSize bytes, since a short packet will end the transfer. If multiple transfers may contain short packets, the CSP field must be set to '1' to enable the next transfer to continue even if a short packet is received. Depending on buffer allocation and interrupt frequency, it can either set the IOC for once in "x" number of TRBs or in the last TRB of each transfer.
  - For OUT endpoints, the transfer can finish prematurely due to a short packet from the host. In this case, the core processes the remaining TRBs, skipping the updates to these TRBs until it reaches TRB of the next transfer. While skipping these TRBs, if any of the TRB it encounters the interrupt setting of ISP or IOC, it will generate the corresponding event once and ignore the interrupt settings of the remaining TRBs until a TRB of next transfer is reached.
  - Device software can reclaim these skipped TRBs even though the HWO still indicates 1 (hardware-owned).
  - For IN endpoints, software cannot stop providing transfers while it is ending transfers with CHN=0 and LST=0, otherwise it is possible that the endpoint is left in a flow-controlled state on the USB.

11.2.2.5.2.4 Transfer resource usage and transfer state

Software allocates one Transfer Resource for an endpoint during initialization. When software issues a Start Transfer command, this Transfer Resource is used. When an XferComplete event happens, the Transfer Resource is released back to software. Similarly, when End Transfer completes, the Transfer Resource is released.

Following is a typical transfer usage summary (not complete usage model):

- Software sets up data buffer(s) and TRB(s) in external memory with the TRB(s) pointing to the buffer(s).
- Software issues Start Transfer with the pointer to the first TRB in the command parameters.
- If software sets up all the buffers and TRBs at the same time (Host and Device Software negotiate the transfer size), then just one Start Transfer is enough, and software waits for a XferComplete event.
- If software did not set up all the TRBs, then every time software adds a new TRB (by setting HWO=1) it must issue an Update Transfer command. The hardware will fetch the TRB again and continue the transfer.
- The End Transfer command is used only during error conditions and not used during normal transfers. For example, if software has set up multiple transfers and if a USB Reset event happens, it must remove all the transfers from the queue using End Transfer with the ForceRM bit set 1.
- A transfer is completed when all the data has been transferred or a short packet has been received. If software is queuing in only single transfers at a time (normal method for mass storage - for ethernet over USB, software can set up multiple transfers using the Chain bit and Continue on Short Packet bit), once XferComplete interrupt has happened, the transfer is completed. When starting a new transfer, software now needs to issue the Start Transfer command.
- An OUT transfer's transfer size (Total TRB buffer allocation) must be a multiple of MaxPacketSize even if software is expecting a fixed non-multiple of MaxPacketSize transfer from the Host.

The following is the usage flow when the device does not know the transfer size and the host is not expected to send short packets to end the transfer. Note that this is not a normal scenario, but some device applications require this flow.

1. The device sets up the TRB(s) with the maximum transfer size expected, and enables all of them (HWO=1).
2. The host sends the OUT transactions, and completes the transfer without sending any short or zero-length packet.
3. The device controller keeps updating the TRBs as required but does not give XferComplete event.

4. The device software implements a timer to count inactivity on the OUT endpoint to detect the end of transfer.
5. When the timer expires, software issues End Transfer command with ForceRM=1, and waits for the command to complete.
6. Software reads the RAM0 cache (stream scratchpad bytecount location) through the slave interface to know the remaining byte count and calculates the received byte count.g.Software calculates the byte address using the following formula:

   dut_bytecount_addr = dut_ram0_base + `DWC_USB3_ADDR_CACHE_STREAMS + (stream_id *(32 + (`DWC_USB3_CACHE_TRBS_PER_TRANSFER * 16))) + (7*4);

   where, stream_id is the Transfer Resource Index (XferRscIdx) of the OUT endpoint, and

   dut_ram0_base = `DUT_REGISTER_BASE_ADDRESS+32'h4_0000; // RAM0 starting address

7. Software sets up the new transfer.

The following figure displays the Transfer Usage State Machine.

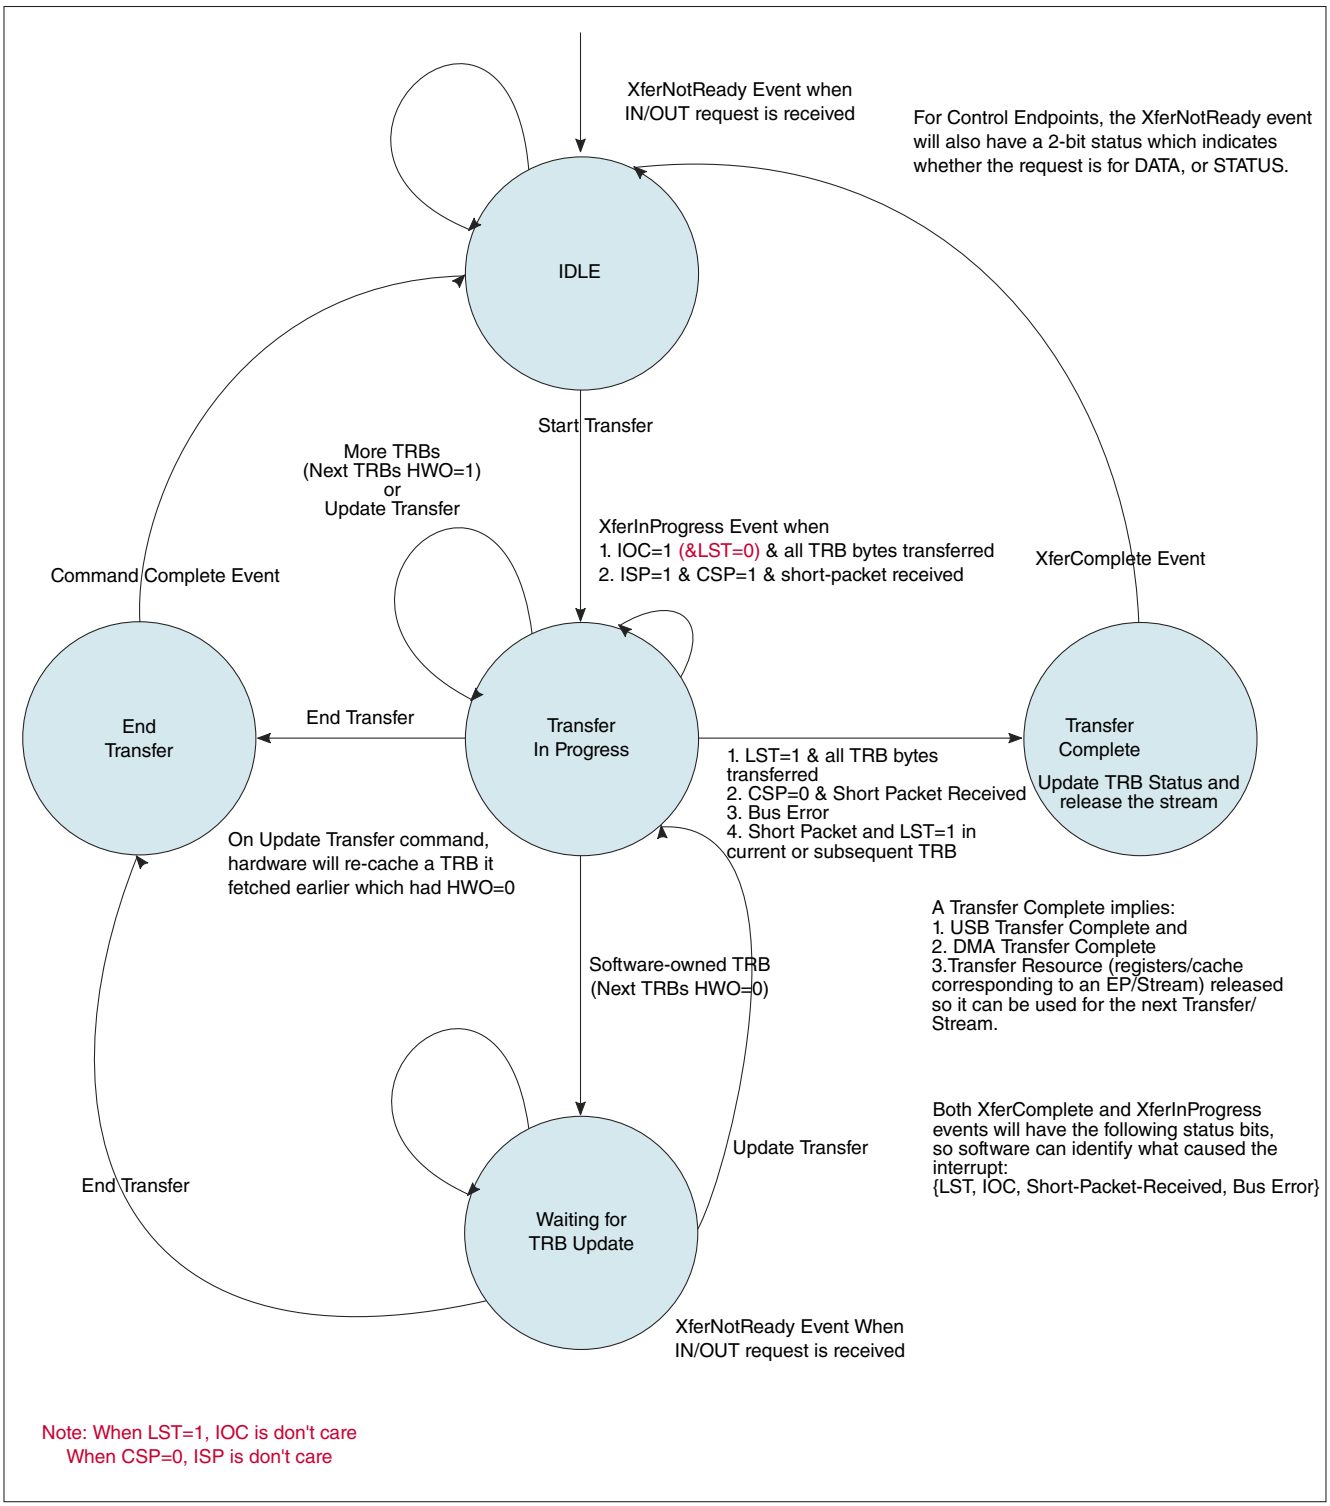

Figure 11-18. Transfer usage state machine

11.2.2.5.2.5 Transfer descriptions

The following sections describe typical transfer processes.

11.2.2.5.2.5.1 Non-isochronous OUT transfers

The sequence below describes a regular, non-isochronous OUT transfer (control-data/ bulk/interrupt).

Table 11-13. Non-isochronous OUT transfer sequence

Steps	Host	Device Core	Device Software
Software sets up data buffers before a host request			
Step 1	-	-	Software sets up Normal TRBs and enables DMA by issuing Start Transfer.
Step 2	-	Device fetches the TRB and caches it.	-
Step 3	Host sends data packets	-	-
Step 4	-	Core receives the packets in RXFIFO and stores them in to TRB data buffers through DMAs. While the RXFIFO has space and the BUS DMA keeps up with the host data transfers, the device receives all the packets. Once all the data is received, the core updates the TRB status and then generates a XferComplete event. In SS mode, if GRXTHRCFG.USBRxPktCntSel is set to, • 0: the NumP sent depends on the DCFG.NumP and bMaxBurstSize • 1: the NumP sent depends on the RXFIFO space available when the packet is received When DMA is slow or CRC fails: • If the RXFIFO overruns or CRC error is detected, device times out in Non-SS mode or asks for the same data packet (through ACK/SeqNumber/Retry Bit) in SS mode. • In HS mode, on NAK the host will issue PING and device will ACK it (if there is enough space in the RXFIFO) and the host resumes with data again. In SS mode, the host will send the requested data. If the device receives any packet with other than the requested data sequence, it will ignore it.	-
Step 5	-	-	Software processes the XferComplete event.
Software sets up data buffers after the host request.			
Step 6	Host sends data packets.	-	-
Step 7	-	Since DMA is not set up, the device will send NAK in Non-SS mode and will send NRDY in SS mode to the host. It also generates an XferNotReady event.	-
Step 8	-	-	On seeing the XferNotReady event, Software sets up TRBs and enables DMA by issuing Start Transfer.
Step 9	-	Steps 2-5 are followed.	-

Table continues on the next page...

Table 11-13. Non-isochronous OUT transfer sequence (continued)

Steps	Host	Device Core	Device Software
Step 10	-	If the core encounters a short packet before the transfer size data programmed in the TRB is received, it skips the remaining TRBs of the transfer. If the core encounters control bits LST, IOC, or ISP it will generate events and, in the case of an LST TRB, the stream will be completed. Software has to reclaim any TRBs skipped with HWO=1.	On detecting a skipped TRB condition, software reclaims the TRBs with HWO=1.

11.2.2.5.2.5.2 Isochronous OUT transfers

This section describes the difference between isochronous and non-isochronous OUT transfers referring to the sequence in Non-isochronous OUT transfers

- In Step 2, if the TRB is not fetched in time, the core discards the packet. In addition subsequent packets in the service interval also will be dropped.
- In Step 4, if DMA is enabled and if RXFIFO overrun happens or CRC fails, the core discards the packet. In addition subsequent packets in the service interval also will be dropped.
- In Step 7, if DMA is not enabled, the core drops the data and generates XferNotReady event.

In general, the TRB chain of a service interval will be released if the core receives DATA0 PID in HS USB 2.0 mode or receives a packet with LPF set in SuperSpeed mode.

Special scenarios are:

- If the core misses this last packet indication, it releases TRB at the service interval boundary.
- If the core encounters a short packet before the transfer size data programmed in TRB is received, it skips the remaining TRBs of the transfer.
- If the core encounters control bits 'LST' or 'IOC' or "ISP" it will generate event and, in the case of LST TRB, the stream will be completed, but software has to reclaim TRBs if any TRBs skipped with HWO=1.

11.2.2.5.2.5.3 Non-isochronous IN transfers

The sequence below describes a regular, non-isochronous IN data transfer (control-data/ bulk/interrupt).

Table 11-14. Non-isochrnous IN transfers

Steps	Host	Device Core	Device Software

Table continues on the next page...

Table 11-14. Non-isochrnous IN transfers (continued)

	Software sets up data buffers before a host request		
Step 1	-	-	Software sets up TRBs and enables DMA by issuing Start Transfer.
Step 2	-	Device fetches the TRB, caches it, and prefetches the data into TXFIFO. Only in SS mode, the core sends ERDY (Async ERDY, even before host requesting data provided endpoint is in flow controlled state. LSP flow is same regardless of if the host asked for it.)	-
Step 3	Non-SS host issues a token request, SS host issues ACK TP to request data.	-	-
Step 4	-	If DMA fetches keep up with host requests, the device sends all the data, updates the TRB status, and then generates an XferComplete event when ACKs for all the packets are received. When DMA is slow: • If the TXFIFO becomes empty on a host data request, the device sends a NAK in Non-SS mode. In SS mode, the device sends NRDY, and when data is available in TXFIFO it sends ERDY and waits for the host request again. • If the TXFIFO becomes empty in the middle of a packet transfer (happens only in Threshold mode), in Non-SS mode the device will invert the CRC. In SS mode, it terminates with EDB after appending the corrupted CRC. The core waits for the host to retry the packet before fetching the data again. If the host retries a packet: • In Non-SS mode, a transmitted packet is kept in the TXFIFO until the ACK arrives (this is immediate in Non-SS mode). If the host retries a packet, it is immediately sent out from the TXFIFO. • In SS mode, before ACK can be received, the core could have sent additional packets in a burst. When a retry happens, NRDY is sent to the host and the TXFIFO is flushed. A DMA command is issued on the master bus to prefetch data from where the host is asking. Once data is fetched into the TXFIFO, the device sends ERDY and waits for host request again. • In Threshold mode, when the TX threshold amount of data is fetched, the device sends ERDY to the host.	-
Step 5	-	-	Software processes XferComplete event.
	Software sets up data buffers after a host request.		

Table continues on the next page...

Table 11-14. Non-isochrnous IN transfers (continued)

Step 6	Non-SS host issues a token request. SS host issues ACK TP to request data.	-	-
Step 7	-	Since DMA is not set up, the device sends s NAK in Non- SS mode, or NRDY in SS mode, to the host. The core also generates an XferNotReady event	-
Step 8	-	-	On seeing the XferNotReady event, software sets up Normal TRBs and enables DMA by issuing Start Transfer.
Step 9	-	Steps 2-5 are followed.	-
Step 10	-	When software knows it is talking to a host that always ends transfers with short packets, and therefore always requires a zero-byte packet to end a transfer, it includes a zero-byte TRB (CHN=0) after the last TRB which is an even multiple of MaxPacketSize. When software does not know if the host is going to do another IN token after receiving the exact number of bytes it expected (and it was a multiple of MPS), it does not include a zero-byte TRB, and sets LST in the last TRB. If the host returns with another IN for a zero-byte packet, it uses the XferNotReady/Start Transfer mechanism to add one zero-byte TRB. This is called "On- Demand."	-

11.2.2.5.2.5.4 Isochronous IN transfers

This section describes the difference between isochronous and non-isochronous IN transfers referring to the sequence in Non-isochronous IN transfers.

- In Step 4, if the TXFIFO is empty when host IN request arrives, the core returns a zero length packet in both Non-SS and SS modes.
- In Step 7, the device returns zero length packet and generates an XferNotReady event.

Special scenarios:

- When data is fetched and there is no request from the host (possibly due to a missing request or corrupted request) the data will be flushed at the end of the service interval (corresponding Micro- Frame) boundary and the core moves onto fetching next service interval data. If there are some TRBs that are not serviced in the service interval, the core will skip these TRBs.
- If the core encounters control bits LST or IOC, it will generate an event, and in the case of LST TRB, the stream will be completed, but has to reclaim TRBs if any TRBs skipped with HWO=1.

11.2.2.5.2.6 Handling ENDPOINT_HALT

On receiving a SetFeature (ENDPOINT_HALT) control transfer, software issues a Set Stall command on the endpoint. Because of the delay from when software issues the command and when it is recognized by the core, other transfer events (XferInProgress, XferComplete) may be received prior to the endpoint being halted. For a description of the Set Stall endpoint command and its effects, see Commands 4 and 5: Set Stall and Clear Stall (DEPSSTALL, DEPCSTALL).

On ClearFeature (ENDPOINT_HALT), software must first remove all pending transfers for the endpoint through the End Transfer command. It may then issue a Clear Stall command on the endpoint followed by Start Transfer to start transfers again. For a description of the Clear Stall endpoint command and its effects, see Commands 4 and 5: Set Stall and Clear Stall (DEPSSTALL, DEPCSTALL).

11.2.2.5.2.7 Handling L1 event during a transfer

This section discusses the scenario in which the software already issued the Start Transfer command but the LPM occurred before or during the data transfer.

When an IN transfer is in progress, (that is, started and not completed yet), and the software sees a link state change event to L1, then the software can use the GDBGFIFOSPACE register (write followed by a read) to determine if the TXFIFO is empty or not. If the TXFIFO is not empty, it can initiate a remote wakeup.

NOTE

- The GDBGFIFOSPACE register is a debug register which gives the 'Space Available" for the endpoint selected with a write prior to the read. If this space available is less than the particular TXFIFO's maximum size, then the TXFIFO is not empty.
- Software can enable the Link State change event for USB 2.0 as there are not a lot of events compared to SS.

11.2.2.5.3 Isochronous transfer programming model

Isochronous endpoints get guaranteed service by the host during a "Service Interval". The service interval for an endpoint is communicated to the host via the endpoint descriptor, and it is configured in the hardware through the DEPCFG command. However, unexpected behavior on the bus may prevent the host from servicing the endpoint as frequently as expected.

Although the endpoint receives "guaranteed" service during the interval, there are no bus-level acknowledgments, which means that there is no guarantee that the host (IN endpoints) or the device (OUT endpoints) receives correct data.

Therefore, the isochronous programming model differs from the bulk programming model to accommodate these two factors:

- No bus-level acknowledgement of packet transmission or reception
- No guarantee that all the data setup for an interval has been transmitted or received

For isochronous endpoints, software has the following responsibilities:

- Set up enough TRBs to keep up with the rate of data transmission or reception
- For FIFO-based IN endpoints, guarantee the validity of the TX data at least 1 micro Frame before the beginning of the interval that the data will be transmitted

Hardware has the following responsibilities:

- Transmit or receive data at the appropriate bus time
- For FIFO-based IN endpoints, delay fetching until 1 micro Frame before the beginning of the interval that the data will be transmitted
- Maintain a 1-to-1 correspondence between Buffer Descriptors and the intervals on the bus
- Report missed isoc intervals and update the buffer sizes in TRBs to reflect the amount of data moved

11.2.2.5.3.1 Definitions

- bInterval: The field in an endpoint descriptor used to communicate the service interval of the device. Its value ranges from 1 to 16, however, the USB 3.0 core supports a range of 1 to 14.
- Service interval: An integral number of microframes (2^[bInterval-1]) during which the host will poll the device to move data.
- Beginning of interval: The interval begins when the least significant (bInterval-1) bits of the bus time are all 0's.
- End of interval: The interval ends when the least significant (bInterval-1) bits of the bus time are all 1's.
- Data payload: The number of bytes to be moved during the service interval. It will be transmitted using MaxPacketSize packets.
- Buffer descriptor: A set of one or more TRBs with CHN=1 and the last one having CHN=0. The group of TRBs represents the data buffers for one service interval.
- Last TRB of a Buffer Descriptor: The TRB within a Buffer Descriptor that has CHN=0. When an interval has completed, this TRB will contain the total remaining buffer size of the Buffer Descriptor andus also the completion status of the interval.

- Microframe (μF): A unit of time on the USB that lasts 125 μs.
- Start of Frame (SOF): The beginning of a microframe.
- FIFO-Based Isoc IN: A sub-type of Isoc IN endpoints that has the characteristic of always assuming the HWO bit in a TRB is '1' and delays fetching of transmit data.
- Prefetch delta: For FIFO-based IN endpoints, TX data may be prefetched as early as 1 μF before the beginning of a Service Interval, but never earlier.
- Retire a TRB: When HW sets the HWO bit to 0 in a TRB and writes it back.
- Retire a Buffer Descriptor: When HW retires at least the first and last TRB of a Buffer Descriptor.
  - Other TRBs of the Buffer Descriptor may not be retired if an interval was missed (IN or OUT) or if a short packet/last packet is received (OUT). In this case, software may reclaim those TRBs even though HWO=1.
- Missed interval: When the device does not move all the data in an interval. This may occur when the host does not poll for all the data, or because of application-side delays that prevent all the data from being moved.
  - For IN endpoints, this occurs when the host does not request all the data prepared in the Buffer Descriptor, or not all the data is fetched from the system bus in time.
  - For OUT endpoints, this occurs when the host does not send a packet, a packet is dropped due to CRC error, or the system bus is too busy to accept the data.

11.2.2.5.3.2 Endpoint configuration

An isochronous endpoint is setup in much the same way as a bulk endpoint, with the following exceptions:

- The bInterval_m1 value in DEPCFG Parameter 1 must be set to the value reported in the endpoint descriptor minus 1. When the core is operating in Full Speed, bInterval_m1 must be set to 0.
- The MaxPacketSize value in DEPCFG Parameter 0 must be set to the same value reported in the endpoint descriptor.
- The "FIFO-based" bit in DEPCFG Parameter 1, bit 31, must be set for FIFO-based isochronous endpoints.
- For the best performance, set the TXFIFOs corresponding to Isochronous IN endpoints to a high priority.

After the endpoint is configured, it can be enabled by setting the appropriate bit in the DALEPENA register.

11.2.2.5.3.3 Transfer configuration

Software describes isochronous transfers through a series of Buffer Descriptors. Each Buffer Descriptor corresponds directly to one service interval of data. The fields within an isochronous TRB are the same as bulk TRBs with the following exceptions:

- The SOF field in an IN endpoint TRB is a don't care. For an OUT endpoint, the core will write this field with the timestamp of the last packet received into the TRB's buffer. This information is not needed for normal operation, only for debug purposes.
- For High-Speed, High-Bandwidth IN endpoints, a maximum of 3 packets can be sent during an interval. The PktCntM1 field ([25:24] of the 3rd DWORD) must be set to the (number of packets in the Buffer Descriptor - 1). For example, if 3 packets are to be transmitted during the interval, this field must be set to 2. For Super-Speed and OUT endpoints, this field is a don't care.
- The first TRB in a Buffer Descriptor must have the TRBCTL field set to the "Isochronous-First" type while all others have this field set to "Isochronous".
- The ISP bit is renamed IMI (Interrupt on Missed Interval) and should be set if software wants to receive an XferInProgress event when at least 1 packet is missed within an interval.
- The IMI bit should be set to the same value in all TRBs of a Buffer Descriptor.
- The CSP bit must be set to 1 (short packets cause the hardware to move to the next Buffer Descriptor, they do not end an isochronous transfer).
- The LST bit should be set to 0 (isochronous transfers normally continue until the endpoint is removed entirely, at which time an End Transfer command is used to stop the transfer).

All other bits and fields (IOC, HWO, CHN, BPTR, BUFSIZ) retain the same behavior as they have for bulk endpoints. If software needs to receive an interrupt after every service interval, it should set the IOC bit to '1' in each TRB. However, if software wants to reduce the interrupt frequency and the application can tolerate some latency, the IOC bit can be set to '0' and the core will not generate a XferInProgress event when the TRB is completed.

For OUT endpoints, the Buffer Descriptor must describe a total buffer size of:

```
(Mult+1)*MaxBurst*MaxPacketSize
```

11.2.2.5.3.4 Starting a transfer

The hardware will report the bus time that the host starts polling the endpoint inside the XferNotReady event. Software will use this value as a reference when issuing the Start Transfer command to serve as time synchronization with the host.

1. Set up TRBs and data buffer for the endpoint.

2. After configuring and enabling the endpoint, wait for an XferNotReady event.

   The XferNotReady event will contain the time that the host started polling the endpoint in the upper 16 bits.

3. Issue the Start Transfer command to the endpoint with a future microframe time written into the upper 16 bits of the DEPCMD register. The future microframe time must be a value that is an integral multiple of intervals after the time reported in the XferNotReady event and aligned to the beginning of an interval. For example, if bInterval is 3 (4 microframes), and the XferNotReady time is 2, the value can be 4, 8, 12, and so on. The future microframe time must also be no greater than 4 seconds past the time reported in the XferNotReady event.
4. If the future microframe time has already passed when the command is received, the core will respond with an error (bit 13 in the Command Complete event).

In this case, software must issue End Transfer, then wait for another XferNotReady event and attempt the command again with a time that is further in the future.Otherwise, the first Buffer Descriptor will be used for the interval starting with the microframe time specified in the Start Transfer command.

11.2.2.5.3.5 Core behavior during an interval

After a transfer has been started, the hardware will perform the following functions for IN endpoints:

1. Fetch TX data as early as one interval prior to the beginning of the interval (call it A) if the HWO bit is set to one in the TRB.
2. Decrement the buffer size of each TRB as packets are transmitted.
3. Retire TRBs when their buffer size has reached 0, issuing an XferInProgress event if the IOC bit is set.
4. If the next interval (B) starts before all the packets have been transmitted for interval A:
   a. Flush the TXFIFO.
   b. Retire the Buffer Descriptor of interval A with a "Missed Isochronous" status.
   c. Retire the Buffer Descriptor of interval B with a "Missed Isochronous" status.
   d. See Checking interval status for a description of how software can determine that an interval ended unexpectedly.
   e. Go to step 1 to prepare for interval C
5. Otherwise, if all the TRBs of interval A are completed, the hardware will prepare for interval B.
6. If the host completes an interval by polling for all the data, but then it polls the endpoint again during the same interval, the hardware will respond with a zero-length packet and no interrupt will be made to software.

7. If the host polls the endpoint prior to the time specified in the Start Transfer command, the hardware will respond with a zero-length packet and no interrupt will be made to software.
8. If the host polls the endpoint during the expected interval and the hardware has no data prepared, the core will respond with a zero-length packet, but no XferNotReady event will be generated because the transfer is active. When the next interval starts, the XferInProgress event is generated (based on ISP and IMI) with the "Missed Isochronous" status, which is the way software finds out that this occurred.

For OUT endpoints, the hardware performs the following functions:

1. If a packet is received for the correct interval represented by the Buffer Descriptor (call it A).
   a. Write the packet into the buffer.
   b. Decrement the buffer size of the TRB.
   c. Write the timestamp of the received packet into the TRB.
   d. Retire a TRB when its buffer size reaches 0, issuing an XferInProgress event if the IOC bit is set.
2. If a short packet or packet with the last packet flag (lpf) is received for the correct interval.
   a. Write the packet into the buffer.
   b. Retire the Buffer Descriptor of interval A with the TRBSTS set to 0.
   c. If the IOC bit is set in the last TRB of the Buffer Descriptor, issue an XferInProgress event with bit [13] set.
   d. Go to step 1 to prepare for interval B.
3. If a packet is received for the correct interval but it has an error (CRC error, RXFIFO overflow), the core will not increment its expected sequence number value which causes future packets within the same interval to be dropped.
4. If a packet is received at a bus time prior to the time specified in the Start Transfer command, it will be dropped.
5. If a packet is received for the correct interval (A), but not enough buffer space is available for the core to write the packet (due to the HWO bit still '0' in one or more of the TRBs of the Buffer Descriptor), no XferNotReady event will be generated. The core will behave as follows:
   a. Wait until software sets the HWO bit to '1' and issues an Update Transfer command
   b. Retire the Buffer Descriptor of interval A with a "Missed Isochronous" status
   c. Go to step 1 to prepare for interval B.
6. If a packet is received for the next interval (B) before all the packets have been received for interval A:
   a. Retire the Buffer Descriptor of interval A with a "Missed Isochronous" status.
   b. Retire the Buffer Descriptor of interval B with a "Missed Isochronous" status.

c. See section Checking interval status for a description of how software can determine that an interval ended unexpectedly.
d. Go to step 1 to prepare for interval C.

Special Considerations for Isochronous OUT Endpoints

For OUT isochronous endpoints, the hardware detects a missed interval when the host sends a data packet in a future interval. It does not detect the missed interval at the exact interval boundary. Therefore, if the host abruptly stops sending isochronous OUT packets, there will be no interrupt or event indicating this to software. Software should use one of the following mechanisms to detect the interruption of isochronous OUT traffic:

1. The ultimate consumer of the isochronous OUT data will detect an underflow.
2. The device driver can use a timer detect that no XferInProgress events have been received for multiple intervals.

If this occurs, software should issue an End Transfer command to the endpoint and wait for a XferNotReady event which signals that the host is ready to resume isochronous traffic.

11.2.2.5.3.6 Checking interval status

As packets are transmitted or received during an interval, the buffer size of each TRB will be decremented. When the host is operating normally and polling for all the interval data, the buffer size of all the TRBs of an IN endpoint Buffer Descriptor will be zero after the interval has completed. For OUT endpoints, if the host sends less data than the Buffer Descriptor was setup for, the remaining buffer size may be greater than 0.

When the interval completes, the final remaining buffer size and missed isoc status is written to the last TRB of the Buffer Descriptor. If MissedIsoc is set, then it means the BUFSIZ is not accurate and may indicate that more data was transmitted or received than in reality. If the MissedIsoc is not set, it means the BUFSIZ field is correct.

When hardware detects the end of an interval (including normal and abnormal ends), it performs the following:

- If it has not already been retired, the first TRB of the Buffer Descriptor will be retired.
- Any non-first TRBs with CHN=1 that had not already been retired will not be written back. HWO will still be 1, and software can reclaim them for another transfer.
- The last TRB of the Buffer Descriptor will be retired with:
  - HWO = 0.

    - BUFSIZ = The total remaining buffer size of the Buffer Descriptor.
    - TRBSTS = "Missed Isoc" if any packets were missed, zero otherwise.
- If the IOC bit is set in the last TRB, or the IMI bit is set and packets were missed, hardware will issue an XferInProgress event

Software can get notification of an interval completing by setting the IOC bit in the last TRB of the Buffer Descriptor. The IOC bit may also be set in any other TRB of the Buffer Descriptor if software wants earlier notification that a TRB has completed. Software can also get only a notification of an interval completing unexpectedly by setting the IMI (Interrupt on Missed Isoc) bit in the last TRB of the Buffer Descriptor. When an interval completes unexpectedly and either the IOC or IMI bit is set in the TRB, the MissedIsoc bit (15) of the XferInProgress event will be set. The following table shows which events are generated in each scenario:

Table 11-15. TRB event generation events

Scenario	IOC	IMI	Action
TRB completed with a MaxPacketSize packet	0	0	No interrupt
	0	1	No interrupt
	1	0	XferInProgress (IOC=1)
	1	1	XrefInProgress (IOC=1)
TRB completed with a short packet	0	0	No interrupt
	0	1	No interrupt
	1	0	XferInProgress (Short=1, IOC=1)
	1	1	XrefInProgress (Short=1, IOC=1)
Interval completed due to missed packet (missed isoc)	0	0	No interrupt
	0	1	XferInProgress (MissedIsoc=1, IOC=1)
	1	0	XferInProgress (MissedIsoc=1, IOC=1)
	1	1	XrefInProgress (MissedIsoc=1, IOC=1)

It is normal to lose two intervals at a time when an error occurs during one interval. One interval is lost because of the host (which may not be polling enough) and the second interval is dropped because the device needs time to synchronize up to the next (third) interval.

11.2.2.5.3.7 Adding intervals to a transfer

Because isochronous endpoints represent a stream of data, the TRBs of an isochronous endpoint will normally be setup in a circular list, such as:

- TRB 1 (CHN=0, IOC=1)

- TRB 2 (CHN=0, IOC=1)
- Link (to TRB 1)

Example: Assume TRB 1 represents the data for the first interval and TRB 2 represents the data for the second interval. Because IOC=1, when the core completes the first interval, it will issue an XferInProgress event which indicates to software that TRB 1 can be analyzed to retrieve the results from interval 1. TRB 1 can the be re-used to represent the data for the third interval by setting HWO=1 and issuing an Update Transfer command.

Each time software sets up TRBs for a new interval, it must follow the guidelines in the Transfer Configuration section. Software will set up TRBs for future intervals when it obtains those buffers from another software layer or when TRBs are retired by the core.

11.2.2.5.3.8 Moderating events

During a transfer, software may enable or disable any endpoint-specific event by re-issuing the DEPCFG command with the "Config Action" set to "Modify" and a modified DEPEVTEN field. All other field. All other fields in all other parameters must remain the same as the initial endpoint configuration.

11.2.2.5.3.9 Other types of isochronous endpoints

The above description of the isochronous endpoint programming model assumes that software is setting up buffers in external memory that apply to certain intervals of data. This is called a "buffer-based" isochronous endpoint.

However, there is another mode that the hardware supports to accommodate other mechanisms of sourcing or sinking isochronous data, called "FIFO-based" and the types are defined by bits [31:30] of DEPCFG Parameter 1. This table illustrates the differences between the models:

Table 11-16. Isochronous endpoints models

Type	FIFO-Based [31]	Bulk-based [30]	TRB Fetch	TRB Write back	TX DMA	Retire Buffer Descriptor at passed interval
Buffer-based	0	0	When HWO=1	Yes	When HWO=1, no earlier than one interval ahead of time.	Yes
FIFO-based	1	0	When internal cache space available	No	No earlier than 1 µF before the interval	Yes
Invalid	1	1				

11.2.2.5.3.9.1 FIFO-based isochronous IN endpoints

The software of some applications is unable to keep up with the short latency and high bandwidth of isochronous traffic and require the data to be sourced and done a sync through external FIFOs. One example is that there are two external TXFIFOs, one for each interval, and an address-to-FIFO-pop logic is implemented so that when the core attempts to read from interval 1's address, the translation logic converts this into a pop signal for interval 1's TXFIFO. When the core attempts to read from interval 2's address, the translation logic converts this into a pop signal for interval 2's TXFIFO.

To describe a FIFO-based implementation, software sets up an endpoint with the "FIFO-based" configuration bit set. This type of endpoint ignores the HWO bit in all TRBs, assuming that the TRB is always valid, and that the core should never write it back. Software chooses the buffer pointers within the TRBs to correspond to the address needed by the translation logic to specify which FIFO should be popped. By also using the CHN bit, headers and payload can be concatenated from different FIFOs. For example, if there are 4 external FIFOs: HA, PA, HB, PB, where HA/HB contain the 4 byte header for 2 intervals and PA/PB contain the 512 byte payload for 2 intervals, this can be described by using the following 5 TRBs:

1. BUFPTR=HA, IOC=0, CHN=1, BUFSIZ=4
2. BUFPTR=PA, IOC=1, CHN=0, BUFSIZ=512
3. BUFPTR=HB, IOC=0, CHN=1, BUFSIZ=4
4. BUFPTR=PB, IOC=1, CHN=0, BUFSIZ=512
5. Link to (1)

Every interval, the core will be creating a 516 byte packet that consists of 4 bytes from the header FIFO and 512 bytes from the payload FIFO. However, if the host does not poll for the packet, the core will skip 1 or 2 intervals of popping, depending on whether it has already started reading the next interval. External logic (or software) is responsible for flushing and refilling alternate FIFOs so that the core is always reading the correct data for the next interval. In normal intervals, the FIFOs will be empty, but when an interval is missed, there may still be data present in the FIFOs.

Software Requirements:

- The "FIFO-based" bit must be set in the DEPCFG when configuring the endpoint.
- No field within any TRB may be changed after the Start Transfer command is issued.
- Data must be valid in the external FIFO at least 1 uF before the beginning of the interval for which the data is intended.

Core Behavior:

- The earliest the core will read from the FIFO will be 1 µF before the beginning of the interval for which the data is intended.
- The core will not write back the TRB after it has completed it.
- The core will re-read the TRB from external memory even though it is not allowed to change.
- The only indication of missed intervals is the XferInProgress event if IOC or IMI is set in the TRBs. No indication will be made of how much data was actually transmitted.

11.2.2.5.3.9.2 FIFO-based isochronous OUT endpoints

The FIFO-based model is also supported for OUT endpoints. In this case, core writes to specific addresses will be translated into external FIFO pushes. The same example from above (4 byte headers and 512 byte payloads) can be applied to OUT endpoints where the headers are split from the payload as the core receives 516 byte packets. The same software requirements and core behavior apply (for example, no writebacks and no indication of how much data was received). External logic assumes that if less than the expected amount of data is pushed into an interval's FIFO, the interval is invalid.

11.2.2.5.3.10 End a transfer

Since isochronous endpoints have no bus-level acknowledgements, it is not necessary to set LST=1 in a TRB to gracefully end an isochronous transfer. Software can issue an End Transfer command to end an isochronous transfer. The core will wait until it can complete operations for the endpoint before returning the Command Complete event in response.

11.2.2.5.4 Control transfer programming model

Control transfers follow a flow of setup/data/status. On the USB bus, there are many error scenarios that can disrupt this flow. The hardware has a special mechanism that automatically recovers from these scenarios as long as software follows this single control transfer programming model.

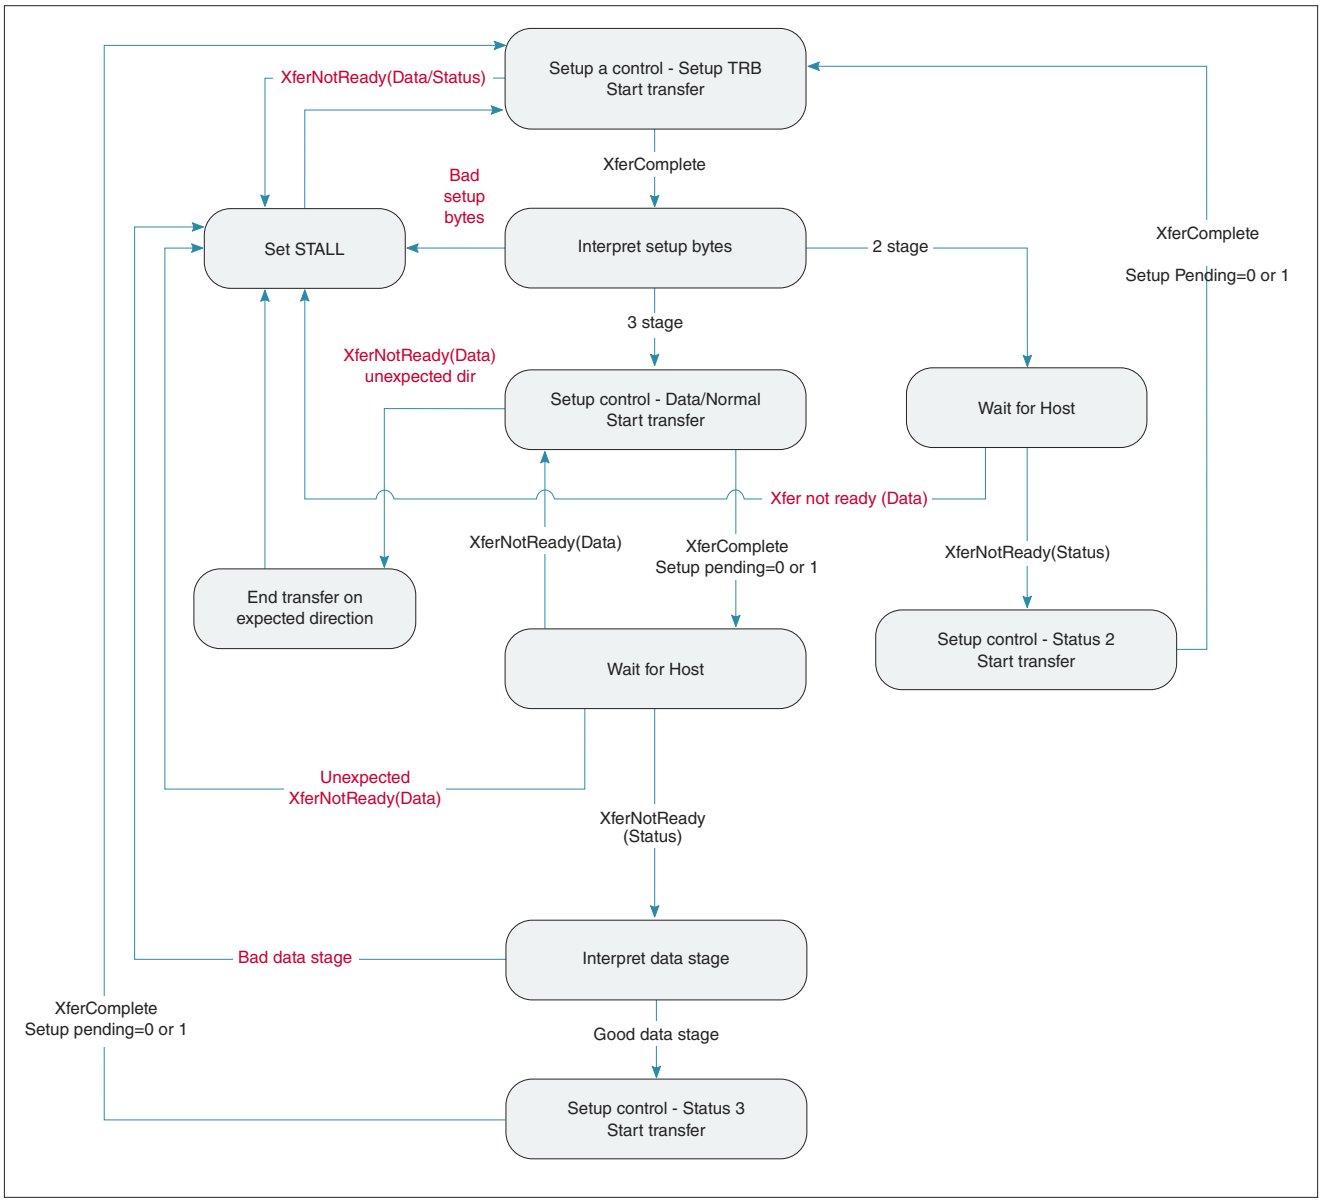

Figure 11-19. Software flow for control transfers

If hardware does not receive a setup packet, it discards the unexpected data and status stages. It does not issue XferNotReady to the application. The hardware will also not generate a XferNotReady event if it receives a setup packet before a TRB is prepared for it. As control endpoints are bi-directional, the IN and OUT directions of the endpoint are used for the different stages as follows:

Control read:

- EP0 - Setup OUT
- EP1 - Data IN
- EP0 - Status OUT/Status TP

Control write or 2-stage transfer:

- EP0 - Setup OUT
- EP0 - Data OUT (if present)
- EP1 - Status IN/Status TP

Set STALL is always issued on EP0, and the XferComplete/XferNotReady events are generated on the correct direction. For other control endpoints, substitute EP0 with the OUT direction (such as, 2, 4, 6) and EP1 with the IN direction (such as, 3, 5, 7). The same programming model is used for USB 2.0 and USB 3.0 control transfers.

11.2.2.5.4.1 Two-stage control transfer programming model

1. Software sets up a Setup TRB and issues Start Transfer on EP0 pointing to the Setup TRB.
2. After XferComplete is received, software interprets the setup bytes. If they are bad, issue Set Stall on EP0 and go back to the step 1. If a XferNotReady (Data/Status) event is received before the XferComplete event for the Setup stage, issue Set Stall. This is an error case where the host is attempting to move data or start the status stage for a previous control transfer that has already completed.
3. Wait for an XferNotReady event for the Status stage which will occur on EP1. If an XferNotReady event for the Data stage is received (either direction), issue Set Stall on EP0 and go back to the step 1. This is an error case where the host is attempting to start the data stage when the setup bytes did not indicate a data stage was present.
4. After XferNotReady (Status) is received, start the status stage by issuing Start Transfer on EP1 pointing to a valid Status-2 TRB.
5. After XferComplete is received on EP1, go back to the step 1.

Although not required, software may look at the Status TRB and examine the Setup Pending bit in the TRB status field. If it is set, it means that this control transfer was aborted on the USB bus and that the host did not receive the Status stage ACK.

11.2.2.5.4.2 Three-stage control transfer programming model

1. Software sets up a Setup TRB and issues Start Transfer on EP0 pointing to the Setup TRB.
2. After XferComplete is received, software interprets the setup bytes. If they are bad, issue Set Stall on EP0 and go back to the step 1. If a XferNotReady (Data/Status) event is received before the XferComplete event for the Setup stage, issue Set Stall. This is an error case where the host is attempting to move data or start the status stage for a previous control transfer that has already completed.
3. Start the data stage by issuing Start Transfer on EP0 (control write) or EP1 (control read) pointing to a valid Control-Data TRB.

   a. If an XferNotReady (Data) event is received for the incorrect direction, software must issue an End Transfer for the data stage it has already started, then issue Set Stall. This is an error case where the host is attempting to move data in the wrong direction.
   b. If a XferNotReady (Data) event is received for the correct direction, ignore the event and continue to wait for a XferComplete event.
4. After the XferComplete event is received, software waits for an XferNotReady event. Although not required, software may look at the completed Data TRB(s) and examine the Setup Pending bit in the TRB status field and the BUFSIZ. If the Setup Pending bit is set or the BUFSIZ is non-zero, it means that this control transfer was aborted on the USB bus and that the host did not complete the data stage.
5. If a XferNotReady (Data) event is received after the XferComplete for the Data stage, it could mean one of two things:
   a. This host is trying to complete the data stage by moving a 0-length packet. This can occur if the data stage was an exact multiple of max packet size. If this is the case, software sets up an extra TRB (with a BUFSIZ of max packet size for control writes, or 0 for control reads), issues Start Transfer, and goes back to the step 4.
   b. This host is trying to move more data than specified in the wLength field of the setup bytes. In this case, software issues Set Stall on EP0 and goes back to the step 1.
6. When the XferNotReady (Status) event is received, software interprets the data stage (for example, number of bytes transferred, content of the control write buffer) and decides if the data stage was successful. If not, it issues Set Stall on EP0 and goes back to the step 1.
7. Start the status stage by issuing Start Transfer on EP1 (control write) or EP0 (control read), pointing to a valid Status-3 TRB.
8. After XferComplete is received, go back to the step 1.

Although not required, software may look at the Status TRB and examine the Setup Pending bit in the TRB status field. If it is set, it means that this control transfer was aborted on the USB bus and that the host did not actually receive the Status stage ACK. When device software sets STALL with the Set Stall command, it is possible that this command can be delayed on the chip bus due to latency or the chip bus servicing other agents. In this case, software can receive an XferNotReady event if the core detects no TRB active before it detected the Set Stall. Software must service these events knowing that it stalled the control command.

11.2.2.5.4.3 Handling fewer requests than wLength

In a control IN transfer, if the host asks for less data than wLength, the core skips the TRBs of the data stage and generates an XferComplete event after encountering the TRB that has LST=1. Hardware sets HWO to 0 in those TRBs that it skipped and in the last TRB. In a control OUT transfer, if the host sends less data than wLength, the core treats this like a short packet received into a TRB with CSP=0. It immediately generates a XferComplete event, not setting the HWO bit in the remaining TRBs to 0. Software needs to reclaim those TRBs that still have HWO=1.

11.2.2.5.4.4 Control OUT transfer examples

The sequence in the following table describes two and three stage control OUT transfers.

Table 11-17. Control OUT transfer

Steps	Host	Device core	Device software
	Setup stage		
1	-	-	Software sets up the Setup TRB and enables DMA by issuing Start Transfer to EP0 (endpoint 0, OUT direction).
2	-	Device fetches the TRB and caches it.	-
3	Host sends SETUP packet.	-	-
4	-	SETUP packet is received in the RXFIFO. There are 24 bytes allocated for each control endpoint, which guarantees reception of the three back-to-back SETUP packets. An ACK handshake is returned in non-SS mode. An ACK TP with NumP=1 is returned in SS mode. After SETUP, bytes are transferred through the DMA, and the core issues an XferComplete event.	-
5	-	If the host starts a Data/Status stage, the core returns NAK in Non-SS mode or NRDY TP in SS mode. If the SETUP request is invalid, core returns STALL (when software sets STALL) in non-SS mode. In SS mode the core returns ERDY, and when the Data/Status stage is received it returns STALL.	Software processes the XferComplete event and decodes the SETUP bytes. If a Data stage is required, it will set up one Control-Data TRB and possibly subsequent Normal TRBs, then issue Start Transfer to EP0 (endpoint 0, OUT direction). If a Data stage is not needed, it will skip to the Status stage. If the SETUP request is invalid, software instead sets the STALL bit by issuing Set Stall command for EP0 (OUT direction).
	Data stage		
6	-	Device fetches the TRB and caches it. In SS mode only, the core will send ERDY.	-

Table continues on the next page...

Table 11-17. Control OUT transfer (continued)

Steps	Host	Device core	Device software
7	Host sends data packets.	-	-
8	-	The NumP for control transfer will be 1. In addition, if another SETUP is received before the data transfer happens on USB, the core will skip the data transfer that software sets up without waiting for it to happen on the USB bus, and send XferComplete (when LST=1 TRB encountered) with the SetupPndg status bit set. Software has to reclaim the TRBs with HWO=1 in the skipped TRBs.	-
9	-	If the host starts a Status stage, the core returns NAK in Non-SS mode or NRDY TP in SS mode.	On seeing the event: • Software decodes the control write data. If the Data stage is OK, then it will wait for XferNotReady with "Control Status Request" set, set up a Control-Status-3 TRB (0-bytes), and enable DMA by issuing Start Transfer to EP1 (endpoint 0, IN direction). • If the Data stage is not OK, then software sets STALL by issuing Set Stall command to EP0.
	Status stage		
10	-	Device fetches the TRB and caches it. In SS mode only, the core will send ERDY	Software sets up a Status stage TRB only after the Data stage of a three-stage control transfer is completed and an XferNotReady event occurred.
11	Host requests status packets.	-	-
12	-	In Non-SS mode, the device will send a zero-length packet if STALL is not set; otherwise, it will send STALL. In SS mode, if STALL is not set, then it sends ACK TP with NUMP=1 else it sends STALL. If another SETUP is received before the status transfer on USB, the core will send XferComplete with the SetupPndg status bit set. The STALL bit will be cleared by the core whenever it receives a SETUP packet. SETUPs are always accepted.	-
13	-	-	On seeing the event: • If there are no other errors, then the transfer has completed successfully.

11.2.2.5.4.5 Control IN transfer examples

The sequence in the following table describes two and three stage control IN transfers.

Table 11-18. Control IN transfer

Steps	Host	Device Core	Device Software
	Setup stage		
1-5	Steps 1-5 are same as Control OUT transfer examples, except that software sets up Tx buffers and Start Transfer is issued to EP1 (endpoint 0, IN direction).		
	Data stage		
6	-	Device fetches the TRB and caches it. It prefetches the data and puts it in the TXFIFO. The core sends ERDY only in SS mode.	-
7	Host requests data packets	-	-
8	-	This step is similar to the step 4 of Non-isochronous IN transfers. The NumP for control transfer is 1. In addition, if another SETUP is received before the data transfer happens on USB, the core will skip the data transfer software has set up without waiting for it to happen on the USB bus and send XferComplete (when LST=1 TRB encountered) with the SetupPndg status bit set. Software has to reclaim the TRBs with HWO=1 in the skipped TRBs and flush the TXFIFO.	-
9	-	If the host starts the Status stage, the core returns NAK in non-SS mode or NRDY TP in SS mode.	On seeing the event: • If the Data stage is OK, then it sets up Control-Status-3 TRB (zero-bytes) and enables DMA by issuing Start Transfer to EP0 (endpoint 0, OUT direction). • If the Data stage is not OK, then software will set a STALL by issuing Set Stall command to EP0 (OUT direction).
	Status stage		
	Same as in Control OUT transfer examples.		

11.2.2.5.5 Stream handling in superspeed

The SuperSpeed stream protocol consists of a negotiation between the host and device concerning the selection of a stream, followed by data movement on the selected stream. The core automatically handles the stream protocol by initiating stream selection and also taking into account streams initiated by the host.

NOTE

This section is not applicable for USB 2.0 mode.

11.2.2.5.5.1 Stream IDs and transfer resources

A stream ID is a 16-bit value which represents an individual flow of data between host and device. For stream-capable endpoints, the stream ID must be non-zero and is used in:

- The Command Parameter field in the DEPCMD register used when issuing a Start Transfer command.
- The Stream ID field in a TRB.
- The EventParam field in an endpoint-specific event (DEPEVT): XferComplete, XferInProgress, XferNotReady, and StreamEvt.

It is necessary to allocate 1 Transfer Resource per endpoint. The cost of each transfer resource is (32 + N_TRBS_PER_XFER x 16) bytes of memory in the descriptor cache. Core can cache maximum four TRBs per transfer.

After the Start Transfer command completes, the hardware returns the 7-bit Transfer Resource Index in the command complete event (and). This index is used only for the Update Transfer and End Transfer commands. In all other places, the Stream ID is used.

11.2.2.5.5.2 Stream selection and stream programming model

Referring to the USB 3.0 Device Stream Protocol State Machine, the Idle state is the state where a device does not have a current stream to work on. When the hardware detects that it is in the Idle state, it will attempt to initiate and move data on a stream by transmitting ERDY to the host.

In order for this to occur, the endpoint must be "primed" and the stream must be both active and ready.

- **Primed**: After a stream-capable endpoint is configured, it is in the disabled state, which prevents the device from initiating any stream selection. After the host performs a Prime transaction, the endpoint is moved into the "Primed" state where it is eligible to initiate stream selection.
- **Active**: Software makes a stream active by issuing a Start Transfer command for the stream. A stream becomes inactive after an XferComplete event or after software issues an End Transfer command.
- **Ready**: After a stream is added via the Start Transfer command, its default state is "ready." The hardware will label the stream as "not ready" if the host gives a NoStream rejection to the hardware's attempt to initiate the stream. If the host

performs a Prime, all currently active streams are automatically set to the "ready" state by hardware.

In the Idle state, the hardware selects a stream from its cache to initiate. Once the core has chosen an active stream, it attempts to initiate and move data on that stream until the endpoint enters the Idle state, which occurs when the host rejects the stream selection (NoStream) or the stream is terminated (PP=0) by the host or device. Therefore, software is required to prepare enough HWO=1 TRBs for at least one packet prior to issuing the StartXfer command.

In device-oriented stream selection class drivers (such as UASP), the host will not reject the device's stream selection. However, other class drivers may be developed in which the host initiates stream selection. In this situation, software will not start any transfers and will wait for a XferNotReady event. When that event is received, software will look at the StreamID in the event and start the transfer associated with the given Stream ID. If for some reason the class driver allows the host to reject a stream that has already been initiated by the host or device, software will receive a Stream (NotFound) event. If this occurs, software may replace the existing stream by issuing End Transfer for it and then issuing Start Transfer for another stream.

Some host implementation scenarios exist where the host and device become out of sync in the stream protocol, creating a deadlock condition where the device waits for the host to issue a Prime transaction while the host waits for the device to issue an ERDY. To resolve potential deadlock conditions, software should perform the following:

1. Implement a time out for stalled transfers on stream-capable endpoints.
2. When the timeout elapses with no data transfer for any stream after a StreamEvent (NotFound) event, restart one of the streams by issuing an End Transfer command followed by a Start Transfer command.

This places the stream in the Ready state and causes the core to transmit an ERDY to the host.

11.2.2.5.5.3 Data movement within a stream

Data movement within a stream is the same as data movement using the Bulk endpoint type (Start Transfer, Update Transfer, and updating TRBs). The XferInProgress, XferComplete, and XferNotReady events are issued as data is transferred between host and device. The Stream ID field in the events indicate which stream within the endpoint is generating the events. If software receives an XferNotReady event with the EventStatus field indicating XferNotActive, it means that the host is attempting to initiate a stream that has not been added to the hardware's cache through Start Transfer. In response to this event, software should add the requested stream if it is available.

11.2.2.5.6 Multiple device interrupt support

The DWC_USB3_DEVICE_NUM_INT parameter allows you to instantiate up to 32 interrupt lines. Each interrupt line is associated with an event buffer described by the GEVNT*n registers. The interrupt number and the event buffer number are the same. When the endpoint is configured with the DEPCFG command, it is mapped to a specific interrupt such that all endpoint-specific events are written to the event buffer selected.

One time static interrupt mapping during the device endpoint configuration is recommended. In some circumstances, software may want to change the interrupt number of an endpoint between transfers. For example, the Bulk Only Transport (BOT) class driver uses a single endpoint for command (CBW), Data IN/OUT, and status (CSW), and you may be interested in routing CBW and CSW to one interrupt and Data IN/OUT to another interrupt. Software can issue a DEPCFG command with the "Config Action" set to "Modify" to change the IntrNum field without affecting the flow control status of the endpoint. This ability to dynamically map interrupt comes with the following restrictions:

- The XferNotReady event must always be disabled on the endpoint
- The interrupt number can only be changed on Non-Stream Bulk endpoints
- The interrupt number can only be changed between transfers (i.e. after a XferComplete event or before issuing a StartXfer command)
- The EPCmdComplete event for the DEPCFG command changing the interrupt number will come on the new interrupt number
- All other fields of the DEPCFG command must match the original configuration of the endpoint, except the event enable bits

11.2.2.5.7 Worst-case response time

The DWC_usb3 controller, as a high-speed device, needs a minimum of three PHY (UTMI/ULPI) clocks to complete processing of the OUT data packet. Therefore, it cannot accept new token for these three clocks. However, for an isochronous transaction, there is no handshake and the next token could come within three PHY clocks after the previous RxActive de-assertion[1]. If this worst-case condition occurs, then the controller

sends NAK for bulk and interrupt tokens and drops isochronous and SETUP tokens. The host handles this as a timeout condition for SETUP packet and retries the SETUP packet, but the ISOC OUT token is dropped.

11.2.2.5.8 Low power operation

1. This can happen theoretically when operating in UTMI 16-bit mode only with worst-case timing/delays with five hubs/cables. The host provides a minimum of 88 HS bit-times (typically, more than that) of Inter Packet Gap between packets and generally will not result in less than three clocks on the device-end UTMI PHY.

11.2.2.5.8.1 Low power operation of USB

The USB 3.0 protocol allows a SuperSpeed host and device to negotiate with each other and decide when to bring their link into a lower power state (U1 or U2). This is accomplished by each side making individual decisions about whether they have any traffic currently pending or if they expect any traffic soon. The device requests low power entry by transmitting an LGO_U1 (or LGO_U2) Link Command and exits low power by using an LFPS handshake. The USB 3.0 Device Controller uses information from the host (bus side) and from software (application side) to decide when the best time to request low power entry is and when to exit from low power. The same calculation is used when the controller decides whether to accept a low power request from the host. The controller maintains state information about each endpoint and whether it is "active" or "paused". If all enabled endpoints are paused from either the application side or the bus side, low power entry is allowed. If at least one endpoint is not paused, low power entry is not allowed. To indicate that it does not have any pending traffic and allow the link to go into a low power state, the software may pause all enabled endpoints using one of the following mechanisms:

- Allow transfers to complete and not start any new ones
- Not setting the HWO bit in the TRBs to '1'

Exception: Software may prepare a Setup TRB for control endpoints without affecting the ability of the link going into low power. Otherwise, an endpoint is considered active on the application side. For these endpoints, the host indicates that it is paused in one of the following ways:

- Setting the Packet Pending (PP) flag to '0' in the DPH
- Setting the PP flag to '0' and NumP to '0' in the ACK TP
- For interrupt endpoints, by not polling the endpoint for two service intervals
- Note: After an endpoint is configured using the DEPCFG command and before the host sends any packets to it, the endpoint is considered to be paused on the bus side

Exception: If the data packet payload has a CRC error, the core responds with an ACK (Retry=1), and the endpoint is not paused. Otherwise, if PP=1 or Deferred=1, the endpoint is considered to be active on the bus side. Control endpoints have an additional condition as follows:

The core does not allow low power entry during a control transfer (starting from the reception of setup packet and ending at the completion of the status stage).If the core is configured for isochronous support, the following additional rules apply:

- The controller enters U0 at SystemExitLatency microseconds prior to the beginning of every microframe to receive the Isochronous Timestamp Packet (ITP).

- A PING causes every isochronous endpoint to wake up and be considered active, preventing low power entry.
- An isochronous endpoint is paused automatically when it transmits or receives the last packet of its interval (lpf=1) or if two intervals pass and the endpoint has not transmitted or received its last packet. In this way, after the PING, the core does not enter low power until all isochronous endpoints have moved their last packet or two intervals pass without another PING.

If all enabled endpoints are paused by software or the host, the core issues an LGO_U1 (or LGO_U2) link command or it responds with an LAU link command to the low power request of the host or hub. Otherwise, the core rejects the low power requests with an LXU link command.

Additionally,

- For bulk endpoints, the USB 3.0 specification says that the device may go to U1/U2 500ms (tERDYTimeout) after transmitting ERDY. It is the responsibility of the software to detect no activity on a bulk endpoint for 500ms or more and issue End Transfer if there is no activity. When the transfer is removed, the endpoint allows U1/U2 entry again.
- Because U1/U2 entry is based on the presence of packets in the TX FIFO and not based on the TRBs that are available to the core, it is possible that an IN endpoint responds with a NRDY, goes to U1, then U0, then transmits an ERDY if the timing and TXFIFO size works out such that the core cannot keep at least one packet in the TXFIFO at all times.
- In addition, before the final decision made to either initiate or accept low power state, device checks the state of DCTL[INITU2ENA][ACCEPTU2ENA][INITU1ENA] [ACCEPTU1ENA]. If the device receives Set Link Function LMP with Force_LinkPM_Accept bit asserted, the device accepts low power request from its link partner independent of endpoints state and DCTL Power control settings.

11.2.2.5.8.2 Low power operation of core

When the link is in the U1, U2, U3, SS.Inactive, SS.Rxdetect, or SS.Disabled state (for USB 3.0) or the USB is in Sleep, Suspend, or V_{BUS}-off mode (for USB 2.0), the core can be put into a low power mode to save power. The core supports the following low power mode:

- **Clock-gating mode**: In this mode, the clocks connected to most of the core modules are gated off. Modules that still get clocks in the low power mode detect wakeup conditions and remove clock gating to other modules when a wakeup condition is detected. Clock-Gating mode can be used when the USB is in any low power state. Clock-Gating mode is enabled by setting the Disable Clock Gating bit in GCTL to 0.

11.2.2.5.8.2.1 Clock-gating mode

Clock-Gating mode is enabled if the Disable Clock Gating bit in the GCTL is set to 0. When the USB/link is in a low power state, the clocks to most of the core modules are gated off automatically by the core. When a wakeup condition is detected by the core, or when the software schedules new work to the core (in U1 or U2 states) or changes the USB/Link state, the core turns on clocks and the entire core goes into active mode.

11.2.2.6 Host programming model

Please refer xHCI specification for detailed information.

11.2.2.6.1 Initializing host registers

To initialize the controller as host, the application must perform the steps described in the xHCI Specification. If intermediate firmware needs to override a coreConsultant parameter or reset value, it can write to the controller-specific global (G*) registers at power-on.

Table 11-19. Overriding global registers in host configuration

Register	Description
GSBUSCFG0/1	Leave the default values if the correct power-on values were selected during coreConsultant configuration.
GTXTHRCFG/ GRXTHRCFG	This is required only if you are planning to enable thresholding. Leave the default values if the correct power-on values were selected during coreConsultant configuration.
GSNPSID	The software can read the Synopsys ID register to find the controller version and configure the firmware for any version-specific features.
GUID	Optionally, the software can program the User ID GUID register, if this register is selected for implementation in coreConsultant.
GUSB2PHYCFG	Program the following PHY configuration fields: USBTrdTim, FSIntf, PHYIf, TOUTCal, or leave the default values if the correct power-on values were selected during coreConsultant configuration.
GUSB3PIPECTL	Program the following PHY configuration fields: DatWidth, PrtOpDir, or leave the default values if the correct power-on values were selected during coreConsultant configuration.
GTXFIFOSIZn/ GRXFIFOSIZn	Program these registers based on the speed used for the FIFO. For details, see the “Architecture” chapter in the *DWC SuperSpeed USB 3.0 Controller Databook*. Unless the packet sizes of the endpoints are application-specific, it is recommended that you use the default value.

Table continues on the next page...

Table 11-19. Overriding global registers in host configuration (continued)

Register	Description
GCTL	Program this register to override scaledown, RAM clock select, and clock gating parameters.
GUCTL	If you want to improve the interoperability with different devices, program this register to override the behavior of the controller in Host mode.
DCTL	If you want to improve interoperability as a Debug Capability Target, program the InitU1/U2Ena and AcceptU1/U2Ena fields to '0' to disable U1/U2 entry.

11.2.2.6.2 Host controller capability registers

For register definition, refer to Capability Registers Length and Host Controller Operational Registers (CAPLENGTH) to Runtime Register Space Offset Register (RTSOFF).

11.2.2.6.3 xHCI implementation details

This section discusses xHCI implementation details specific to the USB 3.0 controller.

11.2.2.6.3.1 LHCRST behavior

The xHCI Specification does not describe the programming model of light reset. It only specifies that the Operational and Runtime Registers that are not contained in the Aux Power well are at their default values.

Light reset must only be applied when USB_DCTL[Run_Stop] is equal to '0' to ensure that there is no discrepancy between hardware and software states. If light reset is applied during a transfer, the behavior on the USB is undefined, and may cause a packet to be terminated abruptly.

On light reset, the hardware resets all non-Aux registers to their default values which means that the port state (which is contained in PORTSC) does not change, but USB_DCTL[Run_Stop] is immediately set to '0' and all the context information about connected devices is lost. It is the responsibility of software to re-initialize the controller.

11.2.2.6.3.2 ENT requirements

In the xHCI Specification, the rules about when the ENT (Evaluate Next TRB) flag in a TRB must be set or cleared are not very strict. However, it states that the ENT flag must be set to '1' in the last Normal TRB when a TD ends with an Event Data TRB.

The controller requires software to follow these rules:

1. Regardless of whether the endpoint is stream-capable or not, if a TD ends with an Event Data TRB, the Normal TRB that precedes it must have ENT set to '1'. This Normal TRB may be separated from the Event Data TRB by a Link TRB
2. In all other cases, the ENT flag must be set to '0' Failure to follow these rules results in undefined behavior.

11.2.2.6.3.3 Behavior on babble error

If a babble error is detected and the received data passes all integrity checks, the host controller may write the received data (up to the expected data length) to the data buffer, and the value of the TRB transfer length field in the babble detected error transfer event shall be consistent with the number of data bytes written to the buffer.

The controller does not write the received data to the data buffer. The entire packet is discarded and the residual byte count is written to the TRB transfer length field.

11.2.2.6.3.4 Max_exit_latency_too_large message

If periodic transfers are on every microframe (Binterval 1), the controller reports max_exit_latency_too_large if PING scheduling is enabled. The xHCI scheduler must prefetch data from the system memory ahead of next microframe, manage non-periodic transfer, and schedule PING before ISOC. Because the system memory access and USB responses are not predictable Quality of Service (QoS) is not guaranteed if the xHCI host needs to perform all of the above for every microframe when U1/U2 is enabled. Therefore, the expectation is to disable U1/U2 if periodic data needs to be scheduled every microframe. In addition, because the U1 exit latency is in the order of 10usec, only very low system-level power saving is achieved even if the scheduler allows U1 transition by reducing QoS.

U1, U2, and U3 link states and exit time observed during lab testing:

- U1: Lowest power saving
  - In this state the chip is active, USB controller is inactive, only the Tx transmitter of the PHY is inactive.
  - U1 exit time per link partner: ~10 - 19 usec
- U2: Higher power saving than U1
  - In this state the chip is active, USB controller is inactive, both the Rx and Tx transceivers of the PHY are inactive.
  - U2 exit time per link partner: ~85 - 115 usec
- U3: Highest power saving

- In this state, the chip and USB controller/PHY are inactive.
- U3 exit time per link partner: 200 - 450 usec

Following are the recommendations for driver to handle periodic endpoints and "max_exit_latency_too_large" message:

- If Binterval of any endpoint is '1', then disable U1/U2 and do not schedule PING ("max_exit_latency" set to 0).
- If periodic scheduling is expected on every microframe, then disable U1/U2 and do not schedule PING.
- If periodic scheduling is expected only on every other microframe, then disable U2 and use U1 exit latency for "max_exit_latency" calculation.
- If ((number of hubs +1) * U2 exit latency) >= (2**(Binterval-1) * 125 usec), then disable U2.
- For all other periodic scheduling use U2 exit latency for "max_exit_latency" calculation.
- If the "max_exit_latency_too_large" error is sent to software, then disable U2 and re-issue ep- config with U1 exit latency.
- If "max_exit_latency_too_large" still happens, then disable U1 and re-issue ep_config with max_exit_latency set to 0 (no PING).

11.2.2.6.3.5 Disabled checks

The xHCI specification requires the host controller to perform some checks to ensure that the xHCI driver does not inadvertently set a parameter to an incorrect value. However, some of those checks are incompatible with existing software and so they are currently disabled.

1. Disabled check for EP State in Input Context

   Section “Configure Endpoint” in the *xHCI Specification* states:

   “else // Not all Input Endpoint Contexts identified by Add Context flag fields = ‘1’ are valid Completion Code =Parameter Error.”

   NOTE

   The xHC must check that all referenced contexts are valid before executing the command. If aninvalid context is detected, the state of the Output Device Context shall not change and the a Command Completion Event is generated with the Completion Code set to Parameter Error."

   Section “Configure Endpoint Command Usage” in the *xHCI Specification* states:

“An Input Endpoint Context is considered “valid” by the Configure Endpoint Command if the Add Context flag is ‘1’ and: 1) the values of the Max Packet Size, Max Burst Size, and the Interval are considered within range for endpoint type and the speed of the device, 2) if MaxPStreams > 0, then the TR Dequeue Pointer field points to an array of valid Stream Contexts, or if MaxPStreams = 0, then the TR Dequeue Pointer field points to a Transfer Ring, 3) the EP State field = Disabled, and 4) all other fields are within their valid range of values.”

Therefore, it suggests the controller must verify the EP State field is 'Disabled'. However, the xHCI CV fails on this check and so it is currently disabled.

2. Disabled check for DCS field in Input Context

   Section “Address Device” in the *xHCI Specification* states:

   “The xHC must check that all referenced contexts are valid before executing the command. If an invalid context is detected, the state of the Output Device Context shall not change and the a Command Completion Event shall be generated with the Completion Code set to Parameter Error.”

   Section “Address Device Command Usage” in the *xHCI Specification* states:

   “The Input Endpoint 0 Context is considered “valid” by the Address Device Command if: 1) the EP Type field = Control, 2) the values of the Max Packet Size, Max Burst Size, and the Interval are considered within range for endpoint type and the speed of the device, 3) the TR Dequeue Pointer field points to a valid Transfer Ring, 4) the DCS field = ‘1’, 5) the MaxPStreams field = ‘0’, and 6) all other fields are within the valid range of values.”

   Therefore, it suggests the controller must verify the DCS field is '1'. However, it was found in lab testing that some drivers do not guarantee DCS is always '1', so this check is disabled.

11.2.2.6.4 xHCI debug capability

NOTE

- The controller supports byte-aligned buffers for each TRB of a transfer. This feature prevents the need for buffer copying in cases where the USB device driver receives unaligned data buffers from another application (for example, Ethernet). Whenever the application controls buffer allocation, however, it must allocate SoC bus width

and burst-aligned buffers to facilitate efficient bus and memory utilization.
- The Host controller does not support zero-length TRB in a Transfer Descriptor (TD) that has multiple chain TRBs. However, if the TD has only a single transfer TRB, then it is supports zero-length TRB.

The xHCI Debug Capability (DbC) allows one of the host ports to negotiate as an upstream (device) port. When this happens, the debug port is called the "Debug Target," and the connected host is called the "Debug Host."

NOTE

- To implement the xHCI Debug Capability, select "Yes" for "Enable xHCI Debug Capability?" in coreConsultant (parameter DWC_USB3_EN_DBC = 1)
- For details on the supported configurations and limitations, see "Supported Configurations ".

Section 7.6 of the xHCI Specification explains the functionality of the Debug Capability. However, it explains mostly the software interface, the operation of the DbC at the lower layers, and the handling of the control transfers. The operation of the bulk endpoints for a Debug Target is explained in the rest of the specification because the TRB structure, TD descriptions, Event Ring descriptions, and Endpoint Context are described in other parts of the xHCI Specification.

The DbC feature merges the host (xHCI Specification) software-side programming model with the device USB-side operations. Within the DbC hardware, this translates to a logic that interprets the DbC/xHCI programming model at the upper layers and interacts with the lower layers in the same way the device hardware interacts.

11.2.2.6.4.1 Debug support in a multi-port configuration

Figure 11-20 shows a multi-port xHCI USB 3.0 host controller in which any one of the ports can be used for debugging. A multi-port xHCI host controller supports concurrent host and debug operation.

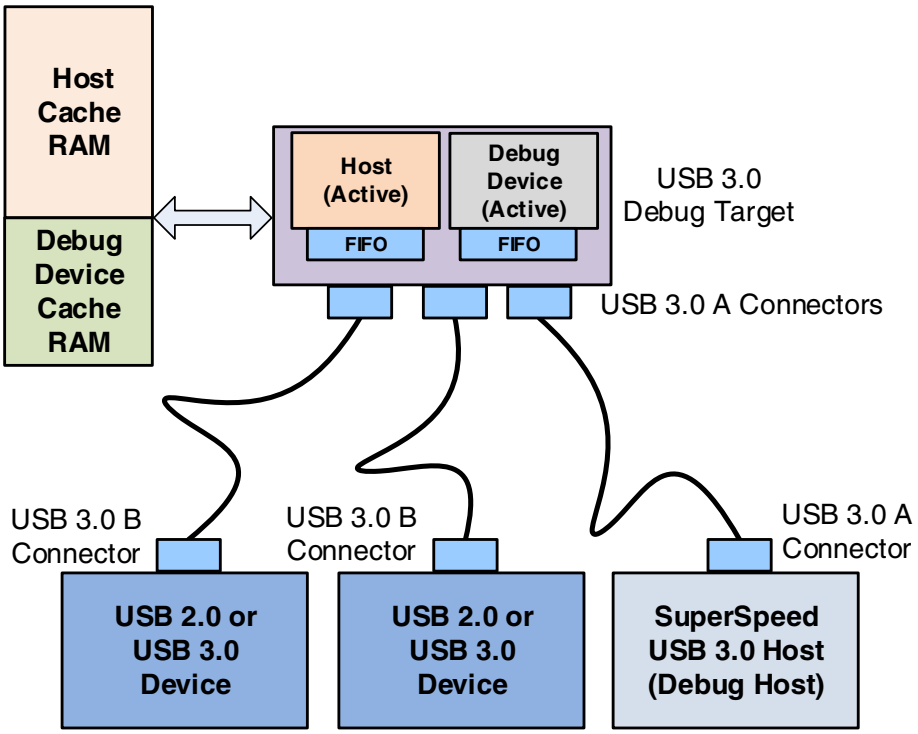

Figure 11-20. Multi-port USB3.0 xHCI-host (Host and debug-device concurrent mode)

11.2.2.6.4.2 Debug support in a one-port configuration supporting either host or debug operation

Figure 11-21 illustrates the operation of a normal one-port xHCI host controller that supports either host or debug operation at any given time. You may need an additional Ethernet, or UART, or USB device controller to support debug operation to support concurrent host and debug operation if you have only a one-port host controller. This adds additional development cost and silicon cost. Also, an additional Ethernet, UART, or USB connector is not desirable in small devices such as mobile phones.

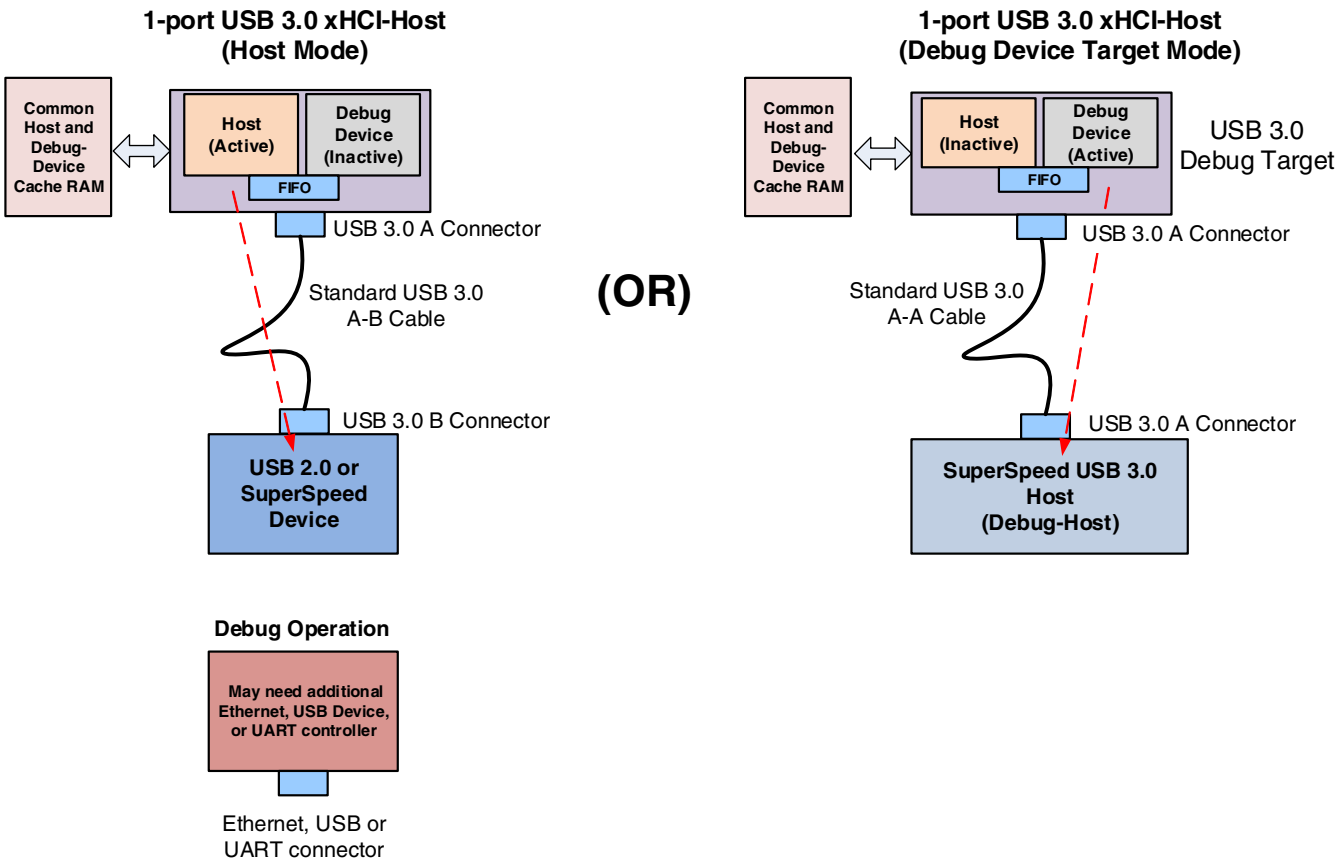

Figure 11-21. One-port USB3.0 xHCI-host (Host or debug mode)

11.2.2.6.4.3 Debug support in a one-port configuration supporting concurrent host and debug operation

The Synopsys xHCI host controller supports concurrent host and debug operation even in a one-port configuration (patent pending). Figure 11-22 illustrates a one-port configuration in which a split USB cable mechanism is used for concurrent host and debug support. The Synopsys xHCI controller supports separate data paths (FIFOs and DMA) for host and debug operation even in a one-port configuration. Similarly, the cache memory also has separate host and debug data structures. The increase in area because of this additional logic is much smaller than adding a separate Ethernet, UART, or USB device controller.

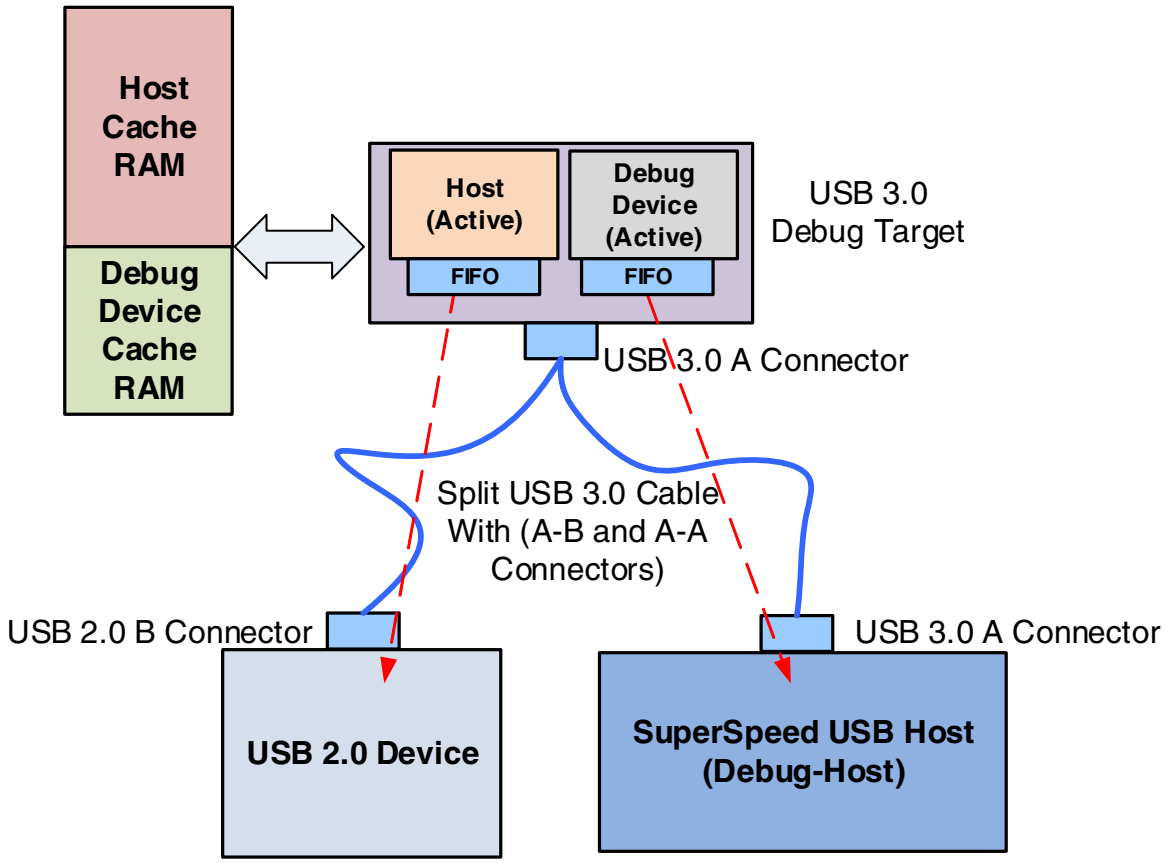

Figure 11-22. One-port usb 3.0 xhci-host (Host and debug-device concurrent mode)

The split cable includes three plugs and two cables.

The details of the plugs are as follows:

- The first plug is a USB 3.0 A plug,
- The second plug is a USB 2.0 B plug, and
- The third plug is a USB 3.0 A plug The details of the cables are as follows:
- The first cable couples the first and second plugs, and includes VBUS, D-, D+, and GND wires.
- The second cable couples the first and third plugs, and includes GND, StdA_SSRX-, StdA_SSRX+, GND_DRAIN, StdA_SSTX-, and StdA_SSTX+ wires.

The first plug is connected to the Synopsys xHCI host controller and the second plug is connected to a USB 2.0 or USB 3.0 device, and the third plug is connected to a USB 3.0 debug host. This provides concurrent USB 2.0 traffic between the Synopsys xHCI host controller and the USB device and SuperSpeed traffic between the Synopsys xHCI host controller and the USB 3.0 debug host.

11.2.2.6.4.4 Operational model

The operational model of the Debug Capability is described in the xHCI Specification. However, further details about the actual implementation of the operational model and its affect on the hardware are detailed in this section.

11.2.2.6.4.4.1 Capability discovery

The software discovers that the DWC_usb3 controller supports the Debug Capability feature by reading through the extended capabilities list. ID 10 is used to indicate that the Debug Capability extended feature is supported, and the software then knows the location of the DbC registers. It can then initialize the DbC registers as described in the xHCI Specification.

11.2.2.6.4.4.2 Port training

The software enables the Debug Capability by setting the `DCCTRL.DCE` field to '1'. This causes the lower layer to advertise that it supports being an upstream port in its Port Capability LMP's. If there are multiple ports exposed, the controller does this across all of the USB 3.0 ports. If the user plugs a host (the Debug Host) into any of these ports, the Debug Host gets trained as a downstream port, and the port that is enabled for Debug Capability gets trained as an upstream port.

When the debug port is selected, the BMU reconfigures TX/RX FIFOs to match the sizes required by the Debug Capability. In addition, the TR switches to select the correct Bus Interfaces to connect the upper and lower layers.

When a port status change occurs in the `DCPORTSC` register for the debug port, a Port Status Change Event is written to the DbC Event Ring, and the `DCST.ER` field is set to '1' to indicate that an event is present.

11.2.2.6.4.4.3 Standard USB request handling

Once the port is trained as an upstream port, the Debug Host initializes the Debug Target (as it normally does for any other device) by issuing a USB reset, `SetAddress`, `GetDescriptor(s)`, and `SetConfiguration`. The Debug Capability LSP module handles each of the control transfers without involving the debug capability driver. After the `SetConfiguration` request, the Debug Target exposes EP1 with an IN and OUT endpoint. The response of the DWC_usb3 controller to each of the possible control transfers is discussed in Control transfers.

11.2.2.6.4.4.4 Transfer handling

The debug capability driver on the Debug Target prepares the TRBs for the OUT endpoint, expecting to receive commands from the host. It rings the “IN TR” doorbell (which corresponds to the OUT endpoint), and this enables the DWC_usb3 controller to receive packets on the OUT endpoint and generate Transfer Events. The software polls the DCST.ER field to determine whether there are events present in the DbC Event Ring. When it sees a transfer event, it knows that the buffers pointed at by the TRBs are now valid. It can interpret the commands sent, and prepare a data or status response on the IN endpoint.

For the IN endpoint, the debug capability driver prepares the TRBs on the “OUT TR”, and then rings the OUT TR doorbell (which corresponds to the IN endpoint). The DWC_usb3 controller starts prefetching the data to be transmitted and transmits ERDY to the host if necessary (that is, if the endpoint is flow controlled on the USB). Retries are automatically handled by the controller which re-fetches the data to be transmitted. There is no communication to the debug capability driver if a retry happens on the USB.

The DWC_usb3 controller supports two transfer rings and assumes that only the following types of TRBs can be on the transfer rings:

- Normal
- Link
- No-Op
- Vendor-Defined: The cores ignores these TRBs as described in section Vendor defined TRB types of the xHCI Specification. The controller generates a “TRB Error” transfer event for any other TRB type.

The controller inherits the following transfer behaviors from the xHCI operational model:

- Waits for a doorbell before fetching TRBs
- Generates Transfer Events when IOC=1
- Fast-forwards to the next TD when the OUT endpoint receives a short packet
- Skips and ignores Vendor-Defined TRBs

11.2.2.6.4.4.5 Endpoint context state

Figure 11-23 shows the Endpoint Context state diagram as illustrated in section 4.8.3 of the xHCI Specification.

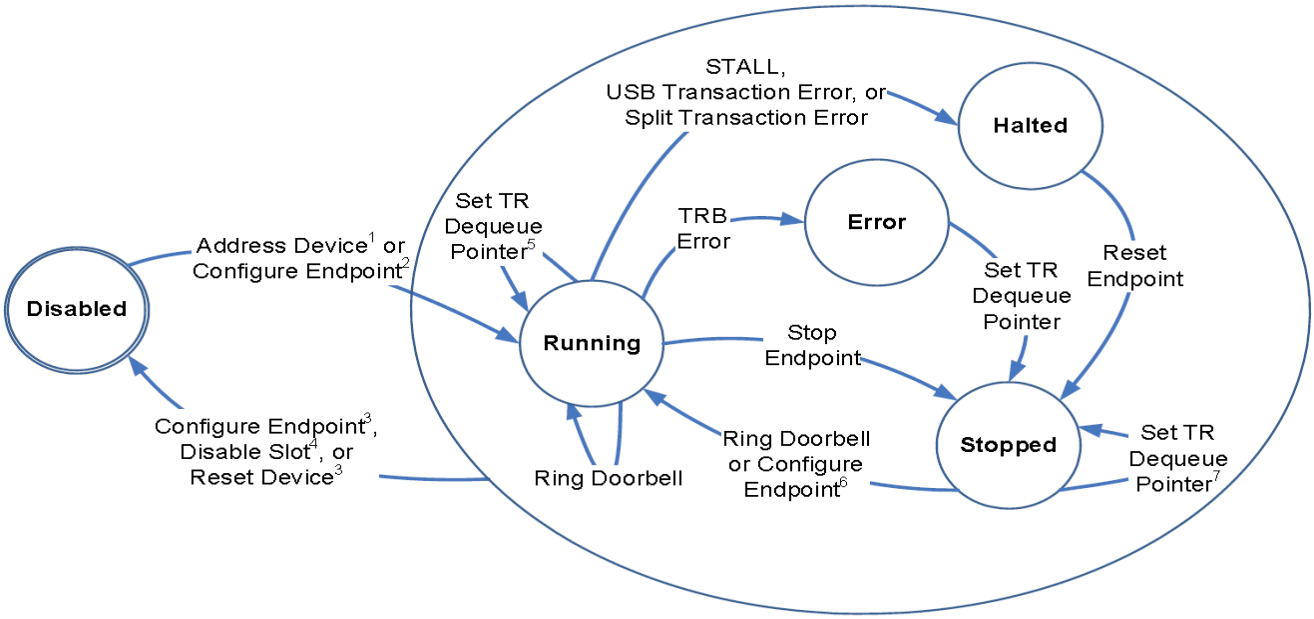

Figure 11-23. xHCI endpoint state transitions

Figure 11-23 is applicable to the endpoints as referenced by the host controller, but for debug capability, the endpoint state diagram is different (see Figure 11-24).

Figure 11-24. DbC bulk endpoint state transitions

The main differences are as follows:

- DbC does not have any “Set TR Dequeue Pointer,” “Stop Endpoint,” or “Reset Endpoint” command
- Address Device and Configure Endpoint are commands issued by the hardware when it receives the

`SetAddress` or `SetConfiguration` control transfer. They are not issued by the software

- The Running state has four substates: Stopped, GetContext, Paused, and Fetching. These substates are not visible to the software, but they are used internally to determine whether the endpoint needs to fetch the Endpoint Context, and whether it is fetching TRBs or not.

The DbC writes the endpoint state to the Endpoint Context during the transitions between the Disabled, Running, Halted, Stopped, and Error states. Even when the transition to the Disabled state is caused by the software setting `DCCTRL.DCE` to '0', the controller still writes the new state to the Endpoint Context despite the fact that the context is not owned by the controller.

11.2.2.6.4.4.6 Halting endpoints

The software can halt one of the bulk endpoints by setting the DCCTRL.HOT or HIT field to '1'. HOT applies to the OUT transfer ring, which is the IN endpoint. HIT applies to the IN transfer ring, which is the OUT endpoint.

When the software writes HOT or HIT with ‘1’, the controller performs the following operations:

1. Propagates the STALL endpoint setting request to the USB clock domain, and waits for the end of the current transaction on the USB

Meanwhile, if the software reads the DCCTRL register, it sees the HOT or HIT field is still '0' which indi- cates that the halt request is not propagated to the USB yet.

1. Starts returning STALL on the USB to any transaction to that endpoint
2. Sets the DCCTRL.HOT or HIT read value to ‘1’
3. Writes out the Endpoint Context with the current value of the TR Dequeue Pointer (after the current transaction is completed on the USB), and “Halted” in the EP State field
4. Generates a Transfer Event if there is an incomplete Normal TRB present in the transfer ring
    a. The TRB pointer references the TRB that the STALL occurred on.
    b. The Transfer Length field may indicate that the TRB is partially completed.
    c. The Completion Code is “Stall Error.”
    d. This event is generated regardless of the value of IOC in the error TRB.
    e. If the TRB ring is empty, or does not contain any Normal TRBs, a “Stall Error” transfer event is not generated because it does not have any TRB to reference.

If the controller is in the process of responding to a transfer on the USB when the software sets the HOT or HIT field to ‘1,’ it completes the current transaction before performing the previous-listed operations. For example, if the controller already responded with an ACK to an OUT packet, that packet is written to the system memory before the transfer event is generated, but any transaction after the HOT/HIT setting receives a STALL response.

When the host sends a ClearFeature(Halt) request to clear the halt on an endpoint, the controller performs the following operations:

1. Clears the STALL condition, and resets the data sequence number to ‘0’.

After this point, any new token on the USB does not receive a STALL response. If the host attempts a transaction to the endpoint before the software prepares a new transfer, the host receives an NRDY response.

1. Writes the Endpoint Context with “Stopped” in the EP State field.

This indicates that the endpoint is not halted on the USB, and the software can update the TR Dequeue Pointer, and ring the doorbell to restart the transfer.

1. Sets the DCCTRL.HOT or HIT read value to ‘0’.

When the software needs to resume transfers on the endpoint, it must wait for the EP State in the Endpoint Context to be “Stopped,” then program the new TR Dequeue Pointer in the Endpoint Context before ringing the doorbell. The controller fetches the new TR Dequeue Pointer from the Endpoint Context the first time the doorbell is rung after the endpoint halted.

The USB endpoint state can be determined by the EP State in the Endpoint Context and the value of the HOT/HIT field as shown in the following table.

Table 11-20. USB endpoint state Vs. HOT/HIT

EP state	HOT/HIT	USB endpoint state
Running	0	Not Stalled
Running	1	Stalled
Halted	0	<Invalid>
Halted	1	Unknown (maybe Not Stalled if the host just sent a ClearFeature (Halt))
Stopped	1	Not Stalled
Stopped	0	Not Stalled

11.2.2.6.4.4.7 TRB error

If an unknown TRB type is encountered on the transfer ring, the controller handles this similar to the HOT/HIT setting described in Halting endpoints. In particular, the controller performs the following operations:

1. Propagates the STALL endpoint setting request to the USB clock domain, and waits for the end of the current transaction on the USB. Meanwhile, if the software reads the DCCTRL register, it sees the HOT or HIT field is still '0' which indi- cates that the halt request is not propagated to the USB yet.
2. Starts returning STALL on the USB to any transaction to that endpoint.
3. Sets the DCCTRL.HOT or HIT read value to ‘1’.
4. Writes out the Endpoint Context with the current value of the TR Dequeue Pointer (after the current transaction is completed on the USB), and “Error” in the EP State field.
5. Generates a Transfer Event
   a. The TRB pointer references to the TRB with the unsupported TRB type.
   b. The Transfer Length field is '0'.
   c. The Completion Code is “TRB Error”.

d. This event is generated regardless of the value of IOC in the unsupported TRB.

Upon receiving the TRB Error transfer event, the software can reset the controller by toggling the DCE from 1->0->1, or can wait for the host to send a `ClearFeature(Halt)` request. When the host sends a `ClearFeature(Halt)` request to clear the halt on the endpoint, the controller performs the following operations:

1. Clears the STALL condition and resets the data sequence number to 0

   After this point, any new tokens on the USB do not receive a STALL response. If the host attempts a transaction to the endpoint before the software prepares a new transfer, the host receives an NRDY response.

2. Writes the Endpoint Context with “Stopped” in the EP State field

   This indicates that the endpoint is not halted on the USB, and the software can update the TR Dequeue Pointer and ring the doorbell to restart the transfer.

3. Sets the `DCCTRL.HOT` or `HIT` read value to ‘0’

   When the software needs to resume transfers on the endpoint, it must wait for the EP State in the Endpoint Context to be “Stopped,” then program the new TR Dequeue Pointer in the Endpoint Context before ringing the doorbell. The controller fetches the new TR Dequeue Pointer from the Endpoint Context the first time the doorbell is rung after the endpoint halted.

11.2.2.6.4.4.8 Event ring

The Debug Capability has its own Event Ring where it places transfer events and port status change events. However, there is no interrupt line that is asserted when there is an event on the Event Ring. The software polls the `DSTS.ER` field to determine when there is an event to be processed.

When there is one location left in the Event Ring before it is full, the controller writes the “Event Ring Full” transfer event to indicate that the Event Ring is too full to write additional events. However, this does not

mean that the events are lost, only that the events are piling up inside the controller and possibly causing back pressure to the Debug Host which eventually causes the controller to stop releasing credits on the USB 3.0 link.

11.2.2.6.4.4.9 Disabled endpoint handling (DCCTRL.DRC/DCR)

The xHCI Specification does not precisely describe the handshake between the hardware and software when an endpoint becomes Disabled and the DbC exits the Configured state, leaving open several different interpretations. The DWC_usb3 controller adheres to the following description of the Endpoint Disabled handling. This text has been proposed as an errata to the xHCI Specification.

There are several conditions which cause an endpoint to transition from the Running to the Disabled state (DbC exits the Configured state). This causes the DCCTRL.DCR field to transition from a '1' to '0' and DCCTRL.DRC to be set to '1'.

- The Debug host initiates a USB Reset.
- The Debug host issues a SetConfiguration(0) device request.
- Timeout occurs in the Port State Machine.
- The USB cable is disconnected.
- The Debug Capability driver writes '0' to the DCPORTSC.PED field. When the bulk endpoint becomes Disabled, the following occurs:
- If there is a valid Transfer TRB on the Transfer Ring, a Transfer Event is generated.
  - The TRB Pointer field of the Transfer Event references the Transfer TRB that the event occurred on.
  - The TRB Transfer Length field of the Transfer Event indicates that the Transfer TRB is partially completed.
  - The Completion Code field of the Transfer Event indicates a USB Transaction Error.
  - This Transfer Event is generated irrespective of the IOC flag being set or not in the associated Transfer TRB.
  - The DbC increments its TR Dequeue Pointer.
- The Endpoint Context is written with
  - TR Dequeue Pointer set to its current value
  - Endpoint State set to Disabled

The software detects this condition by reading the DCCTRL.DRC field as '1' and by reading the Endpoint State as Disabled. In response, the software reads the TR Dequeue Pointer field in the Endpoint Context and updates it to point to the next TRB to be executed after it clears the DCCTRL.DRC field and rings the doorbell.

NOTE

The DbC is not required to advance the Dequeue Pointer of an endpoint to the next TD boundary when a Disabled Endpoint condition occurs.

11.2.2.6.4.4.10 Resets and asynchronous operations

This section discusses the several asynchronous operations which affect the debug capability.

11.2.2.6.4.4.10.1 Resets

- When the software sets DCE from 1 to 0, it invokes a “DCE Reset.”
  - The controller sets the DCPORTSC status change bits to '0.'
  - If the controller is previously in the DbC state, the port exits the DbC state.
- When the Debug Host performs a Hot or Warm Reset, it invokes a “USB Reset.”
  - The controller stops the transfer rings for endpoint 1, and stops responding on this endpoint.
  - The controller does not resume transfers until the Debug Host reconfigures the Debug Target and the software rings the doorbell again.
- When the software sets HCRST or GCTL.CoreSoftReset, it invokes a “Chip Hardware Reset.”

  This causes all asynchronous resets in the controller to be asserted. DCPORTSC is set to 0, DCCTRL is set to 0 (DCE=0), all state machines go back to IDLE, the sticky PORTSC registers are reset, and the PHYs are reset.

- When the software sets LHCRST, it invokes a “Light Reset.”

  This resets the upper layer, the debug capability, and its registers, but not the sticky PORTSC registers. If the debug capability is in an “Upstream Mode” state, this reset causes the DCE bit to go to '0' which in turn causes the root hub (which does not reset on light reset) to go back to downstream mode only.

- GUSB2PHYCFG.SoftReset

  This resets only the individual USB 2.0 PHY.

- GUSB3PIPECTL.SoftReset

  This resets only the individual USB 3.0 PHY.

11.2.2.6.4.4.10.2 Other asynchronous operations

- When the software sets DCE from 0 to 1, it invokes a “DCE Enable.”

  The LSP fetches the DbCIC, enables endpoint 0, and allows upstream connections on its ports.

- When the host sends the device a `SetConfiguration(1)`, it invokes a “Device Configure.”

  The LSP configures EP1 IN and OUT by clearing any residual state, such as STALL, Data Sequence Number, and the SPR flag (synchronization between LSP and PTL).

- When the host sends the device a `SetConfiguration(0)`, it invokes a “Device Deconfigure.”

  The controller stops transfer rings, and stops responding on endpoint 1.

- When the software sets `DCPORTSC.PED` to '1', it invokes a “Port Enable.”
- When the software sets `DCPORTSC.PED` to '0', it invokes a “Port Disable.”

  The port still belongs to the debug capability, but it disconnects from the Debug Host if it was already connected.

11.2.2.6.4.4.11 U1/U2/U3 Entry

The Debug Host enables the Debug Target to initiate U1/U2 entry by sending the `SetFeature(U1_ENABLE)` or `SetFeature(U2_ENABLE)` requests. The U1/U2 entry can be forcefully disabled by the software by setting `DCTL.InitU1/U2Ena` and `DCTL.AcceptU1/U2Ena` to '0'. This may be necessary to improve interoperability with the Debug Hosts and Hubs.

The Debug Device, similar to DWC_usb3 device, accepts and initiates U1/U2 entry. This means that the Debug Device keeps track of its endpoints and the Packet Pending (PP) flag from the Debug Host. If all the endpoints are idle, the controller accepts U1/U2 entry. If the endpoints are idle, and the host has enabled the U1_ENABLE/U2_ENABLE feature, then the Debug Target initiates U1/U2 entry on the link.

The USB 3.0 protocol allows a SuperSpeed host and device to negotiate with each other and decide when to bring their link into a lower power state (U1 or U2). This is accomplished by each side making their individual decisions based on whether they have any traffic currently pending or expect any traffic soon. The device requests low power entry by transmitting an LGO_U1 (or LGO_U2) Link Command and exits low power by using a LFPS handshake.

The Debug Capability uses the information from the host (bus side) and the software (the application side) to decide the best time to request a low power entry and exit from the low power state. The same calculation is used by the controller to decide whether to accept a low power request from the host. The controller maintains the state information about each endpoint and whether it is "active" or "paused". If all enabled endpoints are paused from either the application side or the bus side, the low power entry is allowed. If at least one endpoint is not paused, the low power entry is not allowed.

To indicate that there is no pending traffic and allow the link to go into a low power state, the software pauses all enabled endpoints. Otherwise, an endpoint is considered active on the application side. For these endpoints, the host indicates that it is paused using one of the following ways:

- By setting the Packet Pending (PP) flag to '0' in a DPH
- Setting PP to '0' and NumP to '0' in an ACK TP

Exception: If the data packet payload has a CRC error, the DbC responds with an ACK (Retry=1), and the endpoint is not paused. Otherwise, if PP=1 or Deferred=1, the endpoint is considered to be active on the bus side.

Control endpoints have the following additional condition:

The controller does not allow low power entry during a control transfer (starting from the reception of a setup packet and ending at the completion of the status stage).

If all the enabled endpoints are paused by the software or the host, the controller issues an LGO_U1 (or LGO_U2) link command or it responds with an LAU link command to the low power request of the host or hub. Otherwise, the controller rejects the low power requests with an LXU link command.

Other related information:

- For bulk endpoints, the USB 3.0 Specification says that the device may go to U1/U2 500ms (tERDY- Timeout) after transmitting ERDY. However, it is not possible to force the DbC to enter U1/U2 in this scenario where the host is unresponsive to the ERDY.
- Because U1/U2 entry is based on the presence of packets in the TX FIFO and not based on the TRBs that are available to the controller, it is possible that an IN endpoint responds NRDY, goes to U1, then U0, then transmits an ERDY if the timing and TX FIFO size work out such that the controller cannot keep at least 1 packet in the TX FIFO at all times.
- In addition, before the final decision is made to either initiate or accept a low power state, the DbC checks the state of `DCTL.InitU1Ena/RejectU1Dis/InitU2Ena/RejectU2Dis` bits. If the device receives Set Link Function LMP with `Force_LinkPM_Accept` bit asserted, the DbC accepts a low power request from the host independent of endpoints state and DCTL Power control settings.

For U3, the Debug Device, similar to the normal device, enters and exits U3, as required in the USB 3.0 specification. The Debug Device does not transmit a Function Wake Device Notification because it is not Remote Wakeup capable.

11.2.2.6.4.5 Data structures

The xHCI data structures that are produced and consumed by the Debug Capability are:

- Debug Capability Info Context Data Structure (DbCIC)
- Endpoint Context
- Transfer TRB
- Event TRB

Each of these data structures are described in the xHCI Specification, but details specific to the implementation are described in this section.

11.2.2.6.4.5.1 Debug capability info context data structure

The Debug Target fetches the Debug Capability Info Context data structure when the software sets DCE=1, and uses the information to respond to `GetDescriptor(STRING)` requests from the host.

11.2.2.6.4.5.2 Endpoint context

In Debug Capability, the Endpoint Contexts are fixed to 64 bytes each. Figure 11-25 shows the Endpoint Context.

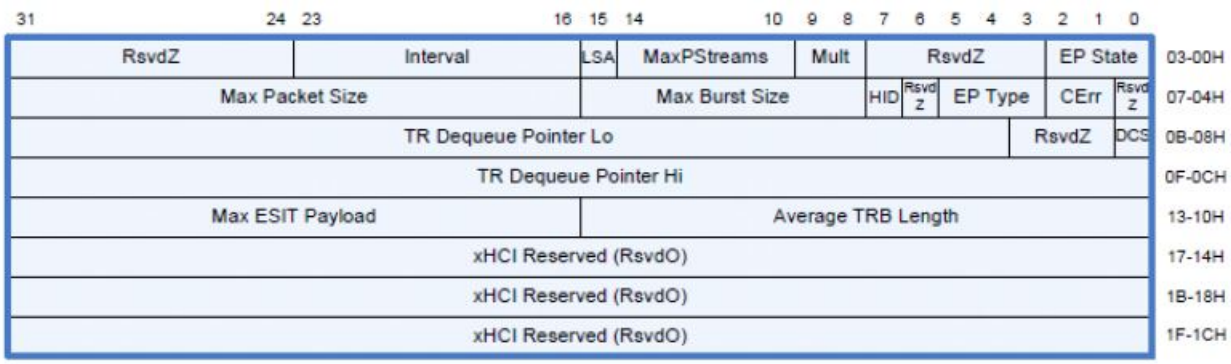

Figure 11-25. Endpoint Context

Even though the Endpoint Context format is the same, only EP State, TR Dequeue Pointer, and DCS fields of the EP Context are applicable to a Debug Target. The following fields are ignored:

- Max Packet Size: Always assumed to be 1024 bytes, unless `GCTL.FRMSCLDWN` is set to a different value, in which case the MPS is 1024 << `GCTL.FRMSCLDWN`
- EP Type: Always assumed to be 2 (Bulk)
- Max Burst Size: Assumed to be 15 (`DWC_USB3_DBC_MAX_BURST_SIZE`) for both IN and OUT endpoints. However, for the OUT endpoint the controller fills in the NumP (number

of receive buffers) field of the ACK TP based on the value in the DCFG.NumP register, which is 4 (DWC_USB3_DEVDB- C_OUT_NUMP) by default.

The other fields (Mult, MaxPStreams, LSA, Interval, CErr, HID, Average TRB Length, and Max ESIT Payload) are not applicable.

11.2.2.6.4.5.3 Transfer TRBs

The following are the only supported Transfer TRBs types:

- Normal
- Link
- No-Op
- Vendor-Defined

NOTE

- The Interrupter Target and BEI fields are ignored because the debug capability does not have an interrupt line.
- The IDT flag in Transfer TRBs must not be set to '1.'
- The ENT flag is ignored, as it is primarily used for stream-based endpoints.

11.2.2.6.4.5.4 Event TRBs

The controller produces the following types of Event TRBs:

- Port Status Change Event
- Transfer Event

The Completion Codes that are generated are:

- Success
- TRB Error
- Stall Error
- Short Packet
- Event Ring Full Error
- USB Transaction Error (see Disabled endpoint handling (DCCTRL.DRC/DCR))

The Babble Detected completion code is not generated, because the controller responds with ACK(Retry) to a TD Babble scenario. The Endpoint ID field in transfer events is ‘1’ for OUT Transfer Ring and ‘2’ for IN Transfer Ring.

11.2.2.6.4.6 Requirements, assumptions, and limitations

This section discusses the various requirements, assumptions and limitations of the xHCI Debug Capability Table 11-21 gives a summary of the limitations.

Table 11-21. xHCI debug capability limitations

Feature	Comments
Incompatible Features	DbC can be configured along with Hibernation and Clock Gating. However, these features are turned off automatically when Debug Capability is enabled by the DbC driver.
U1/U2 Support	The controller supports autonomous entry into U1 or U2, but it is recommended to disable this support via the DCTL register to improve interoperability with the Debug Hosts and Hubs.
Event Data TRB	The controller does not support the use of Event Data TRBs on the Debug Capability Transfer Rings. The Microsoft Debug Capability driver does not use them.
SetFeature(Halt) on EP1	If the debug host issues a SetFeature(ENDPOINT_HALT) request to the debug target's bulk endpoint 1, it receives a STALL response. This request is not supported.
ERDY	The controller transmits an ERDY when it is ready to transmit or receive a packet on the corresponding bulk endpoint, not explicitly when the endpoint's doorbell is rung by the software.
Chained TRBs greater than TRB cache size	The debug capability driver must not create a multi-TRB TD that describes smaller than a 1K packet that spreads across 8 or more TRBs on either the IN TR or the OUT TR.
TD Babble	If the host transmits a packet larger than the TD that the Debug Capability Driver has been setup for it, the debug target respondd repeatedly with ACK(Retry). No Transfer Event is generated for this scenario.
Latency Tolerance Message	The Debug Target does not transmit LTM Device Notifications.
HOT/HIT and Transfer Events	When the Debug Capability Driver sets HOT or HIT to '1', the controller generates a Transfer Event with "Stall Error" only if a Normal TRB is valid in the Transfer Ring. For more information, see Halting endpoints.
Reading DCCTRL.HOT/HIT	Immediately after setting HOT or HIT to '1', the field returns '0' when read until the STALL condition has internally propagated. When the controller is prepared to return STALL on the USB, the HOT/HIT field returns '1' when read. For more information, see Halting endpoints.
Residual DMA after DCE=0	The Debug Capability specification has no feedback after the software sets DCE to '0' to know when the DbC has halted (ala USBSTS.HCHalted). Therefore, it is possible that the controller continues DMA on the system bus to and from data buffers, TRBs, or Endpoint Contexts even after the software has set DCE=0. There is no definition for how long the DMA persists.
DCE Toggling	The software must wait at least 1 millisecond after setting DCE to '0' before setting it back to '1'. For more information, see DCE toggling.

Table continues on the next page...

Table 11-21. xHCI debug capability limitations (continued)

Feature	Comments
Overcurrent on Debug Port	If an overcurrent occurs on the debug port, the controller generates an xHCI port status change event and set the OCA and OCC bits in the associated PORTSC register. For more information, see Overcurrent on debug port.
Zero Length TD's for the OUT endpoint	Zero-length TD's are not allowed on the IN Transfer Ring (OUT endpoint). If the Debug Capability Driver is expecting a zero-length packet, it must prepare a TD that has at least 1 byte.
HCRST behavior	The xHCI Specification mentions that the DbC updates the Endpoint Context TR Dequeue Pointer if HCRST is set to '1'. However, because the debug capability is reset on HCRST, the controller does not update the Endpoint Context TR Dequeue Pointer.

11.2.2.6.4.6.1 Supported configurations

The DWC_usb3 controller can be configured with the Debug Capability hardware in any configuration supported by a host configuration. In particular, the Debug Capability logic can co-exist with the following other configurations:

- Host Only (`DWC_USB3_MODE=1`)
- Dual Role Device (`DWC_USB3_MODE=2`)
- Clock Gating (`DWC_USB3_EN_PWROPT > 0`)
- Hibernation (`DWC_USB3_EN_PWROPT=2`)

However, when the debug capability is enabled (`DCCTRL.DCE=1`), the following features (if configured) are disabled by the hardware:

- Clock gating (`GCTL.DsblClkGtng=1`)
- Hibernation (`GCTL.GblHibernationEn=0`)

11.2.2.6.4.6.2 RAM requirements

When the Debug Capability is enabled (that is, when parameter DWC_USB3_EN_DBC is 1), additional internal RAM is needed due to:

- Extra TxFIFOs and RxFIFOs
- Extra space for the DbC LSP Cache
- DbC RAM-based CSRs

11.2.2.6.4.6.2.1 Additional TxFIFOs and RxFIFOs

ITo support simultaneous host and debug target operation, most configurations require additional RAM and FIFO controllers. One exception is a DRD configuration with a large device TxFIFO RAM requirement.

Table 11-22 indicates the increased RAM requirement, which depends on the number of Host U3 root ports and SS USB instances as specified through coreConsultant. The last column indicates the presence of an additional set of sink/source 2clkfifo buffers. Each set consists of three flop-based FIFOs that are MDWIDTH wide and 8 deep if MDWIDTH is 32 or 64, or 4 deep if MDWIDTH is 128.

Table 11-22. DbC TxFIFO RAM requirements based on configuration

Num ber of U3 Ports	Number of SS USBInstances	TxFIFO RAM +	TxFIFO Controller +	RxFIFO RAM +			Cache RAM +	Sink/ Source Buffer +	
				MDW 32,64	MDW 128	RxFIFO Controller +	MDW 32,64		MDW 128
1	1	256B+2W[1]	1	0	0	0	64B	128B	0
2	1	3.25KB+6W	2	3KB+40B	3KB+64B	1	4*64B	4*128B	1
2	2	256B+2W	1	0	0	0	64B	128B	0
4	2	3.25KB+6W	2	3KB+40B	3KB+64B	1	4*64B	4*128B	1
4	4	256B+2W	1	0	0	0	64B	128B	0

1. W is the number of bytes in a FIFO word. If MDWIDTH is 32, then W is 4; if MDWIDTH is 64, then W is 8; if MDWIDTH is 128, then W is 16.

In all cases in which an additional TxFIFO controller is necessary, an additional TXQ FIFO controller is also necessary along with additional space in RAM0 (64B if MDWIDTH is 32 or 64, or 128B if MDWIDTH is 128). Similarly, in cases in which an additional RxFIFO is necessary, an additional RXQ FIFO controller and RIQ FIFO controller are necessary along with RAM0 space as indicated previously.

Examples:

1. In the single-port configuration (see first row in Table 11-22), one additional TxFIFO controller is necessary along with 256 bytes plus two FIFO words of TxFIFO RAM. If MDWIDTH is 64, then the TxFIFO RAM requires an additional 272 bytes (256 + 2 * 8), and the Cache RAM requires 64 bytes for the extra TXQ.
2. In a two-port configuration with one SS USB instance (see second row in Table 11-22), two additional TxFIFO controllers are necessary along with 3.25KB + 6W TxFIFO RAM, assuming the default three packet buffering requirement for U3 burst operation. One additional RxFIFO is necessary along with 3KB + 40B of RxFIFO RAM, and 4*64B of Cache RAM for the four additional FIFO controllers for the DMA queues (TXQ (2), RXQ, RIQ).
3. In a single-port DRD configuration with four device IN endpoints and a total device TxFIFO RAM requirement larger than the host TxFIFO RAM requirement plus DBC requirement in Table 11-22 (similar to last row but with specified device configuration enabled), no additional FIFO controllers are necessary and no additional FIFO RAM is necessary.

11.2.2.6.4.6.2.2 DbC LSP cache

The DbC LSP uses a part of the internal RAM to track transfers to and from the Debug Host. This is called the DbC LSP Cache. The DbC LSP Cache consists of the following sections:

- 12 DWORDs for the DbCIC (String Descriptor addresses and lengths plus padding)
- 4 DWORDs for EP1 OUT Endpoint Context (referred to in the xHCI specification as the “IN Transfer Ring”)
- 8 DWORDs for EP1 OUT Endpoint Scratchpad
- 4*N DWORDs for EP1 OUT TRB cache
- 4 DWORDs for EP1 IN Endpoint Context (referred to in the xHCI specification as the “OUT Transfer Ring”)
- 8 DWORDs for EP1 IN Endpoint Scratchpad
- 4*N DWORDs for EP1 IN TRB cache

The “N” in the previous equations is the number of TRBs per endpoint to be cached. The default value is 16, so the default space required for the DbC LSP Cache is 12+4+8+4*16+4+8+4*16 = 164 DWORDs, or 656 bytes. This space is added to RAM0.

11.2.2.6.4.6.2.3 DbC RAM-based CSRs

Several of the DbC registers are stored in the internal RAM. These types of CSRs are called “RAM-based CSRs,” and they increase the internal RAM requirement. For DbC, the following registers are RAM-based and increase the internal RAM requirement by 32 bytes:

- DCERSTBA_LO
- DCERSTBA_HI
- DCERDP_LO
- DCERDP_HI
- DCCP_LO
- DCCP_HI
- DCDDI1
- DCDDI2

This space is added to RAM0.

11.2.2.6.4.6.3 Port state machine/root hub

Multiple Debug Target Ports

- Any port may become a debug port, but only one port can be the debug port at a point of time.

- After one port is selected as the debug port, the others stop reporting upstream capable in their Port Capability LMP's.
- Even though the controller prevents two ports from training as upstream ports, exhaustive testing is not done for this scenario because it is assumed that the user does not attempt to simultaneously plug two Debug Hosts into two different ports on the Debug Target.

Port power

- The `vbus_ctrl` is not driven to 0 when the port becomes a debug port. The `vbus_ctrl` is based on the `PORTSC` register.

Overcurrent

- If an overcurrent occurs on a port that is acting as a Debug Target, the `PORTSC` register associated with that port reports the overcurrent.

11.2.2.6.4.6.4 Control transfers

When the controller handles control transfers autonomously, it always responds with NRDY for the first time it receives a STATUS TP, then sends ERDY, and ACKs the status phase when the host repeats it. The reason the controller never ACKs the STATUS TP for the first time is to account for the misbehaving hosts that might continue the data phase for more transactions, or might initiate the data phase in the incorrect direction (IN vs. OUT). By waiting for the status phase, the controller is guaranteed that the host has concluded the data phase.

Table 11-23 lists the controller'd responses to the standard device requests.

NOTE

- As shown in Table 11-23, the Debug Target responds STALL to a SetFea- ture(ENDPOINT_HALT) request from the host. The debug capability cannot be halted from the host, it can only be halted from the debug capability driver.
- The Debug Target responds STALL to a SetInterface(0) request from the host. The USB 2.0 and USB 3.0 specifications allow this behavior when a device supports only one interface.

Table 11-23. Control transfer responses

Request	Index/Value	State	Response
SetFeature	ENDPOINT_HALT (EP1)	All states	STALL
	ENDPOINT_HALT (EP0)	All states	ACK

*	Wrong Index/Value or wrong wLength	*	STALL
*	non-standard bmRequest Type (such as, Class/Vendor/ Reserved)	*	STALL
*	*	Non-supported states	STALL

11.2.2.6.4.6.5 Flow control

The controller has the following behavior:

- When an IN endpoint is flow controlled, the Debug Device transmits an ERDY when it has pre-fetched a packet into the TX FIFO.
- When an OUT endpoint is flow controlled, the Debug Device transmits an ERDY when it has fetched enough TRBs to receive a `MaxPacketSize` packet or the last packet of a TD.

The controller does not transmit an ERDY on a doorbell ring.

11.2.2.6.4.6.6 Bursting behavior for OUT and IN transfers

When the controller, as a Debug Target, responds to OUT and IN transfers, it uses the following mechanisms to throttle the Debug Host:

- For OUT transfers, setting the NumP field in the ACK TP
  - It is not possible or practical for the controller to predict the exact rate of packets entering and exiting the receive FIFO, so the `NumP` field is set based on the `DCFG.NumP` field, which defaults to the `DWC_USB3_DEVDBC_OUT_NUMP` parameter (a value of 4) on reset.
  - You can change this field during controller configuration based on your system simulations to allow or prevent the host from initiating large bursts.
  - This is the same behavior as the Synopsys USB 3.0 Device controller.
- For IN transfers, setting the EOB field in the DPH
  - The controller sets EOB as 1 during an IN transfer burst if the transmit FIFO does not have another packet after the one that is being transmitted to force flow control on the endpoint.

- Once there is a full packet in the transmit FIFO, the controller automatically transmits an ERDY to the Debug Host.
- This is the same behavior as the Synopsys USB 3.0 Device controller.

11.2.2.6.4.6.7 TRB cache size and transfers

The controller contains a TRB cache, one for the IN endpoint and one for the OUT endpoint, that holds a number of TRBs (configured by `DWC_USB3_DBC_TRBS_PER_TRANSFER`, default is 16).

For the bulk IN endpoint, the controller constructs a full packet with the TRBs that are present in the internal cache. This means that the debug capability driver must not create a multi-TRB TD that describes less than a `MaxPacketSize` packet (1K) that spreads across `DWC_USB3_DBC_TRBS_PER_TRANSFER`-1 or more TRBs.

For the bulk OUT endpoint, the controller receives a full packet or a short packet with the TRBs that are present in the internal cache. This means the debug capability driver must not create a multi-TRB TD that describes a buffer less than 1K that spreads across `DWC_USB3_DBC_TRBS_PER_TRANSFER`-1 or more TRBs.

In each of the previous equations, the "-1" is added to account for at most one Link TRB, which may be present in a TD. If more than one Link TRB is present in a TD, the requirement shrinks by the maximum number of Link TRBs that can be in a TD.

11.2.2.6.4.6.8 DCE=0 restrictions

When the software sets `DCCTRL.DCE=0`, several operations take place inside the controller. This section describes some of the assumptions and restrictions when this occurs.

11.2.2.6.4.6.8.1 Data structure ownership

Section 7.6.9 of the xHCI Specification states "While the Debug Capability Enable (DCE) bit in the Debug Capability Control Register (DCCTRL) is '1', the xHC maintains ownership of the data structures." This also implies that when DCE=0, the controller does not own the data structures (DbC Info Context, OUT EP, and IN EP Context). However, due to residual DMA (see Residual DMA), the controller can be in the process of writing to these data structures and therefore there is no guarantee that the controller prevents these writes immediately when DCE is set to '0'.

11.2.2.6.4.6.8.2 Residual DMA

Because the controller may be busy performing a read or write DMA operation on the system bus when the software sets DCE=0, it is not possible to immediately abort those operations. Therefore, the controller completes the DMA operations on the system bus,

and finds a graceful point to finish the DbC halt operation. Unfortunately, there is no defined “Halted” bit in the xHCI Specification, so the software cannot determine when the DMA operations have completed.

11.2.2.6.4.6.8.3 DCE toggling

Because there are a set of operations performed within the controller when the software sets DCE from '1' to '0', and there is no feedback when the controller has completed its residual DbC operations, the software must wait at least 1 millisecond after setting DCE to '0' before setting it back to '1.'

11.2.2.6.4.6.9 TD babble response

A “TD Babble” is when the debug capability driver prepares a TD that is smaller than the amount of data sent by the Debug Host to the OUT endpoint. For example, the debug capability driver prepares an 8 byte TRB to receive an 8 byte packet from the host, but the host instead sends a 1K packet.

The xHCI Specification allows several different responses in this situation. The DWC_usb3 controller responds on the USB with an ACK(Retry) if this happens. If the host continues to send the same packet three times, the host will timeout the transfer and likely reset the Debug Target. There is no indication of the retries to the debug capability driver, but when the reset occurs, the DCCTRL.DCR field is set to '0' and DRC is set to '1' to indicate that the Debug Target exited the Configured state, and requires the debug driver to restart the bulk transfers.

11.2.2.6.4.6.10 TRB Types

The controller supports Normal, Link, No-Op, and Vendor Defined TRB Types. Event Data TRBs are not supported, as they are not required by the Microsoft Debug Capability driver.

11.2.2.6.4.6.11 Latency tolerance message

The controller, when acting as a Debug Target, does not transmit LTM Device Notifications.

11.2.2.6.4.6.12 Overcurrent on debug port

Because some systems use a single overcurrent signal for all ports, the controller cannot determine if an overcurrent on the debug port is on the port itself or whether it is from another downstream port. Therefore, if an overcurrent is detected on the debug port, the controller still sets the OCA and OCC bit in the PORTSC register associated with the port, and generates a port status change event to be consumed by the xHCI driver.

11.2.2.6.4.6.13 Vendor device test LMP

The controller, acting as a Debug Target, has the capability of receiving the Vendor Device Test LMP without error. However, the LMP is dropped with no indication to the software.

11.2.2.7 Device physical endpoint-specific commands

11.2.2.7.1 Command 1: Set endpoint configuration: DEPCFG

This command sets the physical endpoint configuration information.

NOTE

If GUSB2PHYCFG[6] is set to '1', it must be set to '0' prior to issuing this command and may be set to '1' after the command completes.

Table 11-24. Command 1: Set endpoint configuration parameters: DEPCFG

Field	Description
Parameter 2	
31-0	Set to endpoint state when the Config Action field of Parameter 0 is 1. Otherwise, this is Reserved.
Parameter 1	
31	FIFO-based Set to '1' if this isochronous endpoint represents a FIFO-based data stream where TRBs have fixed values and are never written back by the core.
30	Bulk-based Set to '1' if this isochronous endpoint represents a bulk data stream that ignores the relationship of bus time to the intervals programmed in TRBs.
29-25	USB Endpoint Number bit[29:26]: Endpoint number bit[25]: Endpoint direction: 0 OUT 1 IN

Table continues on the next page...

Table 11-24. Command 1: Set endpoint configuration parameters: DEPCFG (continued)

Field	Description
	Physical endpoint 0 (EP0) must be allocated for control endpoint 0 OUT. Physical endpoint 1 (EP1) must be allocated for control endpoint 0 IN.
24	Stream Capable (StrmCap) Indicates this endpoint is stream-capable (MaxStreams != 0).
23-16	bInterval_m1 Set to the bInterval value minus 1. The valid values for this field are 0 through 13. The bInterval value is reported in the endpoint descriptor. When the core is operating in Full-Speed mode, this field must be set to 0.
15	Set to '1' if this bulk endpoint utilizes the External Buffer Control (EBC) mode. This limits the number of outstanding DMA transfers to one read and one write. This is a requirement for the EBC to operate properly. Using EBC without setting this bit to '1' results in undefined behavior.
14	Reserved
13-8	Bits 13-8 are used for Device Endpoint Specific Event Enable (DEPEVTEN). If an enable bit is set to 0, the corresponding event is not generated. Bit 13 Stream Event Enable (StreamEvtEn) Bit 12 Reserved Bit 11 Reserved Bit 10 XferNotReady Enable (XferNRdyEn) Bit 9 XferInProgress Enable (XferInProgEn) Bit 8 XferComplete Enable (XferCmplEn)
7-5	Reserved
4:0	Interrupt number (IntrNum) Applies to IN and OUT endpoints. Indicates interrupt/Event Buffer number on which endpoint related interrupts for this endpoint are generated. This must be set to 0.
Parameter 0	
31-30	Config Action 0 Initialize endpoint state: This action is used when an endpoint is configured the first time. It will cause the data sequence number and flow control state to be reset. DEPCMDPAR2 will be ignored. The encoding of this action is backward compatible with software that previously set "Ignore Sequence Number" to 0. 1 Restore endpoint state: This action is used when reconfiguring an endpoint with saved state after hibernation. It will cause the data sequence number and flow control state to be restored from DEPCMDPAR2. 2 Modify endpoint state: This action is used when modifying an existing endpoint configuration, such as changing the DEPEVTEN event enable bits, interrupt number, or MaxPacketSize. The data sequence number and flow control state will be unchanged, and DEPCMDPAR2 will be ignored. The encoding of this action is backward compatible with software that previously set "Ignore Sequence Number" to 1. When issuing a Endpoint Configuration command with Config Action=Restore, Parameter 2 must be filled in with the same value returned by the Get Endpoint State command prior to hibernation.
29-26	Reserved
25-22	Burst Size (BrstSiz) When field is set to- 0 Burst length = 1

Table continues on the next page...

Table 11-24. Command 1: Set endpoint configuration parameters: DEPCFG (continued)

Field	Description
	1 Burst length = 2, and so on, up to, 15 Burst length = 16 For IN transfers, this value represents the maximum length of the burst that the device attempts when the Host initiates an IN transfer with a TP_ACK. If BrstSiz < the NumP value in the initiating TP_ACK, then the device controller limits the burst length to BrstSiz. If BrstSiz >= the NumP value in the initiating TP_ACK, then the device controller attempts a burst length of NumP. For OUT transfers, this value represents the NumP value utilized in the response TP_ACK from the device controller. The NumP value indicates (to the host) the burst length the device desires. Note: In the special case of BrstSiz=0 (burst length = 1), the TP_ACK from the device controller has NumP=0; which is a flow-control condition. If this value is utilized, then the endpoint enters flow control for each DP received and a subsequent ERDY is transmitted (according to the USB Specification). However, this may have an undesirable impact on the system throughput. To avoid this impact, it is recommended to set BrstSize=1 to prevent the flow-control condition. The trade-off is that the host could potentially burst two OUT data packets to the device, resulting in an ACK for the first packet, and an NRDY for the second packet.
21-17	FIFO Number (FIFONum) Indicates which transmit FIFO is assigned to this endpoint. For control endpoints, the FIFONum value in the OUT direction must be programmed to the same value as the IN direction. This field should be set to 0 for all other OUT endpoints. Even though there may be more than 16 TXFIFOs in DRD mode, the device mode must use lower 16 TXFIFOs.
16-14	Reserved
13-3	Maximum Packet Size (MPS) Applies to IN and OUT endpoints. The application must program this field with the maximum packet size (in bytes) for the current USB endpoint. USB 3.0 supports up to 1024 bytes.
2-1	Endpoint Type (EPType) This is the transfer type supported by this USB endpoint. 00 Control 01 Isochronous 10 Bulk 11 Interrupt
0	Reserved

11.2.2.7.2 Command 2: Set endpoint transfer resource configuration (DEPXFERCFG)

There must be only one transfer resource allocated per endpoint. Start transfer causes the use of the transfer resource. End Transfer or an XferComplete event releases the transfer resource. If software attempts to allocate more transfer resources than have been configured in the hardware, this command will return an error in the CmdStatus/ EventStatus field.

NOTE

If GUSB2PHYCFG[SUSPENDUSB20] is set to '1', it must be set to '0' prior to issuing this command and may be set to '1' after the command completes.

Table 11-25. Command 2: Set endpoint transfer resource configuration parameters: DEPXFERCFG

Field	Description
Parameter 2	
31-0	Reserved
Parameter 1	
31-0	Reserved
Parameter 0	
31-16	Reserved
15-0	Number of Transfer Resources (NumXferRes) Defines the number of Transfer Resources allocated to this endpoint. This field must be set to 1.

11.2.2.7.3 Command 3: Get endpoint state (DEPGETSTATE)

After Get Endpoint State (DEPGETSTATE) command completes, the 32 bits in DEPCMDPAR2 represent the endpoint state to be saved. This includes the current data sequence number, flow control state, and control transfer state (for control endpoints).

This command is only used when the controller enters hibernation. The controller requires the 32 bits of state information when exiting hibernation as part of the DEPCFG command with the Config Action field set to "Restore endpoint state".

NOTE

If GUSB2PHYCFG[6] is set to ‘1’, it must be set to '0' prior to issuing this command and may be set to ‘1’ after the command completes.

11.2.2.7.4 Commands 4 and 5: Set Stall and Clear Stall (DEPSSTALL, DEPCSTALL)

These commands apply to non-isochronous IN and OUT endpoints only.

The application issues a Set Stall command to stall all tokens from the USB host to this endpoint. If the endpoint is in the NRDY state, the STALL state takes priority.

If a transaction is currently in progress when the software issues Set Stall, the behavior depends on the direction of the endpoint:

- For OUT endpoints, the current packet will complete. The core will respond with STALL to the next OUT DP or token.
- For IN endpoints in SuperSpeed, the current burst transaction will complete, and the core will respond with STALL to the next ACK TP. For other speeds, the core will complete the current packet and respond STALL to the next IN token.

For non-control endpoints, the application is responsible for both setting and clearing STALL via the Set Stall/Clear Stall commands. When the application clears the STALL, the endpoint's data sequence number is reset to zero.

For control endpoints, the application issues only the Set Stall command, and only on the OUT direction of the control endpoint. The controller automatically clears the STALL when it receives a SETUP token for the endpoint.

The application must not issue the Clear Stall command on a control endpoint. If the endpoint is in flow control (NRDY) and also in the STALL state, it responds with a STALL for any packet. The only exception is that the controller always responds to SETUP data packets with an ACK handshake, independent of the STALL state.

NOTE

- If GUSB2PHYCFG[6] is '1', it must be set to '0' prior to issuing this command and may be set to ‘1’ after the command completes.
- When issuing Clear Stall command for IN endpoints in SuperSpeed mode, the software must set the "ClearPendIN" bit to '1' to clear any pending IN transcations, so that the device does not expect any ACK TP from the host for the data sent earlier.

11.2.2.7.5 Command 6: Start transfer (DEPSTRTXFER)

This command applies to IN and OUT endpoints.

A Transfer Descriptor (TD) in Device mode is a list of TRBs that comprises one or more transfers. The pointer to a TD is added to the core's cache by the Start Transfer command and removed by an XferComplete event or by the End Transfer command.

Software issues this command indicating that a descriptor is ready to be processed and DMA can start for this endpoint/stream combination. For IN endpoints, this causes the descriptor to be processed, and data is moved from the corresponding memory buffer to corresponding transmit FIFO when the transfer is started. For OUT endpoints, this causes the descriptor to be processed and data is moved from the receive FIFO to corresponding memory buffer.

In response to the Start Transfer command, the hardware assigns this transfer a resource index number (XferRscIdx) and returns the index in the DEPCMDn register and in the Command Complete event. This index must be used in subsequent Update and End Transfer commands.

It is illegal to issue a Start Transfer command for the same TD if it is already present in the core's cache.

Non-stream capable endpoints rules:

- The Stream ID field must be set to 0.
- The HighPri field is reserved.

Stream-capable endpoint rules:

- The Stream ID field must be set to non-zero and match the Stream ID passed into the Start Transfer endpoint command associated with this transfer. In all the TRBs of a transfer, the Stream ID fields must be the same.
- The HighPri field is reserved.

NOTE

- If GUSB2PHYCFG[6] is set to '1', it must be set to '0' prior to issuing this command and may be set to '1' after the command completes.
- Before issuing a start transfer command, software needs to verify whether the link is in U0. If the link is not in U0, software needs to bring the link to U0 by performing a remote wakeup. This is applicable to both SS and USB 2.0 speeds.
- When an IN transfer is in progress, (that is, started and not completed yet), and the software sees a link state change event to L1, then the software can use the GDBGFIFOSPACE register (write followed by a read) to

determine if the TXFIFO is empty or not. If the TXFIFO is not empty, it can initiate a remote wakeup.

Table 11-26. Command 6: Start transfer parameters: DEPSTRTXFER

Field	Description
Parameter 2	
31-0	Reserved
Parameter 1	
31-0	Transfer Descriptor Address (TDAddr Low) Indicates the lower 32 bits of the external memory's start address for the transfer descriptor. Because TRBs must be aligned to a 16-byte boundary, the lower 4 bits of this address must be 0.
Parameter 0	
31-0	Transfer Descriptor Address (TDAddr High) Indicates the higher 32 bits of the external memory's start address for the transfer descriptor.

11.2.2.7.6 Command 7: Update transfer (DEPUPDXFER)

If software uses circular TRB buffers and updates a TRB, whose Hardware Owner (HWO) bit was 0, by setting HWO=1, it must execute the Update Transfer command, specifying the transfer resource index of the TRB in the DEPCMD register. The hardware uses this information to re-cache the TRB.

Software may issue a special “No Response Update Transfer” command by setting CmdAct=0 and CmdIOC=0. In this case, the hardware does not generate a Command Complete event, does not set the CmdAct bit to '0' (because it will be '0'), and software may immediately issue another command to the same endpoint following this one. This special type of Update Transfer may not be used when software depends on the XferNotReady event to setup TRBs (see “On Demand” transfers in Transfer setup recommendations).

Software may issue an Update Transfer command for a transfer resource that has already completed (either due to XferComplete event or an End Transfer command), and the core will detect that the Update Transfer is unnecessary. However, software must not issue an Update Transfer command for a transfer resource index that has never been started.

NOTE

If GUSB2PHYCFG[6] is set to '1', it must be set to '0' prior to issuing this command and may be set to '1' after the command completes.

11.2.2.7.7 Command 8: End transfer (DEPENDXFER)

This command applies to IN and OUT endpoints. Software issues this command requesting DMA to stop for the endpoint/stream specifying the transfer resource index of the TRB and the ForceRM parameter to be set to 1 in the DEPCMD register.

When issuing an End Transfer command, software must set the CmdIOC bit (field 8) so that an Endpoint Command Complete event is generated after the transfer ends. This is necessary to synchronize the conclusion of system bus traffic before the End Transfer command is completed.

For IN endpoints, this command causes descriptor processing to stop and the core stops fetching new data for the endpoint and stops transfers on the USB. The core may truncate a packet being transmitted with the DPPABORT ordered set, does not wait for any pending ACKs from the USB, and does not update the TRB status. For OUT endpoints, this command causes descriptor processing to stop. If there is currently data, it is moved from the receive FIFO to corresponding memory buffer and completed at packet boundary. The core does not update the TRB status.

Use this command under the following conditions:

- When handling USBReset or SetConfiguration, endpoints are closed using this command.
- After receiving a ClearFeature (STALL) control transfer, software issues End Transfer followed by Clear Stall, followed by Start Transfer.
- After an XferInProgress event when the TRB after the one that caused the XferInProgress event has its HWO bit set to '0', this command can be used.
- For isochronous endpoints, if the host stops moving data for many intervals, software may force the end of the transfer and wait for the host to restart.

The hardware does not issue a XferComplete event on End Transfer, but only issues a CommandComplete event.

NOTE

If GUSB2PHYCFG[6] is set to '1', it must be set to '0' prior to issuing this command and may be set to '1' after the command completes.

Table 11-27. Command 8: End Transfer Parameters: DEPENDXFER

Field	Description
Parameter 2	
31-0	Reserved
Parameter 1	
31-0	Reserved

Table continues on the next page...

Table 11-27. Command 8: End Transfer Parameters: DEPENDXFER (continued)

Field	Description
Parameter 0	
31-0	Reserved

End Transfer Command With Hibernation Enabled The following applies only when hibernation is enabled. Prior to hibernation, software will set ForceRM to '0' when it issues End Transfer commands for active transfers. This command may cause a TRB to be written back with intermediate state.When software issues an End Transfer command with the ForceRM bit set to 0, and the core has at least one valid current TRB, it will perform the following:

- Write back the TRB updating the Buffer Pointer and Buffer Size fields to reflect the current state of the TRB.
- Write the value '4' (TRBInProgress) into the TRBSTS field to indicate that this TRB may have been partially used and is still active. This is an indication to software that the original buffer pointer field may have been changed by hardware.
- Set the HWO bit to '0' unless it is a Link TRB. The HWO bit in a Link TRB will be unchanged.

After the state is restored, software may restart a transfer from a partially completed TRB by setting TRBSTS to '0', setting the HWO bit back to '1', and issuing the Start Transfer command.Software is not required to perform any special manipulation on partially completed TRBs. When the core completes a restarted partially complete TRB, it will set TRBSTS back to '0'.

11.2.2.7.8 Command 9: Start new configuration (DEPSTARTCFG)

Software issues this command under the following conditions:

- After power-on-reset with XferRscIdx=0 before starting to configure Endpoints 0 and 1. CmdIOC must be set to '0' and software must poll the CmdAct bit to determine when the command is complete because Endpoint 0 is not yet configured with a valid interrupt number.
- With XferRscIdx=2 when it receives SetConfiguration before starting to configure Endpoints > 1. CmdIOC may be set to '0' or '1'.

This command should always be issued to Endpoint 0 (DEPCMD0).

Hardware resets the transfer resource allocation to the value in the XferRscIdx parameter (must be 0 or 2) upon receiving this command.

NOTE

If GUSB2PHYCFG[6] is set to '1', it must be set to '0' prior to issuing this command and may be set to '1' after the command completes.

11.2.2.8 Power management overview

The following power management features are available in the USB 3.0 core:

- Hibernation (save/restore) in device (L1, L2, U3, Disconnected) and host (U3, Disconnected)
- Hardware-controlled LPM in USB 2.0 host
- Clock gating in device (U1/U2/U3) and host (U1/U2/U3)

When hibernation is supported, the core saves some of its internal state to an external location and allows the USB3 core to be powered off. Small modules, namely the PMUs, detect wakeup conditions and request power be reapplied to the core, at which time the external state is brought back into the core.

Since the PMU modules are not inside the USB 3.0 core, the PMUs can easily be placed anywhere in the chip during floor-planning, adding isolation cell/voltage shifter cells. The PMU modules can be placed in the always ON power domain and the power domain is 0.8 V which could be operating at a different voltage than the USB 3.0 power domain.

Hibernation is described in the xHCI Specification as an optional feature that can be supported.

In addition, this feature is also added to the device controller.

NOTE

- The PMU does not support the following features in Hibernation mode:
  - BC
- It is required that the SuperSpeed PHY must support receiver detection in P3 PowerDown mode.
- In the host mode, the USB 3.0 core does not support clock gating and hibernation when the Debug Capability is enabled during runtime (DCCTRL.DCE=1).
- During the normal host mode of operation, the USB 3.0 core supports clock gating and hibernation features when the Debug Capability is not enabled by the software (DCCTRL.DCE=0).

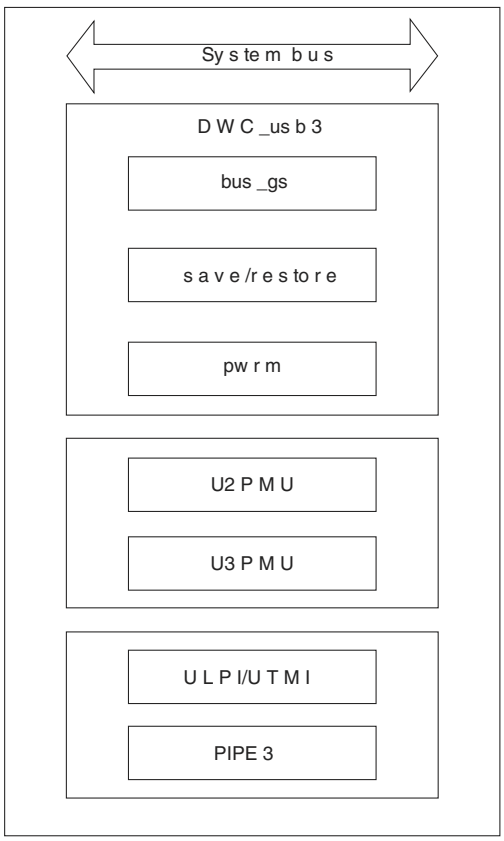

Figure 11-26. Power management hibernation architecture

The second power saving mechanism is hardware-controlled LPM. This is a USB 2.0 host-only feature where the host controller automatically detects the downstream port is idle for a certain amount of time and autonomously initiates an LPM token to the connected device. If the device accepts, the link is put into the standard USB 2.0 Suspend state.

Finally, clock gating is also supported in the host controller as well as in the device controller. The following table gives the list of power saving mechanisms available in USB 3.0 core.

Table 11-28. Power savings support

USB 3.0 State	USB 2.0 State	Device Power Savings	Host Power Savings
U1 (Hardware Initiated)	None	Core: Clock Gating PHY: P1	Core: Clock Gating PHY: P1
U2 (Hardware Initiated)	LPM-L1 (Hardware Initiated)	Core: Clock Gating, LPM-L1 Hibernation PHY: P2/Sleep	Core: Clock Gating, PHY: P2/ Sleep
U3 (Software Initiated)	Suspend (Software Initiated)	Core: Clock Gating, Hibernation PHY: P3/Suspend	Core: Clock Gating, Hibernation PHY: P3/Suspend

Table continues on the next page...

Table 11-28. Power savings support (continued)

USB 3.0 State	USB 2.0 State	Device Power Savings	Host Power Savings
Rx.Detect (Software Initiated)	None	None	Core: Clock Gating, Hibernation PHY: P3/Suspend
SS.Disabled (Software Initiated)	None	Core: Clock Gating, Hibernation PHY: P3/Suspend	None

11.2.2.8.1 Clock gating

The core implements clock gating in the following situations:

- In USB 2.0 device mode
  - When the UTMI suspend or l1_suspend signal is asserted and the core is idle
- In USB 3.0 device mode, when the link is in U1, U2 or U3 state and the core is idle.

In host mode, clock gating is enabled in the following situations:

- When all USB 2.0 ports are in the suspend or L1 Suspend state, and all USB 3.0 ports are in the U1/U2/U3 state, and the core is idle.

Internal clock gating will apply to:

- Modules that use the ram_clk
- Some modules that use bus_clk

Internal clock gating will not apply to:

- Modules that use mac3_clk: When the USB 3.0 PHY is suspended, these modules switch to using suspend_clk, so their power consumption is reduced but the clock is not completely stopped.
- Modules that use mac2_clk: When the USB 2.0 PHY is suspended, these modules switch to using suspend_clk, so their power consumption is reduced but the clock is not completely stopped.
- The bus_gs module, which uses bus_clk. This module detects wakeup on the slave interface and thus needs a non-gated clock.

Clock gating can be enabled or disabled using the GCTL register. The GCTL register is "sticky," it retains its value across soft resets and hibernation.

11.2.2.8.2 Hardware-Controlled LPM

In USB 2.0, the main link power management mechanism was for the host to suspend the link. However, suspending the link requires a long period of idle and was wasteful of power, especially because the host knows ahead of time whether it is going to schedule any traffic. It also required a long period of resume signaling.

The USB 2.0 Link Power Management Addendum [LPM-ECN] added a new token to the USB 2.0 specification, the LPM token. The host has the option of suspending the link quickly instead of waiting for a long period of idle, and communicates its desire to the device by sending an LPM token. The ECN also introduced a terminology for different link states. This new link state was called L1. The traditional USB 2.0 suspend was called L2. The L1 state requires a much shorter resume signaling period too.

An xHCI driver can initiate LPM by writing '2' to the PORTSC.PLS field. However, there is a lot of overhead for an xHCI driver to be constantly trying to keep the link in a low power state. Because of this, the xHCI specification also allows a compatible xHC to be enabled with "Hardware-Controlled LPM" by setting PORTPMSC.HLE as 1. When this happens, the xHC is expected to automatically send LPM tokens when it has no pending transfers and thinks that the link is idle enough to enter L1. This feature is supported by the host core.

11.2.2.8.3 USB PHY power gating

The USB PHY power gating is used to save the leakage power of PHY if it is not required. Follow the steps given below to take PHY into power gating state:

1. Assert PHY_RESET by writing 1'b0 to the PHY_CTRL1[PHY_RESET] bit.
2. Set the PHY_CTRL1[PHY_TEST_POWERDOWN_HSP] and PHY_CTRL1[PHY_TEST_POWERDOWN_SSP] to 2'b11.

NOTE

Both the above steps must have separate writes.

11.2.2.9 Clock domains

The DWC_usb3 has the following clock domains which describes clock usage during SS Only or SS and HS (Host mode) operation:

- USB 3.0 PIPE3 PHY clock
  - This clock is 125 MHz with 32-bit PHY, 250 MHz with 16-bit PHY, or 500 MHz with 8-bit PHY.

  - Separate Rx and Tx clock input pins are provided to make external PHY integration easier. The Tx clock can be an early version of the PHY clock to compensate for output PAD delays.
  - During the lowest SS PHY power-down state (P3), the PHY does not drive this signal; therefore, a suspend clock signal is provided in its place.
- USB 2.0 PHY/MAC clock

  This clock is 30 or 60 MHz in UTMI+ PHY mode, or 60 MHz in ULPI mode

- MAC3 clock (125 MHz MAC3 clock, which is divided PIPE3 clock)

  The MAC3 clock is a divided version of the PIPE3 PHY clock. In Device or single-port Host mode, the MAC3 clock is synchronous to the PIPE3 clock, but may be delayed to tolerate the larger MAC3 clock insertion delay. In multi-port Host and Hub mode, the MAC3 clock and the PIPE3 clock may be asynchronous.

- Bus clock
  The bus clock is system-dependent. The SoC bus bandwidth must be at least the same as USB 3.0 bandwidth. For example, the bus clock needs to be at least 125 MHz with a 64-bit SoC bus to satisfy the device duplex performance requirement of 8 Gbps (125 MHz * 64 = 8 Gbps). For example, in the case of a four-port concurrent host, the bus clock must be at least 250 MHz at 128 bitd to meet 32 Gbps (250 MHz * 128 = 32 Gbps).

NOTE

A system bus interface can have different master and slave types, but they must use the same bus clock.

- RAM clock to meet both MAC and BUS domain bandwidth

  The RAM needs to support twice the USB 3.0 bandwidth: one to service the USB side and the other to service the bus side. In the case of a single-port RAM, the recommended clock speed is at least 250 MHz. In the case of 2-Port mode, it needs to be at least 125 MHz. This is typically connected to PIPE3 or MAC3 clock. If your bus clock is faster than the PIPE3/MAC3 clock, you can connect the bus clock to the RAM.

- Suspend Clock

  During suspend, in order to achieve low power, the PIPE3/MAC3/MAC2/MAC clock is switched to a lower frequency variable clock.

The following clock conditions apply during High Speed (High Speed device connection or only High Speed Devices in Host mode)

- The USB 3.0 PIPE3 PHY clock is gated/shut-down.

- The USB 2.0 PHY/MAC clock is 30 or 60 MHz in UTMI+ PHY mode, or 60 MHz in ULPI mode.
- The MAC3 clock, which is a divided PIPE3 clock, is gated/shut-down.
- The bus clock is system dependent and should be at least 60 MHz to meet a five-clock USB 2.0 turnaround time.
- The RAM clock, to meet both MAC and BUS domain bandwidth, must support twice the USB 2.0 bandwidth; one to service the USB side and one to service the bus side. Minimum 60 MHz; typically, the bus clock is connected to RAM.

11.2.2.10 Reset generation

The following resets can be controlled by registers (GUSB2PHYCFG, GUSB3PIPECTL, GCTL, and USBCMD), and the signal vcc_reset_n:

- USB 2.0 PHY reset
- USB 3.0 PHY reset
- Controller internal reset
- Light reset

The following figure shows the Reset Generation unit.

NOTE

When Hibernation is enabled, PHY reset behavior is enabled only when both vcc_reset_n and vaux_reset_n are asserted.

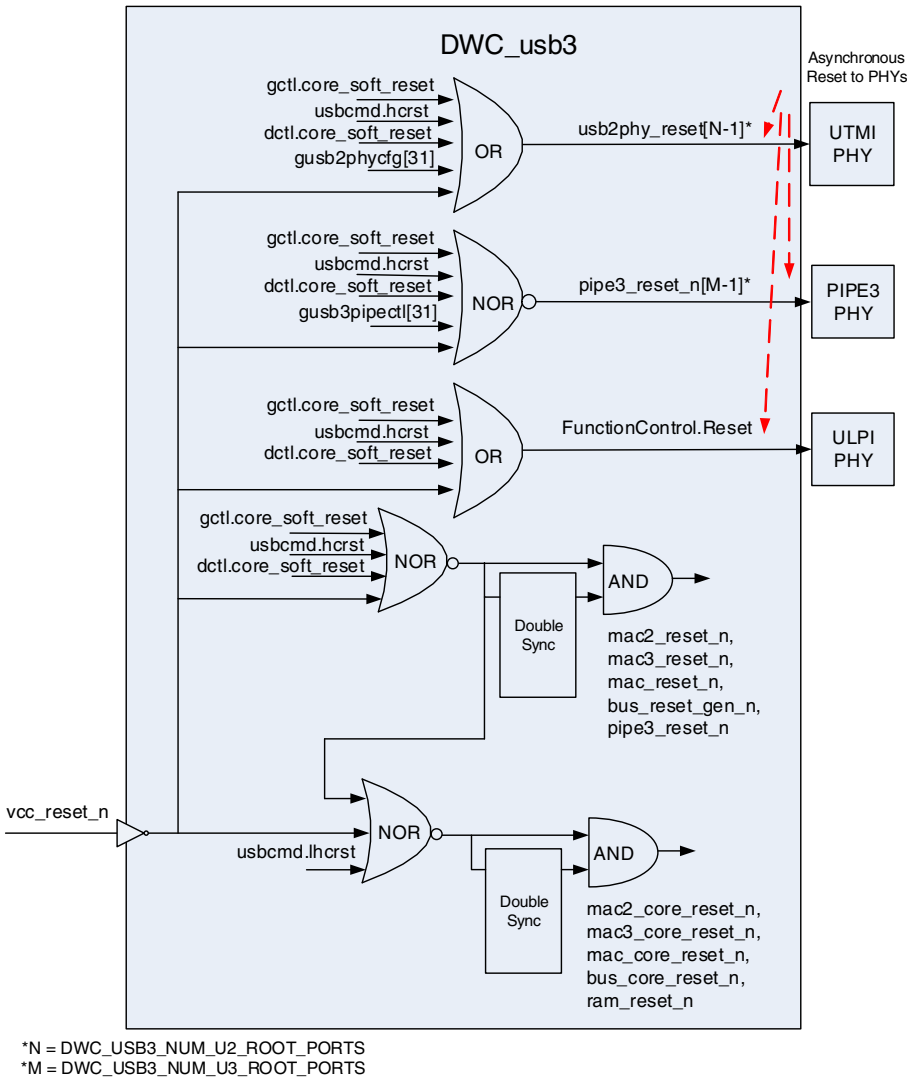

Figure 11-27. Reset Generation

Because there are multiple clock domains in the design, and toggle interfaces are used between clock domain, reset generation requires the following conditions to be met:

- All internal resets are active simultaneously for some period to initialize all the flops. The reset-module (DWC_usb3_rst.v) of the controller takes care of this by asynchronously propagating vcc_reset_n to all the internal resets in the design.
- The external USB 3.0 and USB 2.0 PHY reset requirements must be met. The controller provides pipe3_reset_n and usb2phy_reset signals to achieve these requirements.

11.2.2.10.1 Asynchronous reset

In asynchronous reset mode, the controller generates the PHY resets. You must ensure that vcc_reset_n is active to meet the PHY reset timing. Asynchronous reset mode requires the following conditions to be met:

- Connect pipe3_reset_n to USB 3.0 PHY.
- Connect usb2phy_reset to USB 2.0 PHY.
- Assert the vcc_reset_n signal for a minimum period necessary to reset the USB 3.0 and USB 2.0 PHYs.

Sequence of Asynchronous Resets

Asynchronous resets must be generated in the following sequence:

1. Drive vcc_reset_n for at least a minimum period required to reset USB 3.0 and USB 2.0 PHYs.
2. The controller drives the pipe3_reset_n and usb2phy_reset outputs active as long as vcc_reset_ n input is active. In addition, the controller also drives all the internal resets in the controller.
3. When vcc_reset_n is de-asserted, the controller also de-asserts pipe3_reset_n and usb2- phy_reset outputs. In addition, the controller also removes the internal bus and RAM clock domain resets. However, the controller keeps the internal MAC3 clock domain reset.
4. When pipe3_reset_n is de-asserted, the USB 3.0 PHY drives pipe3_PhyStatus to “0” once the PHY is reset and the pipe3_pclk clock is stable. The controller waits until pipe3_PhyStatus turns “0” before removing the internal reset to the PHY and MAC domains (mac3_reset_n). This ensures that the controller starts Rx detection only after the PHY clock is stable.
5. In the case of the USB 2.0 PHY, after usb2phy_reset is de-asserted, the USB 2.0 PHY drives a stable valid clock based on the PHY specification.

In addition to power-on reset, you can use the Software reset feature. Following figure shows the asynchronous reset and PHY clock sequencing and requirements.

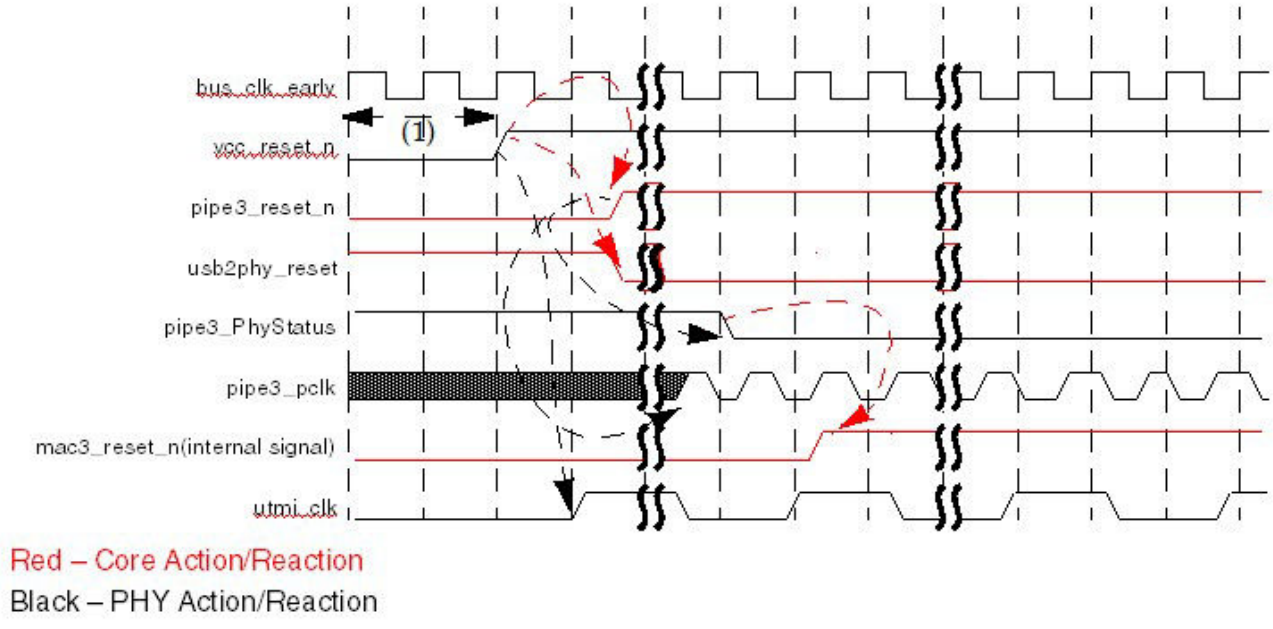

Figure 11-28. DWC_usb3 clock domains and data flow

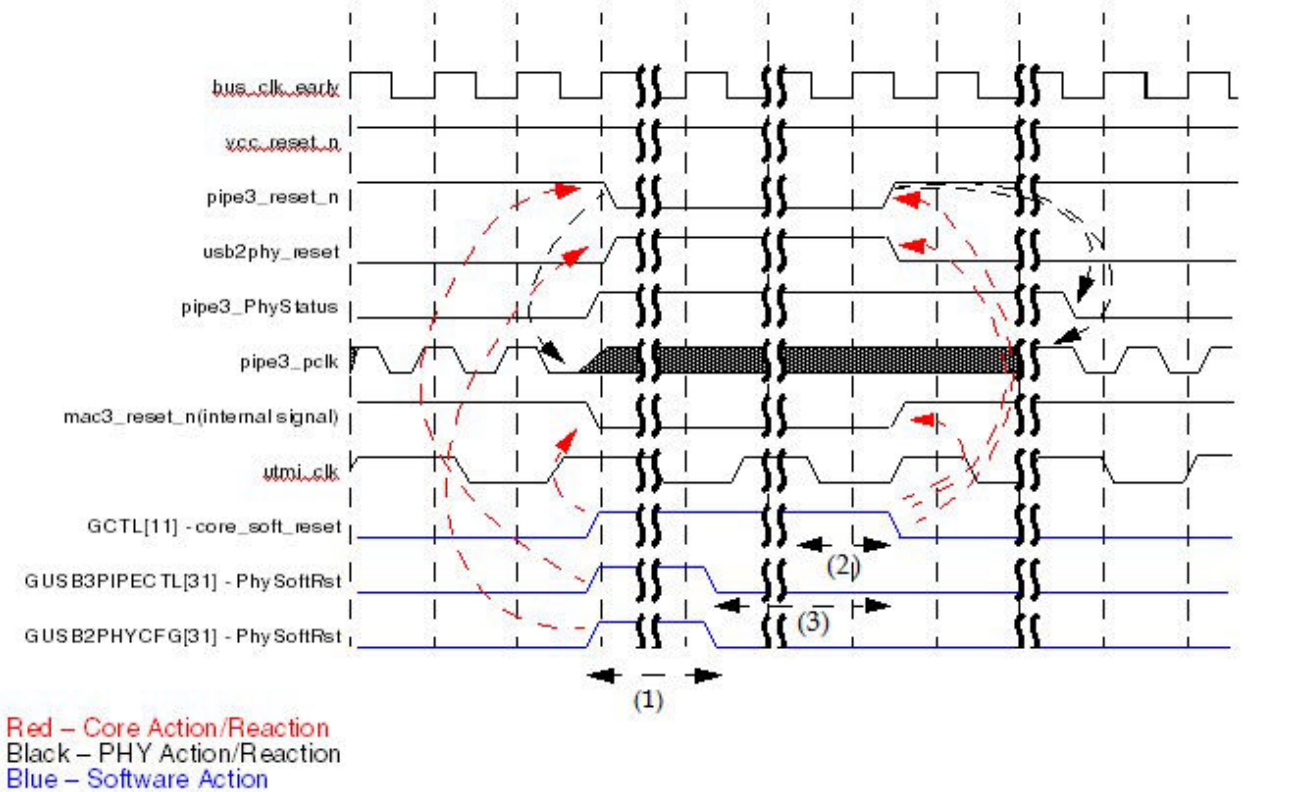
11.2.2.10.2 Software reset

Software reset is an optional feature that allows the software to reset the controller and the PHY whenever it is required. For example, while developing drivers you can use this feature to reset the controller and PHY before you load modules into the driver. This ensures that you do not have to do a hardware reset of your development platform if the driver stops functioning, thereby saving some time.



NOTE

The PHYs can be reset only if you are using the pipe3_reset_n and usb2phy_reset signals from the controller.

The GUSB2PHYCFG, GUSB3PIPECTL, and GCTL registers control the USB 2.0 PHY reset, USB 3.0 PHY reset, and internal reset of the controller. Software resets must be generated in the following sequence:

1. Set GUSB2PHYCFG[31], GUSB3PIPECTL[31], and GCTL[11] to reset the PHYs and keep the controller in a reset state.
2. Reset GUSB2PHYCFG[31] and GUSB3PIPECTL[31] after they meet PHY reset duration. This removes the reset to the PHYs.
3. Wait for the PHY clock to stabilize and reset GCTL[11] bit. This ensures that the reset to all the internal blocks are asserted when all the clocks are stable.

The following figure shows the software reset and PHY clock sequencing and requirements.

(1) – PhySoftRst assertion timing must meet the minimum USB 3.0 and USB 2.0 PHY reset timing.
(2) – The core_soft_reset signal must be de-asserted only after at least 16 clock cycles of the slowest clock; if the suspend_clk is the slowest clock, then use the suspend_clk.
(3) – The core_soft_reset de-assertion after the PhySoftRst de-assertion must be at least after 16 clocks of the slowest clock; if the suspend_clk is the slowest clock, then use the suspend_clk

Figure 11-29. Software resets and PHY clock sequencing and requirements

11.2.2.11 Interrupts

NOTE

This section is for applicable only for non-SSIC device configurations.

The DWC_usb3 controller generates the interrupt[(DWC_USB3_NUM_INT-1):0] signal to indicate the occurrence of an event needing application intervention.

While configuring the controller using coreConsultant, you can select the number of Event Buffers by choosing the “Number of Device Mode Event Buffers” (DWC_USB3_NUM_INT). Each Event Buffer is associated with one interrupt line.

Software allocates memory for the Event Buffers, to receive interrupts, using the GEVNTADR and GEVNTSIZ registers. The GEVNTCOUNT register holds the number of valid bytes in the Event Buffer.

When an event occurs within the controller, the hardware checks the enable bit that corresponds with the event to determine if the event needs to be generated. If it is enabled, the controller writes the event to the Event Buffer, increments the GEVNTCOUNT[15:0] (Event Count) register field in the GEVNTCOUNT register, and generates the hardware interrupt (if not masked and is the correct time to assert the interrupt based on the DEV_IMOD register).

For information on the structure of the Event Buffers, see Device programming model. By reading the Event Buffer, software can decode the type of event that occurred. For information on how to use multiple interrupts, see Multiple device interrupt support.

The DWC_usb3 controller generates following types of interrupt events:

- Command interrupt event
- Device-specific interrupt event
- Device physical endpoint-specific interrupt event
- Interrupt based on TRB settings
- Device interrupt (GSTS[6])
- Battery charger interrupt event

11.2.2.11.1 Command interrupt event

Command interrupt event are generated based on completion of device generic commands or endpoint-specific commands.

Based on whether the command is issued to the generic device or a specific endpoint, there are two types of command interrupt events:

- Device generic interrupt events

  If you set DGCMD[8] (CMDIOC) register bit while issuing a device generic command, you get Generic Command Complete event for that command.

  In the Event Buffer, this event shows up with DEVT[11:8] bits set to 10 (see Table 11-11).

- Device endpoint-specific interrupt events

  If you set DEPCMD[8] (CMDIOC) register bit while issuing a device endpoint-specific command, you get Endpoint Command Complete event for that command.

  In the Event Buffer, this event shows up with DEPEVT[9:6] bits set to 7 (see Table 11-10).

11.2.2.11.2 Device-specific interrupt event

You can use DEVTEN register fields to enable/disable the device-specific events. (See the “DEVTEN” section of the Registers chapter).

If the last bit of the event in the Event Buffer is 1, it indicates a device-specific event. Bits [11:8] indicate the type of device-specific event that occurred. For different types of device-specific events, see bits [11:8] in Table 11-11.

11.2.2.11.3 Device physical endpoint-specific interrupt event

Unlike the case of device-specific commands, for device endpoint-specific commands, you need to issue a DEPCFG command with field [13:8] (DEPEVTEN) set to enable/disable the device endpoint-specific events (Refer bits [13:8] in Table 11-24).

If the last bit of the event in the Event Buffer is 0, it indicates a device endpoint-specific event. Bits [9:6] indicate the type of endpoint-specific event that occurred. For the different types of device endpoint-specific events, see Table 11-10.

11.2.2.11.4 Interrupt based on TRB settings

Based on the TRB control fields (DW 0F-0C), the DWC_usb3 controller generates events, and writes them to the Event Buffer. Note that you must have enabled the required events using the DEPCFG command prior to this step.

For example, when you set the Interrupt on Complete (IOC) bit in a TRB, once the transfer indicated by that TRB (buffer) is completed, the controller issues XferInProgress event with IOC bit set in the event status field of the DEPEVT event. This indicates the buffer is available for software to reuse or release. This helps in freeing up the buffer sooner than waiting for the entire transfer to complete. Note that you must have set XferInProgEn to 1 using DEPCFG command for that specific endpoint for XferInProgress event to occur.

11.2.2.11.5 Device interrupt (GSTS[6])

The GSTS[6] (Device_IP) field indicates that there is a pending interrupt pertaining to the device operation in the Device event queue. This can be used to know if any interrupt is pending before halting the controller.

11.2.2.11.6 Battery charger interrupt event

Battery charger events are captured in the BCEVT register if the corresponding BC event enable bits in the BCEVTEN register is set accordingly.

The GSTS[9] (BC_IP) register bit indicates that there is a pending interrupt pertaining to BC in the BCEVT register.

The DWC_usb3 controller also drives the bc_interrupt signal to indicate a BC event has occurred and it needs application intervention. This signal is driven high as long as any event is set in BCEVT register. Once the application services the interrupt/event, it can clear it by writing a 1 to the corresponding event bit in the BCEVT register.

NOTE

Unlike other interrupt events, all battery charger-related events (those captured in the BCEVT register) are not mapped to the "interrupt" output signal. They are mapped to a separate interrupt line called "bc_interrupt".

11.2.2.11.7 USB core interrupts

Each USB core uses one dedicated vector in the Interrupt Table. The vector numbers associated with each of the cores can be found in the Interrupt section.

With the exception of the wake-up interrupts, all of the interrupt sources are controlled in the USB Cores.

11.2.2.11.8 Wake-up interrupts

Each USB has an associated wake-up interrupt. The wake-up interrupts are generated outside of the USB controller cores, and using dedicated vector. These interrupts are generated by the Power Control blocks which run on the 32 kHz standby clock. The wake-up interrupt is designed to work even when the USB and Arm platform clocks are disabled, such that a wake-up condition on the USB bus can re-activate the Arm platform clocks. Because the wake-up interrupt is generated and cleared on a 32 kHz clock, this interrupt request responds very slowly to clear actions. For this reason, the software must disable the wake-up interrupt to clear the request flag. Disabling the interrupt masks the request instantaneously as this is clocked by the Arm platform clock. The software should wait for at least three 32 kHz clock cycles before re-enabling this interrupt to allow sufficient time for the request flag to clear. Because this interrupt is only used during low power modes of the USB, it is sufficient to enable the wake-up interrupt just prior to entering the USB suspend mode.

11.2.3 External signals

This section contains detailed descriptions of all the USB 3.0 controller signals. Many of the signals for the PHY interfaces are muxed onto the same pins to reduce pin count. The following table shows the USB signals, indicating which interface supports each signal.

Table 11-29. USB 3.0 External signals

Signal	I/O	Description
USB1_D_P	IO	USB PHY Data Plus
USB1_D_M	IO	USB PHY Data Minus
USB1_VBUS	IO	USB PHY VBUS
USB1_ID	IO	USB PHY ID Detect
USB1_TX_P	O	USB PHY 3.0 Transmit Data (positive)
USB1_TX_M	O	USB PHY 3.0 Transmit Data (negative)
USB1_RX_P	I	USB PHY 3.0 Receive Data (positive)
USB1_RX_M	I	USB PHY 3.0 Receive Data (negative)
USB1_RESREF	IO	USB PHY Impedance Calibration
USB1_DRVVBUS	O	VBus power enable.
USB1_PWRFAULT	I	Indicates that a Vbus fault has occurred.

11.2.4 Initialization/application information

The PHY can be configured for fixed equalization by programming relevant control registers in the USB 3.0 PHY.

In order to initialize the USB 3.0 PHY, software should perform the following steps:

1. Write 1'b0 to RX_OVRD_IN_HI.RX_EQ_EN [address 16'h1006: bit 6].
2. Write 1'b1 to RX_OVRD_IN_HI.RX_EQ_EN_OVRD [address 16'h1006: bit 7].
3. Write a fixed value to RX_OVRD_IN_HI.RX_EQ [address 16'h1006: bits 10–8] [equalization setting] (generally 2–4, based on testing in customer environment).
4. Write 1'b1 to RX_OVRD_IN_HI.RX_EQ_OVRD [address 16'h1006: bit 11].

11.2.5 Memory map/register definition

This section describes the registers and data structures in the USB3 module.

NOTE

For USB Wakeup Registers see HSIO BLK_CTRL register description.

11.2.5.1 USB3 register descriptions

USB3.0 registers are 32-bit wide, and the addresses are 32-bit block aligned. To avoid hardware or software incompatibility, the driver must access the registers as 32-bit units. The driver must not access these registers as 8 bit or 16 bit.

11.2.5.1.1 DWC_usb3 memory map

Field	Function
31-14 —	Reserved

Table continues on the next page...

Field	Function
13 CME	CEM Enable For a description of this standard USB register field, see the eXtensible Host Controller Interface for Universal Serial Bus (USB) Specification 3.0.
12 —	Reserved
11 EU3S	Enable U3 MFINDEX Stop For a description of this standard USB register field, see the eXtensible Host Controller Interface for Universal Serial Bus (USB) Specification 3.0.
10 EWE	Enable Wrap Event For a description of this standard USB register field, see the eXtensible Host Controller Interface for Universal Serial Bus (USB) Specification 3.0.
9 CRS	Controller Restore State This command is similar to the USBCMD.CRS bit in host mode and initiates the restore process. When software sets this bit to '1', the controller immediately sets DSTS.RSS to '1'. When the controller has finished the restore process, it sets DSTS.RSS to '0'. **NOTE:** When read, this field always returns '0'.
8 CSS	Controller Save State This command is similar to the USBCMD.CSS bit in host mode and initiates the save process. When software sets this bit to '1', the controller immediately sets DSTS.SSS to '1'. When the controller has finished the save process, it sets DSTS.SSS to '0'. **NOTE:** When read, this field always returns '0'.
7 LHCRST	Light Host Controller Reset For a description of this standard USB register field, see the eXtensible Host Controller Interface for Universal Serial Bus (USB) Specification 3.0. The following bits reset the internal logic of the host controller. Under soft reset, some CSR accesses may fail (Timeout). - HCRST - LHCRST Bit Bash register testing is not recommended.
6-4 —	Reserved
3 HSEE	Host System Error Enable For a description of this standard USB register field, see the eXtensible Host Controller Interface for Universal Serial Bus (USB) Specification 3.0.
2 INTE	Interrupter Enable For a description of this standard USB register field, see the eXtensible Host Controller Interface for Universal Serial Bus (USB) Specification 3.0.
1 HCRST	Host Controller Reset The following bits reset the internal logic of the host controller. Under soft reset, some CSR accesses may fail (Timeout). - HCRST - LHCRST Bit Bash register testing is not recommended.
0 R_S	Run/Stop For a description of this standard USB register field, see the eXtensible Host Controller Interface for Universal Serial Bus (USB) Specification 3.0. Due to side-effects this reguster field is not recommended for Bit-Bash testing.

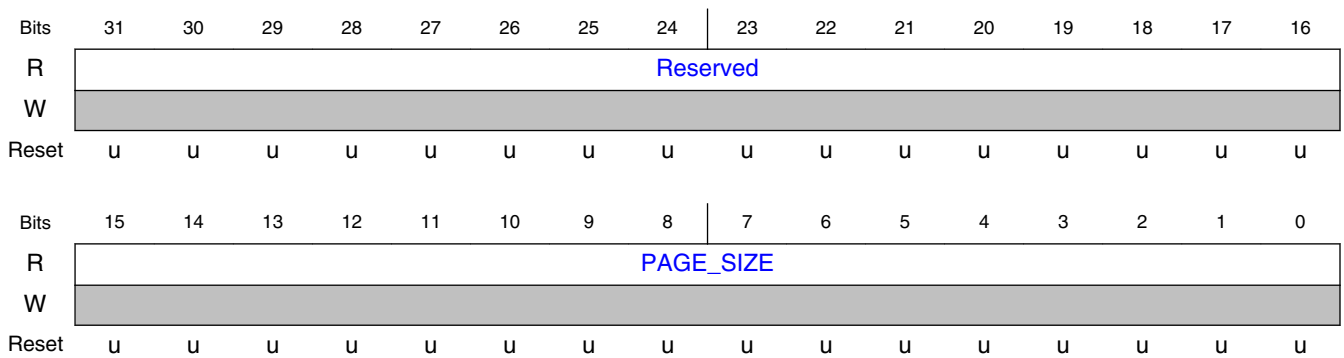
11.2.5.1.12.1 Offset

Register	Offset
PAGESIZE	28h



11.2.5.1.12.2 Function

Use this register to enable or disable the reporting of specific USB Device Notification Transaction Packets being received.

Reset Mask:0xFFFF0000

A Notification Enable (Nx, where x = 0 to 15) flag is defined for each of the 16 possible device notification types. If a flag is set for a specific notification type, a Device Notification Event is generated when the respective notification packet is received. After reset, all notifications are disabled. Refer to section 6.4.2.7 of the DesignWare Cores SuperSpeed USB 3.0 Controller Databookfor more information. This register is written as a Dword. Byte writes produce undefined results.

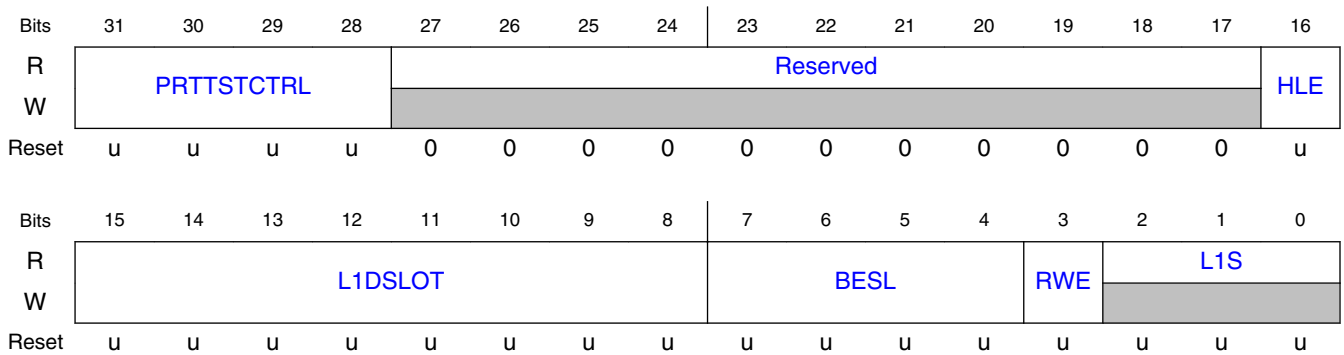
1 PED	Port Enabled/Disabled For a description of this standard USB register field, see the eXtensible Host Controller Interface for Universal Serial Bus (USB) Specification 3.0.
0 CCS	Current Connect Status For a description of this standard USB register field, see the eXtensible Host Controller Interface for Universal Serial Bus (USB) Specification 3.0.

11.2.5.1.24 USB2 Port Power Management Status and Control Register (PORTPMSC_20)

11.2.5.1.24.1 Offset



Register	Offset
PORTPMSC_20	424h

11.2.5.1.24.2 Function

This register is in the Aux Power well.

Reset Mask:0xFFE0000

11.2.5.1.24.3 Diagram

11.2.5.1.24.4 Fields

Field	Function
31-28 PRTTSTCTRL	Port Test Control When this field is '0', the port is NOT operating in a test mode. A non-zero value indicates that it is operating in test mode and the specific test mode is indicated by the specific value. A non-zero Port Test Control value is only valid to a port that is in the Powered-Off state (PLS = Disabled). If the port is not in this state, the xHC shall respond with the Port Test Control field set to Port Test Control Error. Refer to 'Operational Model' topic for using these test modes. The encoding of the Test Mode bits for a USB2 protocol port are: 0: Test mode not enabled 1: Test J_STATE 2: Test K_STATE 3: Test SE0_NAK 4: Test Packet 5: Test FORCE_ENABLE 6-14: Reserved. 15: Port Test Control Error.
27-17 —	Reserved
16 HLE	Hardware LPM Enable For a description of this standard USB register field, see the eXtensible Host Controller Interface for Universal Serial Bus (USB) Specification 3.0
15-8 L1DSLOT	L1 Device Slot For a description of this standard USB register field, see the eXtensible Host Controller Interface for Universal Serial Bus (USB) Specification 3.0.
7-4 BESL	Best Effort Service Latency System software sets this field to indicate to the recipient device how long the xHC will drive resume if it initiates an exit from L1.
3 RWE	Remote Wake Enable

Table continues on the next page...

Field	Function
	For a description of this standard USB register field, see the eXtensible Host Controller Interface for Universal Serial Bus (USB) Specification 3.0.
2-0 L1S	L1 Status For a description of this standard USB register field, see the eXtensible Host Controller Interface for Universal Serial Bus (USB) Specification 3.0.

11.2.5.1.25 USB2 Port Link Information Register (PORTLI_20)

11.2.5.1.25.1 Offset

Register	Offset
PORTLI_20	428h

11.2.5.1.25.2 Function

Port Link Information Register Programming this field with random data will cause side effect i.e. Register Access will fail (Timeout) if the pipe clock is not running or reset is asserted . Bit Bash register testing is not recommended

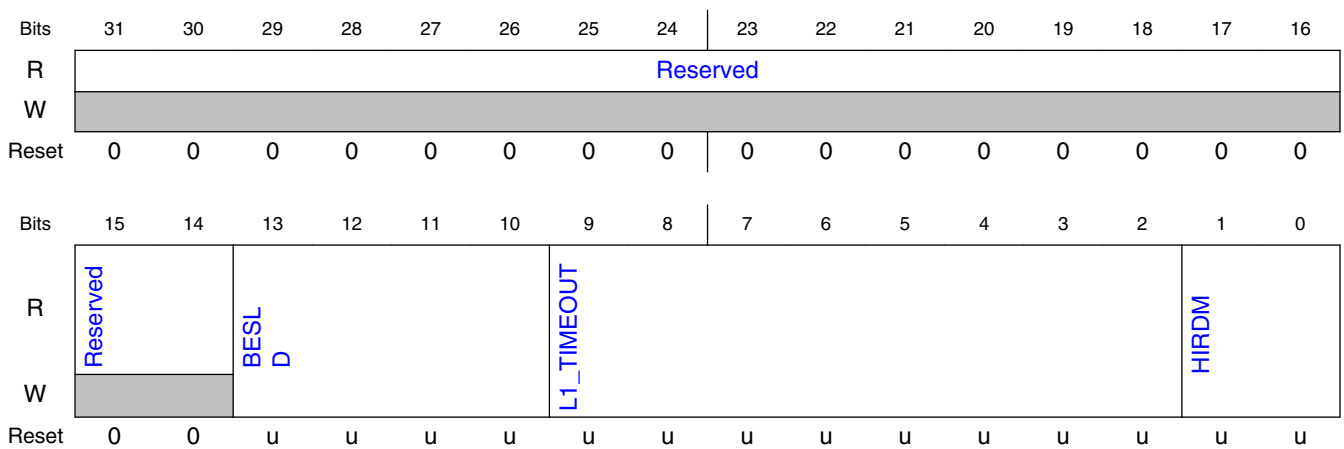
11.2.5.1.25.4 Fields

Field	Function
31-0 —	Reserved

11.2.5.1.26 USB2 Port Hardware LPM Control Register (PORTHLPMC_20)

11.2.5.1.26.1 Offset



Register	Offset
PORTHLPMC_20	42Ch

11.2.5.1.26.2 Function

For a description of this standard USB register field, see the eXtensible Host Controller Interface for Universal Serial Bus (USB) Specification 3.0.

Reset Mask:0xFFFFC000

11.2.5.1.26.3 Diagram

11.2.5.1.26.4 Fields

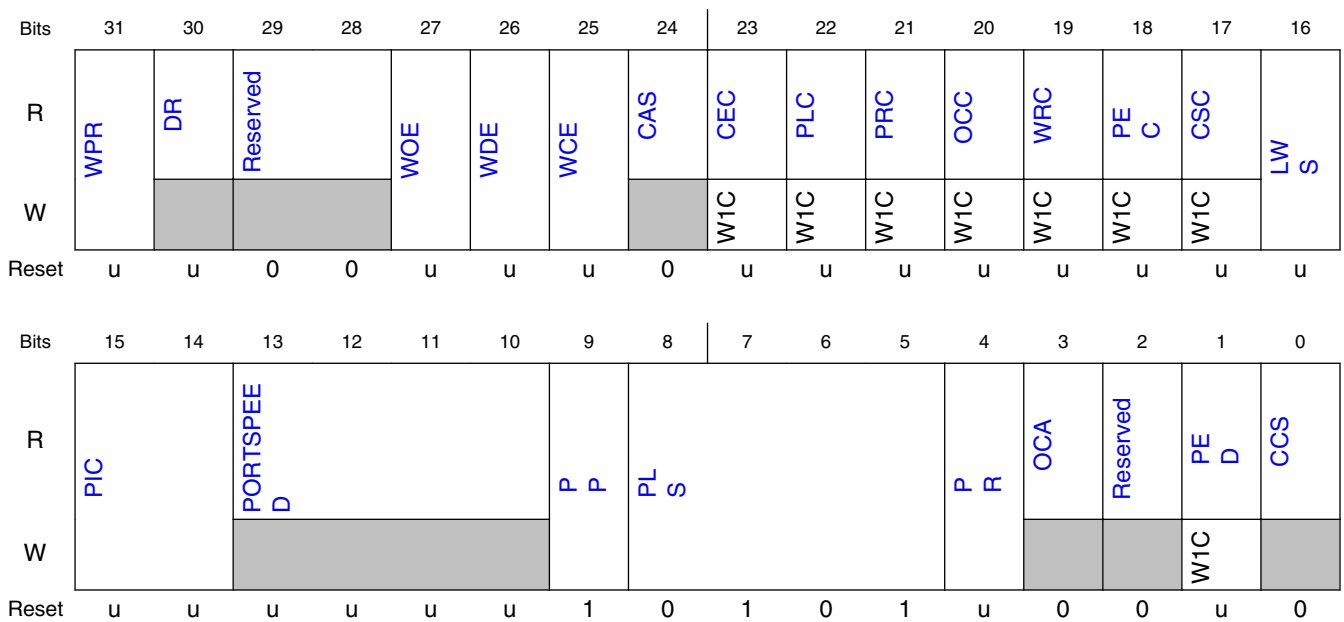
Field	Function
31-14 —	Reserved
13-10 BESLD	Best Effort Service Latency Deep System software sets this field to indicate to the recipient device how long the xHC will drive resume on an exit from U2.
9-2 L1_TIMEOUT	L1 Timeout For a description of this standard USB register field, see the eXtensible Host Controller Interface for Universal Serial Bus(USB) Specification 3.0.

Table continues on the next page...

Field	Function
1-0 HIRDM	Host Initiated Resume Duration Mode

11.2.5.1.27 USB3 Port Status and Control Register (PORTSC_30)

11.2.5.1.27.1 Offset



Register	Offset
PORTSC_30	430h

11.2.5.1.27.2 Function

The PORTSC Register Access fails (Timeout) if the UTMI/ULPI clock is not running or one of the following bits is asserted.
